P04.198**Novel somatic mutations in the S100A2 gene in non-small cell lung carcinoma (NSCLC)**

M. Strazisar, D. Glavac, T. Rott;

Faculty of Medicine, Ljubljana, Slovenia.

Contrary to the recent hypothesis that S100A2 is a tumour suppressor, no somatic mutations have yet been identified. We therefore screened 90 non-small cell lung carcinoma (NSCLC) samples, initially for mutations in S100A2 and then also for mutations in P53 and K-RAS genes. Alterations were detected in 46.7 % of squamous lung cancer (SCC) samples, but we detected only one novel tumour specific mutation, Q23X in squamous carcinoma. We detected four polymorphisms, two of them published for the first time (144+109 C/G and 297+75A/G) and two already published: S62N, in coding region and related to squamous cell carcinoma, and 297+17T/C. In one tumour with the S62N polymorphism, P53 and K-RAS genes were also mutated, while two tumours with the Q23X mutation have a P53 but no K-RAS mutation. Expression profiles of hTERT and COX-2 revealed no significant correlation with tumours having also the S100A2 alterations. To the best of our knowledge, this is the first report describing alterations in the S100A2 gene proving the relation between polymorphic changes in predominantly squamous lung cancer (SCC).

P04.199**Molecular cytogenetic characterization of paraffin-embedded salivary gland tumors by Comparative Genomic Hybridization**G. Florida¹, F. Censi¹, M. Foschini², V. Falbo¹, D. Taruscio¹;¹Istituto Superiore di Sanità, Dept. Cell Biology and Neuroscience, Roma, Italy;²Section of Pathology, University of Bologna, Bellaria Hospital, Bologna, Italy.

Salivary gland tumours (SGTs) are rare tumors of the neck and head with an overall incidence in the Western world of approximately 2.5-3/100.000/year. SGTs are remarkable for their histopathologic and biologic diversity; they include benign and malignant tumors of epithelial, mesenchymal and lymphoid origin. The study of molecular pathogenesis of SGTs is a challenging task because of the rarity and histopathological diversity of these malignancies. Comparative Genomic Hybridization metaphase-based was performed in 10 paraffin embedded Adenoid Cystic Carcinoma samples (ACC). Heterogeneity was detected and gains predominated over losses; no recurrent anomaly was observed. However 3q29, 5q35, 16q24 and 21q22 gains, detected in our study, have been reported and described in literature as ACC loci. The correlation of CGH results with clinical-pathological data and a comparison with literature data will be discussed.

This work has been funded in the frame of "Programma di collaborazione ISS-NIH, Area Malattie Rare" Fasc.526/B and Fasc.7GR1.

P04.200**A case of synovial sarcoma of the pericardium diagnosed by FISH on FNA material**I. Trigo¹, A. Hernandez², M. Vargas¹, M. Diaz², J. Rios², H. Galera-Ruiz², R. Gonzalez-Campora²;¹Unidad de Genética., Sevilla, Spain, ²Dpt of Pathology, Sevilla, Spain.**Case report**

We present a case of 40 year-old woman, without any previous interesting medical history, who presented disnea, cough and fever over several weeks. Thoracic MR revealed a left posterolateral paracardial mass of possible pericardium origin. The cytologic study on material obtained by transesophageic FNA was performed and the tumour was surgically removed. Morphologic diagnosis was a malignant spindle cell tumour consistent with synovial sarcoma (immunohistochemistry profile: EMA, bcl-2, CD-99 and CK 19 positive. S-100, CD-34 and caldesmon negative). SYT gene rearrangement was confirmed by FISH techniques, verifying the localization at SSX2 gene.

The synovial sarcoma is an uncommon mesenchymal tumour with variable epithelial differentiation and represents 5% of cardiac sarcomas and less than 0.1 of all cardiac tumours. It is characterized by t (X;18)(p11;q11), which is present in its four histological types. The microscopic diagnosis is very difficult and the immunochemical techniques are helpful but not conclusive. Consequently other ancillary techniques, such as FISH analysis, are primordial to precise the definitive diagnosis of this entity characterized by the SYT gene rearrangement to SSX2 gene. In the literature review only 18 cases of heart synovial sarcoma have been described and only one of them (biphasic type) was diagnosed by FNA material without FISH contribution. To our knowledge no other FISH studies on cytopathologic material of synovial sarcoma of the pericardium have been reported in the literature.

P04.201**Detection of human telomerase gene (TERC) amplification in cervical neoplasia: A retrospective study of 79 patients with normal smears or mild or moderate dyskaryosis**R. E. Crookes¹, M. Dyson¹, J. H. F. Smith², E. Maltby¹;¹NHS Foundation Trust, Sheffield, United Kingdom, ²Royal Hallamshire Hospital, Sheffield, United Kingdom.

The inclusion of a genetic marker of disease progression for cervical carcinoma along side the histological assessment of Pap smear slides could dramatically reduce the number of diagnostic colposcopic procedures currently performed and increase the sensitivity and specificity of cervical screening programmes.

Recent CGH studies (Heselmeyer-Haddad et al., 2003) indicated the involvement of extra copies of 3q and hence the human telomerase gene (TERC) at 3q26, in invasive cervical carcinoma. Their retrospective study of 59 cervical smears showed that gains of TERC could predict progression from lower grade smear abnormality (mild or moderate dyskaryosis) to CIN3 and invasive carcinoma.

We present the results of retrospective study, using the same TERC probe kit, on a selection of 79 patients with negative, mild or moderate dyskaryosis that later progressed to CIN3/cervical cancer, or regressed to negative. In the cohort of patients classified as cytologically negative that subsequently developed CIN 3, 28.5% were positive for TERC gain. In the cohort of patients classified as mild or moderate that progressed to CIN3/cervical carcinoma, 60% and 82.4% respectively showed gains of TERC. In the cohort patients classed as negative, mild or moderate dyskaryosis that regressed or remained negative 30 out of 33 patients were negative for TERC gains. This concurs with previous studies which have proposed that the acquisition of TERC is an important event in the progression of cervical dysplasia to cervical cancer. The results demonstrate the potential use of TERC as an early prognostic detection of disease progression.

P04.202**Effects of somatic mutations in TP53 on expression of genes involved in cell cycle arrest**D. Macic¹, L. Kapur¹, J. Ramic¹, N. Lojo-Kadic¹, N. Obralic², T. Ceric², S. Beslija², K. Bajrovic¹;¹Institute for Genetic Engineering and Biotechnology, Sarajevo, Bosnia and Herzegovina, ²Institute of Oncology, Sarajevo, Bosnia and Herzegovina.

The TP53, tumor suppressor gene, is a critical regulator of cell division and its inactivation at the gene or protein level contributes to onco-

genesis and cancer progression. Mutations in TP53 are considered to represent the most common genetic alteration and occur in about 50% of human cancers. These mutations may damage the normal function of p53 as a transcription factor and the induction of repair or apoptosis may be diminished. Consequently, genetic alterations may accumulate in the cell.

Evidences from previous studies imply that there is a clear correlation between mutational status of TP53 and expression of genes down the p53-signaling pathway.

We examined the impact of mutations in DNA binding domain of p53 on expression of genes involved in cell cycle arrest, particularly CDK4 and its inhibitor CDKN2.

This study included bioptic samples from 80 breast and colon cancer affected subjects with different malignancy grades.

To test hypothesis that mutation in TP53 can influence expression of CDK4 and CDKN2, TP53 has been subjected to mutational analysis by RFLP followed by sequencing.

Expression of genes involved in cell cycle arrest was measured using SYBR-green based real-time PCR.

Mutations in TP53 were detected in 8% of the examined cases.

We compared expressions of CDK4 and CDKN2 in the samples that harbor a mutation to those without mutations.

Pathohistological findings obtained from clinic were correlated with molecular alterations.

P04.203

Association study of codon 10 polymorphism of the Transforming growth factor-beta 1 (TGF- β 1) gene with prostate cancer and hyperplasia

M. Omrani, S. Bazargani, S. Salari, B. Farshid;

Uromieh Medical Science University, Uromieh, Islamic Republic of Iran.

Introduction: Transforming growth factor-beta 1 (TGF- β 1) has a multifactorial role in the development of cancer. Genetic polymorphisms in codons 10 of the TGF- β 1 gene have been shown to be associated with the production of high or low TGF- β 1 levels. The role of this polymorphism in development of prostate cancer and hyperplasia was investigated.

Material and Methods: Using ASO-PCR method, association between the T (Leu) to C (Pro) polymorphism at codon10 of the TGF- β 1 gene (TGFB1) and the risk of PCa or BPH in 100 controls were determined.

Results: Significant differences in the CC versus TT genotype distribution between PCa patients and male controls ($P = 0.009$), and between BPH patients and male controls ($P = 0.005$) were noticed. Males with the TT genotype had a 1.67-fold increased risk of PCa [95% confidence interval (95% CI) = 1.49-1.87, $P = 0.009$] and TC /TT genotype, 1.14-fold increased risk of PCa [95% confidence interval (95% CI) = 1.02-1.26, $P = 0.047$] and a 1.54-fold increased risk of BPH with the TT genotype (95% CI = 0.98-1.14, $P = 0.005$) and 1.06-fold increased risk of BPH with the TT/TC genotype (95% CI = 0.98-1.14, $P = 0.061$) compared with those with the CC genotype respectively.

Conclusion: Based on our findings, it was possible to conclude that the codon10 polymorphism in TGFB1 may have a significant influence on the development of PCa and BPH and the T allele of TGFB1 gene has the dominant effect on development of PCa and BPH.

P04.204

Subtle microsatellite instability in pediatric gliomas as an indicator of type 1 Turcot syndrome

L. Giunti¹, V. Cetica², U. Ricci¹, S. Giglio³, I. Sardi⁴, M. Paglierani⁴, A. Buccoliero⁴, L. Genitor⁵, **M. Genuardi**^{3,1,4};

¹Medical Genetics Unit, Meyer Children's University Hospital, Florence, Italy,

²Department of Pediatrics, University of Florence, Florence, Italy, ³Medical

Genetics Unit, Department of Clinical Pathophysiology, Florence, Italy, ⁴Department

of Biomedicine, Careggi University Hospital, Florence, Italy, ⁵Neurosurgery Unit, Meyer Children's University Hospital, Florence, Italy.

Type 1 Turcot syndrome (TS1) is characterized by the association of early-onset glial and colorectal tumors and is caused by mutations of the mismatch repair genes. To determine the role of genetic predisposition in glial tumor development, we investigated the frequency of microsatellite instability (MSI) in a series of 38 pediatric gliomas using a panel of 5 quasimonomorphic mononucleotide markers. A pattern of "subtle" MSI for most tested markers was observed in 2 glioblastomas.

In both cases family history was indicative of TS1, as confirmed by the detection of mutations in the *PMS2* and *MLH1* genes. In one case, instability was revealed in diluted DNA samples. Comparison of the MSI patterns in normal (leukocyte and intestinal mucosa) and tumor (glioblastoma and colorectal cancer) samples from one TS1 family revealed that allelic size shifts were smaller in gliomas. Our results indicate that MSI analysis is an important tool to identify TS1-related pediatric gliomas, and that the pattern of microsatellite alterations in gliomas is less pronounced compared to colorectal cancer

P04.205

Analysis of the molecular genetic changes in uveal melanoma

I. K. Manokhina¹, N. V. Sklyarova², S. V. Saakyan², D. V. Zaletaev¹;

¹Laboratory of human molecular genetics, Institute of Molecular Medicine, I.M. Sechenov Moscow Medical Academy, Moscow, Russian Federation, ²Ophthalmology and radiology department, Helmholtz Moscow Research Institute of Eye Diseases, Moscow, Russian Federation.

Uveal melanoma (UM) is the most common primary cancer of the eye and has a strong predilection for hematogenous metastasis, particularly to the liver. Investigation of the specific genetic mechanisms responsible for the malignant behavior of UM could play an important role for the development of new approaches to UM diagnosis and treatment. We investigated 105 UM for allelic losses at chromosomal regions 3p, 3q, 1p, 9p23, 10q23, 13q14, close or within some tumor suppressor genes (*VHL*, *FHIT*, *RASSF1A*, *CDKN2A*, *PTEN*, *RB1*). Moreover, we investigated the methylation status of the promoter regions of these genes.

45 UM (43%) had LOH at all informative loci of chromosome 3, indicating of monosomy 3. Methylation analysis discovered frequent methylation of *RASSF1A* (24 patients, 23%), located at 3p21.3 and inactivated in a large number of human cancers. Important to notice, methylation of *RASSF1A* was found predominantly in UM without monosomy 3 (20 patients). These findings could reinforce the role of *RASSF1A* in the pathogenesis of UM.

LOH at 1p was found in 28 samples mainly at all informative loci (5 MS markers, 1p31.3 to 1p36.3) without any relation to the monosomy 3. Five samples had partial allelic losses at 1p31.3 or 1p36.3. 1p contains wide range of TSGs, and for the moment we could not identify those who might be candidate genes for the UM. Additionally, we conclude that inactivation of the regulation pathway *CDKN2A*→*RB1* with promoter methylation or LOH is not the major mechanism of the pathogenesis in UM unlike cutaneous melanoma.

P04.206

VANGL1 effects cell invasion rather than cell motility

O. Cetin¹, A. Toylu², N. Atabey², Z. Sercan², M. Sakizli²;

¹Pamukkale University, School of Medicine, Department of Medical Biology, Denizli, Turkey, ²Dokuz Eylul University, School of Medicine, Department of Medical Biology and Genetics, Izmir, Turkey.

Van Gogh like 1 (Vangl1) is a transmembrane protein on Wnt planar cell polarity pathway. It has an important role in planar cell polarity and convergent extension in embryonic development. In adults, it is expressed specifically in testis and ovaries as well as in brain and prostate. VANGL1 expression has been shown in several human cancer cell lines including hepatocellular carcinoma (HCC). Our aim in this study was to investigate the changes in the behaviour of the HCC cells whose VANGL1 gene was silenced by siRNA.

VANGL1 expression in HCC cell lines was shown by RT-PCR and real time PCR. The siRNA template which will transcribe the specific hairpin siRNA for VANGL1 gene was designed following the determination of the target sequence. The siRNA template was ligated to a siRNA expression vector and HepG2 cells were transfected. The colonies expressing the siRNA were detected by RT-PCR, quantitative RT-PCR and Western blotting. Motility and invasion of the cells were assessed by Boyden chamber assay while cell cycle analysis was performed by flow cytometry.

The motility of the cells was not effected with gene silencing while there was a three fold decrease in the invasion potential of the cells expressing the siRNA. The proliferation assay revealed no significant difference between the transfected cells and parental cells with regard to S phase cell ratio.

In conclusion, VANGL1 gene has an effect on cell invasion rather than cell motility. Further investigations are needed to understand the mechanisms of this effect.

P04.207

Mutational spectrum of missense VHL gene mutations in Spain and their genotype-phenotype correlation

J. Oriola¹, I. Blanco², I. Salinas³, A. Goday⁴, J. Chillaron⁴, C. Villanova⁵, J. Rosell⁶, S. Pedrinaci⁷;

¹Hospital Clinic, Barcelona, Spain, ²Institut Català d'Oncologia, Barcelona, Spain, ³Hospital Universitari Trias i Pujol, Barcelona, Spain, ⁴Hospital del Mar, Barcelona, Spain, ⁵Hospital Princesa d'Espanya, Barcelona, Spain, ⁶Hospital Son Dureta, Palma de Mallorca, Spain, ⁷Hospital Virgen de las Nieves, Granada, Spain.

Von Hippel-Lindau (VHL) disease (MM#193300) is an inherited neoplastic disorder characterized by a predisposition to develop mainly retinal angiomas (RA), central nervous system hemangioblastomas (HB), clear cell renal carcinomas (CCRC) and pheochromocytomas (PHEO).

It's well known that patients that present microdeletions/insertions, nonsense and deletion mutations usually do not develop PHEO (type 1) but do develop RA, HB and CCRC.

In patients with missense mutations, PHEO can be present (type 2) even as the only feature, or not present. One way to improve our knowledge about the correlation between missense mutations and the phenotype associated is the finding of more and new mutations in families.

We have studied 17 different families with missense mutations (12 different mutations) and their correlation with phenotype. Eight of these mutations fit well with the phenotype previously described: PHEO was present in patients with G114S, R161Q, R167Q (5 families), R167W, Y175C mutations, and PHEO was not present in patients with N78S (2 families), L128R and L178P mutations. Three mutations showed discrepancies with the phenotype previously described according to the presence or absence of PHEO (T157I, Q164R and L184P). We also describe the mutation X214R not reported previously, which was present in a patient with bilateral PHEO. This mutation probably extends protein by an additional 14 aminoacids.

These data support previous associations in eight mutations, add details about genotype-phenotype correlation in three mutations and give information about the phenotype associated to X214R mutation.

ABCB4 gene mutations and differential involvement in liver diseases

D. Degiorgio¹, C. Colombo¹, B. Acaia¹, P. Battezzati², M. Seia¹, L. Costantino¹, V. Paracchini¹, A. Crosignani², S. Nozza¹, M. Antelmi², S. Saino¹, L. Porcaro¹, V. Motta¹, C. Melles¹, D. A. Coviello¹;

¹Fondazione IRCCS, Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena, Milan, Italy, ²University of Milan, S. Paolo School of Medicine, Milan, Italy, Milan, Italy.

ABCB4 gene mutations are responsible for type 3 Progressive Familial Intrahepatic Cholestasis in children (PFIC3), while a possible role in idiopathic cholangiopathies in adults has not been explored. We know that absence or deficiency of the floppase activity necessary for biliary excretion of phosphatidylcholine, leading to lack of phospholipid protection in the bile against the detergent action of bile acids and damage of the biliary epithelium. Our aim was to unveil the role of ABCB4 gene in clinically relevant hepatobiliary diseases in children and adults.

We collected DNA samples from 168 patients (80 children with PFIC3 phenotype, 41 women with Intrahepatic Cholestasis of Pregnancy (ICP), 16 adults with idiopathic cholestasis, 27 adults with primary sclerosing cholangitis (PSC), 4 patients with juvenile cholelithiasis), 150 healthy subjects including 50 two-parous women without ICP. Molecular analysis of ABCB4 gene has been so far completed in 110 patients and 100 healthy subjects.

We observed 52 ABCB4 mutations in 32 patients: 37 were found in 19 PFIC3 children, 5 in 5 ICP women, 7 in 5 patients with PSC, 2 in 2 adults with idiopathic cholestasis and 1 in one patient with juvenile

cholelithiasis. Eleven mutations (9 in PFIC3) cause truncated protein while 41 mutations (12 in adult) cause single amino acid change.

The relative low percentage of patients which co-segregates with ABCB4 mutations suggests a genetic heterogeneity for PFIC3 disease and a possible role of ABCB4 as a modifier or gene susceptibility in adults with chronic or transient cholangiopathies triggered by a cholestatic injury.

P05.002

The autoimmune regulator PHD finger binds to non-methylated histone H3K4 to activate gene expression

T. Org¹, F. Chignola², C. Hetényi³, M. Gaetan², A. Rebane¹, I. Liiv¹, U. Maran³, L. Mollica², M. J. Bottomley⁴, G. Musco², P. Peterson¹;

¹Tartu University, Molecular Pathology, Tartu, Estonia, ²Dulbecco Telethon Institute c/o S. Raffaele Scientific Institute, Milan, Italy, ³Tartu University, Institute of Chemical Physics, Tartu, Estonia, ⁴Istituto di Ricerche di Biologia Molecolare, Pomezia, Italy.

Mutations in Autoimmune Regulator protein (AIRE) cause autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED). AIRE is expressed in thymic medullary epithelial cells where it promotes the expression of tissue-restricted antigens. By the combined use of biochemical and biophysical methods we show that AIRE selectively interacts with histone H3 through its first PHD finger (AIRE-PHD1). AIRE-PHD1 discriminates between different degrees of histone H3 lysine 4 (H3K4) methylation and preferentially binds non-methylated H3K4 (KD ~4 μ M). Accordingly, in vivo AIRE binds and activates promoters containing non-methylated H3K4 in HEK293 cells. We propose that AIRE-PHD1 is a prototype of a new class of PHD fingers that specifically recognize non-methylated H3K4, thus providing a new link between the status of histone modifications and the regulation of tissue-restricted antigen expression in thymus.

P05.003

The co-localization of ASC with A β fibrils in post-mortem brain samples of Alzheimer's disease patients

Z. E. Taskiran¹, B. Balci-Peynircioglu¹, F. Soylemezoglu², E. Yilmaz¹;

¹Hacettepe University Faculty of Medicine Department of Medical Biology, Ankara, Turkey, ²Hacettepe University Faculty of Medicine Department of Pathology, Ankara, Turkey.

Amyloid is an extracellular insoluble protein aggregate which accumulates in several tissues in various clinical conditions. The co-localization of ASC (Apoptosis associated Speck like protein containing a Caspase recruitment domain), a key molecule in both apoptotic and inflammatory processes, with AA type amyloid fibrils has previously been demonstrated by our group. ASC is known to form cytosolic aggregates called specks. The aim of this study was to determine whether the distribution of ASC is altered around A β deposits and senile plaques in post-mortem brain samples of Alzheimer's disease patients. Immunohistochemical staining of paraffin-embedded tissues from post-mortem brain samples of 12 Alzheimer's disease patients revealed co-localization of ASC protein with senile plaques. This co-localization was confirmed by ASC-A β co-staining by using immunofluorescence staining technique. To investigate whether ASC expression was correlated with amyloid deposition, sequential sections from AD patients were analyzed after congo red staining. There was a strong correlation between ASC expression and the presence of amyloid deposits. We further investigate the interaction between ASC and A β in ASC-YFP and APP (Amyloid Precursor Protein) co-transfected COS-7 cells which also demonstrated that specks are located near the intracellular A β deposits. We hypothesize that expression of ASC may be important in the pathogenesis of A β amyloid formation and in senile plaque development in predisposed tissues.) Further functional studies are required to explore the link between ASC and A β amyloid formation.

P05.004

A new candidate haplotype in the ps2 gene associated with late-onset familial alzheimer disease?

J. I. Lao¹, C. Montoriol¹, I. Morer¹, E. Fernández¹, D. Poyatos¹, K. Beyer²;

¹Unit of Molecular Genetics - Medical Lab. Dr. Echevarne, Barcelona, Spain, ²Pathology Department, Hospital Germans Trias i Pujol, Badalona, Spain.

Mutations within the APP, presenilin 1 (PS1) or presenilin 2 (PS2) genes are found in familial Alzheimer disease (AD). Whereas mutations within PS1 cause AD of early or very early onset, APP as well as

PS2 mutations are responsible for both early and late onset familial AD. Promoter and intronic polymorphisms have been detected on both PS genes and some of those have been reported as risk factors for sporadic AD development.

With the aid to detect PS2 mutations in four unrelated late-onset AD patients with familial history we sequenced PS2 exons 3 - 12. Primers were designed to amplify each exon and its surrounding sequences. Since intron 9 is relatively small exons 9 and 10 were coamplified. No mutation within the coding region was detected, instead all four patients carried the haplotype TGTCG corresponding to polymorphisms C129T on exon 3, A(-24)G on intron 3, C261T on exon 4, G(+160)C polymorphism on intron 9 and A(+24)G on intron 11. The polymorphism G(+160)C, located on the shortest of all PS2 introns, had not been identified before. The additional genotyping of fifty non-demented age-matched control individuals revealed that the TGTCG haplotype is present at a very low frequency (2%) in the normal population.

To conclude, the haplotype constituted by five different polymorphisms on the PS2 gene described in the present study seems to be associated with familial AD. The analysis of further familial late-onset AD cases will reveal its importance as diagnostic marker.

P05.005

Mutation detection in ENAM and MMP20 genes in amelogenesis imperfecta

M. Bahaminpour, P. Aref, M. Shahabi, M. Ghandehari Motlagh, B. Seraj, M. Heidari;

School of Dentistry, Tehran, Islamic Republic of Iran.

Amelogenesis imperfecta (AI) is one of the common of inherited tooth disorders. AI is distinguished by abnormality in enamel formation. The frequency of this disease is different through the worldwide. Studies have demonstrated that several genes were associated with AI such as ENAM and MMP20 genes. MMP20 gene is part of a cluster of matrix metalloproteinase (MMP) genes. Protein of the (MMP) family is involved in the breakdown of extracellular matrix in normal physiological processes. ENAM is another gene and it plays crucial role in normal teeth development. The aim of this investigation was to study mutation detection in 10 Iranian families with non-syndromic AI. We carried out a polymerase chain reaction (PCR) and single-stranded conformation polymorphism (SSCP) for mutation detection within ENAM and MMP20 genes. SSCP analysis of genomic DNA from the AI family revealed the presence of an abnormal conformer in the AI patients. DNA Sequencing revealed the presence of mutation in the different part of the subjected. We found genetic changes in patients with different type of inheritances, one patient in exon 4 of MMP20 gene and one patient for ENAM exon 9. The data presented here is in agreement with the previous studies that suggested these genes are associated with tooth disorder. Taken together these findings support MMP20 and ENAM as disease genes, and opened a new window on the molecular mechanism of the AI disease and to the function of the enamelin protein in enamel formation.

P05.006

The role of ATM in monitoring the integrity of mitotic spindle

L. Chessa¹, A. Prodosmo², A. De Amicis¹, M. Gabriele³, M. Piane¹, S. Soddu², E. Cundari³;

¹II Faculty of Medicine, Sapienza University, Roma, Italy, ²Department of Experimental Pathology, Regina Elena Cancer Institute, Roma, Italy, ³Institute of Biology and Molecular Pathology, National Research Council, Roma, Italy.

Centrosomes are cytoplasmic organelles that organize the interphase cytoskeleton and contribute to bipolar spindle formation during mitotic cell division. Dysfunction of the centrosome/centriole regulatory controls can generate supernumerary centrosomes, abnormal mitotic spindles and finally chromosomal instability.

We previously showed that during the cell cycle progression ATM is activated by phosphorylation at Ser1981 at each mitosis and localizes at centrosomes together with p53 phosphorylated at Ser15, so as to keep it inactive at centrosomes when the spindle is correctly in place. In case of disruption of mitotic spindle, as the result of nocodazole damage, the colocalization of ATM and p53 is lost at centrosomes but present in form of spots dispersed in the cytoplasm (Oricchio et al., 2006).

Here we show that in ATM-defective cells (both lymphoblasts and peripheral blood lymphocytes from AT patients) p53 does not colocalize

at centrosomes with gamma-tubulin. In contrast, the colocalization of p53 and gamma-tubulin takes place in Mre11-defective cells established from an AT-LD patient. In conclusion, the monitoring of the mitotic spindle appears to be an ATM-dependent phenomenon.

Incidence of NLGN genes in greek autistic patients

K. Volaki¹, A. Pampanos¹, O. Papadaki-Papandreou², S. Giouroukos², L. Thomaidou², V. Oikonomakis¹, E. Kanavakis¹, S. Kitsiou-Tzeli¹;

¹Department of Medical Genetics, Medical School of Athens University, Aghia Sophia Children's Hospital, Athens, Greece, ²First Department of Pediatrics, Medical School of Athens University, Aghia Sophia Children's Hospital, Athens, Greece.

Autism and Autism Spectrum Disorders (A.S.D.) belong to the group of neurodevelopmental disorders with a prevalence of 5-10/10,000 and male to female ratio 3-4:1.

This study aimed to analyse the Neuroligin 3 gene (*NLGN3*, Xq13) and Neuroligin 4 gene (*NLGN4*, Xp22.3) in patients with A.S.D. The sample includes 367 individuals of Greek origin (169 patients, 154 mothers, 44 first-degree relatives). All patients had been diagnosed with A.S.D. by neurologists, psychiatrists and clinical geneticists according to the DSM-IV criteria. Patients carrying chromosomal aberrations or Fragile X syndrome were excluded from the study. The mutation p.Y74Y of *NLGN3* was examined with ARMS PCR whereas mutations p.R451C of *NLGN3* and p.1186insT of *NLGN4* were screened by dHPLC. Mutations p.Y74Y and p.R451C were not identified in our samples. However, the dHPLC screening for the p.1186insT mutation suggested the existence of a mutation in two samples (in a patient and his mother). Sequencing revealed the c.1597A>G mutation (p.K378R) in *NLGN4*. This gene is thought to play an important role in synaptogenesis and synapse remodelling in the neuronal circuitry of the brain, representing a good functional candidate for A.S.D. This is the first molecular study of individuals with A.S.D. in Greece. Sequencing of the rest of the exons of our samples may allow for a genotype-phenotype correlation in the Greek population.

P05.008

Auto-brewery syndrome - genetic testing

S. Wisniewski, **K. Kordel**, R. Wachowiak;

University of Medical Sciences, Poznan, Poland.

The concentration of ethanol in blood, expired air and urine constitutes important proof to accuse drunk drivers. However the reliability of alcohol concentration analysis results is very often questioned by the lawyers. One of the argument is the opinion that alcohol could be produced in the body, due to "auto-brewery" syndrome - increased level of blood alcohol caused by yeast or bacterial fermentation in the small intestine. Moreover, endogenous alcohol is produced in blood even after human death. Our aim was to prepare genetic test to confirm or exclude presence of microbial flora of intestine and blood. DNA was isolated from blood and intestinal content samples collected during autopsies of car accidents victims and was used in PCR reaction with universal primers targeting the conserved regions ITS1 and ITS2. Autopsy samples were compared with known fungal strains. The results induced us to propose one hybridization fluorescent probe combined with Cy5 and LNA nucleotides. The probe works with LightCycler system in one reaction with SYBR Green and allows to detect specifically 6 common yeast species. The method seems to be fast, cost-effective and decisive in cases of judicial doubts.

Autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED) is a rare autosomic autoimmune disease resulting from the defective function of a gene codifying for a transcription factor named autoimmune regulation (AIRE). The AIRE protein contains several domains among which two PHD fingers involved in the transcriptional

activation. We investigated the function of the two PHD finger domains and the COOH terminal portion of AIRE by using several mutated constructs transfected in mammalian cells and a luciferase reporter assay. The results predict that the second PHD as well as the COOH terminal regions have marked transactivational properties. Our studies indicate a prevalent role of the second PHD since the C446Y mutation, which alters the PHD2 sequence led to a complete loss of the transactivation activity.

The COOH terminal region contains the fourth LXXLL and the PXX-PXP motifs which play a critical role in mediating the transactivation capacity of the AIRE protein. On the other hand, the crucial role of the PXXXP sequence has already been defined by the finding of the disease-causing mutation in the sequence of APECED patients. Our study provides a definition of the role of the PHD fingers in transactivation and identifies a new transactivation domain of the AIRE protein localized in the COOH terminal region.

Homozygosity mapping with SNP arrays as a useful technology for diagnosis in complex diseases as Bardet-Biedl syndrome in consanguineous families

I. Pereiro¹, M. Piñeiro¹, D. Valverde¹, D. Nishimura²;

¹University of Vigo, Spain, Vigo, Spain, ²Department of Paediatrics, Howard Hughes Medical Institute, University of Iowa, Iowa, IA, United States.

Bardet-Biedl syndrome (BBS, MIM 209900) is a rare pleiotropic human genetic disorder that has as primary phenotypic features: early-onset retinitis pigmentosa, obesity, renal abnormalities, limb abnormalities and also a variable degree of cognitive impairment.

This disorder is genetically heterogeneous with twelve genes identified (*BBS1-BBS12*). BBS also shows considerable inter- and intra-familial variation of the phenotype. To date mutation screening has resulted in the identification of approximately 70% of the causative mutations, indicating that additional BBS genes have to be identified.

At the moment is very hard and time consuming to search for mutations in each of the genes involved, as some of them have been implicated in a very low percentage. In this study we employed high-density SNP genotyping for homozygosity mapping in the identification of gene mutations to simplify this task in consanguineous families.

Nine consanguineous families were analyzed, and in five of them linkage to a known BBS loci was detected. Sequencing of the BBS gene that localizes in the locus where linkage was detected, revealed 5 new mutations (G2X, BBS3; L454P and G250R, BBS6; P108 and del 2pb in 372, BBS12). Cosegregation of the mutation in the family corroborates the pattern of autosomic recessive inheritance.

For the rest of the families linkage indicated several novel candidate BBS gene loci.

Hypomorphic mutations in syndromic encephalocoele genes are associated with Bardet-Biedl syndrome

A. Diaz-Font¹, C. C. Leitch², N. A. Zaghloof³, E. E. Davis², C. Stoetzel⁴, S. Rix¹, M. Al-Fadhel⁵, R. A. Lewis⁶, W. Eyaid⁴, E. Banir⁶, H. Dollfus³, P. L. Beales¹, J. L. Badano^{2,7}, N. Katsanis²;

¹Institute of Child Health, London, United Kingdom, ²McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States, ³Laboratoire de Génétique Médicale, Faculté de Médecine de Strasbourg, Université Louis Pasteur, Strasbourg, France, ⁴Department of Pediatrics, King Fahad Hospital, Riyadh, Saudi Arabia, ⁵Departments of Ophthalmology, Molecular and Human Genetics, Pediatrics, and Medicine, Baylor College of Medicine, Houston, TX, United States, ⁶Department of Ophthalmology, Hadassah-Hebrew University Hospital, Jerusalem, Israel, ⁷Institut Pasteur de Montevideo, Montevideo, Uruguay.

Meckel-Gruber syndrome (MKS) is a genetically heterogeneous, neonatal lethal malformation and the most common form of syndromic neural tube defects (NTDs). To date, several MKS genes have been identified, whose protein products affect ciliary function¹⁻⁵. Here we show that mutations in *MKS1*, *MKS3* and *NPHP* both cause Bardet-Biedl syndrome (BBS) and also have a potential epistatic effect on mutations in known BBS loci. Five of six families with *MKS1* and BBS mutations manifested seizures, a feature that is not a typical component of either syndrome. Functional studies in zebrafish showed that *mks1* is necessary for gastrulation movements and that it interacts genetically with known *bbs* genes. These observations are not restricted to

MKS1. We also found two families with missense or splice mutations in *MKS3*, one of which also bears a homozygous nonsense mutation in *NPHP6* that likely truncates the extreme C-terminus of the protein. These data extend the genetic stratification of ciliopathies and suggest that BBS and MKS, although clinically distinct, are allelic forms of the same molecular disorder.

P05.012

Bartter syndrome: think of *CLCNKB*

E. Kamsteeg¹, J. Schoots¹, N. V. A. M. Knoers¹, H. Scheffer¹, L. H. Hoefsloot¹; Radboud University Medical Centre, Nijmegen, The Netherlands.

Bartter syndrome (BS) is an autosomal recessive disorder characterized by renal salt wasting and hypokalaemic metabolic alkalosis. The primary defect is a reduced NaCl reabsorption in the thick ascending limbs of Henle's loop. Four types of recessive BS exist: congenital without (I/II) or with sensorineural deafness (IV) and the milder form (III). Mutations in *SLC12A1*, *KCNJ1*, *CLCNKB* and *BSND* give rise to BSI-IV, respectively. Here, we have analyzed *CLCNKB* in a group of *KCNJ1*-mutation negative BS patients (n=60).

More than half of the published mutations in BSIII are (partial) *CLCNKB* deletions, caused by unequal cross between the homologous *CLCNKA* and *CLCNKB*. Therefore, we have performed multiplex ligation-dependent probe amplification analysis of *CLCNKB*. Deletion of the entire gene has been observed homozygously in four and heterozygously in 2 patients. Three patients have a heterozygous deletion of the 5' end of the gene (promoter region through exon 8). Additionally, sequence analysis revealed a second mutation in the five patients with a heterozygous deletion. In the remaining patients, we have found seven patients with two mutations (both in the homozygous or compound heterozygous state), but also 7 patients with only one mutation. It is unclear whether the second mutation is present elsewhere in the *CLCNKB* gene, or whether one of the other genes involved in BS is mutated.

Together, BS type III has been confirmed in 16 of the 60 BS patients. Since we have found mutations in *KCNJ1* in 10 patients, we suggest that BSIII is more prevalent than BSII.

¹Center for Medical Genetics, Ghent University, Ghent, Belgium, ²Department of Genetic Medicine and Development, University of Geneva Medical School, Geneva, Switzerland, ³Regensburg University Medical Center, Department of Pediatric Ophthalmology, Regensburg, Germany, ⁴Department of Medical and Molecular Genetics, Pathology and Paediatric Endocrinology, Hospital Universitario La Paz, Madrid, Spain, ⁵Department of Medical Genetics, Alberta Children's Hospital, Calgary, AB, Canada, ⁶Department of Endocrinology, East Pole of Lyon Hospitals, and INSERM Unit 0322, Lyon, France, ⁷Center for Human Genetics, Leuven University Hospitals, Leuven, Belgium, ⁸National Centre for Medical Genetics, Our Lady's Hospital for Sick Children, Crumlin, Dublin, Ireland, ⁹Department of Human Genetics, Hôpital du Sart Tilman, Liège, Belgium, ¹⁰Institute of Human Genetics, International Centre for Life, University of Newcastle, Newcastle, United Kingdom, ¹¹St James's University Hospital, Leeds, United Kingdom, ¹²Department of Paediatrics, Hospital 12 de Octubre, Madrid, Spain.

Blepharophimosis syndrome (BPES) is a development disorder caused by *FOXL2* mutations, total gene deletions or extragenic deletions. In 12% of patients however, the molecular defect remains unknown. We hypothesise that copy-number variations (CNVs) or point mutations in *cis*-regulatory regions mapping within the minimal extragenic deletion region could affect *FOXL2* transcription and cause disease.

In a panel of 33 molecularly unresolved BPES patients, one novel extragenic deletion upstream of *FOXL2* was found by array CGH. This deletion overlaps with the previously defined shortest region of overlap (SRO) of upstream extragenic deletions, and was confirmed by qPCR. In addition, qPCR of 25 CNCs located in this SRO revealed putative CNVs in 9 patients, of which the significance is being evaluated. Moreover, sequencing of the 25 CNCs revealed 4 putative pathogenic variants, which are further being investigated by luciferase assays.

Second, we characterized 9 known deletions of the *FOXL2* region using array CGH. In addition, 10 new deletions identified by MLPA were further defined by qPCR. These deletions prove to be highly heterogeneous with regard to deletion size and breakpoint localization. They account for 12% of molecular defects in BPES, highlighting the importance of copy number analysis in BPES.

In conclusion, we showed that copy number changes of *FOXL2* comprise a considerable fraction of the molecular defects in BPES. Moreover, the extensive search for CNVs and point mutations in CNCs mapping distantly of *FOXL2* in BPES patients, support the importance of long distance gene regulation in the molecular pathogenesis of this disorder.

P05.014

Molecular analysis of the *ATP6V1B1* and *ATP6V0A4* genes in distal renal tubular acidosis

I. Carboni¹, E. Andreucci¹, I. Pela², G. Lavoratti³, M. Materassi³, D. Serafini³, M. R. Caruso⁴, M. Rigoldi⁵, M. Genuardi¹, S. Giglio¹;

¹Dept. of Clinical Pathophysiology, University of Florence and Medical Genetics Unit, Meyer Children's University Hospital, Florence, Italy, ²Paediatric Nephrology, Dept. of Paediatrics, University Of Florence and Meyer Children's University Hospital, Florence, Italy, ³Paediatric Nephrology, Dept. of Paediatrics, University of Florence and Meyer Children's University Hospital, Florence, Italy, ⁴Division of Nephrology and Dialysis, OORR Hospital, Bergamo, Italy, ⁵Metabolic Diseases Unit, San Gerardo Hospital, Monza, Italy.

Primary distal renal tubular acidosis (dRTA) is characterized by defective secretion of H⁺ ions by intercalary cells of the collecting duct. Both autosomal dominant (AD) and recessive (AR) forms have been described. The AD form is caused by mutations of the *SLC4A1* gene. The AR form has been associated with mutations of either *ATP6V1B1* - in individuals who usually display sensorineural hearing loss (SNHL) - or *ATP6V0A4* - in individuals who do not have SNHL or show hearing loss only after the first decades of life.

We report on the first investigation of the *ATP6V1B1* and *ATP6V0A4* genes in dRTA patients in Italy. Mutations were identified in 8/8 patients analyzed.

The *ATP6V0A4* Arg807Gln mutation was found at the homozygous state in a patient with severe early-onset SNHL, that is generally not observed in subjects with *ATP6V0A4* defects. Only another case with the same genotype, who had a comparably severe phenotype, is reported in the literature.

A monoallelic *de novo* *ATP6V1B1* mutation (Arg394Gln) was observed in one patient with a typical dRTA renal phenotype without deafness. This mutation has been previously described in two cases, who also were apparently simple heterozygotes.

We also detected three previously unreported mutations, two in *ATP6V0A4* and one in *ATP6V1B1*.

Our results shed further light on phenotype-genotype correlations in dRTA. In particular, the association of a specific monoallelic *ATP6V1B1* mutation with a dRTA phenotype without hearing loss suggests that other genetic mechanisms, in addition to autosomal recessive inheritance, may be associated with *ATP6V1B1* alterations.

P05.015

An *EYA1* gene mutation in intron 8 [c.867+5G>A] causes alternative RNA splicing and is a recurrent mutation causing Branchial-oto-renal syndrome

T. L. Stockley^{1,2}, R. Mendoza-Londono^{1,2}, E. J. Propst^{1,2}, S. Sodhi¹, L. Dupuis¹, B. C. Papsin^{1,2};

¹The Hospital for Sick Children, Toronto, ON, Canada, ²The University of Toronto, Toronto, ON, Canada.

Branchio-oto-renal (BOR) syndrome is a heterogeneous autosomal dominant disorder characterized by branchial arch abnormalities, hearing loss and renal abnormalities. Variable expression of clinical features is found within and between affected families. Mutations in the *EYA1* gene are reported to account for 40-70% of reported BOR syndrome cases. We have developed a strategy for molecular testing of the *EYA1* gene causing BOR syndrome consisting of 1) sequencing of the complete coding region and flanking intronic regions and 2) multiple ligation probe amplification (MLPA) analysis. Using this strategy *EYA1* mutations were identified in 82% (14/17) of a cohort of paediatric BOR syndrome probands. Forty-five percent (5/11) of BOR syndrome probands in our cohort had *de novo* *EYA1* mutations, suggesting that the incidence of *de novo* cases in BOR syndrome is higher than 10%

previously reported. We also describe a previously unreported recurrent *EYA1* gene mutation c.867+5G>A found in 21% (3/14) of *EYA1* mutation-positive BOR probands in our patient cohort. RNA analysis indicates that the c.867+5G>A mutation affects splicing of the *EYA1* gene, and produces an aberrant mRNA transcript skipping exon 8 and leading to a premature termination signal in exon 9. The aberrant transcript lacking exon 8 was present at approximately 50% level of wild-type *EYA1* mRNA in fibroblasts, and suggests that certain transcripts of *EYA1* escape nonsense-mediated decay and encode truncated EYA protein capable of dominant-negative interactions causing disease.

P05.016

BSCL2 and its possible function in adipogenesis

D. Jud, T. Schwarzbraun, C. Windpassinger, K. Wagner; Institute of Human Genetics, Graz, Austria.

Congenital generalized lipodystrophy, first described by Berardinelli (1954) and Seip (1959), is a rare autosomal recessive disorder characterized by near complete absence of adipose tissue from birth or early infancy. Two distinct forms can be distinguished: CGL1 and CGL2, whereas CGL1 is caused by mutations in *AGPAT2* and CGL2 by mutations in *BSCL2*. Whilst mutations in *AGPAT2*, a member of the acyltransferase family, likely cause lipodystrophy by reducing triglyceride synthesis in adipose tissue, the pathogenic effects of mutations in *BSCL2* on a molecular level are not yet fully understood. Further clinical features of both subtypes include severe insulin resistance, acanthosis nigricans, muscular hypertrophy, hepatomegaly, diabetes mellitus and hypertriglyceridemia. However patients with CGL2 show a more severe phenotype with lack of both metabolically active and mechanical adipose tissue, a higher prevalence of mild mental retardation and hypertrophic cardiomyopathy.

To elucidate the function of *BSCL2* in adipogenesis we generated *BSCL2* knock-out flies. These knock-out strains showed altered architecture and distribution of lipid droplets in adipose tissue. Therefore our data suggest that *BSCL2* is involved in lipid droplet formation and/or maintenance in *Drosophila*. To confirm these data in mammals we created a mouse knock-out model for *BSCL2*. We chose the Cre-loxP system to obtain conditional knock-out mice in order to investigate the function of *BSCL2* in relevant tissues specially during adipocyte development. We will apply molecular genetic, histological, biochemical and cell culture methods to further determine the enigmatic role of *BSCL2* in adipogenesis and in the pathophysiology of CGL2.

P05.017

The functional significance of the C1 inhibitor gene promoter mutations

L. Grodecka¹, H. Grombirikova¹, B. Ravcukova¹, J. Litzman², T. Freiburger¹;

¹Molecular Genetics Laboratory, Centre for Cardiovascular Surgery and Transplantation, Brno, Czech Republic, ²Institute of Clinical Immunology and Allergology, Faculty of Medicine of Masaryk University, St. Anne's University Hospital, Brno, Czech Republic.

C1 inhibitor (C1INH) is a key negative regulator of complement activation. Decreased level of functional C1INH causes hereditary angioedema which is usually transmitted as an autosomal dominant trait. Till now, three promoter mutations have been detected in the C1 inhibitor gene (C1NH), one of them (-45 C>A) having been newly identified in our laboratory. Mutations -40 C>G and -45 C>A both appeared to cosegregate with other mutations in coding region, while the third mutation -103 C>T did not. Interestingly, in patients suffering from hereditary angioedema, mutation -103 C>T was found exclusively in homozygous state while heterozygous individuals were healthy. The objective of our work was to assess functional importance of the three promoter mutations on the C1NH gene expression. Results of luciferase reporter gene assay showed that two of the mutations, -40 C>G and -45 C>A, have negligible effect on C1INH expression. Surprisingly, mutation -103 C>T increased luciferase gene expression by 59% in comparison to wild type promoter construct. Yet plasma levels of C1 inhibitor in patients with this mutation were significantly decreased. The reason for this discrepancy is not obvious. However, a negative correlation between amount of mRNA and plasma levels of C1INH has already been described in healthy controls. Such a correlation suggests that a negative feedback regulation of C1INH expression may exist.

This study was supported by grant of IGA MZ CR No. NR 9192-3.

P05.018**Screening for CADASIL in central Italian patients**

L. Pianese¹, A. Cappelli^{1,2}, M. Scarcella³, G. Cacchiò³, P. Staffolani¹, M. Ragno³;

¹Laboratorio Medicina Molecolare, ASUR ZT13, Ascoli Piceno, Italy, ²School of Advanced Studies: Environmental Sciences and Public Health, Camerino, Italy, ³U. O. Neurologia, ASUR ZT13, Ascoli Piceno, Italy.

Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is an inherited autosomal dominant condition characterized by a variable combination of recurrent cerebral ischemic episodes, cognitive deficits, migraine with aura and psychiatric symptoms. It results from mutations distributed throughout the 34 EGFRs (epidermal growth factor-like repeats) of the Notch3 gene, leading to the addition or the loss of a cysteine residue.

We performed genetic testing for Notch3 mutations in 45 probands of different family with suspected CADASIL who had been referred to our service in 2007. DNA samples were analyzed for mutations in all exons of EGFRs using an appropriate screening protocol considering the mutations distribution in exons gene.

The sequence analysis of Notch3 gene revealed the presence of three previously reported missense mutations: C144F in exon 4, G528C in exon 10 and R1006C in exon 19. In particular, the mutation C144F was found in one family, whereas the mutations G528C and R1006C were found in two and seven families respectively, with the same regional origin. These results suggest a higher frequency of exon 10 and 19 mutations in central Italy and confirm that the genetic procedures could be optimized by a geographical region-oriented genetic analysis.

We are extending genetic analysis to the remaining exons of Notch3 gene in patients with clinical and strumental features more suggestive of CADASIL phenotype, negative for EGFRs mutations.

P05.019**KRIT1 gene mutations in Sardinian patients with cerebral cavernous malformations**

M. A. Melis¹, M. Addis¹, R. Congiu¹, C. Meloni¹, A. Lo², M. Melis³, M. Loi³, M. Cau¹;

¹University of Cagliari, Cagliari, Italy, ²Ospedale Regionale per le Microcitemie, Cagliari, Italy, ³Azienda Ospedaliera Brotzu, Cagliari, Italy.

Cerebral Cavernous Malformations (CCM) are CNS vascular anomalies associated with seizures, headaches and hemorrhagic strokes and represents 10 to 20 percent of cerebral lesions. CCM is present in 0.1 to 0.5 of the population. This disorder most often occurs sporadically but may also be familial. Familial cases are inherited as a dominant trait with incomplete penetrance and are estimated to account for 10-40 % of the patients. The identification of the genes involved in such disorders allow to characterize carriers of the mutations without clear symptoms. The first gene involved in CCM1 is KRIT 1. In addition to KRIT1 two other genes have been described: MGC4607 (CCM2) and PDCD10 (CCM3). We selected 14 patients belonging to seven Sardinian families on the basis of clinical symptoms and Magnetic Resonance results. MLPA analysis of KRIT1, MGC4607 and PDCD10 gave negative results. Sequencing analysis of KRIT1 gene was performed in all the patients. We identified a 4bp deletion in exon 9 leading to a premature stop codon in a patient with clear phenotype. The same mutation has been found in three relatives showing very mild symptoms. In 5 subjects belonging to four unrelated families a unique nonsense mutation (C329X) has been found. Haplotype analysis in these four families revealed a common origin of the mutation. These data suggest a "founder effect", already described in different populations.

P05.020**Functional analysis of CD96, a causative gene for a form of C (Opitz trigonocephaly) syndrome**

T. Kaname^{1,2}, K. Yanagi¹, Y. Chinen¹, Y. Makita³, N. Okamoto⁴, K. Kurosawa⁵, H. Maehara¹, Y. Fukushima⁶, A. Bohring⁷, J. M. Opitz⁸, K. Yoshiura^{9,2}, N. Niikawa^{10,2}, K. Naritomi^{1,2};

¹University of the Ryukyus, Nishihara-cho, Japan, ²SORST, JST, Kawaguchi, Japan, ³Asahikawa Medical College, Asahikawa, Japan, ⁴Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, Japan, ⁵Kanagawa Children's Medical Center, Yokohama, Japan, ⁶Shinshu University School of Medicine, Matsumoto, Japan, ⁷Westfälische Wilhelms-Universität, Münster, Germany, ⁸University of Utah School of Medicine, Salt Lake City, UT, United States, ⁹Nagasaki University Graduate School of Biomedical Sciences, Na-

gasaki, Japan, ¹⁰Health Sciences University of Hokkaido, Tobetsu-cho, Japan. The C syndrome is characterized by trigonocephaly associated with unusual facies, psychomotor retardation, redundant skin, joint and limb abnormalities, and visceral anomalies. In an individual with the C syndrome harboring a balanced chromosomal translocation, t(3;18)(q13.13;q12.1), we identified a gene (CD96), which encodes a member of the immunoglobulin superfamily, was disrupted at the 3q13.3 breakpoint. In mutation analysis of karyotypically normal patients with the C or C-like syndromes, we identified a missense mutation in exon 6 of the CD96 gene in one patient and found reduced expression in two patients. In order to know the function of CD96, we established normal CD96 or the mutated CD96 expressed cell lines and investigated their characters especially on cell-adhesion activity and cell-growth activity. Cells with the normal CD96 protein increased both the cell-adhesion and growth activities compared with MOCK cells. On the other hand, cells with the mutated CD96 protein lost the activities in vitro. These findings may indicate that CD96 mutations cause a form of the C syndrome by interfering with cell adhesion and growth.

P05.021**Evidence on microRNA-mediated regulation of CDK5R1 gene expression**

S. Moncini¹, M. Venturin¹, A. Salv², V. Lanzi¹, C. Sabell², G. De Petro², S. Barlat², P. Riva¹;

¹University of Milan, Milan, Italy, ²University of Brescia, Brescia, Italy.

CDK5R1 encodes for p35, an activator of CDK5, which is involved in neuronal migration and differentiation during central nervous system development and has been candidate for mental retardation. We recently reported that the large 3' untranslated region (3'UTR) of CDK5R1 contains regulatory elements affecting transcript stability. Besides several AREs, many microRNAs (miRNAs) target sites have been predicted by PicTar software. We evaluated the expression of nine pre-miRNAs, among the 20 miRNAs predicted to bind CDK5R1, in six cell lines, including two neuroblastoma derived lines. Among the expressed miRNAs, we observed that miR-15a, miR-103 and miR-107 presented a high number of target sites with a free energy <-20 kcal/mol. A preliminary quantitative analysis of the three above miRNAs and p35 showed an inverse correlation between miR-107 and p35 expression, suggesting a negative effect of miR-107 on CDK5R1 expression. Overexpression of miR-107 by transfection of the specific precursor in neuroblastoma SK-N-BE cells showed, after 72 hours, a 45 and 75% decrease in p35 expression respectively using 50 and 100 nM of the precursor.

Transfection of anti-miR-107 will be tested. Luciferase constructs will be used to validate the predicted miRNA target sites in CDK5R1 3'UTR. These preliminary data allow us to hypothesize a role of miRNAs in post-transcriptional CDK5R1 regulation.

P05.022**Expression of ceruloplasmin and ferroportin in human peripheral blood lymphocytes: a new link between iron metabolism and the immune system**

L. Marques, J. Banha, R. Oliveira, L. Costa;

Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisboa, Portugal.

Background: Ceruloplasmin (Cp) is a multicopper oxidase with a relevant role in iron (Fe) metabolism mainly due to its ferroxidase activity. Cp exists in a secreted form (sCp) and a membrane glycosylphosphatidylinositol-anchored form (GPI-Cp). Recent studies showed that Cp ferroxidase activity is required for ferroportin (Fpn) stability on cell surface. Herein we report the expression of both Cp isoforms and Fpn in human peripheral blood lymphocytes (PBL).

Material and Methods: PBL were isolated followed by total RNA extraction, cDNA synthesis and subsequent analysis of Cp and Fpn transcripts by PCR. For immunoblotting, protein extracts from membrane and cytosolic fractions were prepared. For immunofluorescence, cells were cultured with and without PI-PLC (an enzyme that cleaves GPI groups) followed by immunolabeling for Cp and analysis by confocal microscopy.

Results and Conclusion: Both Cp isoforms and Fpn were shown to be expressed at both mRNA and protein level. Cp and Fpn were also shown to be localized at PBL membrane. Confocal analysis of immunolabeled PBL treated with PI-PLC showed a significant reduction of Cp labeling compared to untreated PBL, showing that at least part of

Cp expressed at PBL membrane is GPI-anchored. Altogether, these data show that human PBL express both sCp, GPI-Cp and Fpn. Studying the expression of these proteins in cells of the immune system (IS) may contribute to understanding the regulation of the Fe homeostasis by the IS and also allow to access Cp isoforms and Fpn activities associated to pathological conditions, often neurological, in cells from peripheral blood.

P05.023

Myotonia congenita: identification of eleven new mutations in the CLCN1 gene

J. F. Quesada¹, I. S. Pascual, J. Martíáñez, J. M. Molano;
Hospital Universitario La Paz, Madrid, Spain.

Introduction. Myotonia congenita (MC) is a rare autosomal inherited disorder characterized by muscle stiffness and hypertrophy. MC is inherited in two different forms: a dominant form, designated as Thomsen's myotonia, or a recessive form, designated as Becker's generalized myotonia. However, both forms are caused by mutations in a unique gene, the CLCN1 gene, which encodes the major chloride channel in skeletal muscle. In this communication, we identified 11 new mutations in Spanish patients. We assumed these are disease-causing mutations and no polymorphisms because the mutated amino-acid residues are conserved through evolution. Our future project is to characterize, using patch-clamp analysis, the effect of these mutations on the clc1 channel function.

Patients and Methods. We analyzed DNA extracted from peripheral blood of patients attending to Neurology Services from several tertiary Spanish hospitals. Each CLCN1 exon and boundary intron regions were amplified by the DNA polymerase chain reaction (PCR) and products were DNA sequenced in an ABI Prism® 3130 XL instrument.

Results. We analyzed DNA from 103 patients (51 families) with myotonia as major symptom having previously excluded the myotonic dystrophies. We have found 20 different mutations, including 11 mutations that are not described before. Four mutations (F167L, Y302H, M485V and R894X) were recurrent in our serie.

Conclusions. Analysis of mutations in CLCN1 gene in 51 Spanish families with myotonia suggest that there are remarkable differences in the mutation profiles between Spanish and other Caucasian populations.

P05.024

A silent mutation within protectin (CD59) gene and exon skipping in a family with coeliac disease

C. Vidal¹, J. Borá¹, A. Fenech², A. Xuereb-Anastasí³, C. Scerri¹;

¹Department of Physiology and Biochemistry, Msida, Malta, ²Department of Clinical Pharmacology and Therapeutics, University of Malta, Msida, Malta, ³Institute of Health Care, Msida, Malta.

Protectin (CD59), which inhibits the assembly of the membrane attack complex following complement activation, was reported to be upregulated in coeliac disease [1]. Its gene is located on chromosome 11p12, to which suggestive linkage was observed in a Maltese family with coeliac disease.

Sequencing of CD59, APAF-1 interacting protein and CD44 genes, revealed a number of variants. Two synonymous variants, a C/T transition (rs1071695) in CD44 and a novel G/A change within CD59, were co-segregating with the linked haplotype in all affected individuals. Only one A allele, from 442 chromosomes, was found in the general population (0.23%) and was completely absent in a group of coeliac patients, showing that this is a rare variant found within this family.

Two constructs consisting of normal and mutated exons together with adjacent introns were cloned into pSPL3, and transfected into HeLa and COS-7. Reverse transcriptase-PCR was performed, followed by agarose gel electrophoresis and sequencing. Both wild-type and mutated constructs for the CD59 variant resulted in a normally and an abnormally spliced transcript lacking the exon involved (coding for signal peptide), which was more pronounced in the presence of the A allele. No abnormally spliced transcripts were observed for the other variant within CD44.

In this study, a novel synonymous variant within the CD59 gene was shown to affect splicing, possibly due to effects on the secondary structure of pre-mRNA, increasing the susceptibility to coeliac disease in this family.

P05.025

In depth study of hCYP21A2 in Spanish General Population: High frequency of gene duplications and sequence variations

S. Parajes¹, B. Giménez¹, C. Quinteiro¹, F. Domínguez^{1,2}, L. Loidi¹;

¹Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain, ²Dpto. Fisiología, Universidad de Santiago de Compostela, Santiago de Compostela, Spain.

21-hydroxylase deficiency (21OHD) is one of the most common autosomal recessive disorders. The 21-hydroxylase enzyme is encoded by hCYP21A2 gene, which is highly homologous to the hCYP21A1P pseudogene. The high variability of the CYP21A2 locus hinders the characterization of 21OHD alleles and complicates disease carrier detection and genetic counselling. We present the study of hCYP21A2 in 288 Spanish population chromosomes to estimate frequency of 21OHD carriers, hCYP21A2 duplications and hCYP21A2 novel variations.

hCYP21A2 was sequenced after PCR amplification in two fragments and hCYP21A2 dosage was done by Real-Time PCR. Haplotype construction was based on a Bayesian method using 20 polymorphisms all over hCYP21A2.

Copy number variations. 3.5% of alleles carried two copies of hCYP21A2 associated mostly with p.Gln318X.

Frequency of putative disease-causing alleles. 23 hCYP21A2 mutations were found (8% of alleles): 17 are known to allow 30-60 % of the WT activity, 2 completely impairs enzyme activity, and 4 were novel, which effect on the activity is unknown.

hCYP21A2 polymorphism. 79 different variations were found distributed all over the gene and its close vicinity.

Haplotypes. 75 different haplotypes were identified, most appearing only once, but some recurrent.

This study shows the highest frequency of 21OHD carriers reported by genotyping study. Furthermore, it showed a high frequency of hCYP21A2 duplications with one of the copies mutated and also high frequency of novel mutations with unknown effect on the 21OH activity. These novel variations as well as gene duplications should be considered when doing the genetic 21OHD diagnosis and genetic counselling.

P05.026

Inactivating mutations in the ABCC8 gene in patients with congenital hyperinsulinism of infancy (CHI)

A. Benet-Pagès¹, O. Blankenstejn², S. Lösecke¹, K. Mohnike³, T. M. Strom¹, B. Lorenz-Depiereux¹;

¹Institute of Human Genetics, Technical University Munich and Helmholtz Center Munich, German Research Center for Environmental Health, Neuherberg-Munich, Germany, ²Department of Pediatrics Endocrinology and Diabetes, Charité Campus Virchow, Berlin, Germany, ³Department of Pediatrics and Neonatology, Otto von Guericke University, Magdeburg, Germany.

Congenital Hyperinsulinism of Infancy (CHI) is a genetically heterogeneous disease characterized by severe hypoglycemia due to excessive insulin secretion from pancreatic β -cells. Two histopathologically and genetically distinct groups are recognized among patients with CHI. A diffuse form, which involves the entire pancreas, arises predominantly from autosomal recessive inheritance. A focal form, which shows localized adenomatosis of islet cells within the normal pancreas, arises from a germline mutation of the paternal allele in addition to somatic loss of the maternal allele in adenomatous pancreatic β -cells. The most common cause of CHI are inactivating mutations in the genes coding for the two subunits of the β -cell ATP-sensitive K⁺ channel, ABCC8/SUR1 (regulatory subunit) and KCNJ11/Kir6.2 (pore-forming subunit). We examined 64 children with a diffuse, focal, atypical or unknown form of CHI and sequenced the entire coding region and the exon/intron boundaries of the ABCC8 and KCNJ11 genes. We found 34 mutations (4 homozygous, 7 compound heterozygous, 23 heterozygous) in the ABCC8 gene (53%) and 2 heterozygous mutations in the KCNJ11 gene (3%). In 28 patients (43%) no mutations were identified (see table). Three patients with a heterozygous mutation in the ABCC8 gene and diffuse CHI inherited the mutation from the mother. We missed the second paternal mutation with our screening method. Most likely, the low detection rate is caused by missed mutations in ABCC8/KCNJ11 and further locus heterogeneity.

ABCC8 mutations in 64 children with CHI

Form of CHI	diffuse	focal	atypical	unknown	total
homozygous	3	0	0	1	4
compound heterozygous	7	0	0	0	7
heterozygous	10	9	0	4	23
no mutation	18	1	1	8	28
total	38	10	1	13	62

P05.027**Homozygosity mapping of congenital hyperinsulinism of infancy (CHI) in Italian patients**

A. Gessi¹, M. Proverbio¹, E. Mangano¹, R. Spinelli², M. Bove³, P. Sogno Valin³, S. Di Candia³, I. Zamproni⁴, S. Mora⁴, L. Bosio³, M. Caruso⁵, A. Salvatori⁶, G. Chiumello³, C. Battaglia¹;

¹Department of Science and Biomedical Technologies (DiSTeB), University of Milan, Milan, Italy, ²Institute of Biomedical Technologies (ITB-CNR), Segrate, Italy, ³Department of Pediatrics, Endocrine Unit, IRCCS San Raffaele Scientific Institute, Vita Salute San Raffaele University, Milan, Italy, ⁴Laboratory of Pediatric Endocrinology and BoNetwork, San Raffaele Scientific Institute, Milan, Italy, ⁵Department of Pediatrics, University of Catania, Catania, Italy, ⁶Department of Clinical and Biological Science (DSCB), Pediatric Clinic, University of Insubria, Varese, Italy.

Congenital hyperinsulinism of infancy (CHI) is a heterogeneous disorder due to genetic mutations 80% of which are found in genes encoding both subunits of pancreatic KATP channel ABCC8 and KCNJ11. Other causative genes have been identified but, up-to-date, in 30% of patients the genetic basis of CHI has yet to be determined, suggesting additional locus heterogeneity.

SNP microarrays have improved the possibility for autozygosity mapping of rare disorders with founder mutations, in order to identify disease susceptibility loci.

In our study we have performed a genome wide SNP mapping in twenty two CHI probands and their families using Affymetrix GeneChip® 250K Human Mapping arrays. Using a complex computational approach, we identified long contiguous stretches of copy number neutral-homozygous loci (autozygosity) on chromosomes 1, 5, 7, and 8, both in consanguineous and in non consanguineous families. Three patients, two of which carried a causative mutation on ABCC8/KCNJ11 genes, showed a wide common region of homozygosity on chromosome 11p15. Additionally, two probands shared stretches of homozygosity on chromosomes 4, 6, 10, 11 and 18.

Moreover, one patient, negative for ABCC8/KCNJ11 gene mutations, showed a homozygous region of 79Mb on chromosome 4 containing the causative gene HADH. Direct sequencing of the coding region of HADH gene showed a homozygous C to T transition in exon 6 leading to a premature stop of the synthesized protein. Further refinement of other candidate regions by microsatellites marker analysis and linkage analysis will be necessary to map other disease loci in CHI families.

P05.028**Congenital Nephrotic Syndrome (CNS) caused by a complex genotype in the Nephrin gene (NPHS1) revealing 2 novel mutations**

E. Fylaktou¹, S. Megremis¹, A. Mitsion², C. Stefanidis², S. Kitsiou - Tzeli¹, E. Kanavakis¹, J. Traeger - Synodinos¹;

¹Medical Genetics, Athens University, "Aghia Sofia" Children's Hospital, Athens, Greece, ²Department of Pediatrics Nephrology "P. A. Kyriakou" Children's Hospital, Athens, Greece.

Nephrotic syndrome (NS) is characterized by gross proteinuria, hypoalbuminemia, edema and hyperlipidemia, which in CNS manifest in utero or within 3 months after birth. Inherited impairments of the glomerular filtration barrier are an important cause of NS, and in CNS and infantile NS ~60% of cases are caused by mutations in 4 genes: Nephrin (NPHS1), Podocin (NPHS2), Laminin-β2 (LAMB2) and Wilm's Tumor suppressor gene (WT1). In a newborn with clinical findings compatible with CNS, and his parents, the 27 exons of the NPHS1 gene and 8 exons of the NPHS2 gene were subject to direct DNA sequencing analysis and mutation detection analysis (Surveyor mutation detection kit, Transgenomic, Elancourt, France). No mutations were found in the NPHS2 gene. However, the proband was found to have three heterozygous mutations in NPHS1: c.1096A>C (p.S366R) in exon9, c.649_650delGT (p.Cys217fsX) in exon6 and c.791C>G (p.P264R) in exon7. The mother was found to be heterozygous for c.1096A>C (p.S366R) while the father was heterozygous for the novel c.649_650delGT,

the known c.791C>G (p.P264R) and additionally a novel c.1619C>A (p.A540E) in exon12. In-silico analysis (SIFT, <http://blocks.fhcr.org/sift/SIFT.html>, polyphen, <http://genetics.bwh.harvard.edu/pph>) indicated that p.A540E is not pathological, which is confirmed since the unaffected father also carries c.649_650delGT (p.Cys217fsX) in exon6 and c.791C>G (p.P264R) in exon7. The novel 2bp deletion is predicted to cause a premature termination codon, and since it is apparently in cis to the previously described c.791C>G mutation, presumably the deletion mutation has the over-riding impact on the expression of the phenotype.

P05.029**Creatine deficiency syndromes in Spain: enzymatic and molecular genetic studies**

P. Alcaide^{1,2}, A. Ribes^{3,4}, A. Arias^{3,4}, R. Artuch^{5,4}, J. Campisto^{6,4}, B. Merinero^{1,2}, M. Ugarte^{1,2}, P. Rodríguez-Pombo^{1,2};

¹Centro de Biología Molecular Severo Ochoa. Dpto Biología Molecular. Universidad Autónoma de Madrid, Madrid, Spain, ²CIBERER, Madrid, Spain, ³Instituto de Bioquímica Clínica, Barcelona, Spain, ⁴CIBERER, Barcelona, Spain, ⁵Hospital San Joan de Deu, Barcelona, Spain.

Creatine deficiency syndromes (CDS) are a group of underdiagnosed inborn errors caused by defects in the biosynthesis of creatine or its transporter. The two defects affecting biosynthesis, namely arginine-glycine amidinotransferase (AGAT) and guanidinoacetate methyltransferase (GAMT) are autosomal recessive traits, whereas the creatine transporter (CRTR) is an X-linked disorder.

We present the results of a collaborative CDS prospective screening based on abnormal metabolite excretion or decreased creatine signal in brain MRS in a cohort of patients with mental retardation (MR) and/or suspected metabolic disorder. Three GAMT and nine CRTR cases were selected. Confirmatory diagnosis was assessed by measuring GAMT activity or creatine uptake in fibroblasts using MS/MS methods. Direct sequencing analysis of GAMT and SLC6A8 genes was carried out.

In two of the three potential GAMT patients, deficient activity was confirmed in fibroblasts (<4 % of matched control), and three new sequence variations were detected: c.145delT (p.Y49fs), which appeared in homozygous fashion, and c.316C>T (p.Q106X) and c.407C>T (p.T136M), both in heterozygous fashion. Four out of the nine CRTR cases selected (two from the same family) presented a deficient creatine transport in fibroblasts. Mutational analysis of SLC6A8 gene led us to identify three nucleotide changes, two of them novel: c.1210G>C (p.A404P); c.1079-1081delTCT (p.F360del). All changes identified in both genes fulfilled several criteria to be considered as pathogenic mutations.

Our results confirm the presence of CDS patients in a broad population of neurological patients including those with MR of unknown aetiology highlighting the importance of screening for these potentially treatable disorders.

P05.030**Two novel mutations in the CYP17A1 gene causing Congenital Adrenal Hyperplasia and severe Hypertension in a 46,XY Female Patient**

S. Kofman-Alfaro¹, N. Nájera¹, N. Garibay², G. Queipo¹;

¹Hospital General de México, Facultad de Medicina Universidad Nacional Autónoma de México SDEIPTID.05-1, Mexico City, Mexico, ²Endocrinology Department, Hospital Infantil de México Federico Gómez, Mexico City, Mexico.

In the steroidogenic pathway, cholesterol is converted to pregnenolone which can be processed to either mineralocorticoids in adrenal glands or to sex steroids in the gonads. This effect is due to a 17α-hydroxylation and 17, 20-lyase activity respectively. The microsomal enzyme cytochrome 450c17 has a deep impact in the progress of the steroidogenic pathway because it has both 17α-hydroxylase and 17, 20-lyase enzymes activities. Mutations in the CYP17A1 gene cause 17α-hydroxylase deficiency (17OHD), an unusual form of Congenital Adrenal Hyperplasia (CAH). This anomaly occurs in 1/50000 newborns and it accounts for nearly 1% of the CAH cases. Classical adrenal and gonadal phenotype of the complete 17OHD includes hypertension and hypokalemia, secondary to massive overproduction of the 17-deoxysteroid, 11-deoxycorticosterone (DOC) and corticosterone in patients with a 46,XY female phenotype. Nevertheless, there is considerable variation in the clinical and biochemical features of 17OHD. Approxi-

mately 56 mutations have been described in the *CYP17A1* gene. We present the molecular characterization of two novel mutations in this gene in a Mexican-mestizo 46,XY female with CAH and severe hypertension who does not respond to treatment. Gene sequence revealed a compound heterozygous (K110X/R362H) leading to a complete lack of enzyme activity. The patient was heterozygote for four SNPs. We suggest that these polymorphisms could be related to the failure of blood pressure treatment. We propose that all DSD patients require a multidisciplinary team to determine the etiology and orient the therapeutic approach to minimized medical, psychological and social complications.

P05.031

Molecular genetic analysis of CYP2D6 gene and used methods

E. Flodrova^{1,2}, A. Žourková^{3,2}, T. Kašpárek³, J. Juřica², R. Gaillyová^{1,2};

¹Department of Medical Genetics, University Hospital, Brno, Czech Republic,

²Faculty of Medicine, Masaryk University, Brno, Czech Republic, ³Department of Psychiatry, University Hospital, Brno, Czech Republic.

The cytochrome CYP2D6 is enzyme responsible for metabolism of many commonly used drugs such as tricyclic antidepressants, neuroleptics, beta blockers and antiarrhythmics. CYP2D6 is localized together with pseudogenes CYP2D7 and CYP2D8 at chromosome 22 and it is highly polymorphic. The polymorphisms leads to different individual responses following drug administration and increased risk of adverse reactions or the lack of the therapeutic response. According to the enzymatic activity the population has been grouped as - poor metabolizers, intermediate metabolizers, effective metabolizers, ultra-rapid metabolizers. There are studied influences of polymorphisms to the antidepressants treatment for a long time in Department of Medical Genetics and Department of Psychiatry.

Methods such as direct sequencing and agarose electrophoresis are subsequently combined with more modern, faster and more effective method - Real-Time PCR and High Resolution Melting using the Light Cycler 480 System. Recently we can detect the most frequent null alleles 3* 4* 6* 7* and 8* using the specific fluorescent labeled probes. Up to 99% of poor metabolizers in the Caucasian population can be detected with genetic testing for only 5 alleles (plus allele 5*, which can be detected by using the Sybr green). The High Resolution Melting has been performed for the most frequent SNP's in CYP2D6 gene. Heterozygous samples are readily distinguished from homozygous and wild-type samples with used dyes. This paper provides an overview of current technologies available for assessing polymorphisms in Department of Medical Genetics.

P05.032

The Clinical Use of Fluorescent Repeat-Primed PCR Assay in the Diagnosis of Myotonic Dystrophy Type 1

E. L. Spriggs^{1,2}, P. Frosk¹, R. Ray¹;

¹Molecular Diagnostic Laboratory, Diagnostic Services of Manitoba, Winnipeg, MB, Canada, ²Departments of Biochemistry & Medical Genetics and Pediatrics & Child Health, University of Manitoba, Winnipeg, MB, Canada.

Some trinucleotide repeat expansion disorders require Southern blot analysis to confirm the presence or absence of a large repeat expansion adding days to turnaround time. Cagnoli et al. (2004) successfully applied the use of fluorescent repeat-primed PCR (RPPCR) method to differentiate between patients who are homozygous for a normal-sized allele and those who are heterozygous for a very large expansion for Friedreich ataxia and spinocerebellar ataxia types 10 and 12. Using a slight modification of this RPPCR method, we were able to consistently detect the presence of large repeat expansions in the 3'UTR of the DMPK gene, the mutation underlying myotonic dystrophy type 1. To assess the validity of this assay in a clinical setting, all 63 patient samples and 9 quality assurance samples received over 18 months for myotonic dystrophy type 1 were analyzed by the usual "gold standard" method as well as by RPPCR. In the standard method, the number of CTG repeats is determined using fluorescent PCR followed by capillary electrophoresis. For a situation where only one normal-sized repeat is observed or two normal-sized repeats that are only one trinucleotide repeat apart in size, the sample is further tested by Southern blot analysis. A review of all data showed 100% correlation between the results obtained from the "gold standard" and RPPCR. As RPPCR can only show the presence of the expansion and cannot provide information

regarding size of the expanded allele, Southern blot must be pursued for RPPCR-positive patients. For RPPCR-negative patients, Southern blot analysis is unnecessary.

P05.033

Human miRNAs on chromosome 21 are differentially expressed in Down syndrome fetal hearts

F. Fabbrini, A. Izzo, R. Negri, R. Cicatiello, A. Ferraro, R. Genesio, A. Conti, L. Nitsch;

University Federico II, Napoli, Italy.

We previously demonstrated dosage-dependent upregulation of chromosome 21 (Hsa21) genes and dysregulation of mitochondrial and ECM genes in heart tissues of Down syndrome (DS) fetuses. Some of these dysregulated genes might be responsible for the DS cardiac phenotype, but it is evident that also other functional non-coding sequences, such as miRNAs, might play an important role. miRNAs are highly expressed in the heart and regulate cardiac development and function. Five miRNAs, according to Sanger miRBase, are on Hsa21: miR-99a, miR-125b, let-7c, miR-155 and miR-802. Nothing is known about their expression in trisomic tissues.

We evaluated by qRT-PCR the expression of Hsa21 miRNAs in heart tissues from DS fetuses and controls. We found that miR-99a, miR-125b, let-7c and miR-155 were expressed in 20-22 weeks fetal heart. MiR-802 was not expressed. MiR-99a, miR-155 and let-7c were overexpressed in trisomic hearts, whereas miR-125b was normoregulated. Target genes of upregulated miRNAs were obtained by merging PicTar, TargetScan and MiRanda prediction lists. As miRNAs could affect protein expression by either interfering with RNA translation or promoting mRNA degradation, we evaluated the mRNA expression of target genes of overexpressed miRNAs by using the data set of our previous study. Seventeen targets of miR-99a, 12 of miR-155 and 15 of let-7c were expressed in fetal heart and downregulated in trisomic samples. Target genes possibly involved in DS phenotype were found such as SLC25A4, let-7c target, downregulated in DS hearts and involved in mitochondrial function, and CYP26B1, miR-99a target, showing a dosage-dependent effect on ventricular septal defects.

P05.034

Study of folate genes alteration CBS 844Ins68 and MTR A2756G as maternal risk factor of Down syndrome among Iranian cases

M. T. Mirgani, A. Aleyasine;

National Institute for Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran.

Down syndrome is the most common chromosomal abnormality occurred 1 in 700 live birth. Abnormal segregation of chromosome 21 in meiosis is the cause of trisomy 21. Common polymorphisms in enzymes coding genes in folic acid pathway have been suggested to play role in etiology of chromosome 21 nondisjunction. In this study, the role for 844ins68 polymorphism in cystathionine beta synthase (CBS) gene and A2756G polymorphism in methionine synthase gene (MTR) in folic acid pathway has been investigated as maternal genetic risk factor of Down syndrome among Iranian patients. CBS 844ins68 polymorphism is a 68 bp insertion in exon 8 of this gene and MTR A2756G polymorphism causes an A>G transition at 2756 bp. We have studied 93 mothers having DS children and 116 aged matched control mothers for the frequency of above polymorphisms using RFLP PCR analysis. Genomic DNA was extracted from blood leukocytes by salting out procedure. Frequencies of 844Ins68 polymorphism were 8 (8.6%) in mother cases and 18 (15.5%) in control mothers with no homozygosity in both groups. Frequency of A2756G polymorphism was observed as AA in 56 (60.2%) AG in 33 (35.5%) and GG in 4 (4.3%) in cases mothers and were 56%, 35.3% and 10% among control mothers respectively. Statistical analysis showed no association between 844ins68 and A2756G polymorphisms and risk of Down syndrome in Iranian mothers (P-value for 844Ins68 and A2756G were 0.146 and 0.451 respectively). Combination of these polymorphisms also have no effect on risk of Down syndrome's mother (P-Value was 0.216).

P05.035**Supporting the appropriate ordering of genetic laboratory tests in the UK healthcare workforce**

C. Barker, C. Bennett, C. Cooley, P. Farndon;

NHS National Genetics Education and Development Centre, Birmingham, United Kingdom.

To address an increased need to promote the clinically appropriate and equitable ordering of genetic laboratory tests in the UK, the NHS National Genetics Education and Development Centre is working to raise understanding and knowledge of genetics in the UK healthcare workforce for non-genetics specialists.

The Centre identified the key knowledge and attitudes required to encourage appropriate ordering of genetic laboratory tests as part of a wider project to integrate genetic skills into clinical practice, job planning, evaluation, education and training. The knowledge and attitudes identified allow healthcare staff to recognise where genetic tests will inform clinical management within the limits of their role and where referral is appropriate. Healthcare staff will also be equipped to recognise any social, ethical or legal implications in ordering the genetic laboratory test.

To integrate these skills into clinical practice, the Centre has targeted health professionals for whom genetics is highly relevant and is working with these groups and other professional bodies to identify how genetics affects their clinical practice.

Using this information, the Centre is creating tools allowing healthcare staff to recognise where genetics impacts on their clinical practice. For example, relevant case scenarios allow healthcare staff to draw parallels with their own clinical practice. These tools are further supported by the Centre through the provision of education and training support and learning and teaching resources.

It is envisaged that this work will lead to more appropriate and equitable ordering of genetic tests and ultimately the enhancement of patient care.

P05.036**Vascular type of Ehlers-Danlos syndrome: Evidences for a stochastic effect of COL3A1 haploinsufficiency**A. Plancke¹, M. Holder-Espinasse², V. Rigau³, C. Rene¹, M. Taulan¹, B. Catteau², R. Sfeir², S. Coopman², N. Pallares-Ruiz¹, S. Manouvrier-Hanu², M. Claustres¹, P. Khau Van Kien¹;¹CHU Montpellier/INSERM U827, Montpellier, France, ²CHRU de Lille, Lille, France, ³CHU Montpellier, Montpellier, France.

Mutations that confer an unusual pattern of inheritance in a gene related to a well known genetic disease can sometimes highlight a particular mechanism useful to correlate genotype to phenotype. Here we describe a case of recessive Ehlers-Danlos syndrome (EDS) in a young girl of asymptomatic and related parents (uncle-niece). She exhibited: atrophic scars, extensive bruising, joint hypermobility and died at 12 years-old from an extreme intestinal fragility. According to the Villefranche nosology, she fulfilled the criteria of EDS vascular type for laboratory testing. Total sequencing of COL3A1 cDNA (obtain from skin cultured fibroblasts) identified an homozygous nucleotide duplication (c.479_480dupT) resulting in a premature termination codon (p.Val160fsX46). Studies in genomic DNA showed that this mutation in exon 5 of the COL3A1 gene was inherited from each parent. As expected, the expression analysis (RT-PCR, quantitative-PCR, Immunohistochemistry, WB) showed a strong mRNA decay, which results in an absence of type III collagen in the proband.

This case, shows that a deficit in collagen III is viable in early childhood in Man. Here, the expected COL3A1 haploinsufficiency in her asymptomatic ascendants did not lead to the severe clinical manifestations of EDS vascular type cause by haploinsufficiency of one allele as described in the literature. This case provides evidences for a stochastic effect of COL3A1 haploinsufficiency in Man with (a) modifying factor(s), which remains to be identified.

P05.037**Early myoclonic encephalopathy caused by a disruption of the Neuregulin-1 receptor ErbB4**H. Van Esch¹, B. Ceulemans², J. Vermeesch¹, K. Devriendt¹, L. Backx¹;¹Center for Human Genetics, Leuven, Belgium, ²Rehabilitation and Epilepsy Centre for Children and Youth, Pulderbos, Belgium.

The tyrosine kinase receptor ErbB4 (erythroblastic leukemia viral oncogene homolog 4) plays a crucial role in numerous neurobiological processes in the developing and adult brain. One of the most important and well-studied ligands of ErbB4 is Neuregulin-1 (NRG1) and it was shown that NRG1-ErbB4 signaling is essential for neurobiological processes like neurogenesis, migration, synaptic plasticity and differentiation of neurons and glia. Moreover, recent molecular genetics studies implicate ErbB4 in the pathophysiology of schizophrenia. However, the phenotypic consequences of haploinsufficiency of *ErbB4* are not known, since no coding mutations have been identified until now. Here, we present a patient with early myoclonic encephalopathy and profound psychomotor delay with a *de novo* reciprocal translocation t(2;6)(q34;p25.3), disrupting the *ErbB4* gene. This patient represents the first case of haploinsufficiency for one of the ErbB family members of tyrosine kinase receptors.

P05.038**Mutation analysis of epidermolysis bullosa in the Czech Republic**B. Jerabkova^{1,2}, L. Fajkusova^{1,2}, H. Buckova^{3,2,4}, K. Vesely^{5,6}, R. Gaillyova^{7,2};¹Centre of Molecular Biology and Gene Therapy, Faculty Hospital Brno, Brno, Czech Republic, ²Masaryk University Brno, Brno, Czech Republic, ³Department of Pediatric Dermatology of 1st Pediatric Clinic, Faculty Hospital Brno, Brno, Czech Republic, ⁴Institute of Medical Postgraduate Studies Prague, Prague, Czech Republic, ⁵1st Institute of Pathological Anatomy, St. Ann's Hospital, Brno, Czech Republic, ⁶Medical Faculty of Masaryk University Brno, Brno, Czech Republic, ⁷Department of Clinical Genetics, Faculty Hospital Brno, Brno, Czech Republic.

Epidermolysis bullosa (EB) is a clinically and genetically heterogeneous group of heritable skin disorders. It is characterised by skin blistering and mucous membrane. EB has been divided into three major categories based on the level of blister formation in dermal-epidermal junction zone.

EB is diagnosed by evaluation of clinical findings, by transmission electron microscopic examination of a skin biopsy and immunohistochemical mapping of protein components of dermal-epidermal junction zone from a skin biopsy. Molecular-genetic diagnostics of EB was initiated in 2004.

Dystrophic EB (EBD) is caused by mutations in the collagen type VII (COL7A1), which consists of 118 exons. EB simplex (EBS) is caused by mutations in the keratin 5 (KRT5), which consists of 9 exons and keratin 14 (KRT14), which consists of 8 exons.

DNA from EB patients and their relatives were screened for mutations in COL7A1, KRT5 and KRT14 genes. Analysis was performed using PCR, denaturing high performance liquid chromatography, high resolution melting analysis and direct sequencing. We could identify KRT5 or KRT14 dominant mutations in 11 out of 18 EBS families. As regards 27 EBD probands, we revealed disease causative mutations in 16 patients and screening of COL7A1 is in progress. Prenatal diagnosis of one pregnancy in family with occurrence of EBS predicted the fetus being normal and subsequently a healthy child was born.

Determination of EB at the level of DNA has important implication for final confirmation of diagnosis, possibility of genetic counselling and early prenatal diagnosis.

This work was supported by IGA MH NR9346-3.

P05.039**Erythropoietic protoporphyria in a Czech family caused by a new 84G>A (W28X) mutation in the ferrochelatase gene**J. Prochazkova¹, J. Sper², S. M. Farrag¹, L. Barnincova¹, J. Spical², P. Martasek¹;¹1st School of Medicine, Charles University, Prague, Czech Republic, ²Institute for Clinical and Experimental Medicine, Prague, Czech Republic.

Erythropoietic protoporphyria (EPP) is a disorder with autosomal dominant inheritance caused by partial deficiency of ferrochelatase (FECH). Ferrochelatase is the ultimate enzyme of heme biosynthesis. EPP is characterized by excess accumulation of protoporphyrin, particularly

in the erythroid cells of the bone marrow. Biochemical features of EPP include increased protoporphyrin levels in erythrocytes, plasma, feces, and bile. Clinical manifestations of the disease are characterized by cutaneous photosensitivity, which almost always appears in childhood and includes burning, itching, swelling, and redness in sun-exposed areas. Hepatic failure occurs in some patients (about 1-10% of EPP patients) which may necessitate liver transplantation. The gene encoding human FECH is localized on chromosome 18q21.3, and spans over 45kb with eleven exons. The cDNA encodes a protein containing 423 amino acids, and the enzyme exists as a homodimer of 86 kDa. Each subunit contains residues 65-423 and one [2Fe-2S] cluster. Mutational analyses of the FECH gene revealed a novel unpublished mutation in the FECH gene in a patient from Czech Republic with EPP: a G→A transition at position 84 in exon 2. This point mutation alters to a tryptophan to a stop codon (W28X). The amino acid tryptophan at position 28 is located in a mitochondrial targeting sequence spanning amino acid residues 1-62 that is removed during proteolytic processing. Analyses were carried out on seven members of proband's family; all persons, except one, are asymptomatic carriers. Supported by grants # 1M0520 and MSM 0021 620806 from Ministry of Education, Youth and Sports of Czech Republic.

P05.040

Identification of the molecular defects in Turkish FHL patients assigned to Perforin and Munc13-4 genes

G. Baltı¹, H. Okur¹, N. Akarsu¹, S. Berrak², S. Unal¹, A. Gurgey¹;

¹Hacettepe University, Ankara, Turkey, ²Marmara University, Istanbul, Turkey.

Familial Hemophagocytic Lymphohistiocytosis (FHL) is a rare autosomal recessive, if untreated, fatal disorder of early childhood. The purpose of this study is to evaluate the genetic defects underlying clinical phenotypes observed in Turkish patients with this disorder. The subjects of this study were a total of 79 FHL patients (52M/27F) from 74 unrelated families (consanguinity:62, family history:31). Linkage analysis used for subtyping the patients to FHL type II revealed homozygosity or consanguineous common alleles in 19 of these families. Direct sequencing of Perforin gene led to the identification of 5 different sequence changes in 12 families. Six patients had nonsense W374X mutation in homozygous state except one who was coming from a non-consanguineous family. Two patients had G149S, one V50M, two A91V and one novel A523D homozygous missense changes. Mutations in this gene account for about 16% of Turkish FHL patients in this study. On the other hand, 20 families were found to show either homozygosity or consanguineous common alleles for Munc13-4 gene in the linkage analysis. These patients were screened for mutations in 32 exons of Munc13-4 gene by SSCP/heteroduplex analysis. Sequencing the aberrant bands, thus far, led to the identification of 3 different homozygous mutations in 3 unrelated patients who were coming from consanguineous families. A frameshift (627delT) mutation was detected in a female patient who also had heterozygous A91V mutation in Perforin gene while nonsense (R1065X) and novel missense (R414C) mutations were found in 2 male patients. This study was supported by TUBITAK (Project No: 105S386; SBAG-3193).

Six new mutations in *UNC13D* gene in Russian patients with familial hemophagocytic lymphohistiocytosis (FHL)

N. Poltavets¹, M. Maschan², A. Polyakov¹, G. Novichkova², A. Maschan²;

¹Research Centre for Medical Genetics, Moscow, Russian Federation, ²Federal Research Clinical Center for pediatric hematology, oncology and immunology, Moscow, Russian Federation.

FHL is a rare autosomal recessive disorder of immune regulatory pathways characterized by a defect in natural killer cell function. *UNC13D* gene codes a protein involved in vesicle priming function and its mutations have been shown to cause FHL. We have examined five Russian unrelated patients with FHL in age ranged from 1 to 5 years (two familial and three sporadic cases). We have investigated DNA samples for mutation in *UNC13D* gene coding area by direct sequencing. All our patients were found to be compound heterozygotes, carrying two mutations (c.2343 del 2344-2347 / c.3037 ins G; c.3037 ins G / c.3173 T>C (p.1058 Leu > Pro); c.627 del T / c.1828 ins A; c.322-1 G>A (CD 042833) / c.3037 ins G; c.2215 del 2216-2239 / c.2343 del 2344-2347). Only one mutation c.322-1 G>A (CD 042833) has been previously reported, and six others are new. The mutation c.2343 del 2344-2347

has been observed in two chromosomes and c.3037 ins G in three chromosomes. According to our results we propose that there might be "hot points" in *UNC13D* gene, where mutations are found with higher frequency.

Familial hypercholesterolemia: experience from a portuguese genetic department

I. M. Gaspar¹, A. Gaspar², S. Martins³, A. Mourato⁴, M. Antunes³, L. Sousa⁴, A. Cabra⁵, D. Gaspar⁶, O. Moldovan⁷, M. Simao⁷, I. Gomes⁷, H. Santos⁷, C. Alves⁸, S. Silva⁸, A. Medeiros⁸, M. Bourbon⁸;

¹Centro Hospitalar Lisboa Ocidental, Lisboa, Portugal, ²Consulta de Prevenção de Doenças Cardiovasculares, Serviço de Pediatria - Hospital de Santa Maria, Lisboa, Portugal, ³Consulta de Prevenção de Doenças Cardiovasculares, Serviço de Pediatria Hospital de Santa Maria, Lisboa, Portugal, ⁴Consulta de Prevenção de Doenças Cardiovasculares, Serviço de Pediatria Hospital de Santa Maria, Lisboa, Portugal, ⁵Consulta de Prevenção de Doenças Cardiovasculares, Serviço de Pediatria Hospital de Santa Maria, Lisboa, Portugal, ⁶Centro Estudos - Ministério de Educação, Lisboa, Portugal, ⁷Serviço de Genética Médica, Hospital de Santa Maria, Lisboa, Portugal, ⁸Unidade de Investigação Cardiovascular, Instituto Nacional de Saúde, Lisboa, Portugal.

Familial Hypercholesterolemia (FH) is an autosomal dominant disorder, usually caused by mutations on the low density lipoprotein receptor gene (LDLR), the gene encoding apolipoprotein B (APOB) or Proprotein Convertase Subtilisin/Kexin type 9 (PCSK9) which is associated with premature atherosclerosis and coronary heart disease (CHD).

OBJECTIVES: Clinical and molecular characterization of patients and their children with family history of premature CHD and abnormal lipid profile.

MATERIAL AND METHODS: a clinical questionnaire from the "Portuguese FH Study" was completed, characterized their lipid profile and study mutations in LDLR, APOB and PCSK9 genes.

RESULTS: We observed 163 persons, 111 adults and 52 children in 56 families. 13 patients with CHD were younger than 50 years of age. The mean total cholesterol was 264, 41 mg/dL and 294,09 mg/dL and mean LDL-cholesterol was 189.87 mg/dL for and 206.1 mg/dL for children and adults respectively. All families received counseling regarding lifestyle and dietary modifications. After dietary or pharmacological therapy, mean cholesterol was 222,14 mg/dL and 238,6 mg/dL and mean LDL-cholesterol was 148.25 mg/dL and 160.6 mg/dL for children and adults respectively. Molecular study of the LDLR gene was performed in 56 families, and a mutation was found in 23 families. No mutations were identified in APOB or PCSK9 genes.

CONCLUSION: Molecular study of FH patients offers the possibility of identification of the mutation in relatives at risk for premature atherosclerosis. Early diagnosis allows earlier lifestyle modifications and dietary or pharmacological intervention in mortality and morbidity.

P05.043

Functional analysis of potencial splice site mutations by RT-PCR of LDLR mRNA isolated from fresh blood mononuclear cells

A. C. Alves, M. A. Duarte, A. M. Medeiros, L. Marques, V. Francisco, M. Bourbon;

Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisboa, Portugal.

Familial hypercholesterolemia (FH) is an autosomal dominant disorder associated with high risk of coronary heart disease. FH is caused mainly by inherited defects on the Low Density Lipoprotein Receptor gene (LDLR) resulting in increased circulating LDL cholesterol. Of the many different LDLR mutations found in FH patients worldwide, about 6 % of single base substitutions are located near or within introns and are predicted to result in exon skipping, retention of an intron or activation of cryptic sites during mRNA splicing. Ten such mutations, four of them novel, were found in the "Portuguese FH Study", and those whose effect on splicing was untested have been investigated by RT-PCR of *LDLR* mRNA isolated from fresh blood mononuclear cells. Four of these variants (313+6 T>C, 1060+1G>A, c.2389G>T (p.V776L), 2547+1G>A) caused exon skipping, and one caused retention of an intron (c.1359-5C>G), while two others (c.2140+5 G>A and c.1061-8T>C) had no apparent effect. Variants in two patients lost to follow-up could not be tested experimentally, but they almost certainly affect splicing because they disrupt the invariant AG or GT in acceptor (818-2A>G) or donor (1845+1delG) splice sites. These mutations rep-

resent 9% of all mutations in the "Portuguese FH Study". Our findings emphasize that care must be taken before reporting the presence or absence of a splice site mutation in *LDLR* for diagnostic purposes. Our study also demonstrates that relatively simple, quick and inexpensive RNA studies can evaluate putative splicing mutations that are not always predictable by available software, thereby reducing genetic misdiagnosis of FH patients.

P05.044

Co-occurrence of four mutations in a clinical case of Familial Mediterranean Fever

I. Navarro-Vera¹, B. Hernandez-Charro¹, M. Sanchez¹, P. Armero¹, R. Marín², P. Madero¹;

¹Centro de Análisis Genéticos, Zaragoza, Spain, ²Hospital Puerta del Mar, Cadiz, Spain.

Familial Mediterranean Fever (FMF) type 1 is characterized by recurrent short episodes of fever associated with different inflammatory processes. MEFV is the only gene currently known to be associated to FMF. E148Q in exon 2 and several mutations in the exon 10 of MEFV are the most common. FMF is inherited in an autosomal recessive manner, so both parents of a proband are considered obligate carriers. We studied a FMF clinical case and his family and surprisingly four different mutations were found.

The family consisted in the affected proband, a sister and the parents, all of them unaffected. The study was carried out by bidirectional sequencing of exon 10 and targeted mutation analysis by RFLPs of E148Q mutation in exon 2 of MEFV gene.

The E148Q was present in heterozygous state in the proband. The sequencing analysis of the exon 10 showed the p.R653H and p.I640M mutations and the deletion p.I692del, all of them previously described. The study of familial samples revealed the presence of two mutations in each and everyone: father p.I640M and p.R653H, mother E148Q and p.I692del and sister p.I640M and p.R653H (haplotype in *cis* phase from his father).

The inheritance pattern showed that each parent carries two mutations in *cis* phase, the sister inherited the wild type phase of the mother and the mutated phase of the father and the affected son is therefore carrying all four mutations.

This case makes us aware of the importance of considering the haplotype phase of multiple mutations in recessive disorders.

P05.045

MEFV Mutations in Turkish Patients Suffering From Familial Mediterranean Fever

O. Cilingir¹, M. Ozdemir¹, M. H. Muslumanoglu¹, E. Tepeli¹, G. Bademci¹, C. Korkmaz², O. Kutlay¹, U. Demir¹, H. Aslan¹, B. Durak¹, S. Artan¹;

¹Eskisehir Osmangazi University, Medical Faculty, Department of Medical Genetics, Eskisehir, Turkey, ²Eskisehir Osmangazi University, Medical Faculty, Department of Rheumatology, Eskisehir, Turkey.

Familial Mediterranean fever (FMF) is an autosomal recessive periodic disorder. Over 50 mutations have been identified in the MEFV gene responsible for FMF. For diagnosis of FMF; molecular methods and Tel-Hashomer Clinical Criteria (THCC) can be used. AIM: To identify distribution and frequency of the MEFV gene mutations in Turkish FMF patients, compare two molecular different techniques and correlation of clinical-molecular diagnosis. PATIENTS-METHODS: The study was carried out on 604 clinically diagnosed Turkish FMF patients. Mutation screening of the MEFV gene was performed by sequencing of exon 10 in 448 patients and by FMF specific StripAssay (PCR-Reverse Hybridization) for E148Q, P369S and F479L mutations of exons 2,3, and 5, respectively in 256 patients. RESULTS: Of the 604 unrelated patients investigated, 344 (56.95%) had one or two mutations : 85 patients (24.71%) were homozygous; 88 (25.58%) were compound-heterozygous; 171 (49.71%) were heterozygote mutations. Of the mutations, M694V (A>G), V726A, M680I (G>C), R761H accounted for 65.99, 19.18, 17.44, and 4.36 %, respectively. StripAssay was observed completely correlate with direct sequencing in 100 patients. For determining the correlation between mutation status, clinical diagnosis with THCC was investigated in 90 patients. Only 33 patients were exactly diagnosed by THCC whereas 53 patients were reported mutations by StripAssay. CONCLUSION: Exon 10 is the most common site for FMF mutations whereas exons 2,3 and 5 accounts for 11.63% of the cases. The most common mutation among Turks is M694V (A>G). As a result,

StripAssay for 12 common mutations might be used in routine mutation screening analysis.

P05.046

Promoter studies in the FA genes

D. Meier, K. Neveling, D. Schindler;

Department of Human Genetics, Biocenter, Wuerzburg, Germany.

Fanconi anemia (FA) is a rare genome-instability disorder with the frequent presence of congenital malformations and bone marrow failure. Other characteristic features include predisposition to FA-typical malignancies and cellular hypersensitivity to DNA-interstrand crosslinking. At least 13 genes and corresponding complementation groups are underlying the disease. Eight of the FA proteins (FANCA, -B, -C, -E, -F, -G, -L and -M) and other components assemble in a nuclear complex, the FA "core complex".

Little if any is known about the promoter regions. However, identification and characterization of the promoters would be essential for understanding the regulation of transcription, including intergenic regulation, of the FA genes. Our aim is to provide an explanation for the equimolar composition of the core complex. We used a variety of *in silico* methods to predict potential promoter regions. To confirm these, we have set up dual luciferase reporter assays. We cloned the identified regions (~1kb) in the pGL3 basic vector that carries the reporter gene for firefly luciferase. As co-reporter we used the pRL null vector that contains the renilla luciferase gene. With these constructs, we transfected HeLa and HEK293 cells to assay luciferase activity using a luminometer. In a second approach we used mutated constructs to detect any decrease of activity. Further characterization includes transcription factor binding sites and conserved sequence elements. First results indicate that there is generally strong promoter activity. Short half-life of the gene products is consistent with high transcriptional activity of the FA genes, and rapid regulation in response to DNA damage.

P05.047

MYCN gene mutation screening in 9 patients with Feingold syndrome

A. Nougayrede, C. Golzio, A. Munnich, S. Lyonnet, J. Amiel, L. de Pontual; INSERM U-781, Department of Genetics, Necker Hospital, Paris, France, Paris, France.

MYCN is a transcription factor amplified in about 30% of neuroblastoma. *MYCN* is also the disease-causing gene in Feingold syndrome, with a dominant mode of inheritance. Feingold syndrome is defined by microcephaly, digital anomalies (syndactyly, brachymesophalangy), digestive atresia (oesophagus, duodenum), facial features (retrognathism, small palpebral fissures) and occasional malformations of heart, kidney and spleen.

We studied the coding sequence of *MYCN* in 9 patients and found 3 mutations in the bHLH or the Leucine Zipper domain: 2 frameshift mutations leading to a truncated protein and a nonsense mutation. Loss-of-function is highly likely for frameshift mutations, while a dominant-negative due to altered DNA binding and preserved dimerisation is hypothesised for the nonsense mutation. *MYCN* deletion are currently being tested for the remaining patients.

We performed *in situ* hybridization on human embryos (Carnegie stages 12, 15 and 17) to determine *MYCN* expression pattern during development. At C12, *MYCN* is ubiquitous expressed. Later (C15 and C17), expression is restricted to mesencephalon, diencephalon, spinal cord, limb buds, oesophagus and stomach, in accordance with Feingold syndrome features. *MYCN* is also expressed in the primitive mesonephros and the Rathcke pouch. These later findings argue for kidney anomalies to be regarded as a feature of Feingold syndrome and raise the hypothesis of an endocrine involvement for the short stature observed in the syndrome.

Molecular characterization of familial hypercholesterolemia in Iranian patients

M. -. Hashemzadeh Chaleshtori¹, E. Farrokhi¹, F. Shayesteh², M. Modarres², M. Shirani³, F. Roghani Dehkordi³, K. Ghatreh Samani³, G. Mobini¹, M. Bani-talebi¹, K. Ashrafi¹, M. Shahrani¹, N. Parvin¹;

¹Cellular and Molecular Research Center, Shahrekord, Islamic Republic of Iran,

²Department of Biology, School of Basic Sciences, Payam-e-noor University,

Esfahan Center, Esfahan, Islamic Republic of Iran, ³Department of Cardiology,

School of Medicine, Shahrekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran, ⁴Department of Clinical Chemistry, School of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran.

Familial hypercholesterolemia (FH) is an autosomal dominant disorder caused mainly by mutations in the low-density lipoprotein receptor (LDLR) and apolipoprotein B (APOB). Until now, the molecular basis of FH has been demonstrated in detail in many populations, but there is still very limited Molecular data concerning FH in Iran. The aim of this study was to characterize the LDLR and APOB gene mutations in an Iranian population.

A total of 50 non-related Iranian heterozygous FH subjects were studied. All samples were initially tested for 3 common APOB gene mutations including R3500Q, R3500W and R3531C using PCR-RFLP assay. Subsequently, LDLR gene were screened partially (exons 2, 4, 6, 7, 8, 9, 10, 12 and 14) by PCR-SSCP analysis and positive results were confirmed by DNA sequencing.

Four previously reported polymorphisms 1413 G>A, 1725 C>T, 1773 T>C and 2140 +5G>A were found in 18% of population studied. Moreover, no variation was found in APOB gene. Our data indicated that LDLR and APOB gene mutations have not contribution to FH in Iranian population studied here. However, we examined 3 common APOB mutations and 9 exons of LDLR in only 50 patients, and to determine the role of these genes in developing FH in Iran, more samples/populations needed to be investigated for the whole coding regions and promoter of the genes.

P05.049

Correlation of MEFV gene mutations and bone mineral density in children with familial mediterranean fever

A. Bukulmez¹, H. Samli², U. Dundar³, R. Koken¹, V. Kavuncu³, M. Solak⁴;

¹Afyon Kocatepe University, School of Medicine, Department of Pediatrics, Afyonkarahisar, Turkey, ²Afyon Kocatepe University, School of Medicine, Department of Medical Genetics, Afyonkarahisar, Turkey, ³Afyon Kocatepe University, School of Medicine, Department of Physical Medicine and Rehabilitation, Afyonkarahisar, Turkey, ⁴Afyon Kocatepe University, School of Medicine, Department of Medical Biology, Afyonkarahisar, Turkey.

Objective: Familial Mediterranean Fever (FMF) is an inherited disorder caused by an abnormal recessive gene. Virtually all cases are due to a mutation in the MEFV gene, which codes for a protein called pyrin or marenostenin. The aim of this study is evaluating the correlation between bone mineral density and mutations in children with FMF.

Methods: 36 prepubertal children diagnosed FMF according to Tel Hashomer Criteria were included in the study. Bone mineral density (BMD) was measured in all patients by dual energy X-ray absorptiometry, both at the lumbar spine (antero-posterior projection of L1-L4) and total body. BMD data were expressed as grams per centimeter square and standard deviation scores (Z score). The five MEFV gene mutations (M694V, M694I, V726A, M680I, E148Q) were scanned in all cases by PCR-ELISA method. According to the results of the genetic investigation, cases were grouped as cases with no scanned mutations and cases with heterozygous and homozygous mutations.

Results: Both lumbar vertebrae and total body bone mineral density of the patients were found to be low. No differences were detected among BMD values of the groups.

Conclusion: In conclusion, no significant relation was detected between MEFV gene mutations and BMD in the patients with FMF. This result does not mean there is no low bone density risk in patients with FMF. Due to this, we think that study will be significant with more patients and in association with biochemical markers, signs of bone health.

P05.050

The prevalence of familial Mediterranean fever gene mutations in patients with rheumatic heart disease

Y. Tunca, I. Simsek, C. Koz, I. Sari, H. Erdem, S. Pay, D. Gul, A. Dinc; GATA, Ankara, Turkey.

BACKGROUND: Acute rheumatic fever (ARF) has been considered in the differential diagnosis of familial Mediterranean fever (FMF) because these two diseases have some clinical and laboratory similarities. There are also autopsy reports of rheumatic mitral stenosis in patients with FMF and amyloidosis. Moreover, a history of ARF during childhood is not infrequent in patients with FMF.

OBJECTIVE: To investigate the prevalence of familial Mediterranean fever gene mutations in patients with rheumatic heart disease.

METHODS: A total of 21 patients with rheumatic heart disease were enrolled. The diagnosis of mitral stenosis was established with echocardiography or angiography. Patients with predominant mitral regurgitation or isolated aortic or tricuspid valve disease were excluded. Genetic analysis was carried out by the NanoChip® Molecular Genetics Workstation.

RESULTS: Four of the patients were found to have heterozygote MEFV mutations. Three of these mutations were E148Q/- and one was V726A/-.

CONCLUSION: In the light of our preliminary results, we may conclude that the frequency of MEFV mutations are not higher than the normal population. Further studies with larger sample sizes are needed for better understanding the possible relationship between these two disorders and to clarify whether specific mutations play role in the pathogenesis.

P05.051

Comparison of mutations screening assay on MEFV gene in Turkish FMF patients.

B. Eroglu Kesim^{1,2}, O. Kagnici^{1,3}, G. Karatas¹, S. Guz Eroglu¹, S. Eraslan^{1,4}, A. Dagdemir¹, Y. Laleli¹;

¹Duzen Laboratuaries Groups, Istanbul, Turkey, ²Sisli Etfal Training and Research Hospital, Medical Genetic, Istanbul, Turkey, ³Istanbul university institute for experimental medicine, Istanbul, Turkey, ⁴Genklinik Genetics, Genetic Diagnostic Center, Istanbul, Turkey.

Familial Mediterranean fever (FMF) is an autosomal-recessive disorder characterized by recurrent attacks of fever and serositis common in eastern Mediterranean populations. Over 70 mutations have been identified in the MEFV gene responsible for FMF. The aim of this study is to determine the frequency of the mutations which has been reported comparatively rare, to define the most effective mutation set, and to select the most suitable DNA analysis system for Turkish FMF patients.

1709 patients were referred by specialists to the Molecular Genetic Diagnostic Centrum of Duzen Laboratuaries Groups from various regions of Turkey. First, mutation screening of the MEFV gene was performed for the 3 most common mutations, namely M694V, M680I, V726A, in 1182 unrelated patients by polymerase chain reaction and restriction enzyme digestion analysis. The rate of mutation detection was 46.2% and these three mutations accounted for 64.4%, 22.6% and 12.7% of the alleles, respectively. Second, we investigated 12 mutations (E148Q, P369S, F479L, M680I G>C, M680 G>A, 1692del, M694V, M694I, K695R, V726A, A744S and R761H) in 527 patients using reverse dot-blot hybridization (RDBH) assay. We found the rate of detection to be 50.5%. The most common mutations were found to be M694V, E148Q, M680I, V726A and R761H. Percentage of these mutations were 47.7, 19.9, 14.3, 9.8 and 4.1, respectively. Our study showed that the RDBH method increased the detection rate of FMF mutations about 4% compared to PCR-RFLP method for Turkish population.

P05.052

Missense mutations in the forkhead domain of FOXL2 lead to subcellular mislocalization, protein aggregation and impaired transactivation.

E. De Baere¹, L. Mounné², H. Peters³, B. P. Leroy⁴, A. De Paep¹, R. A. Veitia², D. Beysen¹;

¹Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, ²INSERM U567, Team21, Genetics and Development Department, Institut Cochin, Paris, France, ³Institute of Medical Genetics, Charité - Universitätsmedizin Berlin, Berlin, Germany, ⁴Department of Ophthalmology, Ghent University Hospital, Ghent, Belgium.

Mutations of FOXL2, encoding a forkhead transcription factor, have been shown to cause blepharophimosis syndrome (BPES), characterized by an eyelid malformation variably associated with premature ovarian failure. Recently, polyalanine expansions and truncating mutations were shown to lead to protein mislocalization, aggregation and altered transactivation. Here, we study the molecular consequences of 17 naturally occurring FOXL2 missense mutations on subcellular localization and transactivation capacities in cellular systems. Most of these mutations map to the conserved DNA-binding forkhead domain (FHD). According to their subcellular localization in COS-7 cells, the mutant proteins could be divided into four groups. We also studied the trans-

activation capacity of the mutants in FOXL2 expressing granulosa-like cells (KGN). Several mutants led to a loss-of-function, while others might induce a dominant negative effect. Interestingly, one mutant that is located outside the FHD (S217F), proved to be hypermorphic and to have no effect on intracellular protein distribution. Clinically this mutation gives rise to a mild BPES phenotype, and to growth hormone deficiency. In general, missense mutations located in the FHD lead to a classical BPES phenotype, but cannot be correlated with the presence of an ovarian phenotype. However, a potential predictive value of localization and transactivation assays in the making of genotype-phenotype correlations is proposed. In conclusion, this is the first study to demonstrate that a significant number of missense mutations in the FHD of FOXL2 lead to mislocalization, protein aggregation and altered transactivation, and to provide insights into the pathogenesis associated with missense mutations of FOXL2 in human disease.

P05.053

The spectrum of GALT gene mutations in south regions of Russia

S. Mordanov, F. Lagkueva, S. Matulevich, S. Amelina, G. Listopad, S. Kutsev; Rostov State Medical University, Rostov-on-Don, Russian Federation. Galactose-1-phosphate uridylyltransferase (GALT) deficiency galactosemia is clinically heterogeneous autosomal recessive disorder. Newborn screening can identify patients with GALT deficiency galactosæmia. The diagnosis needs to be confirmed by enzyme activity test. Unfortunately, in many cases the results of GALT activity measurement can be ambiguous and further molecular testing is required. More than 200 point mutations were revealed in the GALT gene, but the prevalence of these mutations varies among ethnic groups. Classical galactosemia newborn screening was started in Russia during 2006/2007 years. Total of 160 990 newborns were screened in South Russia and 11 patients with galactose level more than 7,2 mg/dL were revealed. Blood samples of these patients were submitted for confirmatory testing for classical galactosæmia. The GALT gene were sequenced in all cases. The mutational spectrum included five missense mutations M142L, H186Y, Q188R, K285 N, N314D. The classical galactosemia was revealed in 4 cases with genotypes Q188R / Q188R, K285 N / M142L, H186Y / N, K285N / N; Duarte variant was revealed in 5 cases with genotypes Q188R / N314D, Q188R / N314D, N314D / N314D, N314D / N, N314D / N. In 2 cases mutations were not founded

P05.054

Novel mutations in the gap junction gene GJB2 show that keratoderma is associated with connexin protein transport defects

M. A. M. Van Steensel¹, E. A. de Zwart-Storm¹, P. Martin², M. van Geel¹; ¹University of Maastricht, Maastricht, The Netherlands, ²University of Glasgow, Glasgow, United Kingdom. Mutations in the skin expressed gap junction gene GJB2 (coding for connexin26) cause a plethora of sometimes severe skin disorders with sensory deafness. Specific mutations are associated with distinct phenotypes and the reasons for this strong genotype-phenotype correlation are poorly understood. Commonly used functional parameters of gap junction functionality, such as dye transfer and electrical conductance, do not correlate with disease phenotype or severity. We have now identified a number of novel mutations that are specifically associated with palmoplantar keratoderma. Using fluorescent fusion proteins, we show that this skin symptom may be specifically caused by protein transport defects. What's more, its severity is inversely correlated to that of the transport defect. We are now working to understand the cellular sequelae of the disturbed protein trafficking. Preliminary data indicate that ER stress responses may be involved.

P05.055

Analysis of GJB2 gene exon 2 in Latvian patients with nonsyndromic sensorineural hearing loss

O. Sterna^{1,2}, N. Pronina¹, I. Grinfelde¹, S. Kuske³, D. Bauze¹, R. Lugovska¹; ¹Medical Genetics clinic, University Children's Hospital, Riga, Latvia, ²Rigas Stradins University, Riga, Latvia, ³Latvian Childrens' Hearing centre, Riga, Latvia.

Background: Nonsyndromic hearing impairment (NSHI) is the most common form of deafness. Mutations in the GJB2 gene, which encodes gap-junction beta-2 protein (connexin 26), are the main cause

of recessive NSHI. It has been identified that one particular GJB2 mutation named 35delG is the most prevalent for the populations of the European origin.

Materials: We obtained DNA samples from patients with prelingual NSHI in whom syndromic forms and environmental causes of deafness had been excluded, their relatives and individuals with hearing loss positive family history.

Methods: DNA was extracted from whole blood. The GJB2 gene exon 2 analysis was performed using PCR, enzymatic restriction and automated sequencing.

Results: 55 unrelated patients were screened for the GJB2 mutations. Mutations were detected in 67 of 110 (61%) tested alleles. Four different mutations in the GJB2 gene have been identified in Latvian patients with NSHI: 35delG, 311-324del14, 235delC and M34T. 28 patients (51%) are homozygous for 35delG mutation, four patients (7%) are compound heterozygotes for 35delG and 311-324del14 mutations, one patient (2%) has genotype 35delG/235delC and one patient (2%) is heterozygous for M34T mutation. One heterozygous 51del12insA mutation was detected in unaffected individual with positive family history.

Conclusion: Our results verify the GJB2 mutations to be causative for NSHL and confirm previous reports on the mutation distribution. Still, the cause of hearing loss remains unclear for patients with no or single GJB2 mutation. However, GJB2 related diagnosis cannot be excluded until mutations in non-coding regions and adjacent GJB6 gene have been screened.

P05.056

Role of CYP1B1 mutations in Primary Open-Angle Glaucoma

P. López-Garrido^{1,2}, F. Sánchez-Sánchez^{1,2}, J. Escribano^{1,2}; ¹Genetics, Castilla-La Mancha University Medical School, Albacete, Spain, ²Cooperative Research Network on Age-Related Ocular Pathology, Visual and Life Quality, Instituto de Salud Carlos III, Madrid, Spain.

Glaucoma is a complex and genetically heterogeneous disease characterized by the progressive apoptotic death of retinal ganglion cells. Primary open-angle glaucoma (POAG) is the most common form of glaucoma, featured by an adult onset (>40 years), a gonioscopically open angle, and a reduced outflow facility. Heterozygous mutations in CYP1B1 gene are presented in the 4-9% POAG patients of different populations.

Our purpose is to establish the genotype-phenotype relationship in Spanish POAG patients carrying CYP1B1 mutations. We have analyzed the enzymatic activity of different CYP1B1 mutations found in these patients, in transfected HEK-293T cells. The CYP1B1 enzymatic activity assay was carried out using ethoxyresorufin as a substrate in a fluorimetric assay.

CYP1B1 mutations found in POAG patients show reduced enzymatic activity, supporting that loss of function mutations may play a role in the development of POAG.

P05.057

Analysis of secretion and processing of wild type myocilin and myocilin-glaucoma mutants co-expressed in cell lines

J. Aroca-Aguilar^{1,2}, F. Sánchez-Sánchez^{1,2}, F. Martínez-Redondo^{1,2}, M. Coca-Prados³, J. Escribano^{1,2};

¹Área de Genética. Facultad de Medicina /CRIB. UCLM, Albacete, Spain, ²Cooperative Research Network on Age-Related Ocular Pathology, Visual and Life Quality, Instituto de Salud Carlos III, Madrid, Spain, ³Department of Ophthalmology and Visual Science, Yale University School of Medicine, 300 George St, R.8100, New Haven, 06510, CT, United States.

Glaucoma is a leading cause of irreversible blindness worldwide. The main known risk factor for this disease is an elevated intraocular pressure (IOP), mainly caused by an increased resistance to aqueous humour outflow. Heterozygous mutations in the olfactomedin-like domain of the myocilin gene (MYOC) cause autosomal dominant juvenile-onset glaucoma, and approximately 4% of all adult-onset primary open-angle glaucoma (POAG) cases. The mechanisms by which these mutations elevate IOP and cause glaucoma are currently controversial. It has been described that myocilin undergoes an intracellular endoproteolytic processing by calpain II, in the middle of the polypeptide chain, which is reduced by glaucoma-associated MYOC mutations.

To gain insight into the molecular mechanisms by which mutations in the MYOC gene lead to glaucoma, we have analyzed, by SDS-PAGE

and Western blot, the secretion, endoproteolytic processing and extracellular aggregates of wild-type myocilin and 5 glaucoma-associated myocilin mutants (E323K, R346T, Q368X, P370L and D380A) transiently co-expressed in a cell line in culture. Our results show that coexpression affects secretion and proteolytic processing of wild type and mutant myocilins. These phenomena could play a role in the development of glaucoma.

Screening for glucocorticoid-remediable aldosteronism among hypertensive patients in Bulgaria

J. A. Matrozo¹, R. Saraeva², R. Bogeska², R. Kaneva², I. Kremensky², S. Zacharieva¹;

¹University Hospital of Endocrinology "Akad. Ivan Pentchev", Sofia, Bulgaria,

²Molecular Medicine Center, Medical University of Sofia, Sofia, Bulgaria.

Background. Primary aldosteronism (PA) is currently considered the most frequent form of endocrine hypertension. Glucocorticoid-remediable aldosteronism (GRA) is a genetic variety of PA, affecting about 1% of patients, which is inherited in an autosomal dominant pattern. GRA is caused by a chimaeric gene with aldosterone synthase activity originating from an unequal crossing-over between the CYP11B1 (11 beta-hydroxylase) and CYP11B2 (aldosterone synthase) genes. Hypertension in GRA can be severe leading to cerebrovascular complications at a young age and female carriers of the mutation have a higher incidence of preeclampsia during pregnancy. On the other hand GRA can be successfully treated by glucocorticoids, which justifies its screening and early diagnosis. **Objective.** The aim of this study was to assess the prevalence of GRA among patients with confirmed PA. **Methods.** The study population consisted of 170 hypertensive patients, referred to a specialized Endocrinology department. In order to identify patients with PA we used the aldosterone to renin ratio and the Captopril test. The diagnosis of PA was confirmed in 11 subjects who were investigated for GRA using the long PCR technique. **Results.** None of our patients was positive for the CYP11B1/CYP11B2 chimaeric gene. **Conclusions.** Our study demonstrated that GRA can be successfully excluded in patients with PA, using the long PCR technique. Further studies in larger groups of patients are needed to evaluate the prevalence of GRA among patients with PA, which is probably lower than previously reported

The *crv4* mouse model reveals a new role of the metabotropic glutamate receptor type 1 (*Grm1*) in the kidney glomerulus

A. Puliti^{1,2}, V. Conti^{1,3}, G. Caridi⁴, A. Corbelli⁵, L. Musante^{3,4}, F. Piccardi⁶, J. L. Guenet⁷, G. Candiano⁴, R. Gusmano³, M. P. Rastaldi⁶, R. Ravazzolo^{1,2};

We recently described the *crv4* mouse mutant, where a spontaneous mutation causes the lack of the metabotropic glutamate receptor type 1 (*Grm1*). Homozygous *crv4* mice exhibit a complex phenotype, mainly characterized by ataxia and by morphological and functional renal anomalies.

By PCR screening of a cDNA library of human tissues, we found *Grm1* expressed in the kidney. Expression of *Grm1* was also evidenced by amplifying and sequencing cDNA obtained from renal tissues of wild type mice. The expression of the receptor was confirmed in wild type renal tissues by western-blot and immunofluorescence analyses, using specific antibodies.

Electron microscopy analyses of the *crv4* kidneys, compared to the wild type, evidenced major glomerular alterations of the glomerular basement membrane and the podocytes, and immunofluorescence analyses of specific podocyte proteins, such as nephrin, synaptopodin, and ZO1, showed a reduced expression in the mutated mice.

Urine analyses by ELISA showed a statistically significant albuminuria in *crv4* homozygous relative to wild type mice.

These evidences support a recent hypothesis according to which podocytes communicate by neuron-like mechanisms. The podocyte, similarly to the neuronal cell, has vesicular structures for the exocy-

tosis/endocytosis and release of glutamate. In this view, mutations of molecules involved in such mechanisms may be added to other known genetic causes of glomerulopathies.

Identification, characterization and regulatory role of a new TFII-I family member, GTF2IRD2, located at the Williams-Beuren Syndrome locus

A. Antonelli¹, M. I. Tussie-Luna², A. L. Roy², L. A. Pérez-Jurado^{1,3};

¹Unitat de Genètica, Universitat Pompeu Fabra, U-735 CIBERER, Barcelona,

Spain, ²Dept. of Pathology, Tufts University School of Medicine, Boston, MA,

United States, ³Programa de Medicina Molecular i Genètica, Hospital Vall

d'Hebron, Barcelona, Spain.

GTF2I, *GTF2IRD1* and *GTF2IRD2* are three related genes located in the 7q11.23 Williams-Beuren Syndrome (WBS) locus that encode different members of the TFII-I family of transcription factors, characterized by the presence of several HLH-like domains known as I-repeats. The functions of *GTF2I* and *GTF2IRD1*, hemizygotously deleted in all typical WBS patients, have been studied in depth. However, little is known about *GTF2IRD2*, a multicopy gene that is variably deleted in WBS patients, and thus a candidate to influence the variable severity of the phenotype. We have studied the function of the three expressed *GTF2IRD2* copies termed medial, telomeric and the chimeric found in some WBS patients. *In vitro* transfection assays in COS7 cells revealed that all three *GTF2IRD2* proteins formed heterodimers with *GTF2I*, but only the *GTF2IRD2*-tel copy could interact with *GTF2IRD1*. The cellular localization pattern was different among the three proteins. *GTF2IRD2*-tel protein appears mainly nuclear while the *GTF2IRD2*-chi was found to be mostly cytoplasmatic. The *GTF2IRD2*-tel and *GTF2IRD2*-med proteins, but not the *GTF2IRD2*-chi, changed their distribution pattern when co-transfected with *GTF2I* and *GTF2IRD1*. In addition, the *GTF2IRD2*-tel protein was able to activate transcription of the *c-fos* gene in a synergistic way with *GTF2I*. In conclusion, *GTF2IRD2* proteins appear to act as transcription regulators by virtue of interacting with *GTF2I* and *GTF2IRD1* with different functional outcomes. The variable amount of the different TFII-I family proteins in WBS patients, depending on deletion breakpoints, could contribute to modulate the variable expression of target genes and thus the WBS phenotype.

Investigating Factor V (G1691A), Prothrombin (G20210A) and Methylenetetrahydrofolate reductase (C677T) gene polymorphisms in recurrent pregnancy loss

H. Samli¹, N. Imirzalioglu¹, G. Koken², A. Ozgoz¹, G. Ceylaner³, S. Ceylaner³;

¹Afyon Kocatepe University, School of Medicine, Department of Medical Genet-

ics, Afyonkarahisar, Turkey, ²Afyon Kocatepe University, School of Medicine,

Department of Obstetrics and Gynecology, Afyonkarahisar, Turkey, ³Zekai Tahir

Burak Women's Hospital, Department of Genetics, Ankara, Turkey.

In 75% of women trying to be pregnant, early pregnancy loss occurs. Habitual abortion is the termination of two or more consecutive pregnancies before 20th gestational week.

Various etiologic factors are responsible for recurrent pregnancy loss. In the performed studies these factors are reported to be, 7% chromosomal abnormalities, 10% anatomic problems, 15% hormonal irregularities, 6% unclear reasons and 55-62% coagulation protein/platelet problems. The importance of genetic defects causing deficiency in the coagulation system are better understood recently. Among them the most frequently related ones are some of the mutations take place in the Factor V, Prothrombin and the MTHFR genes.

In our study we objected to investigate the existence of the FV Leiden, Prothrombin and MTHFR gene mutations in 110 women with recurrent pregnancy loss and in 30 women with healthy children and no pregnancy loss. Mutation screening was performed by PCR-RFLP method using Hind III and Hinf I restriction enzymes for the blood samples of which DNAs were isolated.

FV Leiden, Prothrombin, MTHFR mutations were detected to be 13.6%, 6.4%, 55.5% in the case and 6.7%, 6.7%, 53.3% in the control groups, respectively. No significant differences were detected between the case and the control group according to the mutation frequencies. It is thought that the risk of pregnancy loss is related to the combined augmentation of the thrombophilic mutations rather than a specific mutation. Probably, investigating prevalence of more thrombophilic mutations in women with habitual abortion will be more significant.

P05.062**Duplication of exons 1 to 22 of the F8 gene: a new mechanism related to multiple copies of the intron 22 int22h sequence?**

C. Costa^{1,2}, E. Bieth³, P. Boisseau⁴, S. Letourneau¹, F. Dastot^{1,2}, E. Girodon-Boulandet^{1,2}, M. Goossens^{1,2};

¹AP-HP, Groupe Henri Mondor-Albert Chenevier, Laboratoire de Génétique Moléculaire, Créteil, France, ²INSERM U841, Département de Génétique, équipe 11, Université Paris 12, Créteil, France, ³Hôpital Purpan, Laboratoire de Génétique Médicale, Toulouse, France, ⁴CHU Hotel Dieu, Service de Génétique Médicale, Laboratoire de Génétique Moléculaire, Nantes, France.

Interspersed repeats account for 56% of the euchromatic X chromosome sequence, compared with a genome average of 45%. Intrachromosomal duplications are estimated to account for 2.59% of the X chromosome while interchromosomal duplications account for a very small fraction 0.24% of the X chromosome. Among these duplications are well-described cases that are associated with genomic disorders. Some disorders may result from rearrangements involving duplicated sequences in Xq28, such as in haemophilia A. In severe haemophilia A, mutations are frequently the results of inversions between a sequence in intron 22 (int22h-1) of the F8 gene and one of two more distally located copies (int22h-2, int22h-3) described to be in the same orientation. Recently a novel finding from analysis of the DNA sequence of the human X chromosome (Ross et al, Nature 2005) has revealed that the two distal copies are in opposite orientations. Recombination should then produce deletion or duplication rather than inversion. A deletion consistent with this prediction has been reported in a family in which carrier females are affected by a high spontaneous-abortion rate in pregnancy. We report here the first case of duplication of exons 1 to 22 in a carrier female in a family where none haemophilic patient was available. The duplication was detected by MP-LC (Multiplex Liquid chromatography) and confirmed by MLPA. We believe this new rearrangement could be linked to the multiple copies of the intron 22 sequences and would confirm the hypothesis that recombination could produce duplication.

P05.063**A comparison of quantitative real time PCR (Q-RT-PCR) and Multiple Ligation-Dependent Probe Amplification (MLPA) for molecular diagnosis of deletions in cases of severe haemophilia A**

Hospital Sant Pau, Barcelona, Spain.

Haemophilia A (HA) is an X-linked bleeding disorder caused by mutations in coagulation factor VIII. The identification of HA carriers is an essential part of genetic counselling. Large rearrangements frequently occur within the F8 gene in severe haemophiliacs. These include the intron22 inversion (40-45%) the intron1 inversion (2-5%) and gross deletions encompassing one or more exons (5-10%). Although gross deletions are readily detectable in males, the identification of heterozygosity in possible carriers of these families constitutes a challenge. To identify a deleted allele over the background of the normal allele in these carriers, we previously set up a Q-RT-PCR method employing LightCycler technology. A comparison was performed with the recently described MLPA P178 FVIII probemix that contains probes for each of the 26 exons of the F8 gene. We studied patients with deletions in exon 13, in exons 23-25, in exon 15 and in exons 1-22. Carrier and non-carrier females from these families previously defined by quantitative or marker analysis were also tested. MLPA results in HA patients revealed the absence of the peak in the corresponding exon(s). There was a complete correlation with results in the carrier group (one copy of the corresponding exon(s) by Q-RT-PCR and 40- 55% of reduced relative peak area in MLPA) and also in the non carrier group (two copies and 85-100% of peak area). MLPA may be incorporated into routine molecular diagnosis of severe HA after screening of inversions. Supported by Fundació Catalana d'Hemofilia, CIBERER, Real Fundació Victoria Eugenia.

P05.064**Investigation of human mitochondrial DNA in Iranian Hypertrophic Cardiomyopathy (HCM) patients**

M. Montazeri¹, M. Houshmand¹, E. V. Zaklyazminskaya²;

¹NRCGEB, Tehran, Islamic Republic of Iran, ²Russian Research Center of Medical Genetics Laboratory of DNA Research, Mosque, Russian Federation. Mitochondrial (mt) DNA defects, both deletions and tRNA point mutations, have been associated with cardiomyopathies. The aim of the study was to determine the mtDNA mutations in Hypertrophic cardiomyopathy (HCM) Iranian patients.

Hypertrophic cardiomyopathy (HCM) is widely accepted as a pluricausal or multifactorial disease. Because of the linkage between energy metabolism in the mitochondria and cardiac muscle contraction, it is reasonable to assume that mitochondrial abnormalities may be responsible for some forms of HCM. We analysed the whole mitochondrial genome in a series of 31 patients with HCM for alterations and compared the findings with those of 30 control subjects. A total of X sequence changes could be identified. These sequence changes were distributed among the whole mitochondrial DNA (mtDNA). An increased number of novel missense mutations could be detected nearly in all genes encoding for protein subunits in HCM patients subjects. Four mutations were found that are unpublished. The c.4384T>C in tRNA glutamin, c.9063A>G in ATPase6, c.2071 T>C, c.3170C>A, in noncoding MTRNA2 16S. Also 33 polymorphisms were identified in this study which had not been published in the MitoMap database. The c.16189T>C mutation in the D-loop region that is associated with susceptibility to DCM could be detected in 3% of patients as well as in 0% of controls. Furthermore, mtDNA mutations may play an important role in pathogenesis of cardiac arrest which has remained unexplained for long.

P05.065**Investigation of 69 common mutations in MYH7 gene in Iranian population with hypertrophic cardiomyopathy**

M. Montazeri¹, M. Houshmand¹, M. Ghani Kakhki¹, G. Estahbanat², M. M. Peyghambari³, E. V. Zaklyazminskaya⁴;

¹nrcgeb, Tehran, Islamic Republic of Iran, ²Iran University of Medical Sciences Shaheed Rajaie Cardiovascular Medical Center, Tehran, Iran, Tehran, Islamic Republic of Iran, ³Iran University of Medical Sciences Shaheed Rajaie Cardiovascular Medical Center, Tehran, Iran., Tehran, Islamic Republic of Iran, ⁴Russian Research Center of Medical Genetics Laboratory of DNA Research, Moscow, Russia., Moscow, Russian Federation.

Hypertrophic cardiomyopathy is characterized by hypertrophy of ventricles and intraventricular septum. Patients could develop serious complications including heart failure, arrhythmias and sudden death. Familial hypertrophic cardiomyopathy is a single gene disorder and has autosomal dominant inheritance. In this study we focused on exons 13-15 and 19-21 of MYH7 gene and introns located between them, which contain hotspots for so called "malignant mutations" that increase sudden cardiac death risk. Methods: Fifty unrelated Iranian patients with hypertrophic cardiomyopathy were selected sequentially and informed written consent was obtained from them. Exons 13-15 and 19-21 of MYH7 gene and their related introns were amplified by polymerase chain reaction. Then PCR products were sequenced. Results: Mutations were detected in fourteen (28%) of the patients. We didn't find any malignant mutation, but three mutations were found in targeted exons. One of them, A10419C (N444T) in exon 14, may be a novel mutation.

P05.066**A novel mitochondrial DNA tRNAIle (m.4322dupC) mutation associated with idiopathic dilated cardiomyopathy**

S. Mahjoub¹, D. Sternberg², R. Boussaada³, S. Filouf⁴, F. Guemira⁴, R. Mechmech³, C. Jardef³, S. Ben Arab¹;

¹Faculté de Médecine de Tunis, Tunis, Tunisia, ²Fédération de génétique-UF Cardio et Myogénétique, Hôpital Pitié-salpêtrière, Paris, France, ³Hôpital La Rabta, Tunis, Tunisia, ⁴Hôpital Salah Azaiez, Tunis, Tunisia.

Dilated cardiomyopathy (DCM) is a heart muscle disease characterized by cardiac dilatation and impaired contraction of the left ventricle (LV) or both ventricles. The age at disease onset is highly variable, ranging from early childhood to late adulthood. Only 50% of patients with DCM survive >5 years after diagnosis. Approximately 20% to 25% of cases seem to have a genetic component. DCM can be transmit-

ted as autosomal dominant and recessive, X-linked, or mitochondrial traits. Mitochondrial DNA (mtDNA) defects are found in an increasing number of cases of DCM. We identified a novel heteroplasmic mitochondrial DNA (m.4322dupC) mutation in tRNA^{Leu} gene associated with isolated dilated cardiomyopathy (DCM) as maternal trait. Mutation screening techniques and automated DNA sequencing were performed to identify mtDNA mutations and to assess heteroplasmy in family's proband and healthy control subjects. All family members tested had heteroplasmic mtDNA (m.4322dupC) mutation. We also screened 350 normal controls for this mutation and found no evidence of heteroplasmy.

The m.4322dupC mutation was found in the skeletal tissue from the proband that exhibited slightly reduced deficiency of mitochondrial respiratory chain enzymes (complex III). The present study reports the novel m.4322dupC mutation in tRNA^{Leu} gene, which is possibly associated to the disease, to isolated DCM. It was localized in a hot-spot region for mutations and is possibly pathogenic because of a cosegregation with the matrilineal transmission of DCM.

P05.067

Analysis of the 12SrRNA and tRNASer(UCN) genes (mtDNA) in patients with nonsyndromic hearing loss from different Russia regions

L. U. Dzhemileva¹, A. M. Tazetdinov¹, O. L. Posukht², K. A. Barashkov³, E. K. Khusnutdinova¹;

¹Institute of biochemistry and genetics, Ufa, Russian Federation, ²Institute of Cytology and Genetics, Siberian Branch of Russian Academy of Sciences, Novosibirsk, Russian Federation, ³Yakutsk Research Centre, Siberian Branch of Russian Academy of Medical Sciences, Yakutsk, Russian Federation.

Hearing loss is common congenital disorder and more than 50% of deafness has a genetic cause. The m.1555G>A (12SrRNA) was confirmed as the main cause of aminoglycoside induced deafness in different populations. Families with maternally inherited sensorineural hearing loss are also described in association with A7445G, T7511C, and 7472insC mutations in the tRNASer(UCN) gene. We report here the results of mutational screening for 12S rRNA and tRNASer(UCN) genes among Cx26- and Cx30-negative deaf individuals of different ethnicity from different regions of Russia. Previously, 301 unrelated patients from Volga-Ural region, 78 unrelated patients from the Republic Sakha (Yakutia, northeastern Siberia), and 119 deaf patients (75 unrelated families) from the Republic Altai (south Siberia) were analyzed for Cx26 and Cx30 mutations. Different variations at the 961 position in 12S rRNA gene have been found among deaf individuals from Volga-Ural region. Five patients of different ethnicity (Russian, Tatar, Latvian) with m.961insC, two Tatars with m.del961TinsC_n, three Russian patients with m.961T>G (one from Volga-Ural region and two from Altai), and one Russian with m.961T>A, were detected. Also, the m.7444G>A (tRNASer(UCN)) was found in one Russian patient with NSHL. Finally, m.7445G>C (tRNASer(UCN)) was found in two sibs of one Kazakh family (Altai region) in whom moderate sensorineural hearing loss was co-existed with goiter. Further studies are needed to confirm pathogenicity of some mtDNA variations associated with deafness in patients from some regions of Russia.

P05.068

Prevalence of the GJB2 mutations in Iranian patients with deafness

M. Hamid¹, M. T. Akbar²;

¹Pasteur Institute of Iran, Tehran, Islamic Republic of Iran, ²Tarbiat Modaras University, Tehran, Islamic Republic of Iran.

The commonest form of non-syndromic recessive deafness is caused by mutation in GJB2, encoding gap junction beta 2 protein on chromosome location 13q11. It is known as DFNB1 responsible for half of autosomal recessive non-syndromic deafness. The most frequent mutation 35delG accounts for about 60-80% of mutations in white people of European.

In this study, we report the frequency of the GJB2 gene mutations in 31 unrelated Iranian families from 48 subjects affected by hereditary hearing loss (HHL).

Eight different mutations were detected in 12 families (38.7%) by using direct-sequencing technique in coding region of GJB2 gene. Cx26 related deafness mutations (35delG, R127H, V271+E114G, Y155X, M163V and a novel 355-356 delGA) were identified in 9(29%) families

in heterozygous form, 3(9.67%) (35delG/35delG and R143W/ R143W) and 1 (3.2%) (R32H+35delG) were homozygous and compound heterozygous respectively.

Two polymorphisms V153I and (F154F +F146F) also were detected in four families and a polymorphism S86T was identified in all cases. In this population study, our data showed that the rate of GJB2 mutations is high in heterozygous form so other loci and genes related to deafness must be investigated. Moreover, the most frequent mutation was 35delG because 9 out of 18(50%) mutant alleles had this mutation. This is lower than that reported in western populations

P05.069

Hereditary Congenital Hearing Loss: molecular analysis of Connexin 26, 30 and A1555G Mitochondrial Point mutation in Italian population

L. Trotta¹, P. Castorina¹, F. Sironi¹, U. Ambrosetti¹, A. Cesarani¹, L. Garavelli², P. Formigoni², A. Murr³, D. Cuda³, D. A. Coviello¹, P. Primignani¹;

¹Fondazione IRCCS, Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena, Milan, Italy, ²Arcispedale S. Maria Nuova, Reggio Emilia, Italy, ³Ospedale Guglielmo da Saliceto, Piacenza, Italy.

Mutations in GJB2, encoding the gap-junction protein Connexin26, are the most common cause of non-syndromic hearing loss (NSHL) and account for about 32% of cases in the Caucasian population. We analyzed 852 patients and identified mutations in 527/1662 chromosomes. We characterised 40 different mutations and 6 polymorphisms in 299 NSHL patients. More than 100 different mutations are described but one is particularly common, the 35delG, accounting for about 68% of all the Cx26 alleles we identified. The GJB6 gene deletion, del(GJB6-D13S1830), which can cause hearing loss in combination with GJB2 mutations in trans, has been found in 3 of our patients, while the del(GJB6-D13S1854) was not present in our patients' population. Our results show that GJB2/GJB6 genes account for less than 30% of NSHL in the screened cohort of patients and confirm that the 35delG mutation is the most frequent one. Moreover, 27 affected subjects were compound heterozygous for recessive GJB2 allele not including 35delG and 8 were carrying dominant mutations (T55N, P58A, D179N and R184Q), indicating that the complete sequence of the gene is needed for an appropriate molecular diagnosis. The analysis of the deafness-causing A1555G substitution in MTRNR1 mitochondrial gene was carried out in patients with one or without Cx26 recessive mutations. We found 21 affected subjects carrying the A1555G and the subsequently family analysis performed in each case has led to the pre-symptomatic identification of this mutation in relatives.

P05.070

GJB2 analysis in Portuguese cochlear implant users

J. Chora¹, T. Matos¹, S. Andrade², J. Humberto², M. Alves², L. Silva², C. Ribeiro³, G. Fialho¹, H. Caria^{1,3};

¹Center of Genetics and Molecular Biology, University of Lisbon, Lisbon, Portugal, ²ORL Department - Centro Hospitalar de Coimbra, Coimbra, Portugal, ³Higher College of Health, Polytechnic Institute of Setúbal, Setúbal, Portugal.

Hearing impairment affects approximately 1 in 1000 newborns and at least 60% of these cases have a genetic origin. Despite large genetic heterogeneity, mutations in a single gene - GJB2 - are the most frequent genetic cause of severe to profound pre-lingual recessive deafness in many populations. Therefore, GJB2 became the most important gene in the understanding of deafness. Hearing loss is a condition that interferes with the development of the child at a cognitive and language level. Therefore early diagnosis of deafness is important for earlier rehabilitation, namely through the use of cochlear implants. These devices replace the cochlea in a physiological context. Some studies suggest a correlation between the GJB2 genotype of the implanted individual and a phenotype that allows the success of rehabilitation due to cochlear implant

The aim of our study is to analyse the GJB2 gene in a sample of 100 Portuguese cochlear implant recipients. All individuals, presenting non-syndromic sensorineural severe to profound bilateral recessive deafness prior implantation, were implanted in the Centro Hospitalar de Coimbra. Screening of GJB2 gene was performed by PCR and sequencing in of the entire coding region. The results obtained may represent a valuable indicator when counselling candidates for cochlear implantation.

P05.071

Characterization of the *Dfna5* promoter region

K. Vrijens, L. Van Laer, G. Van Camp;

Center Medical Genetics, University Antwerp, Antwerp, Belgium.

DFNA5 mutations cause a non-syndromic, progressive, sensorineural hearing loss in humans. Four different mutations have been identified at the genomic level, all leading to exon 8 skipping at the mRNA level. As a consequence, it was hypothesised that *DFNA5*-related hearing loss is associated with a gain-of-function, and that only skipping of exon 8 leads to disease. With the objective to clarify the molecular basis of this gene's regulation, we have characterized the mouse *Dfna5* promoter region.

Initially, *in silico* analyses of the mouse *Dfna5* promoter region were performed followed by 5'-RACE experiments using mouse cochlear cDNA. The latter enabled us to identify the cochlear *Dfna5* transcription initiation site (TIS) *in vitro*. Subsequently, constructs were generated for transfection experiments in HEK293 cells. After confirmation of the core promoter region in a 400bp construct surrounding the suspected TIS, constructs of increasing length were generated to identify regulatory elements. Both an enhancer and a silencer element could be identified in the region upstream of the TIS. Next, transfection experiments performed with the organ of Corti cell line OC-k3 demonstrated that the suspected core promoter also drives expression in inner ear cells. Furthermore the enhancer and silencer elements act similarly in OC-k3 cells. Transfections using the 400bp construct in reverse orientation were performed as negative control. However, this construct also revealed promoter activity, suggesting the presence of an antisense regulatory element. Finally, transcription factor binding sites in the *Dfna5* regulatory region were identified using several computer modelling programs.

P05.072

Mutational screening of *GJB2* non-coding regions in Portuguese hearing loss patients

T. D. Matos¹, H. Simões-Teixeira^{1,2}, H. Caria^{1,3}, D. P. Kelsell⁴, G. Fialho¹;

¹Center of Genetics and Molecular Biology, University of Lisbon, Lisbon, Portugal, ²Unidad de Genética Molecular, Hospital Ramón y Cajal, Madrid, Spain, ³Higher College of Health, Polytechnic Institute of Setúbal, Setúbal, Portugal, ⁴Centre for Cutaneous Research, Institute of Cell and Molecular Science, Barts and The London School of Medicine and Dentistry, Queen Mary, University of London, London, United Kingdom.

Many hearing loss mutations in the *GJB2* gene have been described in the last decade, being most of them located within the coding region. During this period, only a few mutational studies were performed on the non-coding regions of the gene. Such studies focused on the first exon, the donor splice site and, occasionally, the promoter region. None, to our knowledge, has ever included the whole 3' UTR. Two pathogenic mutations have so far been reported in *GJB2* donor splice site, and recently we have found a novel pathogenic mutation, -3438 C>T, occurring in the *GJB2* basal promoter. These mutations, or novel ones, in the *GJB2* non-coding regions may therefore be involved in other unelucidated cases of hearing loss.

In this study, we analysed by sequencing the *GJB2* promoter, exon 1, donor splice site and 3'UTR of about 100 unrelated Portuguese patients previously screened for *GJB2* coding region mutations.

An interesting finding was the identification of one homozygote for the -493del10 deletion upstream *GJB2* basal promoter, without any accompanying *GJB2* coding mutation. The significance of this mutation is yet unclear. However, in a previous study, over 6% of carriers, but no -493del10 homozygotes, were found in a control sample of 630 individuals, which might suggest this could be a pathogenic recessive mutation. Results regarding other non-coding variants are being assessed.

These data, and the previous reports on pathogenic non-coding *GJB2* mutations, justify routine screening of these regions in order to improve molecular diagnostic and genetic counseling of hearing loss patients.

P05.073

Genetic etiology and spectrum of mutations in *GJB2* and *SLC26A4* genes

D. Raskova, D. Stejskal, P. Seeman, M. Putzova, E. Hlavova, O. Bendova, J. Stoilova, R. Pourova, I. Vackova;
GENNET, Praha, Czech Republic.

Hereditary hearing impairment clinic was established at our institute in October 2003. 226 families have been investigated until October 2007. Genetic etiology of hearing impairment was found at 70,35 % of families (53,46% with autosomal recessive inheritance, 15,10% with autosomal dominant inheritance and 13,83% with genetic syndromes, chromosomal aberrations and another genetic diseases with deafness, at 17,61 % families the mode of inheritance could not be determined). The rest (29,65%) were families with idiopathic hearing loss. The mutations in the *GJB2* gene (Cx26) were investigated at 321 patients by sequencing of entire coding region of *GJB2*. In patients carrying only one pathogenic mutation the IVS 1+1 G to A mutation in the non-coding region was further tested. We found 4 mutations not reported before (Ala149Thr, Ile140Ser, c.683+3 C to A, Gly130Val). At least one pathogenic mutation was found at 157 (48,91%) patients. Both pathogenic mutations were detected at 65 (20,25%) patients. No pathogenic *GJB2* mutation was detected at 134 (41,74%) patients and 30 (9,35%) patients are carriers of various polymorphisms or mutations not reported before. The mutation 35delG is by far the most common of all pathogenic mutations and with mutations Trp24Stop, 313del14 and -3170 G to A accounted in total for 95% of all causal mutated alleles in all patients.

Molecular genetic analysis of *SLC26A4* gene was introduced in Czech Republic in 2006. 23,08% patients with congenital deafness, goiter or enlarged vestibular aqueduct (EVA) have both pathogenic mutations of *SLC26A4* gene.

P05.074

A Systems Biology Approach to Hearing: Combining Genomic, Proteomic and microRNA Characterization

K. B. Avraham¹, T. Elkan¹, A. Dror¹, R. Elkon¹, T. Satoh², G. Toren¹, R. Hertzano¹, M. Imler³, J. Beckers³, E. Hornstein⁴, D. M. Fekete², L. M. Friedman¹;
¹Department of Human Molecular Genetics & Biochemistry, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, ²Biological Sciences, Purdue University, West Lafayette, IN, United States, ³GSF-National Research Center for Environment and Health, GmbH, Neuherberg, Germany, ⁴Department of Human Molecular Genetics, Weizmann Institute of Science, Rehovot, Israel.

Systems biology involves studying the interaction and interplay of many levels of biological information. We have combined transcriptomic and proteomic analyses of cochlear and vestibular sensory epithelia in order to identify networks of genes and proteins essential for the development and function of these inner ear organs. We further identified microRNAs (miRNAs) that are uniquely expressed in the auditory and vestibular sensory epithelia using bioinformatics tools and experimental approaches, including microarray profiling and *in situ* hybridization.

Expression profiling of vestibular and cochlear sensory epithelia using Affymetrix microarrays and proteomics analysis using the Q-TOF mass spectrometer with ITRAQ labeling has led to the identification of genes and protein networks which function differently in the cochlear and vestibular systems. A network analysis was applied to determine if a set of proteins of interest are physically connected, assuming that physical interaction between proteins points to some common function/pathway/complex. Two major sub-networks emerged from the integrated transcriptomic-proteomic clusters, indicating multiple interactions between proteins expressed in the cochlear and vestibular systems.

miRNAs are recognized as important regulators of gene expression at the post-transcriptional level and mutations in miRNAs can lead to disease. Combining our transcriptomic and proteomic data with miRNA identification in the inner ear has led us to make predictions regarding putative targets, which are being experimentally validated. For a number of miRNAs, morpholino experiments in zebrafish demonstrated abnormalities in inner ear development and/or structure, demonstrating the importance of these miRNAs in the inner ear. These miRNAs are candidates for causing deafness.

P05.075**Three novel mutations in SLC40A1 gene causing hemochromatosis type 4**V. Koubi¹, F. Houriez², C. Delacroix², J. Marie³, S. Pissard^{1,4};¹laboratory of genetics, AP-HP, Hop Henri Mondor, creteil, France, ²Hematology Unit, AP-HP, Hop cochin, Paris 13, France, ³Hematology Unit, AP-HP, Hotel dieu, Paris 1, France, ⁴University Paris 12, Creteil, France.

The Hemochromatosis type 4 (OMIM : 606069, 2q32) is caused by mutations in the SLC40A1 gene which encodes the ferroportin, a 10 transmembrane domains protein's which export iron from enterocytes and RE cells to blood transferrin. It is supposed to be regulated through interaction with the hepcidin. Nowadays, 21 mutations and 7 polymorphisms of the SLC40A1 gene are described. It is the most frequent etiology for the "non HFE" hemochromatosis and it is inherited as an autosomal dominant trait. We found common mutations in SLC40A1 in 13 from 93 families referred to the laboratory for a "non HFE" hemochromatosis : G490D, G490S, G80S, V162Del and Q248H. The Study of three families which do not displayed a typical HH 4 iron overload (hyperferritinemia and low transferrin saturation), allowed us to discovered 3 new mutations : c. 212C > T (p.Ser71Phe) in exon 3, c.697C > A (p.Ala232Asp) in exon 6 and c.797T > C (p.Met266Thr) in exon 7. All patients were heterozygous for the mutation and the autosomal dominant inheritance has been proven for p.Ser71Phe mutation since HH type 4 and mutation were present in mother and son. Interestingly, from those 3 mutations two are located in the loop between the TM domain 4 and 5 (p.Ala232Asp and p.Met266Thr) where are located 11 from the 21 mutations already described giving more evidences for the role of this loops in the function or the regulation of this protein. This work highlight the frequency of HH type 4 and brings data to better understand the function of the protein.

P05.076**Novel SLC40A1 mutations in Centre-South Mediterranean families with autosomal dominant iron overload.**F. C. Radio¹, S. Majore¹, N. Preziosi¹, A. Villa¹, M. De Muro², R. Villan³, C. De Bernardo¹, P. Grammatico¹;¹Medical Genetics, "Sapienza University", S. Camillo Hospital, Rome, Italy,²Emathology, University "Campus Biomedico", Rome, Italy, ³Epathology,

S. Camillo Hospital, Rome, Italy.

Iron overload due to mutations in ferroportin is the most common form of "Non HFE hemochromatosis". Ferroportin disease or hemochromatosis type IV has a dominant inheritance and two main clinical phenotypes. Most cases show early increase in serum ferritin in the presence of a low-normal transferrin saturation, iron loading predominantly in reticuloendothelial cells and, sometimes, low tolerance to the phlebotomy program. On the contrary, some cases are similar to the typical "classical hemochromatosis" characterized by early high transferrin saturation and prevalent parenchymal iron overload.

Different kind of mutations in the iron exporter ferroportin (SLC40A1) result in hemochromatosis type IV. Loss-of-function mutations cause an impairment of iron export from reticuloendothelial cells with tissue iron accumulation but decreased availability of iron for circulating transferrin. Instead a phenotype overlapping with 'classical hemochromatosis' is the result of gain-of-function mutations in SLC40A1.

We describe four novel missense mutations and a rare polymorphism (p.Arg561Gly) in ferroportin (SLC40A1) found in members of five different families of Centre-South Mediterranean showing autosomal dominant iron overload. Both loss-of-function (p.Ala69Thr; p.Asp181Asn) and gain-of-function (p.Arg296Gln; p.Tyr501Cys) mutations are recognizable in these families, so that a genotype-phenotype correlation is possible.

P05.077**Detection of large duplications within the FVIII gene by MLPA**S. Rost¹, S. Loeffler¹, A. Pavlova², J. Oldenburg², C. R. Mueller¹;¹Dept. of Human Genetics, University of Wuerzburg, Wuerzburg, Germany,²Inst. of Hematology and Transfusion Medicine, University of Bonn, Bonn, Germany.

Haemophilia A is caused by a variety of different mutations in the FVIII gene: missense and nonsense mutations, small and large deletions and insertions, as well as large inversions. So far, only one duplication of a whole exon of the FVIII gene, exon 13, has been published by an Italian working group. Duplications comprising whole exons are dif-

ficult to detect by the usually applied methods for mutation screening in X-chromosomal linked disorders.

In about 80 haemophilia A patients (from a total of approx. 2000) we could not identify any mutation by long range PCR, DGGE and additional sequencing of all 26 exons and flanking intronic regions of the FVIII gene. These patients were investigated by multiplex ligation-dependent probe amplification (MLPA, MRC-Holland) for large duplications. We detected eight exon-spanning duplications of different length in nine haemophilia A patients. In two patients we found duplications of only one exon: exon 13 and 14, respectively. The other duplications affected more than one exon: exons 1-5, exons 5-25, exons 23-25, exons 2-25, exons 14-21 and exons 7-11, respectively. All duplications were confirmed by DHPLC analysis (denaturing high performance liquid chromatography).

In conclusion, we found large duplications in the FVIII gene to be causative mutations for haemophilia A in about 10% of all pre-screened patients in which we could not detect any mutation by the conventionally used methods.

MLPA is a convenient method for detection of large duplications and also deletions of whole exons particularly in X-chromosomal linked disorders as haemophilia A.

P05.078**Frequency of factor VIII intron-1 inversion among hemophilia A patients from Republic of Macedonia and Republic of Bulgaria**E. Sukarova Stefanovska¹, M. Bojadzievska¹, V. Dejanova², P. Tchakarova³, G. Petkov³, G. D. Eftremov¹;¹Research Center for Genetic Engineering and Biotechnology, Macedonian Academy of Sciences and Arts, Skopje, The former Yugoslav Republic of Macedonia, ²Center for Transfusiology, Medical Faculty, Skopje, The former Yugoslav Republic of Macedonia, ³Pediatric Clinic, Medical Faculty, Stara Zagora, Bulgaria.

Hemophilia A (HA) an X-linked bleeding disorder, is characterized by a wide allelic heterogeneity, as numerous mutations are spread out through the whole exonic, intronic and regulatory regions of the factor VIII gene. The most recurrent molecular defect is the inversion involving the intron-22, accounting for >40% of the patients with severe disease. Recently, Bagnall et al. (Blood, 2002) reported an inversion of intron-1 as a further recurrent mutation. The prevalence of this mutation is between 0.6 and 5%, according to reports from different groups.

The aim of this study was to determine the frequency of intron-1 inversion among 57 severe hemophilia A patients from Republic of Macedonia and 40 patients from Republic of Bulgaria. DNA samples from all 97 patients were analyzed for the presence of intron-22 inversion. Patients negative for the intron-22 inversion, were screened for the intron-1 inversion. Two PCR reactions flanking each *int1h* repeat (intronic and extragenic) were used.

We have identified the presence of intron-1 inversion in four out of 57 (7.0%) severe HA patients from Republic of Macedonia. None of these patients exhibited inhibitor development. Analysis of the factor VIII gene haplotypes demonstrated that the intron-1 breaking inversion has occurred independently in three (out of four) patients. No intron-1 inversion was detected among HA patients from Bulgaria.

Our data highlight the importance of analysis of the intron-1 inversion in the severe HA cases from Republic of Macedonia. This will benefit both genetic counseling and the study of the relationship between genotype and inhibitor development.

P05.079**Molecular analysis of a novel deletion at Exon 4 of factor IX gene in a hemophilia B patient**L. Kokabee^{1,2}, E. Kamali¹, S. Zeinali¹, S. Jamali¹, M. Karimipour¹;¹Pasteur Institute of Iran, Tehran, Islamic Republic of Iran, ²Khatam university, Tehran, Islamic Republic of Iran.

Hemophilia B (HB) is an X-linked bleeding disorder caused by the functional deficiency of blood coagulation factor IX. The disease is due to heterogeneous mutations in the factor IX gene (F9), located at Xq27.1. It spans about 34 kb of genomic DNA.

Molecular analysis of F9 gene in a severe Iranian HB patient and carrier testing for the family referred from Kashan hemophilia center. After obtaining informed consent, genomic DNA was extracted from the peripheral blood of the patient and his mother and sister by standard methods. PCR amplification and single strand conformation poly-

morphism (SSCP) techniques were performed for scanning of the all functional-important regions of the F9 gene. An abnormal SSCP profile was identified in exon 4 of the gene for this patient. Then, direct sequencing was done by chain termination method.

The deletion of 19 nucleotides (10503-10521 del) was detected in this patient in exon 4

which is not reported in hemophilia B mutation database, previously.

The patient's mother and his sister were heterozygous for this deletion.

A novel deletion of 19 nucleotides (10503-10521 del) in exon 4 leading to frame shift in the epidermal growth factor1(EGF1) domain. Exon 4 encoded a first epidermal growth factor-like domain, which shows homology to epidermal growth factor (EGF) and, in addition, contains conserved carboxylate residues including a β -hydroxyaspartate at amino acid 64. This domain binds an additional Ca²⁺ with high affinity. In conclusion, this deletion causes a severe form of disease as observed in this patient.

P05.080

Complete Maternal Isodisomy Causing Reduction to Homozygosity for a Novel LAMB3 Mutation in Herlitz Junctional Epidermolysis Bullosa

D. Castiglia¹, M. Castori¹, G. Floriddia¹, E. Pisanesch², C. Covaciu¹, I. Torrente², G. Zambruno¹;

¹IDI-IRCCS, Rome, Italy, ²CSS-Mendel Institute, Rome, Italy.

Herlitz junctional epidermolysis bullosa (HJEB) is a very rare lethal genodermatosis characterized by blister formation with tissue separation within the lamina lucida of the basement membrane zone. It is genetically heterogeneous, being caused by null mutations in the LAMA3 (18q11.2), LAMB3 (1q32), or LAMC2 (1q25-q31) genes encoding for the alpha3, beta3 and gamma2 subunits of laminin 332. Although it is usually inherited in an autosomal recessive fashion, four cases have been described in which the disease arose from reduction to homozygosity for a mutant allele caused by uniparental disomy (UPD). Here, we report on a baby presenting with multiple blister formation at birth and who died due to acute respiratory insufficiency secondary to upper airway obstruction at 1 year of age. The diagnosis of HJEB was first confirmed by immunopeptide mapping of a skin biopsy. Molecular analysis identified a novel frameshift mutation at the homozygous state in LAMB3. Parental genotyping established the mother as a healthy carrier, while in the father the mutation was absent. Haplotype analysis of 8 intragenic and 15 extragenic polymorphisms, spanning the entire chromosome 1, demonstrated that the proband was homozygous for a single maternal haplotype. The present case represents the fifth example of UPD in HJEB. Based on literature data and our experience in genotyping 20 HJEB patients from several European countries, reduction to homozygosity due to UPD is not exceptional in this condition and should be considered in sporadic cases in order to properly counsel the couple.

P05.081

Genetic causes of hearing loss in the Iranian population a 10 year study

H. Najmabadi¹, C. Nishimura², K. Kahrizi¹, N. C. Meyer², N. Bazazzadegan¹, J. L. Sorensen², M. Mohseni¹, Y. Riaza Hosseini¹, M. Malekpour¹, G. Asaadi Tehrani¹, A. Daneshi³, M. Farhad³, P. Imani⁴, A. Anousheh¹, A. Nazeri¹, S. Abedini¹, N. Nikzat¹, S. Arzhang¹, R. J. H. Smith²;

¹Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, ²Molecular Otolaryngology Research Laboratories, Department of Otolaryngology, University of Iowa, Iowa, IA, United States, ³Research Center of Ear, Nose, Throat, and Head and Neck Surgery, Iran university of Medical sciences, Tehran, Islamic Republic of Iran.

Approximately one in 1000 newborns has severe-to-profound deafness, which has a genetic basis in more than half of this group. In ~70% of congenitally deaf newborns the loss is nonsyndromic.

The purpose of this study has been to determine the cause of syndromic and non-syndromic hearing loss in the Iranian population.

Over a 10 year period, 2434 families segregating deafness have been referred to Genetics Research Center in Tehran. In each of these families, informed consent was obtained. Every family was screened for mutations in GJB2 and GJB6. Following this screen, in 300 families with three and more affected individuals with presumed ARNSHL, we

screened total of 22 loci by STR markers. In families in which autozygosity by descent was not identified at any of these loci, a genome-wide screen was completed.

Our data show that 15.3% of the Iranian population with ARNSHL segregate mutations in GJB2. The most prevalent mutation in this gene was 35delG, although more than 20 mutations have been identified, five of which are unique to the Iranian population. We also identified novel GJB2 mutation in an endogenous population segregating ADNSHL in village north of Iran.

The second and third most prevalent causes of ARNSHL were mutations in SLC26A4 andTECTA. We have also found mutations in PJKV and TMC1 in one family each.

We have identified a number of families segregating syndromic hearing loss. Totally, we have been able to determine the genetic cause of hearing loss in over 30% of families referred to our center.

P05.082

The investigation of NPHS1 gene in children with Hereditary Proteinuria Syndrome

O. Ryzhkova¹, N. Poltavets¹, L. Prihodina², A. Polyakov¹;

¹Research Center for Medical Genetics, Moscow, Russian Federation, ²Research Center of Pediatrics and Child Surgery, Moscow, Russian Federation.

Hereditary Proteinuria Syndromes (HPS) is a group of inherited diseases in which proteinuria is the primary clinical manifestation. The genetic cause of these diseases is mutations in genes providing the structure and function of filtration barrier.

DNA from 63 children with idiopathic nephrotic syndrome in age are ranged from 1 to 17 years, consisting of 33 boys and 30 girls, have been analyzed. The disease manifestation had been observed at the age ranged from 1 month to 16 years. The control group has consisted from 50 healthy persons. The mutations in NPYS1 gene were investigated by using SSCP-analysis and consequent sequencing.

No mutations in coding and regulation regions of this gene were found.

At researched patients has been revealed five single nucleotide substitution (table 1), one of which c.605-20 A> C has not been described earlier. For specification of influence of this substitution by occurrence of Proteinuria Syndrome, we investigated frequency of occurrence in control sample. Authentic distinctions have not been revealed.

We have not found significant distinctions allele frequency of four others polymorphisms NPYS1 gene between our patients and control group. We think that contribution of these polymorphisms to disease is unimportant.

Minor allele frequency of polymorphisms NPYS1 gene in our patients and control group (%)

exon	polymorphism	HPS group	control group	Fisher exact test (P)
Ex3(c.349G>A)	c.349A	25	26	0.87
Ex10(c.1175C>T)	c.1175T	2	4	0.45
Ex10(c.1223G>A)	c.1223A	4	3	0.72

Minor allele frequency of polymorphisms NPYS1 gene in our patients and control group (%)

exon	polymorphism	HPS group	control group (our data)	Fisher exact test (P)
Ex7(c.791C>G)	c.791G	1	1	1
Ex6(c.605-20A>C)	c.605-20C	1	0	0.5

P05.083

Analysis of SPASTIN in a Spanish series shows both recurrent and novel mutations

M. Zennaro¹, G. Martinez-Nieto¹, A. Sesar², M. Arias², I. J. Posada³, B. Ares², J. Pardo², M. Seijo², C. Navarro², C. Andrade², A. Carracedo^{1,7,8}, M. J. Sobrido^{1,7};

¹Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain, ²Department of Neurology, Hospital Clínico, Santiago de Compostela, Spain, ³Department of Neurology, Hospital 12 de Octubre-Universidad Complutense, Madrid, Spain, ⁴Sección de Neurología, Hospital do Salnés, Pontevedra, Spain, ⁵Department of Pathology, Hospital do Meixoeiro-CHUVI, Vigo, Spain, ⁶Department of Neurology, Hospital Xeral-Cies, Vigo, Spain, ⁷Centro para Investigación de Enfermedades Raras (CIBERER) ISCIII, Santiago de Compostela, Spain, ⁸Grupo de Medicina Xenómica-Universidad, Santiago de

Compostela, Spain.

Hereditary spastic paraparesis (HSP) is a progressive gait disorder with spasticity of the limbs. HSP shows both clinical and genetic heterogeneity and can be autosomal dominant (AD-HSP), autosomal recessive or X-linked recessive. The most prevalent form of AD-HSP involves the *SPG4* locus encoding spastin, a member of the AAA family of ATPases. The frequency of *SPG4* mutations in our population is unknown. We studied 56 patients (43 families, 33 of them Galician, 10 from other regions of Spain), most with uncomplicated forms of HSP. The 17 exons of *SPG4* and exon-intron boundaries were sequenced. Novel mutations and sequence variations of unknown significance were checked in 186 Galician controls. We identified six mutations, three of them novel. The same truncating mutation was present in four apparently unrelated pedigrees. We found four sequence variations of unknown significance, one synonymous polymorphism and six other sequence alterations not found in the literature or databases but unlikely to be pathogenic (either present in controls or not co-segregating with the phenotype when several affected family members were available). In summary, 9/43 families (21%) were positive for *SPG4* mutations and another four families (9%) harbour sequence variations of unknown significance. If we consider only the cases with definitive autosomal-dominant inheritance, the frequency of *SPG4* mutations rises up to 60% in our series, confirming that *SPG4* causes most of the AD-HSP also in our community. In the cases with no mutations the cause may be in other genes or mutations not detectable by sequencing of the coding region.

P05.084

Mutational analysis of the *ACVR1* gene in Italian patients with Fibrodysplasia Ossificans Progressiva (FOP)

R. Boccardi¹, D. Bordo², M. Di Duca³, F. S. Kaplan⁴, E. M. Shore⁴, M. Di Rocco⁵, R. Ravazzolo^{1,6};

¹G. Gaslini Institute - Laboratory of Molecular Genetics, Genova, Italy, ²National Cancer Research Institute, Genova, Italy, ³G. Gaslini Institute - Laboratory on Pathophysiology of Uremia, Genova, Italy, ⁴University of Pennsylvania School of Medicine, Philadelphia, PA, United States, ⁵G. Gaslini Institute - second Unit of Pediatrics, Genova, Italy, ⁶University of Genova and CEBR, Genova, Italy.

Fibrodysplasia Ossificans Progressiva (FOP, MIM 135100) is a rare genetic disorder characterized by the presence of a congenital great toe malformation and progressive heterotopic ossification that transforms skeletal muscles to bone following a well-defined anatomic pattern of progression. Heterotopic ossification begins in childhood, either spontaneously or upon induction of stimuli such as trauma, and progresses episodically throughout adulthood. FOP is usually sporadic, however, some familial cases with an autosomal dominant pattern of inheritance with variable expression have been described. Linkage analysis in these families led to identification of *ACVR1/ALK2* as the gene responsible for FOP. All familial and sporadic cases with a classic FOP phenotype that have been analysed are heterozygous for the identical mutation, c.617G>A leading to R206H substitution. The only reported exception is a recently described de novo mutation, G356R, associated with a slowly progressing form of FOP. The *ACVR1* gene encodes the activin A type I receptor, a serine/threonine kinase receptor for bone morphogenetic proteins (BMPs) belonging to the TGF-beta receptor family. In this study, we report *ACVR1* mutational analysis in a group of 17 Italian FOP patients. We confirmed the presence of the recurrent R206H substitution in 14 patients and we identified a novel mutation (R258S) in the *ACVR1* kinase domain in one patient. We used bioinformatic tools to predict functional effects on the protein caused by the identified mutations and constructed a 3D molecular model of the R258S mutant in order to gain a better understanding of the possible effects of this newly described mutation.

P05.085

Hereditary hyperferritinemia and cataract syndrome - genetic study of a Portuguese family from the Azores

A. R. Couto^{1,2}, P. Sousa^{1,2}, M. Santos^{1,2}, J. P. Pinheiro^{1,2}, I. Dutra^{1,2}, M. Soares^{1,2}, A. Palma³, G. Porto², M. de Sousa², J. Bruges Armas^{1,2};

¹SEEBMO-HSEAH, Angra do Heroísmo, Portugal, ²IBMC-Instituto de Biologia Molecular e Celular da Universidade do Porto, Porto, Portugal, ³Servico Oftalmologia-HSEAH, Angra do Heroísmo, Portugal.

Hereditary hyperferritinemia cataract syndrome (HHCS) is an autosomal dominant disorder characterised by the presence of cataracts with

markedly elevated serum ferritin levels without iron overload. Ferritin is the major protein involved in iron storage and is composed of H and L subunits. The translation of these subunits depends on the iron status of the cell and is regulated by the interaction between the iron responsive element (IRE) present in the mRNAs 5' noncoding region and cytoplasmic iron regulatory proteins. HHCS is caused by mutations in the IRE of the ferritin light chain (FTL) gene.

In this study we have investigated the genetics of a three generation Azorean kindred with typical HHCS in 3 individuals (2F;1M). The proband was identified, after detection of hyperferritinemia, through the review of clinical findings and biochemical tests. Hereditary haemochromatosis frequent mutations in the HFE, TFR2 and FPN1 gene were screened. All participants gave informed consent before being included in the study.

DNA was extracted from whole blood. Promoter and coding regions of the human FTL gene were subjected to PCR amplification and sequenced bidirectionally. Screening of HFE mutations was performed by PCR-SSO.

The affected individuals are heterozygous for HFE mutation, H63D. Sequencing of FTL gene in the affected individuals identified a heterozygous mutation in position 47 relative to transcription initiation site in the descending part of the IRE (47G>A). None of the unaffected individuals from the family had the referred mutation.

P05.086

Identification of eight novel mutations in German patients with Hereditary Hemorrhagic Telangiectasia (HHT) and detection of a significant association between mutations in the *ACVRL1* gene and liver involvement

Background: Hereditary hemorrhagic telangiectasia (HHT), or Osler-Weber-Rendu disease, is an autosomal dominant inherited disorder of the vascular tissue. This genetically heterogeneous multi-systemic dysplasia shows a wide variation in its phenotypic expression. Up to 78% of the HHT patients show hepatic arteriovenous malformations (HAVM), but the molecular basis of liver involvement is still unknown. In approximately 75% of the patients, mutations can be identified by sequencing of the two known HHT genes, *ACVRL1* (*ALK1*) and *ENG*. Genotype-phenotype correlations are not yet fully defined, but previously, we and others showed that hepatic involvement is associated with *ACVRL1* mutations, but rarely caused by mutations in the *ENG* gene.

Patients and methods: In a new cohort of 18 adult HHT patients we performed sequencing analysis of the *ACVRL1* and *ENG* gene.

Results: Eight novel and 8 already described mutations (10 missense mutations, 2 small in-frame deletions, 3 premature stop mutations and 1 small frameshift deletion) were identified. Analysis of our entire data revealed statistically significant differences in the distribution of *ACVRL1* and *ENG* mutations among HHT patients with and without HAVM (p=0.0016).

Conclusion: Our data support the growing evidence for a significant correlation between mutations in the *ACVRL1* gene and liver involvement in HHT, and suggest that molecular genetic testing in HHT patients is important for prognosis with respect to liver disease.

P05.087

The GNE protein binds to alpha actinin 1

S. Amsilli¹, H. Zer², S. Hinderlich³, M. Becker-Cohen¹, D. G. MacArthur⁴, K. N. North⁴, S. Mitrani-Rosenbaum¹;

¹Hadassah Hebrew University Medical Center, Jerusalem, Israel, ²Hebrew University of Jerusalem, Jerusalem, Israel, ³Technische Fachhochschule Berlin, Berlin, Germany, ⁴The Children's Hospital at Westmead, University of Sydney, Sydney, Australia.

Hereditary inclusion body myopathy (HIBM) is a rare neuromuscular disorder

caused by mutations in *GNE*, the key enzyme in the biosynthetic pathway of sialic acid. While the mechanism leading from *GNE* mutations to the HIBM phenotype is not yet understood, we searched for proteins potentially interacting with *GNE*, which could give some insights about novel putative biological functions of *GNE* in muscle. We used a Surface Plasmon Resonance (SPR)-Biosensor based assay to search for potential *GNE* interactors in anion exchanged fractions of human skeletal muscle

primary culture cell lysate. Analysis of the positive fractions by *in vitro* binding assay revealed α -actinin 1 as a potential interactor of *GNE*. The direct interaction of the two proteins was assessed *in vitro* by SPR-Biosensor based kinetics analysis and in a cellular environment by a co-immunoprecipitation assay and confocal co-localization in 293T cells. The interaction of *GNE* with α -actinin 1 might point to its involvement in α -actinin mediated processes, including cytoskeleton organization and signaling pathways. In addition these studies illustrate for the first time the expression of the non-muscle form of α -actinin, α -actinin 1, in mature skeletal muscle tissue, opening novel avenues for its specific function in the sarcomere.

P05.088

NTRK3, a gene involved in the enteric nervous system development, is related to Hirschsprung disease

A. Sánchez-Mejías^{1,2}, M. Ruiz-Ferrer^{1,2}, R. M. Fernández^{1,2}, M. D. Mena^{1,2}, M. Lopez-Alonso^{1,2}, G. Antiñolo^{1,2}, S. Borrego^{1,2};

¹Unidad de Gestión Clínica de Genética, Reproducción y Medicina Fetal, Hospitales Universitarios Virgen del Rocío, Seville, Spain, ²Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), ISCIII, Seville, Spain.

Hirschsprung disease (HSCR) is a developmental disorder characterized by the absence of ganglion cells in the myenteric and submucosal plexuses along a variable portion of the distal intestine, due to a defect of neural crest neuroblasts migration process. Manifestation of the disease has been linked to the dysfunction of 2 principal signalling pathways involved in the enteric nervous system (ENS) formation: the RET-GDNF and the EDN3-EDNRB receptor systems. Because of its etiopathogenesis it results tempting to speculate that additional signalling pathways implicated in intestinal neurodevelopment could also be involved in HSCR. In this way, the NTF3/TrkC signalling pathway had been shown to play an essential role in the development of the ENS, together with the evidences showed by murine models lacking or over-expressing NTF-3, and the differential localization of the receptor in ganglionic versus aganglionic region of HSCR intestine suggest a potential role for those genes in the pathogenesis of HSCR. We have sought to evaluate the candidature of the *NTRK3* gene, encoding the TrkC receptor, as a susceptibility gene for Hirschsprung disease. Using direct sequencing analysis and dHPLC technology we have screened the *NTRK3* coding region and the intron/exon boundaries in 143 Spanish HSCR patients. A total of 4 previously described polymorphisms and 12 novel sequence variants were detected. Of note, we have detected a novel aminoacid substitution in the protein sequence in a multiplex HSCR family. *In silico* studies point that structural alterations might be introduced in the mutated protein, suggesting a pathogenic role for Hirschsprung disease.

Nrf2-related oxidative stress response and impaired dopamine biosynthesis in a PC12 cell model of Huntington's disease

W. M. C. van Roon-Mom¹, B. A. Pepers¹, P. A. C. 't Hoen¹, C. A. C. M. Verwijmeren¹, J. T. den Dunnen¹, J. C. Dorsman², G. B. van Ommen¹;

¹LUMC, Leiden, The Netherlands, ²Free University, Amsterdam, The Netherlands.

Huntington's disease (HD) is a devastating disease for which currently no therapy is available. It is a progressive autosomal dominant neuro-

degenerative disorder that is caused by a CAG repeat expansion in the HD gene, resulting in an expansion of polyglutamines at the N-terminal end of the encoded protein, designated huntingtin, and the accumulation of cytoplasmic and nuclear aggregates. Not only is there a loss of normal huntingtin function, upon expansion of the CAG repeat there is also a gain of toxic function of the huntingtin protein and this affects a wide range of cellular processes. To identify groups of genes that could play a role in the pathology of Huntington's disease, we studied mRNA changes in an inducible PC12 model of Huntington's disease before and after aggregates became visible. This is the first study to show the involvement Nrf2-responsive genes in the oxidative stress response in HD. Oxidative stress related transcripts were altered in expression suggesting a protective response in cells expressing mutant huntingtin at an early stage of cellular pathology. Furthermore, there was a down-regulation of catecholamine biosynthesis resulting in lower dopamine levels in culture. Our results further demonstrate an early impairment of transcription, the cytoskeleton, ion channels and receptors. Given the pathogenic impact of oxidative stress and neuroinflammation, the Nrf2-ARE signaling pathway is an attractive therapeutic target for neurodegenerative diseases.

MyBPC3 (Myosin binding protein C) associated hypertrophic cardiomyopathy in young Maine Coon cats appears to be a recessive disease caused by the synthesis of mutated protein

M. T. Nyberg Godiksen¹, I. A. Laursen², T. Nielsen³, S. Granström¹, P. Højrup³, J. Koch¹, M. Christiansen²;

¹Faculty of Life Sciences, University of Copenhagen, Frederiksberg, Denmark,

²Department of Clinical Biochemistry, Statens Serum Institut, Copenhagen,

Denmark, ³Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense, Denmark.

Human hypertrophic cardiomyopathy (HCM) is a primary disorder of the myocardium associated with sudden death, stroke and heart failure. It is caused by mutations in genes coding for sarcomeric proteins. HCM in the Maine Coon cat (MCO) is a good spontaneous model of human HCM. Variants in the MyBPC3 gene, coding for myosin binding protein-C (MYBP-C), are associated with human HCM. The mutation A31P in MyBPC3 is associated with familial HCM in MCO and we screened a large cohort of unrelated MCO cats to establish the association between this mutation and feline HCM.

Two-hundred-eighty-seven MCO cats (mean age of 2.2 years, 23 with HCM) were genotyped for the A31P. Mutation screening was performed by DNA sequencing. Heart proteins were extracted from two MCO cats, separated by SDS-PAGE, the MYBP-C band was trypsin digested and sequence variants identified by mass-spectrometry (MS).

A31P had a minor allele frequency of 0.20. The odds ratio for having HCM was 10.7 (95%-cfi: 3.3 - 34.4) in homozygous cats. The presence of MYBP-C with the A31P variant in heart tissue was verified by MS in a homozygous MCO cat.

MyBPC3 associated HCM in MCO express itself as a recessive disease in young cats, as a single A31P allele does not confer an increased risk of HCM. However, the potential for late-onset of disease may cause the significance of the genetic variant to be underestimated. The presence of the A31P variant MYBP-C in hearts suggests that the disease is caused by the presence of a "poisonous polypeptide".

Myocyte function and gene defects in arrhythmogenic right ventricular dysplasia: clinical phenotypes and open problems for clinical genetics

N. Marziliano, M. Grasso, A. Pilotto, E. Serafini, M. Tagliani, E. Disabella, B. De Giorgio, P. Cassini, M. Pasotti, E. Arbustini;

IRCCS Policlinico San Matteo, PAVIA, Italy.

Background. Desmosome proteins' defects are associated with right ventricular (fibro)-fatty replacement of myocardial tissue (Arrhythmogenic Right Ventricular Cardiomyopathy/Dysplasia, ARVC/D, MIM #609040 and #107970). The most investigated genes are: JUP (Junctional Plakoglobin, 17q21), PKP2 (Plakophilin-2, 12p11), DSC2 (Desmocollin 2, 18q12.1), and DSG2 (Desmoglein 2, 18q12.1-q12.2), DSP (Desmoplakin, 6p24). We screened the five genes in a consecutive series of 65 patients with ARVC/D fulfilling (n=3) and non-fulfilling (n=62) McKenna et al. criteria and 55 DCM patients with arrhythmias, two with suspected myocarditis, and one with a wrong diagnosis of

amyloidosis.

Methods. The ARVC/D was diagnosed on McKenna et al. criteria (1994), the DCM according to the WHO criteria. The coding and flanking regions of the five genes were analysed by direct automated sequencing of the heteroduplex amplicons.

Results. We identified 38 mutations in 110 index patients (24 of the 65 ARVC/D patients and 14 of the 55 DCM patients), with 4 patients carrying double/compound heterozygous mutations and 2 carrying a triple heterozygosity; the segregation of the gene defects with the phenotype was confirmed in the 3 probands who fulfilled the criteria of ARVC/D: two carried a missense and frameshift mutations and one a frameshift mutation.

Conclusions. The recurrence of double/triple mutants raises serious problems in molecular diagnosis and family study, especially when the family is small and segregation cannot be assessed, in particular the prediction of the development of the disease in young mutation carriers. Due to the current uncertainties, healthy mutation carriers should undergo regular clinical monitoring.

P05.092

Development of a method for the genetic screening of 537 mutations associated with hypertrophic cardiomyopathy and analysis of a large cohort of patients

M. Hermida-Prieto¹, L. Monserra², M. I. Rodriguez-Garcia³, J. Gimeno-Blanes⁴, F. Marín-Ortuño⁴, L. Cazón¹, I. Alvario¹, M. Brión⁵, A. Carracedo⁵, A. Castro-Beiras²;

¹Instituto de Ciencias de la Salud, La Coruña, Spain, ²Complejo Hospitalario Universitario Juan Canalejo, La Coruña, Spain, ³Instituto de Ciencias de la Salud - RECAVA, La Coruña, Spain, ⁴Hospital Virgen de la Arrixaca, Murcia, Spain, ⁵Centro Nacional de Genotipado, nodo de Santiago de Compostela, La Coruña, Spain.

More than 500 different mutations have been associated with the development of hypertrophic cardiomyopathy (HCM). However, genetic diagnosis has not been till now a useful tool for clinicians because of its limited availability and high cost.

Objectives: the development of a genotyping platform to identify all the mutations that have been associated with HCM, to perform the screening of a large cohort of patients with HCM with this platform, and to evaluate the clinical factors associated with the presence of mutations.

Methods: We analyzed by Massarray SNPtyping 537 mutations in 15 genes: MYH7 (224), MYBPC3 (169), TNNT2 (37) TPM1 (11), ACTC (7), MYH6 (5), MYL2 (11), MYL3 (5), MYLK2 (1), MYO6 (1), PRKAG2 (9), TCAP (2), TNNC1 (3), TNNI3 (33) and TTN (9) in 773 consecutive index patients with HCM.

Results: We identified 74 different mutations (MYBPC3 34, MYH7 24, TNNT2 5, TNNI3 5, TPM1 2, TNNC1 1, MYH6 1, ACTC 1, MYLK2 1) in 163 different patients (21%) (MYBPC3 in 98 pts, MYH7 43, TNNI3 11, TNNT2 10, ACTC 7, MYH6 6, TPM1 2, MYLK2 2, TNNC1 1)(17 patients had 2 mutations and 1 was homozygous). Mutations were found in 100/392 pts from center C (26%), 37/147 from center M (25%) and 26/234 from center A (16%).

Conclusions: Genetic screening of known mutations in HCM provides the identification of mutations in 20 to 40% of our index patients. The likelihood of a positive diagnosis is higher in patients with familial disease and in patients with sudden death risk factors.

P05.093

Unusual presentation of Kelley-Seegmiller syndrome

I. Sebesta^{1,2}, B. Stiburkova¹, J. Minsk¹, L. Dvorakova¹, M. Hrebicek¹, I. Rychlík³, Z. Vermerova⁴;

¹Institute of Inherited Metabolic Disorders, Prague, Czech Republic, ²Institute of Clinical Biochemistry, Prague, Czech Republic, ³2nd Department of Internal Medicine, Third Faculty of Medicine, Prague, Czech Republic, ⁴Department of Pathology, Third Faculty of Medicine, Prague, Czech Republic.

Kelley-Seegmiller syndrome means partial deficiency of hypoxanthine-guanine phosphoribosyltransferase (HPRT), which is an X-linked genetic defect of purine metabolism. Characteristic features are hyperuricemia, nephrolithiasis and gout, resulting from uric acid overproduction. Female carriers have somatic cell mosaicism of HPRT activity, and are healthy with normal enzyme activity in erythrocytes. Only few females suffering from gout with this disorder were described.

We report a 50 year-old woman, who did not experience neither gout,

nephrolithiasis nor hyperuricemia. She was never on allopurinol. Uric acid was quantified by specific enzymic method and erythrocytes enzyme with plasma purine metabolites were measured by HPLC methods. Detailed purine biochemical investigations revealed in repeat serum uric acid concentrations within normal limits (314±12 µmol/l); increased plasma levels of hypoxanthine:19.8 µmol/l (control values 2.5±1.0 µmol/l) and xanthine: 7.5 µmol/l (control values 2.4±0.7 µmol/l); HPRT activity in erythrocyte lysate was surprisingly very low: 8.6 nmol/h/mg Hb (control values :113 ±11 nmol/h/mg Hb). Mutation analysis using direct sequencing revealed heterozygous form of previously described mutation in the 3rd exon of HPRT gene, c.215A>G (Y72C). Subsequent analysis showed skewed X-inactivation ratio in favour of mutant allele (> 25:75), which could explain enzyme defect. Although enzyme deficiency with urate overproduction (presenting as high plasma oxypurines) is evident, the reason for normal serum urate concentrations remains uncertain. Such results have not been reported in a female with HPRT deficiency. In conclusion our finding shows the need of detailed purine investigation in asymptomatic female members of family with partial HPRT deficiency.

P05.094

Heterochromatic genes undergo epigenetic changes and escape from silencing in ICF syndrome

M. Brun¹, E. Lana¹, C. Grunau¹, A. Mégarbané², G. Lefranc¹, P. Sarda³, A. De Sario¹;

¹CNRS UPR 1142, Montpellier, France, ²Saint-Joseph University, Beirut, Lebanon, ³Hopital Arnaud de Villeneuve, Montpellier, France.

ICF (Immunodeficiency, Centromeric Instability, and Facial Anomalies), is a rare autosomal-recessive disorder. Most of the ICF patients were born from consanguineous marriages and about 60% have mutations in the DNMT3B, a *de novo* DNA methyltransferase. ICF syndrome is characterized by a marked immunodeficiency (patients tend to have low levels of immunoglobulins); facial anomalies are a heterogeneous trait and centromeric instability is the most typical feature of the disease. The juxtacentromeric heterochromatin of chromosome 1, 9, and 16 is markedly undercondensed and is involved in chromosome rearrangements and multiradiate associations. The instability correlates with a severe hypomethylation of the classical satellites 2 and 3, which are the major components of constitutive heterochromatin. It is unknown how loss of DNA methylation in non-coding sequences accounts for the multiple symptoms associated with the ICF syndrome. Having observed that in tumor cells and cancer cell lines heterochromatic genes become hypomethylated and escape from silencing, we asked whether the same process is found in ICF syndrome. In this work we showed that heterochromatic genes are strongly hypomethylated and some of them escape from silencing in ICF cells relative to controls. Having observed that some heterochromatic genes remain silent, in spite of loss of methylation, we concluded that hypomethylation is necessary but not sufficient to have transcription in heterochromatic regions. ChIP experiments will show whether the activation of heterochromatic genes is regulated by histone modifications. Aberrant transcription of heterochromatic genes may contribute to some of the symptoms that are associated with ICF syndrome.

P05.095

Clinical and Molecular study of SCN1A-related Epilepsy in Iranian families

A. Ebrahimi¹, H. Tonekaboni², S. Zeinali², M. Houshmand¹;

¹NIGEB, Tehran, Islamic Republic of Iran, ²-Shahid Beheshti Medical science University, Tehran, Islamic Republic of Iran, ³Biotechnology Research Centre, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran.

SCN1A-related seizure disorders encompass a spectrum that ranges from simple febrile seizures (FS) and generalized epilepsy with febrile seizures plus (GEFS+) at the mild end to Dravet syndrome at the severe end. The phenotype can vary even within the same family. SCN1A-related seizure disorders are inherited in an autosomal dominant manner. Most SCN1A-related Seizures are the result of a *de novo* heterozygous mutation. The proportion of cases caused by *de novo* mutations varies by phenotype. The percentage of probands with an SCN1A-related seizure disorder and an affected parent decreases as the severity of the phenotype in the proband increases. Material and methods: Diagnostic classification of patients followed on Classification and Terminology of the International League Against Epilepsy

(1989). Family History, Electroencephalography (EEG) recordings and CT Scan were obtained from most patients. The study was approved by the Iranian institutional ethics committees. DNA was obtained from 50 unrelated families with idiopathic generalized epilepsy as index families. The 26 exons of SCNIA were screened for deletions and duplications by MLPA. In order to find point mutations and SNPs each exon individually amplified from genomic DNA in PCR reactions using intronic primers and were analyzed by Single Strand conformation Polymorphism gel electrophoresis (SSCP) and conformation-sensitive gel electrophoresis (CSGE) and so the PCR products with mobility variants were sequenced by ABI sequencer. We have identified some new intronic variants in SCNIA and new mutations too, in patients with IGE subtypes.

Allele and genotype frequencies in the patients and in the control groups were compared statistically.

P05.096

Molecular genetic analysis of SCN4B gene in Russian patients with idiopathic ventricular arrhythmias

E. Ivanova¹, H. Zaklyazminskaya²;

¹Russian Research Center for Medical Genetics, Moscow, Russian Federation,

²Center of Molecular Genetics, Odintsovo, Russian Federation.

Cardiac channelopathies is a new class of diseases characterized by high risk of life-threatening arrhythmias and sudden cardiac death with apparently normal heart. Mutations in more than 10 different genes can cause these diseases. For different disorders within this group approximately 25-60% patients remain genotype negative. Recently, a new gene SCN4B encoding β_4 -subunit of Na_v1.5 was shown in Long QT Syndrome (LQTS) family. The aim of this work is to screen mutation in SCN4B gene in patients with idiopathic ventricular arrhythmias and to estimate the prevalence of genetic alterations in this gene in Russian patients. The DNA samples of 48 unrelated patients (mutations in KCNQ1, KCNH2, SCN5A, KCNE1 and KCNE2 had been excluded) with ventricular arrhythmias had been analyzed. Fourteen patients had LQTS, 14 patients had Brugada Syndrome (BrS) and 20 patients had Idiopathic Ventricular Tachycardia (IVT). Molecular genetic testing was performed by PCR-SSCP analysis with following direct sequencing of abnormal conformers. We did not find any disease-causing mutation in SCN4B gene. We suppose that SCN4B-associated arrhythmias are extremely rare in Russian patients with LQTS, BrS and IVT. Polymorphism c. C174T (p. C58C) in exon 2 was found within group of patients with BrS. The prevalence of this SNP among the patients with BrS and control group (100 unrelated unaffected individuals) was about 7% without significant differences. Thus, it's unlikely that c. C174C can significantly modify Na⁺-channel function. By now, routine analysis of SCN4B gene for patients without mutations in KCNQ1, KCNH2, SCN5A, KCNE1 and KCNE2 seems to be inexpedient.

P05.097

CS expression in infertile men correlates with the efficiency of the spermatogenic process

S. Bonache¹, E. Terribas¹, J. Sánchez², L. Bassas², S. Larriba¹;

¹Medical and Molecular Genetics Center-Fundació IDIBELL, BARCELONA,

Spain, ²Andrology Service-Fundació Puigvert, BARCELONA, Spain.

Germ cells use mitochondrial Krebs cycle (KC)/electron transport system and glycolysis for the maintenance of their ATP concentration, but each stage of spermatogenesis rely on one or other pathway for ATP production. Interestingly, spermatocytes and spermatids RNA and protein synthesis is highly dependent on mitochondria as the major ATP supplier.

Citrate synthase (CS) is the first enzyme in the KC. We have assessed the role of KC in the progression of spermatogenesis by the CS gene expression analysis in testicular biopsies of 39 non-obstructive and 20 obstructive infertile men. Samples were classified into four groups, from 1 (total absence of germ cells) to 4 (conserved spermatogenesis), on the basis of the Johnsen score count.

The current method has been the real time RT-PCR [LightCycler™ Instrument (Roche) and SYBR Green I fluorescence dye] and the relative quantification strategy, using cyclophilin-A as an endogenous control gene. The Mann-Whitney U test was used to analyse gene expression differences between groups.

CS transcript levels positively correlated with all germ cell stages number but a negative correlation was found with Sertoli cells supporting

the greater contribution of germ cells to CS transcription. Transcript levels of CS were significantly decreased in spermatogenic failure-affected-samples (p=0.01), suggesting to play a role in the efficiency of spermatogenesis. Additionally, its significant correlation with the elongated spermatid number may indicate that CS has an active transcription in the latest stages of spermatogenesis with potential implications in the metabolic activity of sperm.

Differential susceptibility of imprinting centers to epimutations under DNA demethylation influence

E. A. Sazhenova¹, I. N. Lebedev¹, A. V. Ereemeev², A. V. Svetlakov²;

¹Institute of Medical Genetics, Tomsk, Russian Federation, ²Center of Reproductive Medicine, Krasnoyarsk, Russian Federation.

Genomic imprinting is an epigenetic phenomenon, which is involved in regulation of embryonic development, placental function and neurobehavioural processes. Changes in differential methylation of imprinting control (IC) regions are one of the possible mechanisms leading to aberrant gene inactivation or loss of imprinting associated with some hereditary diseases and cancer. However, incidence of epimutations in different imprinted loci as well as underlying mechanisms of its arising remains elusive. Previously we have reported about differential susceptibility to epimutations of three IC's in spontaneous abortions and described the loss of methylation of KCNQ1OT1 in 9.5% of embryos. The aim of the present research was analysis of methylation stability of previously investigated IC's (SNURF-SNRPN, H19/IGF2, KCNQ1OT1) under influence of DNA demethylating agent such as 5-aza-2-deoxycytidine *in vitro*. Fetal fibroblasts cell cultures from 17 induced abortions (9.6±0.2 weeks of pregnancy) with normal karyotype were treated by 5-aza-2dC with 5 µg/ml for 72 h. Methylation analysis was performed by methyl-specific or methylation-sensitive PCR. A normal differential methylation of SNURF-SNRPN and H19/IGF2 was observed in all cell cultures after 5-aza-2dC treatment. As to KCNQ1OT1, all cell cultures have revealed a loss of methylation in maternal allele. Loss of imprinting in KCNQ1OT1 was observed in our previous research of spontaneous abortions as well as in most children born after IVF procedures with Beckwith-Wiedemann syndrome reported in literature. Our results indicate a different susceptibility of IC's to epimutations, providing evidence for KCNQ1OT1 as a «hot spot» of aberrant epigenetic modifications in the human genome.

Infantile neuroaxonal dystrophy: challenges for identification and new advances in prenatal diagnosis

W. Lissens¹, G. Buyse², J. Misson³, L. Lagae², C. Ceuterick-De Grootte⁴, R. Van Coster⁵, E. Schmedding¹, S. Seneca¹, L. De Meirleir¹;

¹University Hospital UZ Brussel, Brussels, Belgium, ²University Hospitals K.U.

Leuven, Leuven, Belgium, ³CHU Sart-Tilman, Liège, Belgium, ⁴Born-Bunge

Institute, Antwerp, Belgium, ⁵University Hospital Ghent, Ghent, Belgium.

Infantile neuroaxonal dystrophy (INAD; OMIM #256600) is a rare disease belonging to the group of neurodegenerative disorders together with NBIA (neurodegeneration with brain iron accumulation, PANK2 gene, OMIM #234200), KARAK syndrome and Schindler disease (OMIM #609241). These diseases share the pathologic feature of axonal degeneration with distended axons throughout the central nervous system. In previous work there has been some controversy regarding whether INAD is a separate entity or is part of a spectrum of diseases with panhothenate kinase-associated neurodegeneration (PANK). Based on molecular studies of the PANK2 gene it became clear that INAD and PANK are genetically heterogeneous disorders. Recently, a gene PLA2G6, encoding a phospholipase A2, has been recognized as causing INAD. However, there is still some overlap in phenotypes resulting from deficiencies in the PLA2G6 and PANK2 genes. We present here the clinical features, diagnosis and molecular results of four patients from three unrelated families in whom a definitive diagnosis could be made by molecular analysis.

In all four patients clinical data and biochemical studies were in agreement with a diagnosis of neuroaxonal dystrophy. Molecular studies of the PLA2G6 were performed to confirm this diagnosis. The two male siblings from family 1 were homozygous for a p.Val371Met substitution; there was no apparent consanguinity in this family. A healthy carrier female was born after prenatal diagnosis through chorionic villus

sampling. The 2 other patients were from consanguineous parents, and were homozygous for a previously described p.Leu481Gln mutation and a frameshift mutation resulting from a 2bp duplication, respectively.

¹Bioinformatics ErasmusMC, Rotterdam, The Netherlands, ²Clinical Genetics ErasmusMC, Rotterdam, The Netherlands, ³Pathology ErasmusMC, Rotterdam, The Netherlands, ⁴Radiology ErasmusMC, Rotterdam, The Netherlands, ⁵Child Neurology ErasmusMC, Rotterdam, The Netherlands.

We describe in a sibship of 11 children from consanguineous parents 2 apparently distinct disorders. Seven sibs suffer from autosomal recessive arterial tortuosity syndrome (ATS) caused by a homozygote GLUT10 mutation, as reported before (Coucke, Nat Genet, 2006). We classified the second disorder and report linkage studies to identify a distinct recessive locus. Five sibs present with a neurodevelopmental disorder, consisting of neonatal hypotonia, severe psychomotor retardation, no independent deambulation, progression to tetraplegia, excessive drooling, strabismus, no speech development, no signs of denervation, no seizures and prolonged survival. The oldest patient is 25 years old. Four of them have also ATS, but the fifth has no sign of arterial tortuosity and is heterozygote for the familial GLUT10 mutation. Brain MRI of this patient shows asymmetric widespread loss of periventricular white matter with normal myelination and cerebellar atrophy. MRI of the other neurologically affected sibs is similar, with the addition of arterial tortuosity. Brain autopsy of one of the five sibs who died of aspiration shows signs of neuro-axonal dystrophy. DTI and fiber track data analysis from MRI suggest a combined neuron and myelin damage. We undertook linkage analysis for a second recessive locus in these five sibs and excluded loci for known white matter disorders, spastic paraplegias and infantile neuroaxonal dystrophy. We found instead linkage for a new chromosomal locus. We conclude that the neurological disorder in this family represents a new type of early onset upper motor neuron disease leading to early selective loss / under-development of pyramidal tracts.

Investigation of cytokine expression pattern associated with the pathogenesis of inflammatory bowel disease

D. IANCU¹, M. Diculescu², C. Iancu¹, E. Neagu¹, A. Constantinescu¹, C. Constantinescu¹, G. Girbea¹, L. Barbarii²;

¹National Institute of Legal Medicine, Bucharest, Romania, ²Fundeni Clinical Hospital – Gastroenterology Department, Bucharest, Romania.

Inflammation is the shared pathophysiological element for the two main inflammatory bowel diseases (IBD), Crohn's disease (CD) and ulcerative colitis (UC) but its contribution to the triggering and maintaining the pathological condition is still incompletely understood. Our objective was to investigate the pro-inflammatory gene expression profile in colonic mucosa of IBD patients in order to establish correlations with IBD form and disease activity.

RNA was extracted from colonic biopsy samples obtained from IBD patients, after informed consent. The samples were initially screened for inflammatory gene expression profile with a MLPA kit (SALSA R009, MRC Holland) which allows detection of 40 RNA molecules in the same PCR reaction. Subsequently, the selected mRNAs were quantified using RT real-time PCR in individual gene expression assays. We investigated a total of 50 patients with IBD, 33 with CD and 17 with UC. Our preliminary results show an increased expression of some monocyte-derived cytokines (IL1B, IL1RN, IL8, IL12, MIF) and some inflammation associated transcription factors (NFkB, NFkBIA). The cytokines' expression pattern in apparently normal mucosa showed a reduced but still significant inflammatory response.

P05.102

Regulatory elements at *INS* gene and Neonatal Diabetes

I. Garin¹, J. Locke², G. Pérez-Nanclares¹, R. Martínez¹, L. W. Harries², L. Castaño¹, G. Pérez de Nanclares¹;

¹Endocrinology and Diabetes Research Group, Hospital de Cruces, Barakaldo, Spain, ²Department of Molecular Genetics, Royal Devon and Exeter Foundation Trust, Exeter, United Kingdom.

Introduction: Insulin secretion is tightly regulated to maintain blood glucose levels within a narrow physiological range. Recent studies have reported heterozygous missense mutations at *INS* gene in permanent neonatal diabetes (PND). Multiple discrete sequence elements within the proximal promoter region (5'UTR) affect insulin expression, and also the 3'-untranslated (3'-UTR) region has been identified as critical for murine preproinsulin mRNA stability.

Objective: To evaluate the putative contribution of *INS* in unrelated subjects with unexplained neonatal diabetes (ND =14).

Methods: the 3 exons (including untranscribed exon 1), intron-exon junctions and the 5' and 3' untranslated regions of *INS* were PCR amplified with specific primers and direct sequencing was performed.

Results: No mutations were identified in the coding sequence. However, we detected 5 novel variants. Three of them were situated in the first exon:

- One patient presented 2 contiguous variants in compound heterozygosis (c.[-332C>G]+[-331C>G]).

- One patient carried a heterozygous variant (c.-170A>G).

One patient presented an intronic variant (c.188-31G>A) which was inherited from the father, who also presented with PND.

In a patient with PND a homozygous variant was detected in the 3'UTR (c.*59A>G). Both parents carried this variant and both presented with glucose intolerance. This variant is situated at the 6th nucleotide within in the polyadenylation signal site; (AAAUAA - AAUAG).

Conclusions: Alterations in regulatory elements at *INS* are associated with an earlier onset of PND compared to previously described coding mutations. Mutations in the insulin gene are rare in Spanish patients with neonatal diabetes.

P05.103

FoxP3 expression on different stage of type 1 diabetes mellitus

P. V. Apanovich¹, T. V. Nikonova², T. A. Muzaffarova¹, M. V. Shestakova², A. V. Karpukhin¹;

¹Research Centre For Medical Genetics, Moscow, Russian Federation, ²Endocrinological Research Center, Moscow, Russian Federation.

FoxP3 expression is considered as key factor for autoimmunity preventing. It is known that FoxP3 expression level is decreased under type 1 diabetes mellitus. However there no information about the expression level on different stage of this disease.

We investigated FoxP3 expression among for the first time revealed type 1 diabetes mellitus patients (up to 1 year, early disease stage) and a group of patients through 15-25 years after disease beginning (late stage of disease). FoxP3 expression level was determined comparative to expression of GAPDH gene or CD4 gene expression level by Real Time PCR. It was revealed that FoxP3 expression was increased on late stage of disease relatively to early disease stage as with GAPDH so CD4 genes. There were 0,32±0,13 on early disease stage and 1,1±0,35 on late stage for FoxP3 expression level (P= 0,02). The increasing of FoxP3 expression may means the decreasing of autoimmune reaction on advanced stage of diabetes. Possibly it reflect equilibrium state of immunity and produced by β-cells antigene.

P05.104

The influence of the genetic polymorphisms on the transcription factor binding to the IL-4 promoter.

Y. V. Gervaziev¹, L. V. Olenina², S. A. Mazurina³, V. B. Gervazieva³;

¹V.N. Orekhovich's Institute of Biomedical Chemistry RAMS, Moscow, Russian Federation, ²Institute of Molecular Genetics, Moscow, Russian Federation, ³I.I. Mechnikov's Institute of Vaccines and Sera RAMS, Moscow, Russian Federation.

Background: Promoter polymorphisms of IL-4 gene C-33T and C-590T are well described. They influence both IL-4 and serum IgE concentrations in a human organism. **Objective:** To evaluate the mechanism of the phenotypic effect of these polymorphisms, specifically to identify the transcription factors (TF) selectively binding to these loci.

Methods: Sequences flanking these loci were analyzed *in silico* to

predict the TF binding the selected regions. This prediction was experimentally analyzed by EMSA with nuclear extract of Jurkat T-cell line. The sequences of Cy5-labeled ds oligonucleotides flanked the polymorphic loci and were 39bp (C-33T) and 35bp(C-590T) long. **Results:** It was predicted that TFs Oct-1, CREB, C/EBP and GATA could selectively bind C-33T polymorphism locus while MZF-1, Sox-5, PU.1, AP-2, GR, VDR, E2F-1 and T3R-alpha could bind C-590T locus. We observed that C-33T EMSA probes associated with two specific complexes. The TFs slightly discriminated between -33C and -33T probes. The unlabeled consensus ds oligonucleotides for the Oct-1 completely inhibited the lower shift band. Both bands were not inhibited by the oligonucleotides corresponding to the C/EBP, CREB and GATA binding sites. As for C-590T polymorphism, two specific bands were observed in the sample with -590C probe rather than -590T probe. They were not inhibited by the unlabeled concurrent probes for the predicted TF binding. **Conclusions:** Oct-1 transcription factor could be responsible for the phenotypic effect of C-33T IL-4 promoter polymorphism. The factor responsible for the C-590T polymorphism does exist but should yet be identified. The work was supported by the RFBR grant 08-04-01535.

P05.105

Effect of Semax treatment on expression of the neurotrophins and their receptors in ischemic rat hippocampus

V. V. Stavchansky¹, L. V. Dergunova^{1,2}, A. B. Botsina², T. V. Tvorogova², V. I. Skvortsova², S. A. Limborska^{1,2};

¹Institute of Molecular Genetics RAS, Moscow, Russian Federation, ²Institute of Stroke RSMU, Moscow, Russian Federation.

Neurotrophins are known as natural neuroprotectors involved in proliferation, differentiation and survival of neuronal and glial cells. We analyzed the effect of synthetic polypeptide *Semax* (Met-Glu-His-Phe-Pro-Gly-Pro) upon expression of neurotrophins *Bdnf*, *Ngf*, *Nt3* and their receptors *TrkB*, *TrkA*, *TrkC*, *p75* in rat hippocampus after global cerebral ischemia. The study was carried out on 2-3-month-old male Wistar rats (n=85). After 15 minutes of irreversible bilateral common carotid artery occlusion the animals were exposed to intraperitoneal injection of either *Semax* or saline 1, 4 and 8 hours after the occlusion. Ischemic rats with saline injection were used as control groups. The mRNA expression of neurotrophins and its receptors was assessed by relative quantification using *real-time RT-PCR*. *Gapdh* was used as the reference gene. The neurotrophins' transcription was increased compare with the level of these transcripts in control animals: for *Bdnf* at 1h, 2h and 12h; for *Ngf* at 1h, 12h and 24h and for *Nt3* at 1h and 12h after operation. Under *Semax* treatment the mRNA expression of neurotrophin's receptors was increased compare with control as well: for *TrkB* at 30 min, 1h and 24h, for *TrkC* at 8h and 12h, and for *p75* at 2h, 4h and 12h after occlusion. The level of *TrkA* mRNA was decreased at 1h, 2h, 4h, and 24h after surgery; at 8h it was increased. It could be suggested that neuroprotective effect of *Semax* is possibly mediated by neurotrophins and its receptors.

P05.106

Semax and its C-terminal Pro-Gly-Pro tripeptide change the transcription profile of growth factors and their receptors genes after focal cerebral ischemia in rats

V. G. Dmitrieva¹, L. V. Dergunova¹, O. V. Povarova², V. I. Skvortsova², S. A. Limborska¹;

¹Institute of Molecular Genetics RAS, Moscow, Russian Federation, ²Institute of Stroke RSMU, Moscow, Russian Federation.

Neuroprotective polypeptide *Semax* is used for acute therapy of stroke. The effect of *Semax* and its C-terminal PGP tripeptide on mRNA expression of 84 genes representing growth factors and their receptors in the lesioned cortex of rat brain after 3 h of permanent middle cerebral artery occlusion (pMCAO) was analyzed using the Rat Neurotrophin and Receptors gene array ("RT² ProfilerTM PCR Array, Superarray). Under *Semax* treatment in the lesioned cortex mRNA expression of 19 genes was altered, the change in transcription of 7 genes of these 19 also was observed under ischemic conditions. PGP promoted the transcriptional alteration of 23 genes. The list of genes which mRNA expression was changed under *Semax* treatment only partly coincided with the list of genes that was changed under PGP treatment; the direction of such transcription alteration was the same. The most marked (two times and more) alteration of mRNA expression under *Semax* and

PGP treatment was observed for *Lif*, *Galr1*, *TrkA* and *p75*. Some of the genes which mRNA expression were changed by *Semax* treatment only: *Fos*, *IL10ra*, *Il1b* and *Tgfb1*; and by PGP treatment only: *Fgf2*, *Hctr1*, *Tacr1*, *Ntf5* and *Ptger2*. Hence it was suggested that *Semax* effects observed earlier do not reflect only PGP activity. Obviously the mechanisms of action of these peptides are not the same and they each have their own specific effects. From the list of genes altered by *Semax* or PGP two types of growth factor targets were suggested: neural tissue (neurons and glial cells) and vascular cells.

¹National Institute of Neurology and Neurosurgery Manuel Velasco Suárez, Mexico City, Mexico, ²National Autonomous University of Honduras, Tegucigalpa, Honduras, ³RIKEN Brain Science Institute, Saitama, Japan, ⁴UCLA, Los Angeles, CA, United States, ⁵National Epilepsy Center, Shizuoka, Japan, ⁶Hiroshima University, Hiroshima, Japan, ⁷Nagoya City University, Nagoya, Japan, ⁸Shiga Medical Center for Children, Moriyama, Japan, ⁹Children's Medical Center, Saitama, Japan, ¹⁰Ichikawa General Hospital, Shiga, Japan, ¹¹University of Miyazaki, Miyazaki, Japan, ¹²Tokyo Woman's Medical University, Tokyo, Japan.

Background: Juvenile myoclonic epilepsy (JME) accounts for 3 to 12% of all epilepsies. In 2004, the GENESS Consortium demonstrated 4 missense mutations in *Myoclonin1/EFHC1* of chromosome 6p12.1 segregating in 20% of Hispanic families with JME. Objective: To examine what percentage of consecutive JME clinic cases have mutations in *Myoclonin1/EFHC1*. Methods: We screened 44 consecutive patients from Mexico and Honduras, and 67 patients from Japan using heteroduplex analysis and direct sequencing. Results: We found five novel mutations in transcripts A and B of *Myoclonin1/EFHC1*. Two novel heterozygous missense mutations (c.755C>A and c.1523C>G) in transcript A occurred in a singleton from Mexico and another singleton from Japan. A deletion/frameshift (C.789del.AV264fsx280) in transcript B was present in a mother and daughter from Mexico. A non-sense mutation (c.829C>T) in transcript B segregated in 4 clinically and 7 epileptiform-EEG affected members of a large Honduran family. The same non-sense mutation (c.829C>T) occurred as a de novo mutation in a sporadic case. Finally, we found a three-base deletion (-364^-362del. GAT) in the promoter region in a family from Japan. Conclusion: Nine percent of consecutive juvenile myoclonic epilepsy cases from Mexico and Honduras clinics and three percent of clinic patients from Japan carry mutations in *Myoclonin1/EFHC1*. These results represent, the highest number and percentage of mutations found for a juvenile myoclonic epilepsy causing gene of any population group.

P05.108

Long QT Syndrome: Two Novel Exonic KCNH2 Mutations

K. Banihashemi¹, S. Saber², E. Zaklyazminskaya³, M. Houshmand⁴, M. Eftekharzadeh⁵, F. Fazelifar⁶, M. Rostam⁷, M. Khosroheidari⁸;

¹GPEF, Ministry of Science, Research and technology, Tehran, Islamic Republic of Iran, ²Special Medical Center, Tehran, Islamic Republic of Iran, ³Russian Academy of Science, Moscow, Russian Federation, ⁴NRCGEB, Tehran, Islamic Republic of Iran, ⁵Tehran Arrhythmia center, Tehran, Islamic Republic of Iran, ⁶Rajaii Heart Hospital, Tehran, Islamic Republic of Iran.

Introduction. K Channels made with the **KCNH2** protein are active in the heart muscle, where they transport potassium ions out of cells. The gene contains 15 exons spanning approximately 19 kb on chromosome 7q35. A feature of K channelopathy is pronounced prolongation of the QT interval and arrhythmia that can lead to sudden death.

Materials and methods. The subjects studied included a 6 members family with 3 out of them involved with LQTS. Genomic DNA was extracted according to a standard method, and then **KCNH2** were PCR-amplified and sequenced for identifying LQTS-causing mutations. Results. Two exonic novel mutation of **KCNH2** in the exon 6 which was present also both in his mother and his elder sister and also One more novel intronic mutation.

Discussion. The present data, combined with those from previous studies, give more information on **KCNH2** mutations which affect loop and pore proteins. The proband, a 16 years old boy with novel muta-

tion in exon 6 (C>T) which converts arginin into lysine . Additionally there was an intronic mutation (C>A) which has not been reported up to this time although predicted to have no effect on protein truncations. In conclusion, this is the first frameshift mutation in Iranian population and we have provided additional data of *KCNH2* mutations in LQTS patients. These findings will contribute to further understanding of the function and structure of *KCNH2* and the phenotype-genotype correlation in hereditary LQTS.

P05.109

Gene scanning of *KCNQ1* and *KCNE1* by high-resolution melting analysis

A. Bittnerová¹, J. Kadlecová¹, T. Novotný², R. Gaillyová¹, M. Kozák², L. Křivan², J. Špinar²;

¹University Hospital Brno, Department of Medical Genetics, Brno, Czech Republic, ²University Hospital Brno and Masaryk University, Department of Internal Medicine and Cardiology, Brno, Czech Republic.

KCNQ1 encodes the larger subunit (KvLQT1) and *KCNE1* the small subunit (MinK) of the I_{Ks} protein. I_{Ks} protein is the slowly activating delayed rectifier potassium channel. Mutations in single genes reduce the I_{Ks} current and cause the similar Long QT Syndrome (LQTS) phenotype. LQTS is a cardiovascular disorder characterized by an abnormality in repolarization, leading to a prolonged QT interval.

KCNQ1 consists of 16 exons and encodes a protein of 676 amino acids. There have been identified 246 mutations in this gene. *KCNE1* consists of just 3 exons, encoding a protein of 129 amino acids. Only 30 mutations of this gene have been found.

For the mutation scanning we have used multiplex SSCP with sensitivity about 80 %. Now, we detect the mutations using high-resolution melting analysis. This method is based on PCR in the presence of the double-strand DNA binding dye, and tracking the nucleic acid melting by monitoring the fluorescence of the sample across a defined temperature range. Melting profiles can be used to identify the presence of sequence variation within the amplicon. The method has almost 100% sensitivity and specificity when used on products up to 400bp. We have used this method for detection of 7 described mutations (S225L, T312I, G314S, G325R, T587M, A590T and R591H) in *KCNQ1* and two SNPs (S38G and D85N) in *KCNE1* with the sensitivity 100 %. This work was supported by grants IGA MZ CR NR/9340-3, MSM 0021622415 and by the Czech Society of Cardiology.

Identification of mutations in *KLK4* genes among Iranian patients with amelogenesis imperfecta

P. Aref, M. Bahaminpour, M. Shahrabi, M. Ghandehari Motlagh, B. Seraj, M. Heidari;

Faculty of dentistry, Tehran, Islamic Republic of Iran.

Amelogenesis imperfecta (AI) refers to a group of inherited tooth disorders characterized by abnormal enamel formation. The incidences of AI vary widely; from 1 in 700 people in northern Sweden to 1 in 14,000 people in the United States. In spite of the fact that many studies have been carried out in different centers on molecular aspects of this disorder, the genetic basis of non-syndromic forms of AI is unknown. So far, four genes have been documented that associated with AI, AMELEX, ENAM, *KLK4* and *MMP20* genes. We performed molecular genetic studies on 10 Iranian families with different models of inheritances according to pedigree analysis. In this study, three genes including ENAM, *KLK4*, and *MMP20* which account for majority of AI and autosomally inherited were chosen for mutation detection by a polymerase chain reaction (PCR) and single-stranded conformation polymorphism (SSCP). Our results from SSCP revealed genetic alterations in ENAM, *MMP20* and *KLK4* genes. We found mutations in *KLK4* exon 3 in 7 patients. In order to identify the type of mutation, samples were subjected for DNA sequencing. Our findings suggested that the incidences of *KLK4* mutations in Iranian population might be higher than other population.

P05.111

Three novel mutations in the lactase gene (LCT) underlying congenital lactase deficiency (CLD)

S. Torniaainen¹, C. Catass², T. Rout³, C. Gijsbers⁴, E. Savilahti⁵, I. Järvelä^{1,6};

¹Department of Medical Genetics, University of Helsinki, Helsinki, Finland,

²Department of Paediatrics, Università Politecnica delle Marche, Ancona, Italy,

³Department of Paediatrics, University of Turku, Turku, Finland, ⁴The Juliana Children's Hospital, The Hague, The Netherlands, ⁵Hospital for Children and Adolescents, University of Helsinki, Helsinki, Finland, ⁶Helsinki University Hospital, Laboratory Service, Helsinki, Finland.

Background: Congenital lactase deficiency (CLD) is a severe gastrointestinal disorder of newborns that is inherited as an autosomal recessive trait and is enriched in the isolated Finnish population. The diagnosis is based on clinical symptoms and low lactase activity in intestinal biopsy specimens. Five mutations in the lactase gene (LCT) have so far been identified to underlie CLD.

Methods: To search for new mutations underlying CLD we assayed disaccharidase activities in intestinal biopsy specimens and screened the coding region of LCT gene by direct sequencing from one Italian, two Finnish and two Turkish patients with clinical symptoms compatible to CLD .

Results: Three novel mutations in the LCT gene were identified. A single nucleotide substitution leading to an amino acid change S688P in exon 7 and a premature stop codon E1612X in exon 12 of the LCT were present in the patient of Italian origin. A novel substitution of R1587H in exon 12 was found in a heterozygous form from one Finnish patient. Both Finnish patients were heterozygous for the Finnish founder mutation Y1370X. Analyses of another Finnish patient are still ongoing. The previously reported missense mutation G1363S in exon 9 was found in a homozygous state in two siblings of Turkish origin. Comparison of clinical phenotype and the location and/or type of a mutation in the LCT gene shows that all mutations lead to a similar phenotype.

Conclusions: A total of eight mutations are known in CLD. This is the first report of mutations in non-Finnish patients.

P05.112

Functional characterization of point mutations in the *LDLR* gene found in Portuguese patients with clinical diagnosis of familial hypercholesterolaemia.

S. Silva¹, D. Patef², A. K. Soutar², M. Bourbon¹;

¹Instituto Nacional de Saúde Dr Ricardo Jorge, Lisbon, Portugal, ²MRC-Clinical Sciences Centre, London, United Kingdom.

The LDL receptor is a surface glycoprotein that mediates binding and uptake of cholesterol-rich lipoproteins from plasma, in particular LDL. Mutations in the *LDLR* cause familial hypercholesterolaemia (FH), which results in defective catabolism of LDL leading to premature atherosclerosis and CHD.

Five missense mutations found in the *LDLR* gene during the "Portuguese FH Study", responsible for protein variants V408L, W469R, S627P, P664S and V838M, were studied in order to assess their pathogenicity.

The different *LDLR* mutants were generated by site-directed mutagenesis and expressed in CHO-IIdIA7 cells lacking endogenous expression of *LDLR*. To determine the effects of mutations on *LDLR* function we measured saturable binding plus internalization and degradation of ¹²⁵I-labelled LDL at 37°C and estimated mature *LDLR* at cell surface by immunoblotting.

All mutant constructs resulted in production of a detectable mature protein in CHO-A7 cells, except variant W469R which accumulated the precursor form. Variants W469R and V408L were severely impaired in their ability to mediate uptake and degradation of ¹²⁵I-LDL and showed reduced amounts of *LDLR* at cell surface. Variant S627P retained ~40% and P664S ~60% of normal *LDLR* activity. V838M variant showed essentially the same activity as the wild-type *LDLR*.

Results suggest that four of the variants studied are mutations causing disease in patients carrying those alterations and V838M is a rare non-pathogenic variant. The severe effect that V408L mutation has in *LDLR* function does not correlate with the patient's phenotype, suggesting other genetic or/and environmental factors may be involved in phenotype modulation.

Genetic testing for Leber Congenital Amaurosis (LCA): a 3-year experience

F. Coppeters¹, S. De Jaegere¹, T. de Ravef¹, I. Casteels³, F. Meire⁴, N. Van Regemorte², A. De Paepe¹, P. J. Coucke¹, B. P. Leroy^{1,6}, E. De Baere¹;

¹Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,

²Center for Human Genetics, Leuven University Hospitals, Leuven, Belgium,

³Department of Ophthalmology, Leuven University Hospitals, Leuven, Belgium,

⁴HUDERF, Hôpital Des Enfants Reine Fabiola, Brussels, Belgium, ⁵Centre de Génétique de Bruxelles, Free University of Brussels, Brussels, Belgium, ⁶Department of Ophthalmology, Ghent University Hospital, Ghent, Belgium.

LCA is genetically highly heterogeneous with the involvement of large disease genes, which hamper genetic testing. The purpose of this study was to determine the prevalence of mutations in 6 common LCA genes in 108 LCA patients, mainly of Belgian origin, in order to optimize a genetic screening strategy for LCA.

First, LCA chip screening revealed a mutation in 23% of all patients. Second, direct sequencing of AIPL1, CRB1, CRX, GUCY2D, and RPE65 revealed causal mutations in 4.6%. Third, we performed targeted mutation analysis of the CEP290 mutation c.2991+1655A>G. We found this mutation in both homozygous (2/108) and heterozygous (16/108) state. A second mutation was identified through sequencing of the total coding region. Subsequently, the remaining patients were screened for 4 additional recurrent CEP290 mutations. p.Lys1575X was found in 3.7% and c.[3310-1G>A;3310C>A] in 0.9%, demonstrating that c.2991+1655A>G is not present in all CEP290-related LCA cases. A second mutation was identified in 3 cases; cDNA sequencing is ongoing in the other ones. Finally, sequencing of the total coding region of CEP290 is being performed in the remaining 39 cases. So far, this revealed a homozygous mutation in one case.

In conclusion, we found mutations in 50% of all patients (22% in CEP290; 15% in CRB1; 6% in RPE65; 3% in AIPL1; 2% in CRX and 2% in GUCY2D). A combined genetic testing strategy consisting of LCA chip analysis and targeted mutation screening of 5 recurrent CEP290 mutations, represented an efficient first-pass screening, revealing causal mutations in 44.4% of our LCA population.

P05.114

Genetic study of Tunisian patients with Leigh syndrome: presence of the T8993G mutation in the MT-ATP6 gene and 2 new mutations in the MT-ND2 and MT-ATP8 genes

E. Mkaouer-Rebai¹, W. Chaar², S. Younes³, R. Bousoffara², M. Sfar², N. Belguith¹, C. Triki⁴, F. Fakhfakh¹;

¹Laboratoire de Génétique Moléculaire Humaine. Faculté de Médecine, Sfax, Tunisia, ²Service de Pédiatrie. Hôpital Taher Sfar., Mahdia, Tunisia, ³Service de Neurologie. Hôpital Taher Sfar., Mahdia, Tunisia, ⁴Service de Neurologie, C.H.U. Habib Bourguiba de Sfax., Sfax, Tunisia.

Leigh syndrome (LS) is a genetically heterogeneous, neurodegenerative disorder that predominantly affects children in early infancy or childhood and leads to death within months or years. This disorder is characterized by necrotic lesions in the brainstem, basal ganglia, and thalamus. The symptoms are variable, but in most cases include psychomotor retardation, optic atrophy, ataxia, dystonia, failure to thrive, vomiting, seizures, and respiratory failure. Mutations causing Leigh syndrome have been found in both mitochondrial and nuclear DNA. Most of the described mitochondrial mutations were in ND3 and ND5 and a few ones were in ND6 and ND4. In addition, there are single case reports of mutations in synthetic genes such as tRNA^{Trp} and tRNA^{Lys} genes. In the present study, we carried out a systematic sequence analysis of mitochondrially encoded complex I subunits: ND2, ND3, ND4, ND5 and ND6 in 16 Tunisian patients with Leigh syndrome. We also performed a sequence analysis of the mitochondrial ATPase 6, tRNA^{Val}, tRNA^{Leu(UUR)}, tRNA^{Trp} and tRNA^{Lys} genes in these patients. Mitochondrial DNA sequencing of these genes revealed the presence of the T8993G mutation in the ATPase 6 gene in 1 patient belonging to a Tunisian family with maternally inherited Leigh Syndrome (MILS). In this family, we also found 3 new mutations responsible for amino acid changes in a highly conserved region of the MT-ATP 6 protein. In addition, we detected 60 known polymorphisms, 19 new nucleotide variants and 2 novel mutations in 2 patients with Leigh syndrome in the ND2 and in the ATPase 8 gene.

P05.115

A novel mutation of the lipoprotein lipase gene associated with childhood hypertriglyceridaemia

S. Kalkan¹, A. Alpman², E. A. Arikian², H. Akir², M. Coker¹, F. Ozkinay²;

¹Ege University Medical Faculty, Department of Pediatrics, Subdivision of Metabolic Disorders, Izmir, Turkey, ²Ege University Medical Faculty, Department of Medical Genetics, Izmir, Turkey.

Familial LPL deficiency is a rare autosomal recessive disorder that affects about 1/1.000.000 children. Patients with classical lipoprotein

lipase deficiency present in the first several months of life with masked hypertriglyceridaemia, often ranging between 5000 to 10.000 mg/dl. Hypertriglyceridaemia caused by decreased or absent lipoprotein lipase (LPL) activity is associated with increased blood lipoproteins. LPL plays a functional role in regulation of the lipoproteins. To date, approximately 140 mutations have been identified within LPL gene in human genome. Most of the mutations are located within the coding region of this gene. We performed DNA sequencing of 9 exonic regions of LPL gene including promotor region of 10 patients with hypertriglyceridaemia. We detected one novel homozygous missense mutation that alters amino acid at position 221 (I221T). The homozygous mutation causes the substitution of Isoleucine to Threonine at codon 221 in exon 5. We evaluated the characteristic of patients, laboratory findings and associated disorders. Treatment of patients with LPL deficiency is difficult. Therefore, detection of mutations might be useful for better therapy and prenatal diagnosis of the patients.

³Universitat Pompeu Fabra, Barcelona, Spain, ⁴CIBERER-U735, Barcelona, Spain, ⁵Parc Científic de Barcelona, Barcelona, Spain, ⁶Universitat de Barcelona, Barcelona, Spain.

Lysinuric protein intolerance (LPI) or hyperdibasic aminoaciduria type 2 (OMIM 222700) is a rare autosomal inherited disease, caused by defective cationic amino acid transport 4F2hc/y⁺LAT-1 at the basolateral membrane of epithelial cells in the intestine and kidney. LPI is a multi-systemic disease with a variety of clinical symptoms, such as osteoporosis, hypotonia, growth delay, pulmonary insufficiency, or renal insufficiency. LPI is diagnosed by the presence of excessive urine excretion of dibasic amino acids, especially lysine, and by their poor intestinal absorption that leads to low plasma levels of dibasic amino acids. The SLC7A7 gene, which encodes the y⁺LAT-1 protein, is mutated in LPI patients. Mutation analysis of the two promoters and all exons of the SLC7A7 gene was performed in ten patients from nine unrelated LPI families from different ethnic backgrounds. Point mutation screening was performed by exon direct sequencing and a new multiplex ligation probe amplification (MLPA) assay was set up for large rearrangement analysis. Eleven SLC7A7 specific-mutations were identified in these patients. Two out of seven novel mutations were large rearrangements of the SLC7A7 gene.

Our methodical process of identification of Malignant hyperthermia causal RYR1 mutations

I. Valášková^{1,2}, E. Flodrová¹, Š. Prášilová¹, P. Kuglík^{1,3};

¹University Hospital, Dept. of Medical Genetics, Brno, Czech Republic, ²Masaryk University, Faculty of Medicine, Dept. of Biology, Brno, Czech Republic,

³Masaryk University, Faculty of Science, Dpt. of Experimental Biology, Brno, Czech Republic.

Our work is focused on performing of an effective and relative inexpensive molecular genetic diagnostic assay of malignant hyperthermia (MH), life-threatening and frequently fatal disorder triggered by commonly used anesthetics. Susceptibility to MH (MHS), dominantly inherited predisposition to MH, is diagnosed by using an invasive diagnostic test on excised muscle bundles, the in vitro contracture test (IVCT). An alternative diagnostic test to IVCT is mutation analysis of the ryanodine receptor (RYR1) gene. RYR1 is an essential component of the calcium homeostasis of muscles in mammals. Defects in the RYR1 gene in humans (19q13.1) are associated with MH. Until now, 29 RYR1 mutations causing MH have been listed by European MH Group. A detection of MH causative RYR1 mutations can be used as predictive genetic testing. Our aim is to develop sufficient, effective and fast mutation-detection procedures aimed at direct detection of MH causative RYR1 mutations. To date we established molecular diagnostic assays to detect RYR1 mutations using screening methods. Sequencing the

entire RYR1 complementary DNA (cDNA) and melting point analysis of fluorescently labelled probes after high speed PCR amplification on real-time enabled us to confirm MH diagnosis on molecular level in 50 MHS individuals. Recently we establish High-resolution melting (HRM) as a method that allows RYR1 mutation scanning and genotyping. We expect that our methodical process of identification of MH causal mutations in MHS patients and subsequent performing noninvasive predictive genetic testing in their family members decrease number of individuals which would have to undergo the invasive IVCT.

P05.118

Mutation screening of *FBN1* and *TGFBR2* genes in patients with Marfan and marfan-like syndromes from Russia: 4 mutations and 11 polymorphisms have been found

R. Valiev, R. Khusainova, E. Khusnutdinova;

Institute of biochemistry and genetics, Ufa, Russian Federation.

Marfan syndrome (MFS) is an inherited autosomal dominant connective tissue disorder. Abnormalities appear in skeletal, ocular and cardiovascular systems. The main cause of MFS is mutations in the fibrillin1 gene (*FBN1*). Recently, the transforming growth factor beta receptor 2 gene (*TGFBR2*) has been shown to be associated with a second type of this disorder with typically mild or absent ocular involvement (MFS type 2) as well as with classical MFS. We analyzed 30 exons of *FBN1* gene and 4 exons of *TGFBR2* gene in 80 patients with MS and marfan-like syndromes from different regions of Russia. SSCP analysis revealed different abnormal migrating patterns. We identified two missense mutations (G1176Y in 28 exon and C2489Y in 60 exon) which affects cbEGF-like motifs of fibrillin-1 protein in two patients with classical MFS symptoms. We also found 9 polymorphisms both in coding and non coding regions of *FBN1* gene, five of them are not previously described. One novel mutation (c.670C>T; T223M) has been found in *TGFBR2* gene in two unrelated patients with marfan-like syndrome who did not fulfill Ghent nosology and who did not have mutations in *FBN1* gene. Mutation T223M affects highly conserved serine/threonine protein kinases catalytic domain that leads to change phospho transferring status of *TGFBR2* protein. In addition two novel polymorphisms have been found in intronic regions of *TGFBR2* gene. Mutation screening of *FBN1* and *TGFBR2* genes continues.

P05.119

Novel mutations of *FBN1* in Czech population

E. Prusová, A. Bóday, P. Riedlová, J. Fiser, S. Tavandiz, M. Kučerová, M. Radina;

JG Mendel Cancer Centre, Nový Jičín, Czech Republic.

Marfan syndrome (MFS) is a heritable autosomal dominant disorder of connective tissue with prevalence of between 1 in 5-10 000. Approximately 25% of MFS patients are sporadic cases due to new mutations. MFS is noteworthy for its clinical variability. Major features of the MFS include cardiovascular disorders (dilatation and dissection of ascending aorta), eye disorders - *ectopia lentis*, defects of skeletal system - *pectus carinatum*, *pectus excavatum* and/or other diagnostics criteria as *arachnodactyly*.

MFS is caused by mutations in fibrillin 1 gene (*FBN1*) resulting in defective glycoprotein fibrillin-1. *FBN1* is located on chromosome 15 at locus q15-q21.1. Recently, there are showed that two other genes *FBN2* (5q23-q31) and *TGFBR2* (3p22) influence MFS.

Since 2006 we have done a molecular analysis for MFS diagnosis in Czech Republic. The molecular analysis includes mlpa (multiplex ligation-dependent probe amplification), separation of PCR products by SSCP (single-strand conformation polymorphism) and sequencing. We have performed mutation detection on 150 patients with suspected MFS. There were detected 20 novel mutations.

P05.120

Large deletions account for a significant fraction of mutations in Marfan syndrome

B. M. Rhode, L. Föhse, M. Stuhmann, J. Schmidtke, M. Arslan-Kirchner;

Institute of Human Genetics, Hannover Medical School, Hannover, Germany.

Marfan syndrome (MFS) is an autosomal dominant hereditary disorder of connective tissue caused by mutations in the *FBN1* gene. Cardinal manifestations include proximal aortic aneurysm, *ectopia lentis*, and involvement of the skeletal system. About 60 to 90% of the cases with clinically diagnosed Marfan syndrome can be explained by a *FBN1*

mutation. This rate can be raised by subsequent sequencing analysis of the genes *TGFBR1* and *TGFBR2*.

We tested 45 patients without identified mutation in the three genes by use of MLPA (multiplex ligation-dependent probe amplification) and investigated whether large deletions in the *FBN1* gene would increase the mutation detection rate sufficiently for incorporation of MLPA in the routine diagnostics of Marfan syndrome. The patients fulfilled or partially fulfilled the diagnostic criteria (Ghent nosology).

We identified three large deletions in the 3' region of the *FBN1* gene; ranging from exon 50 to 54, exon 55 to 58 and exon 58 to 63 (the last one was previously described by Singh et al., J. Mol. Cell. Cardiol. 2007). A fourth deletion comprised the complete *FBN1* gene. Break-points of the deletions were determined by long-range PCR techniques. Implications for the resulting protein product, as well as the phenotypes of the patients, will be discussed.

We estimated a deletion detection rate of 9% in this pre-screened patient group, corresponding to an overall rate of 3% among all patients with MFS. These data imply an inclusion of MLPA analysis in the routine diagnostics of Marfan syndrome.

P05.121

Alternative splicing variants of *MCPH1* with distinct functions

I. Gavvovidis¹, M. Trimborn², L. Weissflog¹, H. Hanenberg³, H. Neitzel⁴, D. Schindler¹;

¹Department of Human Genetics, University of Würzburg, Würzburg, Germany,

²Institute of Medical Genetics, Charité University Medicine, Berlin, Germany,

³Department of Pediatric Oncology Hematology and Immunology, Childrens Hospital, Heinrich Heine University, Dusseldorf, Germany, ⁴Institute of Human Genetics, Charité University Medicine, Berlin, Germany.

Primary microcephaly (MCPH) is an autosomal recessive disorder characterized by pronounced reduction of brain size and variable mental retardation without additional neurological deficits. Four underlying genes have been identified to date. Hallmark of patients with mutations in the *MCPH1* gene (MIM# 606858; MIM# 607117) is a cellular phenotype of premature chromosome condensation, PCC, in the G2 phase and delayed decondensation in G1. *MCPH1* is located on human chromosome 8p23.1, consists of 14 exons, and encodes the protein microcephalin containing one N-terminal and two C-terminal BRCT-domains as well as an NLS sequence.

RT-PCR showed alternatively spliced variants of *MCPH1*-mRNA. In addition to the full length *MCPH1* (*MCPH1*-L), we detected a variant skipping exon 8 (*MCPH1*-S) and another without exons 9-14 (*MCPH1*-B). The resulting polypeptides are lacking the NLS or the two C-terminal BRCT-domains, respectively.

Expression of any of the three variants as GFP-fusion proteins by retroviral transfer resulted in complementation of the PCC phenotype in *MCPH1*-deficient cells. In contrast, a construct containing *MCPH1* without the N-terminal BRCT-domain (*MCPH1*Δ1-7) did not complement the PCC phenotype, suggesting a role of this domain in regulating chromosome condensation, presumably through interaction with condensin II.

The fluorescent signals confirmed nuclear localization of all three variants. For *MCPH1*-S a GFP-signal was detected in the cytoplasm as well, which appeared to co-localize with the centrosomes, whilst *MCPH1*-L and *MCPH1*-B re-localized to chromatin during anaphase. In addition, variants containing C-terminal BRCT domains re-localized to gamma-H2AX foci indicating participation of these variants in DNA-damage responses.

P05.122

Investigation of six mental retardation loci (*MCPH1*, *MCPH2*, *MCPH3*, *MCPH4*, *MCPH5*, and *MCPH6*) associated with microcephaly in northeast & southeast of Iran

H. Darvish¹, G. Bahrani Monajemi¹, F. Rakhshan², A. Zadeh-Vakil², A. Naghavi², M. Mohseni¹, S. Ghasemi Firouzabadi¹, G. Mollashahi Sanatgar², J. Oveis², S. Banihashemi¹, F. Behjati¹, K. Kahrizi¹, H. Najmabadi¹;

¹Genetics Research Center, University of Social Welfare and Rehabilitation

Sciences, Tehran, Islamic Republic of Iran, ²University of medical science, Zahedan, Islamic Republic of Iran.

Primary autosomal recessive microcephaly is defined as a reduction in head circumference. Six out of ten Non-Syndromic Autosomal Recessive Mental Retardation (NS-ARMR) loci associated with microcephaly (*MCPH1*-*MCPH6*) and belong to the family of *MCPH* (autosomal re-

cessive primary microcephaly). So far four genes have been identified: *MCPH1*, encoding Microcephalin; *MCPH3*, encoding CDK5RAP2; *MCPH5*, encoding ASPM, and *MCPH6*, encoding CENPJ. *MCPH5* and *MCPH1* are the most common loci based on *MCPH* heterogeneity studies in Pakistani and Indian populations. The objective of this study was to investigate prevalence of ARMR associated with microcephaly in Iranian families from northeast & southeast of Iran. A total of 20 consanguineous families with two or more affected individuals with ARMR inheritance pattern have been collected after obtaining consent form. Clinical examination and exclusion of chromosomal abnormalities of the families were completed and followed by homozygosity mapping using STRs (Short Tandem Repeats) markers for six mentioned *MCPH* loci. Sequencing was performed for the linked families. Nine out of twenty families were linked to four of these loci as follows: Five were linked to *MCPH5* (25%), and *MCPH1*, *MCPH2* were linked to one family each (5%), and two were linked to *MCPH6* (10%). We have been able to identify four novel mutations in four families of the *MCPH5*. According to our findings *MCPH5* seems to be the most prevalent loci in Iranian families with mental retardation and microcephaly. Sequencing for the other linked families is currently underway.

P05.123

MicroRNA expression and post-transcriptional target genes analysis from one pair of monozygotic twins discordant for trisomy 21: understanding phenotypic variability in DS patients

C. Borel, S. Deutsch, C. Gehrig, M. Gagnebin, S. E. Antonarakis;

Department of Genetic Medicine and Development, University of Geneva Medical School, CH, GENEVA, Switzerland.

The understanding of the molecular pathogenesis of trisomy 21 (T21) is remarkably poor since it is not clear how the extra copy of HSA21 leads to a wide range of phenotypes. We investigated a new class of functional sequences: microRNAs (miRNAs), that act primarily as post-transcriptional repressors of target genes through 3'UTR interactions. We studied microRNA gene variation on primary fibroblasts and heart tissue from one pair of monozygotic twins discordant for T21. Expression was assayed using Taqman qRT-PCR on 365 mature miRNAs, 4 of which are encoded by HSA21. Most of deregulated microRNAs are tissue specific. Around 12% (fibroblasts) and 25% (heart) of microRNAs show a statistically significant difference between the T21 and normal twin, with an average up-regulation of 1.6fold and down-regulation of 0.6fold. Expression levels revealed that HSA21-miR-155 and HSA21-miR-99a are up-regulated about 2fold in fibroblasts and heart tissue, respectively. We have also examined transcripts that are post-transcriptionally deregulated in T21 and potential target genes of those deregulated microRNAs. To do so, we separated RNA molecules of primary fibroblasts from the same pair of twin in a sucrose gradient according to their association with ribosomes. Pools of fractions corresponding to the heavy ribosomal fraction (translated RNA) and total RNA were hybridized to a gene expression microarray. We identified 45 and 63 transcripts with a post-transcriptional up-regulation and downregulation in the T21 twin, respectively. To complete this study, we are currently looking for predicted miRNA target genes and correlated miRNA expression with the expression of its target genes.

P05.124

Distinctive patterns of miRNA expression in human muscular disorders

I. Eisenberg^{1,2}, A. Eran¹, H. G. Lidov¹, P. B. Kang¹, I. S. Kohane¹, L. M. Kunkel^{1,2};

¹Children's Hospital Boston, Boston, MA, United States, ²Howard Hughes Medical Institute, Boston, MA, United States.

The muscular disorders are a heterogeneous group of inherited diseases characterized by muscle wasting and progressive weakness, resulting in significant morbidity and disability. Although considerable progress has been made in the understanding of these disorders, the underlying molecular pathways remain poorly understood. In light of their involvement in modulating cellular phenotypes we hypothesized that miRNAs might be involved in the regulation of the pathological pathways leading to muscle dysfunction. We describe a comprehensive miRNA expression profile aiming to identify new elements involved in the regulatory networks of muscle and the signature pattern of 185 miRNAs associated with ten common myopathological conditions in human. While five miRNAs were found to be consistently dysregulated

in all samples analyzed suggesting that these miRNAs are involved in a common underlying regulatory pathway among all diseases, other miRNAs were identified to be dysregulated only in one given disease and not in any of the others thus pointing to their involvement in a unique regulatory mechanism.

The subsequent identification of potential target genes and the unraveling of biological signaling pathways involved in this regulatory level in these disorders, point to an additional dimension of regulation of muscle function mediated by miRNAs. Together with the tight post transcriptional regulation at the mRNA level identified in Duchenne and Miyoshi myopathy and specific mRNA:miRNA predicted interactions, some of which are directly involved in compensatory secondary response functions and others in muscle regeneration, these findings suggest an important role of miRNAs in the pathology of muscular dystrophy.

P05.125

Multiple Sclerosis Disease and Mitochondria

M. Houshmand;

NIGEB, Tehran, Islamic Republic of Iran.

Multiple Sclerosis (MS) is a multifocal demyelinating central nervous system disorder. To assess relationship between mtDNA haplogroups and MS, we have sequenced the mtDNA HVS-I in 54 MS patients and 100 control subjects. In this study, kinetic analysis of mitochondrial respiratory chain complex I enzyme was performed on intact mitochondria isolated from fresh skeletal muscle in MS patients (n =10) and control subjects (n =11). The frequencies of the Asian (M, BM) and European (N, J, K) mtDNA haplogroups in five major regions of Iran was investigated. Unexpectedly, the frequencies of the Asian haplogroups M and BM were low in Iran (2.34% for haplogroup M; 17.6% for haplogroup BM and 80.06% for haplogroup N).

We have found that haplogroups A and K are significantly more abundant in MS patients ($P=0.042$ for haplogroup A and $P=0.0005$ for haplogroup K). Our findings showed that complex I activities were significantly reduced ($P=0.007$) in patients compared with control. However, we could not find deletion in mtDNA of patients with MS. Our results revealed that 15 (75%) out of 20 MS patients had point mutations. This study suggested that point mutation occurred in mtDNA might be involved in pathogenesis of MS. Our data suggest that Iranian tribes probably played a remarkable role in the formation of these ethnic groups. It gives the indication that the haplogroup J may be older than 6000-10000 years, and probably developed in Iran, and then expanded to different regions in Europe and Northwest Asia.

P05.126

The coexistence of an East-Asian mitochondrial anthropological marker and the C8270T, A8332C, and A8347C mtDNA mutations in a Hungarian family with dystonia and juvenile stroke syndrome

A. Gal¹, K. Pentelenyi¹, V. Remenyi¹, B. Csany², G. Tomory², I. Rasko², M. J. Molnar^{1,3};

¹Department of Neurology, Semmelweis University, Center of Molecular Neurology, Budapest, Hungary, ²Biological Research Center, Szeged, Hungary, ³Montreal Neurological Institute, McGill University, Montreal, QC, Canada.

The high variability of the mitochondrial genome contributes to the phenotype of the mtDNA-related disorders. MtDNA mutations have been associated with a variety of clinical manifestations. The 9-bp deletion between mtDNA 8271-8280 was originally thought to be an anthropological marker for peoples of East-Asian origin.

The proband was investigated for marked dystonic features. The clinical symptoms started after a long lasting episode of fever and elevated serum ammonia and lactate level. His brother had transient hyperkinesia, right hemiparesis. Their mother had in her childhood a stroke with aphasia and right hemiparesis. Presently she has moderate truncal ataxia, hypoacusis and cognitive dysfunction.

The mtDNA analysis of the proband found a 9bp deletion "CCCCCTCA" in the mtDNA at the position nt8271-8280, and one C8270T substitution between COII and tRNA^{Lys} genes in the non-coding hypervariable segment, and two SNPs (A8332G and A8347C) in the tRNA^{Lys} gene. The C8270T SNP is a pathogenic mutation, the A8332G and A8347C SNPs are not described in the literature. None of the three SNP was found in our 100 control cases. The affected Hungarian family belongs to an ancient B mitochondrial haplogroup.

Conclusion: The B haplogroup and the 9 bp small deletion indicate the east-Asian origin of this family which could be explained by the Hungarian history. The 9 bp deletion may serve as a susceptibility factor for further mtDNA alterations. We assume that the clinical symptoms are related to the pathogenic C8270T mutation and the coexistences of the A8347C and A8332G mutations may modify the clinical symptoms.

P05.127

Mitochondrial nonsyndromic hearing impairment: the Spanish exception?

D. Feldmann¹, L. Jonard¹, A. F. Roux², C. Lemarechal³, K. Olszewski¹, C. Francannet⁴, R. Couderc¹, F. Denoyelle¹, S. Marlin¹;

¹AP-HR, Paris cedex 12, France, ²génétiq ue moléculaire IURC, Montpellier, France, ³Génétiq ue Inserm U613, Brest, France, ⁴génétiq ue médicale, Clermont-Ferrand, France.

Nonsyndromic sensorineural hearing impairment (NSHI) can be caused by few mitochondrial mutations. Among these mtDNA mutations, A1555G mutation in the 12S rRNA gene has been worldw idely reported and is associated with NSHI maternally transmitted or with aminoglycoside-induced NSHI. A high frequency of A1555G was observed in Spain.

From a large cohort of NSHI patients studied in the National Reference Center for Genetic Deafness in Paris, France, we selected 156 unrelated patients with NSHI maternally inherited and 124 sporadic NSHI exposed to aminoglycosides before hearing loss onset. A1555G was studied by PCR-restriction enzyme analysis and confirmed by sequencing. Absence of GJB2 mutations and GJB6 deletions was verified.

A1555G mutation was observed in 7 of the 156 NSHI familial cases (4,5%) and in 0 of the 124 sporadic cases. The 7 families with A1555G originated respectively from China, Martinique, Arab/Israel, Portugal, Iran, Madagascar and Spain. Homoplasmic A1555G mutation was detected in all the descendants of the oldest studied mother. The HI was present in 51 of the 102 maternal relatives. The calculated penetrance of A1555G in this study is 50%. The HI was very heterogeneous with an onset ranging from 0 to 30 years and a severity varying from mild to profound.

This study shows that the frequency of A1555G in NSHI maternally inherited is lower in France than in Spain (4,5% versus 61%) and in sporadic cases (0 versus 3%). This reported variability could be due to the different use of aminoglycoside antibiotics in the two countries or to genetics factors.

P05.128

Mitochondrial ATPase 6 gene as a hot spot for Neurodegenerative disorders?

M. Banoei, M. Houshmand;

National Institute of Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran.

The mitochondrial DNA (mtDNA) may play an essential role in the pathogenesis of the respiratory chain complex activities in neurodegenerative disorders such as Huntington's disease (HD), Spinocerebellar Ataxias (SCA), and Multiple Sclerosis (MS), Ataxia-Telangiectasia (AT), Friedreich's Ataxia (FA) and Duchene Muscular Dystrophy (DMD) as neuromuscular disease. Dysfunction of the mitochondrial Respiratory Chain (RC) has been shown in patients with neurological disorders. The tRNA genes mutations are one of hot spots that cause mitochondrial disorders.

To determine mtDNA damage, we investigated deletions based in four areas of mitochondrial DNA, in a group of 120 patients clinically diagnosed with one of mentioned neurological disorders. We screened for tRNA^{Leu}, tRNA^{Lys}, COII, ATPase6/8 and NDI genes of mtDNA of patients with HD, SCA, MS, AT, FA and DMD.

Results showed that ATPase 6 gene is a hot spot region rather than other regions. Several new nucleotide variations resulting in amino acid changes were observed in patients that altered protein structure regarding to essential changes in amino acids.

The secondary mitochondrial respiratory chain defects encountered in these disorders can also be explained by mitochondrial that degenerate either as part of a more widespread cellular insult, or as a consequence of a different specific defect. Most mitochondrial proteins have to be imported from the cytoplasm and directed to the mitochondria. So this study suggests that the high rate of mutations in ATPase 6

could be result in interaction of nuclear protein with mtDNA genome.

P05.129

Screening for MELAS mutations in Italian patients having stroke-like episodes

V. Andreoli¹, F. Trecroci¹, A. Nucera², A. La Russa¹, M. Liguori¹, I. Manna¹, P. Spadafora¹, M. Caracciolo¹, G. Di Palma¹, R. Cittadella¹;

¹Institute of Neurological Sciences-National Research Council, Pianolago di Mangone (CS), Italy, ²Stroke Unit- Neurology, Santa Maria Nuova Hospital, Reggio Emilia, Italy.

Mitochondrial encephalomyopathies are a multisystemic group of disorders that are characterised by a wide range of clinical, biochemical, and genetic mitochondrial defects. Among this group of disorders, the Mitochondrial myopathy, Encephalopathy, Lactic Acidosis with Stroke-like episodes (MELAS) syndrome is one of the most frequently occurring maternally inherited mitochondrial disorders. The age of onset is highly variable and it is very rare in patients over the age of 40. Mutations in tRNA, especially A3243G in the *MTTL1* (tRNA^{Leu}) gene, are accounted for more than 80% of the cases and other mtDNA mutations such as T3271C have also been described. We analyzed 55 Italian patients clinically exhibiting stroke-like episodes, migraine, ataxia and dementia for the two primary mutations mentioned above in the *MTTL1* gene. This molecular investigation was carried out using PCR-RFLP with the restriction endonuclease *Apa I* and *Afl II* respectively. None of the patients or the 25 controls subjects, matched for ethnic background, gender and age, were found to carry these mutations (A3243G and T3271C) in homoplasmic/heteroplasmic form. However, after direct sequencing of the *MTTL1* gene and a part of the *MT-ND1* gene, we no detected mt-mutations in the tested patients and controls and we confirmed that MELAS is an extremely rare disease. Moreover, we also found a A3480G synonymous variation in the *MT-ND1* in a 51-year-old man, whose medical history was significant for ischemic stroke of undetermined origin and increase in lactate level in blood.

P05.130

Two novel mitochondrial DNA mutations in muscle tissue of a patient with limb-girdle myopathy

S. Seneca¹, A. Meulemans², B. De Paep³, J. De Bleecker⁴, J. Smet⁵, L. De Meirleir⁶, W. Lissens¹, R. Van Coster³, I. Liebaers¹;

¹Center for Medical Genetics, UZ Brussel, Brussels, Belgium, ²Department of Pediatrics, ULB, Brussels, Belgium, ³Department of Neurology & Pediatric Neurology and Metabolism, Ghent University Hospital, Ghent, Belgium, ⁴Department of Neurology, Ghent University Hospital, Ghent, Belgium, ⁵Department of Pediatrics & Center for Medical Genetics, UZ Brussel, Brussels, Belgium.

Patients with an oxidative phosphorylation (OXPHOS) disorder often present with complex clinical features, including neurological and muscular dysfunction. Mutations underlying these diseases are located in the mitochondrial or nuclear genome. Here, we report on a forty-eight-year-old woman suffering from mild limb girdle myopathy. The enzymatic activities of the OXPHOS enzymes in skeletal muscle tissue of the patient were within the control ranges. However, activity staining following BN-PAGE showed a decreased complex III activity and the presence of complex V subcomplexes. Immunocytochemistry demonstrated a mosaic staining pattern in a minority (about 20%) of the muscle fibers for complex I (subunit 20kd) and complex IV (subunit I). Molecular analyses identified two novel heteroplasmic mitochondrial DNA nucleotide aberrations in muscle tissue : an insertion, m.5888insA in the mt-tRNA^{Tyr} gene and an alteration, m.14639A>G, changing a leucine into a serine residue in the ND6 gene. Less than 1% of both mutant alterations were present in the patient's fibroblasts, while they were undetectable in her blood and in blood and fibroblasts from her mother.

Single muscle fiber analyses clearly demonstrated that COX-deficient fibers, as compared to COX-positive fibers, harbored a significantly higher level of both mtDNA mutations. These results, together with previously defined canonical criteria determining the pathogenic character of mtDNA analyses, suggest that both nucleotide changes are pathogenic mutations.

P05.131**A novel splicing mutation in the HNF1a gene in an Italian family with MODY3 disease**A. Cappelli^{1,2}, S. Silvestri³, P. Staffolani¹, A. Consoli¹, L. Pianese¹;¹Laboratorio Medicina Molecolare, ASUR ZT13, Ascoli Piceno, Italy, ²School of Advanced Studies: Environmental Sciences and Public Health, Camerino, Italy, ³Scuola di Specializzazione in Biochimica Clinica, Camerino, Italy, ⁴Università degli Studi "G. d'Annunzio", Chieti, Italy.

Maturity-onset diabetes of the young (MODY) is a monogenic form of diabetes mellitus characterized by autosomal dominant inheritance, early age of onset and a primary insulin secretion defect. More than 200 different mutations in the hepatocyte nuclear factor 1a HNF1a gene have been shown to cause a common type of MODY, called MODY3. Mutations span the entire gene and most types of mutations have been described; e.g. insertion/deletion mutations, missense mutations, nonsense mutations and splice site mutations. Recently, partial and whole gene deletion mutations also were described.

In the present study we screened for mutation the HNF1a gene in a proband which fulfilled the criteria for MODY3, using direct sequence. The examination was extended to the proband's family: an affected father and unaffected mother and sister.

Here we report the identification of a novel HNF1a mutation at conserved splice acceptor site of exon 5 (IVS4nt-1 G>T) that cosegregated with diabetes in the family. Using a neural network based program, this mutation might be expected to result in the skipping of the exon immediately 3' to the mutation and the utilization of the next available AG site for exon 6. Alternatively, a cryptic AG splice acceptor site in intron 5, at -75 bp 5' to the natural site, could be recruited resulting in inclusion of some intronic sequence. However, truncation of the protein results in both cases. Examination of mutant mRNA transcript will be necessary in order to assess the precise consequence of this mutation.

P05.132**Contribution of the dHPLC to the diagnosis of VHL somatic mosaicism**S. Lefebvre¹, C. Gressier¹, P. Delobre¹, N. Burnichon^{2,3}, S. Pinson¹, A. Gimenez-Roqueplo^{2,3}, R. Salomont⁴, S. Richard^{5,6}, A. Calender¹, S. Giraud¹;¹Hospices civils de Lyon, Hôpital Edouard Herriot, Service de génétique, Lyon, France, ²Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Département de génétique, Paris, France, ³Université Paris Descartes, Faculté de médecine, Paris, France, ⁴Assistance Publique-Hôpitaux de Paris, Hôpital Necker, Service de Néphrologie pédiatrique, Paris, France, ⁵Faculté de médecine Paris-Sud, Service de génétique oncologique EPHE, Paris, France, ⁶Institut Gustave Roussy, UMR8125, Villejuif, France.

Detection and characterization of somatic mosaicism are difficult because of the low frequency of mutant alleles. We report here the diagnosis of two cases of VHL somatic mosaicism identified by dHPLC.

The Von Hippel Lindau disease (VHL) is an autosomal dominant inherited syndrome, predisposing to the development of various tumours, notably retina hemangioblastomas and pheochromocytomas. Analysis for constitutional change of the VHL gene is realized by sequencing and QMPSF. For two patients addressed for VHL suspicion, the sequencing did not show mutation. However for each patient, on two different frequent change sites, second peaks (respectively c.482G>A and c.500G>C) were discriminated but their heights were small (1/5 of the normal peak) and difficult to differentiate from the usual background noise.

We analyzed these two patients by dHPLC. For each patient, aberrant profile was observed, similar but reduced relative to profile with known mutation at the same site.

With dHPLC collector, we collected and sequenced separately the various peaks. We could clearly observe a superposition of two nucleotides in equivalent heights, which allowed us to confirm the VHL somatic mosaicism.

These two patients need follow-up like other VHL patients even if they have not presented all the characteristic attacks of this syndrome.

We began a retrospective work by dHPLC on the patients addressed for a suspicion of VHL disease, with early or multiple attacks and without identified mutation.

P05.133**Interaction between MTHFR polymorphisms and development of myopathyc process (hypothesis approbation)**V. C. Sacara¹, E. V. Scvortova²;¹Centre of reproductive health and medical genetics, Chisinau, Republic of Moldova, ²Moldavian State University, Chisinau, Republic of Moldova.

Background: Polymorphisms of the MTHFR gene can influence the methionine metabolic pathway and folate metabolism. The methylation process is essential for the regulation of gene expression controlling the development and function of the muscles. We noted that DMD patients with the same deletion in the dystrophine gene had different clinical features and severity of pathology process. The main conception of our hypothesis is that exist an interaction between MTHFR polymorphisms and development of myopathyc process.

Methods: We analyzed DNA from a case-control study in the RM of 50 DMD probands and 114 controls. MTHFR variant alleles were determined by a PCR-RFLP. Control group data is taken from publication Skibola *et al.*, 1999. The genotyping protocol for the detection of the MTHFR C677T and A1298C polymorphisms were adapted from MG-Center, Moscow (prof. Polyakov A.). Statistic analyses were performed by using SISA.

Results: We found the MTHFR C677C allele present among 3(6%) DMD and 61(53.5%) controls ($X^2=32,9, P=0,00$), the C677T genotype among 27(54%) DMD, 39(34.2%) controls ($X^2=5,66, P=0,02$), and the T677T allele 20(40%) DMD, 14(12.3%) controls ($X^2=16,25, P=0,00$). For MTHFR 1298, the A1298A genotype was observed in 33(66%) of DMD, 49(43.0%) of the controls ($X^2=7,37, P=0,00$), the A1298C allelic variant was observed in 11(22%) DMD, 54(47.4%) controls ($X^2=9,35, P=0,00$), and the rarer C1298C variant was observed among 6(12%) case and 11(9.6%) controls ($X^2=0,21, P=0,65$).

Conclusions: According to our data were observed statistically significant differences between DMD and control MTHFR genotypes, except C1298C. The MTHFR T677T genotype was higher among DMD patients as we know this mutation leads to reduced MTHFR activity and influence on myopathyc process.

P05.134**Mutational analysis of the MTHFR gene in four patients with homocystinuria due to severe MTHFR deficiency**R. Urreiziti^{1,2}, U. Fanhoe¹, A. Langkilde¹, C. Esteves¹, M. Cozar^{1,2}, M. Vilas-eca^{3,2}, R. Artuch^{3,2}, A. Baldellou⁴, L. Vilarinho⁵, B. Fowler⁶, A. Ribes^{7,2}, D. R. Grinberg^{1,2}, S. Balcells^{1,2};¹Dpt de Genetica, IBUB, Universitat de Barcelona, Barcelona, Spain, ²Centro de Investigacion Biomedica en Red de Enfermedades Raras (CIBERER), ISCIII, Barcelona, Spain, ³Department de Bioquimica Clinica, Hospital Sant Joan de Deu, Barcelona, Spain, ⁴Unidad de Enfermedades Metabolicas, Hospital Infantil Miguel Servet, Zaragoza, Spain, ⁵Instituto de Genetica Medica Jacinto Magalhaes, Porto, Portugal, ⁶Metabolic Unit, University Children's Hospital, Basel, Switzerland, ⁷Divisio d'Errors Congenits del Metabolisme (IBC), Departament de Bioquimica i Genetica Molecular, Hospital Clinic, Barcelona, Spain.

Methylenetetrahydrofolate reductase (MTHFR) catalyzes the reduction of 5,10-methylenetetrahydrofolate to 5-methyltetrahydrofolate, which acts as a methyl donor in the remethylation of homocysteine to methionine. Disruption of MTHFR activity results in severe hyperhomocysteinemia and causes vascular and neurological disorders and developmental delay. Four patients with severe hyperhomocysteinemia and hypomethioninemia were examined with respect to their symptoms, their MTHFR enzyme activity and their genotypes at the MTHFR gene. We found three novel mutations: two missense mutations c.664G>T (p.V218L) and c.1316T>C (p.F435S), and a one bp deletion c.1768delC (p.L590C fs X70). We also found c.1420G>T (p.E470X), a previously reported nonsense mutation. Four new genotypes were identified: Patient 24 was homozygous for p.V218L and the common polymorphism p.A222V (c.667C>T); patient 73 was homozygous for p.E470X; patient 86 was homozygous for p.F435S and the common polymorphism p.E429A (c.1298A>C); and patient 95 was homozygous for c.1768delC. Patient 24 presented an MTHFR enzyme activity below 7% of control level, while patients 73 and 95 had MTHFR enzyme activities below 1%. All patients presented symptoms of severe central nervous system disease and microcephaly. Two of them suffered a fatal stroke (patient 73 at 18 months and patient 86 at age 14 years). Patient 24 was the mildest, with a diagnosis at age 18 years. Patient 95 could be diagnosed at age 11 months and is improving upon

treatment with betaine. Genotype-phenotype analysis points to less severe outcomes for the patients with missense changes as opposed to the ones whose mutations consisted on gross derangements of the MTHFR protein.

P05.135

Mutational spectrum of *KRT5* and *KRT14* genes in patients with epidermolysis bullosa simplex (EBS)

H. H. Lemmink¹, M. C. Bolling², G. Janssen¹, K. Kooi¹, G. Matthijs³, Y. J. Vos¹, M. F. Jonkman²;

¹Department of Genetics, University Medical Centre, Groningen, The Netherlands, ²Center for Blistering Diseases, Dermatology, University Medical Centre, Groningen, The Netherlands, ³Centre for Human Genetics, Leuven, Belgium. Epidermolysis bullosa simplex (EBS) is a hereditary skin blistering disorder caused by mutations in the genes for keratin 5 (*KRT5*) or keratin 14 (*KRT14*). Mutations disrupt intermediate filament assembly in epidermal basal cells mostly resulting in autosomal dominant EBS. We screened 72 unrelated EBS patients, the majority of which is of Dutch origin. Five patients were from Belgium and one patient was from Slovenia. A total of 20 different heterozygous *KRT5* and 15 different heterozygous *KRT14* gene mutations were identified in 50 patients. Only one patient carried one missense *KRT5* mutation in addition to one missense *KRT14* mutation. Each of three mutations, Arg125Cys and Arg388Cys in *KRT14* and Arg187Pro in *KRT5*, were detected in three or more patients. Approximately 80% of the total number of *KRT5* and *KRT14* mutations were missense mutations. In patients with the severe EBS type Dowling-Meara (EBS-DM) *KRT5* mutations were predominantly located at the highly conserved C-terminal 2B domain. Mutations located at the N-terminal H1 and 1A rod domain of the *KRT5* protein were detected in patients with the milder EBS type Weber-Cockayne (EBS-WC). In contrast, *KRT14* gene mutations located at the N-terminal H1 and 1A domain were mostly present in patients with EBS-DM and *KRT14* mutations at the C-terminal 2B domain preferably in patients with the EBS-WC phenotype. We conclude that there is a reverse correlation between mutations located at the N- and C-terminal end of the *KRT5* and *KRT14* proteins and their subsequent association with either severe Dowling-Meara or milder Weber-Cockayne EBS phenotypes.

A novel family with lamin B1 duplication associated with adult-onset leukoencephalopathy

A. Brussino¹, G. Vaula², C. Cagnoli¹, A. Mauro³, L. Pradotto⁴, D. Daniele⁵, E. Di Gregorio¹, M. Barberis¹, C. Arduino¹, S. Squadrone⁶, M. Abete⁶, N. Migone¹, O. Calabrese⁷, A. Brusco¹;

¹Department of Genetics, Biology and Biochemistry - SCDU Medical Genetics, Torino, Italy, ²SCDU Neurologia II, Az. Osp. San Giovanni Battista, Torino, Italy, ³Department of Neurosciences, University of Torino, Torino, Italy, ⁴Department of Neurology, IRCCS Istituto Auxologico Italiano, Piancavallo (VB), Italy, ⁵SCDU Neuroradiology, Az. Osp. San Giovanni Battista, Torino, Italy, ⁶C.Re.A.A., Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle d'Aosta, Torino, Italy, ⁷Department of Experimental Medicine and Diagnostics, Medical Genetics Unit, University of Ferrara, Ferrara, Italy.

Hereditary leukoencephalopathies are rare disorders characterized by progressive white matter damage in the brain, with or without involvement of the peripheral nervous system. The inheritance is usually recessive, autosomal or X-linked. The autosomal dominant varieties include Alexander disease, CADASIL, and the phenotype recently described in four families with adult-onset (40-50 yrs) and initial autonomic dysfunctions due to duplication of the LMNB1 gene (Padiath et al, 2006).

To better define the prevalence of lamin B1 gene defects, we selected eight unrelated Italian probands with hereditary, adult-onset diffuse leukoencephalopathy. Seven showed pyramidal/cerebellar symptoms; six were compatible with an autosomal dominant transmission. LMNB1 full gene deletion/duplication and point mutations were tested by Taqman real-time PCR and direct sequencing.

One proband carried a 140-190 Kb duplication involving the entire LMNB1, the AX748201 transcript and the 3' end of MARCH3. Clinical and neuroimaging data of this proband and an affected relative overlapped with the features of the LMNB1 duplication described by Padiath et al. No LMNB1 gene defects were identified in the remaining seven probands.

In conclusion, LMNB1 duplication appears to be associated only to a subset of the adult-onset, autosomal dominant leukoencephalopathies, sharing the following features: onset with autonomic dysfunction, diffuse T2-hyperintensity of supra- and infra-tentorial white matter, sparing of U-fibers and optic radiations. The more variable phenotypes in the seven families lacking LMNB1 defects, suggests that other genes might be involved in the autosomal dominant leukoencephalopathies.

Investigation of inflammatory gene expression profile in acute myocardial infarction

L. Barbari¹, R. Stanescu Cioranu², D. Ianu¹, C. Ianu¹, A. Constantinescu¹, E. Neagu¹, C. Constantinescu¹, G. Girbea¹, D. Dermengiu¹, C. Macarie²;

¹National Institute of Legal Medicine, Bucharest, Romania, ²National Institute of Cardiovascular Diseases "C.C. Iliescu", Bucharest, Romania.

The inflammatory reaction is a key factor influencing the time course of a coronary artery disease and plays a significant role in the clinical outcome of the patients with acute myocardial infarction (MI). Knowing the profile of inflammatory molecules involved in the myocardial injury could contribute to the design of new appropriate therapeutic approaches. Our study aimed to identify the cytokines' type and level produced by the circulating leukocytes by looking for the RNA expression level of the corresponding genes. RNA samples were isolated from blood samples retrieved at different intervals after a MI and analyzed to quantify the expression of 40 proinflammatory genes using the MLPA method.

Our results show an intense overexpression for IL1B, IL1RN, MIF as well as for the NFkB transcription factor, with a peak at 24 h after MI and a slow decrease towards the 30th day. Patients associating diabetes mellitus had an excessive inflammatory response with a slower decrease, corresponding to previously reported data. Our study method was able to reliably illustrate the inflammatory profile associated with the MI event. Selected cytokines will be further investigated by RT real-time PCR in order to accurately identify their level and to reveal their contribution to the pathological changes in MI.

The *OLR1* splice variant "LOXIN" as a protective genomic biomarker for myocardial infarction.

L. Vecchione¹, I. Files², R. Mango¹, I. M. Predazzi¹, F. Baldin², F. Amati¹, S. Biocca², F. Romeo^{3,4}, G. Novelli^{5,4};

¹Department of Biopathology, Tor Vergata University, Rome, Italy, ²Department of Neuroscience, Tor Vergata University, Rome, Italy, ³Department of Internal Medicine Tor Vergata University, Rome, Italy, ⁴Department of Cardiovascular Medicine, University of Arkansas for Medical Sciences, Little Rock, AR, United States.

The human lectin-like oxidized low-density lipoprotein receptor-1 (LOX-1), encoded by the *OLR1* gene, is a scavenger receptor that has been implicated in the pathogenesis of atherosclerosis. LOX-1 activation is an important mechanism that contributes to plaque instability and subsequent development of acute coronary syndromes. Association studies have implicated *OLR1* gene variants in myocardial infarction (MI) susceptibility/protection. We identified a new functional splicing isoform of the *OLR1* gene, named LOXIN lacking the extracellular lectin binding domain. *In vivo* and *in vitro* studies revealed that this isoform is protective against myocardial infarction. This effect is mediated by a dominant-negative mechanism on LOX-1 function through the formation of non-functional LOX-1/LOXIN hetero-oligomers. Genomic and expression studies performed in mice and in non-human primates demonstrate the absence of LOXIN in these species. This suggests that LOXIN might be a recently selected allele. All these results confirm and extend the importance of *OLR1* gene in the pathogenesis of myocardial infarction making LOXIN an attractive new target for prevention and treatment of acute coronary syndromes.

Brain-region specific copper metabolism in rats with copper deficiency induced by Ag-ions

P. Babich, N. Platonova, N. Tsybmalenko, L. Puchkova;

Research Institute of Experimental Medicine, Saint-Petersburg, Russian Federation.

Copper is an essential trace element that plays a vital role as a catalytic co-factor for a variety of cuproenzymes. Simultaneously, copper

is toxic to cells, not least due to its ability to catalyze, via the so-called Fenton reaction, the generation of aggressive free radicals. Therefore, every organism has mechanisms to control cellular uptake, distribution, detoxification and elimination of copper. Genetic defects in any of these mechanisms as well as ecological abnormalities of copper balance result in neurodegenerative diseases. The systems that maintain copper homeostasis in mammalian brain are investigated poorly. This work was done using Wistar rats received 50 mg AgCl per kg of body weight, daily, in four weeks. This model is characterized with copper-deficit in blood serum and normal copper metabolism in liver. Concentration of copper, zinc, iron, and silver was determined in cortex, cerebellum, hippocampus, hypothalamus, amygdaloid body, hypophysis by atomic-absorptive spectrometry. Copper-transporting proteins (CTR1, ATP7A/B, APP) and cuproenzymes (ceruloplasmin (Cp), GPI-Cp, SOD1, COX (Cox4i1)) mRNA levels were determined with semiquantitative RT-PCR. Protein amounts were valued by Western blot. Furthermore Cp and SOD1 enzymatic activity were measured. It was shown that Ag-ions are selectively accumulated by hypophysis. Hypophysis accumulates Fe and Zn as well. Cu level is decreased in hypothalamus only. At the same time copper-transporting genes expression is going lower in all brain regions. The same is right for secretory cuproenzymes (Cp, GPI-Cp). While level of intracellular cuproenzymes (SOD1, COX) doesn't change. Effect of copper deficit in blood on copper metabolism in brain regions is discussed.

P05.140

Differential expression of neurokinin B and hemokinin 1 in human immune cells

T. E. Klassert¹, F. Pinto², M. Hernández¹, M. L. Candenás², M. López¹, M. C. Hernández³, J. Abreu³, T. A. Almeida¹;

¹Instituto Universitario de Enfermedades Tropicales de Canarias, La Laguna, Spain, ²Instituto de Investigaciones Químicas, CSIC, Sevilla, Spain, ³Departamento de Neumología, Hospital Universitario de Canarias, La Laguna, Spain.

Substance P (SP), neurokinin A (NKA), neurokinin B (NKB) and the recently identified hemokinin-1 (HK-1) are members of a family of structurally related peptides known as tachykinins. They are mainly synthesized in the central and peripheral nervous system, but are also present in peripheral non-neuronal cells.

In humans, substance P (SP) is the most extensively studied tachykinin and is present, along with the NK-1 receptor, in several inflammatory and immune cells. In these cells, SP has shown to play an important role in the regulation of immune functions and inflammatory responses. Up to day, there are no studies about the expression pattern of NKB and HK-1 in inflammatory and immune cells in humans. In the present study we have detected for the first time NKB and HK-1 mRNA in human lymphocytes, monocytes, neutrophils and eosinophils. In addition, and using immunocytochemistry with two different antibodies, we have detected the presence of NKB protein in all these cellular types. These findings reinforce the suggestion that tachykinins play a central role in the pathophysiology of the inflammatory process.

P05.141

Crosstalk between NF-kappaB and Wnt/beta-catenin pathways and anhidrotic ectodermal dysplasia

C. Cluzeau¹, E. Bal¹, P. Guigue¹, N. Chassaing², S. Hadj-Rabia^{1,3}, C. Bode-mer^{1,3}, P. Calvas², M. Vincenç¹, A. Munnich¹, A. Smah¹;

¹INSERM U781, Paris, France, ²Service de génétique médicale, Toulouse, France, ³Service de dermatologie, Paris, France.

Anhidrotic ectodermal dysplasia (EDA) is an ectodermal differentiation disorder characterized by sparse hair, abnormal or missing teeth and inability to sweat. X-linked EDA, caused by mutations in EDA gene encoding ectodysplasin, a member of the TNF family, is the most frequent form. The autosomal dominant and recessive EDA forms, clinically identical to X-linked forms, may result from mutations in two loci: ED3, encoding Edar, ectodysplasin receptor and ED2, encoding Edaradd, Edar adapter molecule necessary in signal transduction. Edar is activated by ectodysplasin and uses Edaradd as an adapter to activate NF-kappaB signaling pathway. Wnt/beta-catenin pathway plays a central role during embryonic development and is widely involved in carcinogenesis. This pathway has been recently involved in skin appendages formation. A crosstalk between NF-kappaB and Wnt/beta-catenin pathway was described.

We confirmed by transactivation experiments that Edar receptor inhib-

its Wnt/beta-catenin pathway. We then studied the effects of seven recessive and dominant mutations identified in Edar gene on both pathways. Dominant mutations totally impaired NF-kappaB activation and Wnt/beta-catenin downregulation, while recessive ones only disrupted the Edar effect on both pathways.

We first demonstrated that Wnt/beta-catenin inhibition by Edar is dependent of NF-kappaB activation using a dominant negative form of IkkappaBalpha inhibitor. We then proved by Western Blot analysis and immunofluorescence that beta-catenin was neither degraded nor delocalized after NF-kappaB activation by Edar. Furthermore, beta-catenin/TCF4 interaction, necessary for Wnt/beta-catenin transcriptional activity, was not disrupted upon Edar transfection and NF-kappaB subunits p65 and p50 did not interact with beta-catenin in these conditions.

P05.142

Nijmegen breakage syndrome in Ukraine: molecular and cytogenetic studies

H. Makukh¹, L. Chorna¹, B. Tretjak¹, H. Bezkorovaina¹, G. Akopian¹, L. Kostyuchenko², N. Markevush¹;

¹State institution "Institute of Hereditary Pathology of Academy of Medical Science of Ukraine", Lviv, Ukraine, ²Lviv Specialized Children's Clinic, Lviv, Ukraine.

Nijmegen breakage syndrome (NBS) is considered as a rare autosomal recessive disease, but its actual prevalence is not known. 95% of NBS patients are of Slavic descent and 90% of them are homozygous for a founder 657del5 mutation in the NBN gene. In 1999-2007 a total of 26 patients were diagnosed with NBS in Ukraine, 23 of which residing in Western Ukraine region.

We performed 208 molecular-genetic tests of the 657del5 mutation NBN gene among the group of patients with microcephaly and identified 24 homozygous for 657del5 mutation. It had been performed 4 prenatal NBS diagnostics and we identified two homozygous and two heterozygous fetus for 657del5 mutation.

We detected the specific chromosomal rearrangements in lymphocyte cell culture of NBS patients: 3% of the cases - inv(7)(p13q35), 2% - t(7;14)(q35;q11), t(7;7)(p13;q35), del(7)(q35), del(14)(q11), 1% - t(7;14)(p13;q11). An additional marker chromosome (10% of the cells with translocations) and nonspecific chromosomal abnormalities (mostly 1, 3, 8 and 9) were found too.

As the expression of IL-10 may influence the development and progression of tumor we studied the distribution of three biallelic polymorphisms at positions -1082, -819 and -592 of the promoter region of IL-10 gene. The haplotype IL-10 GCC (37%) was found to be the most frequent.

Genetic heterogeneity of nonbullous congenital ichthyosiform erythroderma

N. N. Vasserman, V. A. Galkina, O. N. Makienko, E. G. Okuneva, G. E. Rudenskaya;

Research Center for Medical Genetics, Moscow, Russian Federation.

Nonbullous congenital ichthyosiform erythroderma (NCIE, MIM 242100) is a severe autosomal recessive disorder. About 90% of affected newborns present as "collodion babies". Many patients die in neonatal period from disorders of thermoregulation and infections. In survivors, though, skin lesions improve with age, few patients have neurological symptoms, while others live with little or no problems. NCIE is genetically heterogeneous. To date, TGM1, ALOX12B, ALOXE3, ABCA12, CYP4F22 responsible genes were identified, and mutations in the latter two are rare.

We performed DNA diagnostics in five NCIE families of which mutations were found in four: one of Azerbaijan and three of Russian ethnicity. (1) In a consanguineous Azerbaijan family two affected children died within first days, their DNA samples were unavailable. In parents a novel TCM1 mutation Arg142His was detected. On prenatal DNA diagnostics the mutation was not found in the fetus, thus the prognosis was favourable. (2) The couple abandoned the affected baby and had no information about him. Parents were found heterozygous for novel ALOX12B mutations: Ala597Glu and Tyr97Stop. Prenatal DNA diagnostics revealed unfavourable prognosis since the fetus inherited mutations from both parents. (3) In a family with a deceased newborn child a novel ALOX12 mutation Asn594His was identified in the father and a previously recorded Tyr521Cys in the mother. (4) In a

non-consanguineous family the 5-year-old patient was examined. The girl survived infancy problems and by 5 years had only mild ichthyosiform skin lesions. Homozygosity for ALOX12 mutation Ala597Glu was detected.

P05.144

Investigation of CYFIP1 and CYFIP2 genes in patients with autosomal recessive non-syndromic mental retardation

G. Guven¹, H. Kayserilif, A. Uzumcu², H. Eris², B. Karamar², S. Basaran², O. Uyguner²;

¹Istanbul Medical Faculty, Child Health, Istanbul, Turkey, ²Istanbul Medical Faculty, Child Health, Istanbul, Turkey.

Autosomal recessive inheritance of non-syndromic mental retardation (ARNSMR) may account for approximately 25 % of all patients with non-syndromic mental retardation (NSMR). Up-to-date, 12 chromosomal loci have been mapped and only four genes have been identified to cause ARNSMR. CYFIP1 (15q11) and CYFIP2 (5q33.3) genes, belonging to CYFIP family by sequence similarity, interests the scientist if any role in mental retardation due to their interactions with FMR1 protein. Suggested function of CYFIP1 in axonal growth and brain specific editing of CYFIP2 was of our further interest to investigate these genes in our highly selected ARNSMR families. 20 consanguineous families with one or more affected individuals were included into our study after through clinical check up to exclude any known syndromes and/or chromosomal or sub-telomeric abnormalities followed by search from fragile-X point of view. Our strategy was to perform homozygosity mapping to CYFIP1 and CYFIP2 genes and sequence the informatively homozygous families. Four in/delSNPs for CYFIP1 gene and four in/del SNPs plus 2 STRs for CYFIP2 gene were selected to be used for linkage. Presently our investigation is continuing and our results will be presented at our poster session.

P05.145

NPHS2 recurrent and novel mutations in children from Greece and Cyprus with steroid-resistant nephrotic syndrome

K. Voskarides¹, C. Makariou¹, G. Papagregoriou¹, N. Stergiou², N. Printza³, E. Alexopoulos⁴, A. Elia⁵, F. Papachristou³, A. Pierides⁶, E. Georgak², C. Deltas^{1,7};

¹University of Cyprus, Nicosia, Cyprus, ²Agia Sophia Childrens Hospital, Athens, Greece, ³Hippokraton Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece, ⁴Aristotle University of Thessaloniki, Thessaloniki, Greece, ⁵Archbishop Makarios III Hospital, Nicosia, Cyprus, ⁶Hippokraton Private Hospital, Nicosia, Cyprus, ⁷The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

The idiopathic nephrotic syndrome occurs mainly in children, most of whom respond well to steroid therapy, however 15-20% of these children are steroid-resistant, frequently progressing to end-stage renal failure. Mutations in the NPHS2 gene, encoding podocin, are an important cause of infantile sporadic Steroid Resistant Nephrotic Syndrome (SRNS) occurring in 2.8-28% of the cases, depending on the studied population. To a lesser extend, mutations in the WT1 gene are also found in patients with SRNS. For the first time in Hellenic population, we performed mutational analysis of the NPHS2 (including promoter region) and WT1 (exons 8 and 9) genes, studying 18 children from Greece and 6 from Cyprus with SRNS. For our investigation we used a screening method based on the SURVEYOR endonuclease digestion, which identifies and cleaves at mismatched base pairs in heteroduplexes, followed by direct PCR-DNA sequencing. No mutation or polymorphism was identified in exons 8 and 9 of WT1. In the NPHS2 gene, we identified two known mutations (418delG, R229Q) and one novel mutation (L305P), in two out of the 24 children (8.3%), in addition to nine known polymorphisms. Amino acid residue L305 is at the C-terminal of the protein and is highly conserved evolutionarily, possibly because of the functional association of this domain with nephrin and CD2AP. Although the studied cohort was small, our investigation supports the usefulness of the availability of a molecular diagnostic facility for SRNS cases, in a routine clinical setting, as it assists in the correct management of such children.

P05.146

LMX1B mutational analysis in two Nail-patella syndrome patients: evidence for the presence of mosaicism

M. Marini¹, A. Baban¹, D. Maria Teresa¹, H. Gaspar², I. Mammì³, M. Lerone⁴, R. Ravazzolo¹, R. Bocciardi¹;

¹Molecular Genetics and Cytogenetics Unit, Genoa, Italy, ²Institute for Medical Genetic, University of Zurich, Zurich, Switzerland, ³ULSS 13 Regione Veneto Consultorio genetico, Dolo, Italy, ⁴Molecular Genetics and Cytogenetics Unit, G. Gaslini Institute, Genoa, Italy.

Nail-patella syndrome (NPS, MIM#161200) is a rare autosomal dominant disorder characterized by hypoplastic or absent patellae, dystrophic nails, dysplasia of

the elbows and iliac horn, and, less frequently, ocular damage.

In the 40% of cases a glomerular defect is involved and inter- and intra-familial expression variability is reported.

Mutations in the human LMX1B gene have been demonstrated to be responsible for NPS in 90% of cases.

In this study we present evidence of somatic mosaicism in two cases of NPS.

The first case is a patient carrying the c.599G>A substitution in exon 4

(Arg200Gln). This mutation was also detectable in the healthy father as a low height A peak superimposed to G. On the contrary, in the patient the two peaks appeared at equal height, as expected in a heterozygote. The second patient is heterozygous for the c.592C>T substitution in exon 4 (Arg198Stop). Also in this case the hypothesis of mosaicism in the healthy father was raised by the presence of the C and T peaks with significantly different height. These analyses were repeated in several independent reactions with fully comparable results. The presence of the mutated alleles in the two fathers was confirmed by subcloning the PCR products: as expected in the hypothesis of mosaicism, the wild-type allele-bearing colonies were significantly more represented than the colonies with the mutated one.

To our knowledge these are the first reported cases of inheritance of a mutated LMX1B allele in NPS patients from a mosaic parent.

P05.147

Screening for melanocortin-4 receptor mutations in a cohort of Dutch obese children

L. van den Berg¹, F. Blom¹, H. Delemaire-van de Waa², P. Heutink³;

¹departments of Paediatrics and Clinical Genetics, section Medical Genomics, VU University Medical Center, Amsterdam, The Netherlands, ²department of Paediatrics, VU University Medical Center, Amsterdam, The Netherlands, ³section Medical Genomics, VU University Medical Center, Amsterdam, The Netherlands.

The most common monogenic form of obesity is caused by mutations in the gene encoding the melanocortin 4 receptor (MC4R). This receptor integrates orexigenic and anorexigenic signals in the hypothalamus to regulate food intake and energy expenditure. We have screened the coding sequence and the minimal promoter region of MC4R of 221 random patients from our VUmc center for childhood obesity. We found 18 variants in these patients, four of which were not described previously. Two of the new variants (-1101C>T and -312T>C) are not expected to be pathogenic because they are not evolutionary conserved in mammals and because they are not located in predicted regulatory regions of the gene. The new variant -705A>T may influence gene expression because it is located in a regulatory element. This variant was found in a 3-year-old girl with a body mass index standard deviation score (BMI-SDS) of 3.4. The new variant 910C>T results in a leucine > phenylalanine change. It was found in a 17-year-old girl with a BMI-SDS of 3.4. Of the 14 known variants that we found, two have been shown to have functional effects by others (Tyr35STOP and G231S). In conclusion, we detected two pathogenic mutations and several possible pathogenic mutations in 221 random patients of our obesity clinic. We will extend our research by screening additional patients, studying cosegregation of mutations and obesity in families, studying phenotypic characteristics of MC4R mutation carriers, and functional studies of new mutations.

P05.148

Exon resequencing, mutation detection, and copy number analysis in syndromic oesophageal atresia

M. Storer¹, E. Howard¹, V. Martin², G. LeFebvre¹, A. Coffey¹, C. J. Shaw-Smith¹;

¹Wellcome Trust Sanger Institute, Cambridge, United Kingdom, ²Institute of Child Health, London, United Kingdom.

Oesophageal atresia and/or tracheo-oesophageal fistula are common malformations occurring in approximately 1 in 3500 births. In around half of cases (syndromic oesophageal atresia, overlapping with the VACTERL association), there are associated anomalies, cardiac malformations being the most common. Recently, three separate genes with a role in syndromic oesophageal atresia have been identified: those for Feingold syndrome (N-MYC), anophthalmia-oesophageal-genital (AEG) syndrome (SOX2), and CHARGE syndrome (CHD7). It is likely that other genes play a role in foregut development, and dosage sensitive chromosomal loci presumably harbouring these as yet unidentified genes have recently been highlighted (refs 1 and 2).

We are collecting DNA samples from patients with syndromic forms of oesophageal atresia and the VACTERL association. We are analyzing these samples by exon resequencing in the CHD7, N-MYC, SALL1 and SOX2 genes (additional genes, including FANCB and FANCC are currently being added to the panel); and by high resolution array-based comparative genomic hybridization (arrayCGH). To date, we have analyzed 50 samples. No de novo copy number changes have as yet been identified. A de novo frame shift mutation has been detected in CHD7 in a single patient with some features of CHARGE syndrome.

By adopting this comprehensive approach to the analysis of a single malformation, we hope to identify other genes involved in human foregut development and to continue to provide a research-based service to the Clinical Genetics community for this patient group.

Mutational spectrum of the Oral-facial-digital type I syndrome: a study on a large collection of patients

B. Franco^{1,2}, C. Prattichizzo¹, M. Macca^{1,2}, V. Novelli¹, G. Giorgio¹, A. Barra¹, OFDI collaborative group;

¹Telethon Institute of Genetics and Medicine-TIGEM, Naples, Italy, ²Department of Pediatrics, University Federico II, Naples, Italy.

Oral-facial-digital type I (OFDI; MIM 311200) syndrome is a male-lethal X-linked dominant developmental disorder belonging to the heterogeneous group of Oral-facial-digital syndrome (OFDS). OFDI is characterized by malformations of the face, oral cavity and digits. CNS abnormalities and cystic kidney disease can also be part of this condition. This rare genetic disorder is due to mutations in the OFD1 gene that encodes a centrosome/basal body protein necessary for primary cilium assembly and for left-right axis determination, thus ascribing OFDI to the growing number of disorders associated to ciliary dysfunction. We now report a mutation analysis study in a cohort of 100 unrelated affected individuals collected worldwide. Putative disease-causing mutations were identified in 81 patients (81%). We describe 67 different mutations, 64 of which represent novel mutations, including 36 frame-shift, 9 missense, 11 splice-site and 11 nonsense mutations. Most of them concentrate in exons 3, 8, 9, 12, 13 and 16, suggesting that these exons may represent mutational hotspots. Phenotypic characterization of the patients provided a better definition of the clinical features of OFD type I syndrome. Our results indicate that renal cystic disease is present in 60% of cases with >18 years of age. Genotype-phenotype correlation did not reveal significant associations apart for the high-arched/cleft palate most frequently associated to missense and splice-site mutations. Our results contribute to further expand our knowledge on the molecular basis of OFD type I syndrome.

P05.150

The Opitz syndrome gene product MID1 assembles a microtubule-associated ribonucleoprotein complex

B. Aranda Orgilles¹, A. Trockenbacher², J. Winter³, J. Aigner¹, A. Köhler², E. Jastrzebska¹, J. Stahl⁴, R. Schneider^{2,3}, S. Schweiger^{1,5};

Germany, ⁵Medical School, Division of Pathology and Neuroscience, Dundee, United Kingdom.

Opitz BBB/G syndrome (OS) is a heterogeneous malformation syndrome mainly characterised by hypertelorism and hypospadias. In addition, patients may present with several other defects of the ventral midline such as cleft lip and palate and congenital heart defects. The syndrome-causing gene encodes the X-linked E3 ubiquitin ligase MID1 that mediates ubiquitin-specific modification and degradation of the catalytic subunit of the translation regulator protein phosphatase 2A (PP2A). Here, we show that the MID1 protein also associates with elongation factor 1 α (EF-1 α) and several other proteins involved in mRNA transport and translation, including RACK1, Annexin A2, Nucleophosmin and proteins of the small ribosomal subunits. Mutant MID1 proteins as found in OS patients lose the ability to interact with EF-1 α . The composition of the MID1 protein complex was determined by several independent methods: (1) yeast two-hybrid screening, (2) immunofluorescence, (3) a biochemical approach involving affinity purification of the complex, (4) co-fractionation in a microtubule assembly assay and (5) immunoprecipitation. Moreover, we show that the cytoskeleton-bound MID1/translation factor complex specifically associates with G- and U-rich RNAs and incorporates MID1 mRNA, thus forming a microtubule-associated ribonucleoprotein (RNP) complex. Our data suggest a novel function of the OS gene product in directing translational control to the cytoskeleton. The dysfunction of this mechanism would lead to malfunction of microtubule-associated protein translation and to the development of OS.

Among the oral-facial-digital syndromes, the oral-facial-digital type 1 syndrome (OFD 1) is characterised by X-linked dominant mode of inheritance. Clinical features include facial dysmorphism with oral, tooth and distal abnormalities, polycystic kidney disease and central nervous system malformations. A high clinical overlap exists between the different types of OFD syndrome. OFD1 DNA sequencing analysis remains negative in 30 to 50% of cases. We hypothesized that large genomic rearrangements could account for the majority of these unexplained cases. A series of 25 index cases (29 patients) with OFD1 phenotype and normal OFD1 DNA sequencing analysis were screened for OFD1 rearrangements by QMPSF and relative quantitative real-time PCR analyses. Five large deletions (exons 1-8, exons 1-14, exons 10-11, exon 17 and exons 13-23) were identified in five index cases, accounting for 20 % of negative mutation patients after DNA sequencing. Among the remaining negative index cases, a family history compatible with dominant X-linked inheritance was found in one case only. Using DNA sequencing, QMPSF and relative quantitative real-time PCR analyses, the OFD1 alteration detection level remains incomplete. However, it is likely that sporadic patients without OFD1 alterations

are affected by another OFD syndrome. Given the percentage of large genomic rearrangements, we suggest that routine molecular screening of *OFD1* gene should include first DNA direct sequencing analysis. QMPSF and relative quantitative real-time PCR analyses could be performed in mutation negative patients, especially in severe cases highly suggestive of *OFD1* with a prenatal diagnosis request.

PINK1 mutations and the risk of Parkinson's disease in family members of Southern Italy

V. Scornaienchi¹, I. C. Cirò Candiano¹, D. Civitelli¹, S. Carrideo¹, F. Annesi¹, P. Tarantino¹, F. E. Rocca¹, E. V. De Marco¹, G. Provenzano¹, V. Greco¹, G. Nicoletti¹, G. Squillace¹, P. Ragonese², M. D'Amelio², G. Savettieri², G. Annesi¹;
¹Institute of Neurological Sciences, National Research Council, Piano Lago di Mangone, Italy, ²Department of Clinical Neurosciences, University of Palermo, Palermo, Italy.

Mutations in *PINK1* gene are associated with both familial recessive and sporadic early-onset parkinsonism (EOP). The *PINK1* gene codes for a protein (PTEN-induced kinase1) with a catalytic serine/threonine kinase domain. Several groups have demonstrated that *PINK1* protein can be localized to mitochondria in vitro. Moreover, functional studies have shown that *PINK1* protein may have a neuroprotective role as wild-type *PINK1* protects cells against proteasomal inhibition. This protective effect is abrogated by mutations in the *PINK1* gene. Herein we investigated a possible association of *PINK1* gene mutations in southern Italian families with monogenic parkinsonism.

Fourteen families with PD were investigated for the presence of *PINK1* mutations; five had EOP (mean age at onset 36 years) and 9 had familial late-onset disease (LOP, mean age at onset 65 years). Genomic DNA was extracted from blood. *PINK1* exons were amplified by PCR and sequenced.

We characterized a novel homozygous mutation (889delG, D297fsX318) in the exon 4 of *PINK1* gene in two brothers with EOP from a Sicilian consanguineous family. This mutation causes a frameshift in translation and a premature termination of *PINK1* protein leading to the loss of most of its kinase catalytic domain. No other family members carried the homozygous deletion in the exon 4. We did not find this mutation in 200 chromosomes from healthy Sicilian individuals.

In conclusion, *PINK1* mutations are uncommon in our southern Italian families with EOP and LOP. The present study confirms that *PINK1* mutations are a cause, even if rare, of EOP in the examined population.

Parkinson's disease (PD) is the second most prevalent age-associated neurodegenerative disorder, affecting over one million individuals worldwide. The main pathological hallmark of PD is the loss of dopaminergic neurons within the *substantia nigra*, leading to insufficient formation and action of dopamine in the basal ganglia circuitry. The cardinal clinical signs are muscle rigidity, resting tremor, bradykinesia and, in more advanced cases, postural instability.

miRNAs are abundant in the brain and are essential for efficient brain function. Increasing evidence implicates miRNA dysfunction in PD pathogenesis. Although much has been learned in recent years about the genetic aetiology of familial PD, far less is known about the molecular mechanisms underlying the vast majority of cases, which are the focus of our study. To identify novel susceptibility genes for idiopathic PD, we are using the "genomic convergence" approach with microRNA profiling. This strategy converges data from whole-genome linkage studies with expression profiling experiments to determine which candidate genes to test in family-based association studies. We are currently conducting microRNA expression profiles in peripheral blood mononuclear cells of 20 PD patients and 20 controls using microarrays spotted with probes for 452 human microRNAs. The microRNAs differentially expressed and respective target genes mapping to linkage peaks will later be tested for allelic, haplotypic and genotypic associa-

tion with PD. We believe that this approach will allow us to identify specific miRNAs and miRNA target genes playing a role in idiopathic PD.

P05.154

Mutation screening of exon 3 of *Parkin* gene in a young cohort of Iranian PD patients

S. S. Banihosseini^{1,2}, M. H. Kazemi³, S. Shojae⁴, A. Alavi⁵, G. Shahidi⁶, F. Sina⁶, B. Zaman⁶, H. Sadeghi⁷, K. Parsa⁷, E. Elahi⁸;

¹Students' Scientific Research Center (SSRC), Medical Sciences, University of Tehran, Tehran, Islamic Republic of Iran, ²Iranian National Elite Foundation, Tehran, Islamic Republic of Iran, ³School of Medicine, Medical Sciences, University of Tehran, Tehran, Islamic Republic of Iran, ⁴Department of Biotechnology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran, ⁵School of Biology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran, ⁶Iran University of Medical Sciences, Hazrat Rasool Hospital, Tehran, Islamic Republic of Iran, ⁷Neurosurgery Department, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.

Parkinson's disease (PD) is the second most prevalent neurodegenerative disorder, and the most common movement disorder affecting more than 1% of individuals over 60 years old in Western populations. This is the first genetic study on Iranian PD patients. Mutations in the *Parkin* gene are often observed in patients affected with early onset PD, particularly familial forms of early onset PD. In this study, we screened exon 3 of the gene by direct sequencing in a young cohort of Iranian PD patients. The cohort consisted of 96 patients, with a mean age of onset of 41.8 yrs. (range 10-75 years). The variation c.C245A, which causes substitution of alanine by glutamic acid at residue 82 (A82E) of the coded protein, was observed in three unrelated patients in the heterozygous state. This missense causing variation has previously been reported in control individuals and is unlikely to be associated with disease. One patient seemed to carry a homozygous deletion mutation encompassing exon 3, as this exon failed to be amplified in repeated PCR attempts. Age of onset of PD in the patient carrying the putative deletion mutation was 28 years.

P05.155

Novel missense mutation in exon 44 of *LRRK2* observed in patients affected with Parkinson's Disease

F. Ghazavi¹, S. Shojae², N. Farboodi¹, Z. Fazlali¹, G. Shahidi³, F. Sina³, B. Zaman³, H. Sadeghi⁴, K. Parsa⁴, E. Elahi⁵;

¹School of Biology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran, ²Department of Biotechnology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran, ³Iran University of Medical Sciences, Hazrat Rasool Hospital, Tehran, Islamic Republic of Iran, ⁴Neurosurgery department, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran, ⁵Center of Excellence in Biomathematics, School of Mathematics, Statistics and Computer Science, College of Science, University of Tehran, Tehran, Islamic Republic of Iran.

Parkinson's Disease (PD) is the second most common neurodegenerative disease. The pathologic characteristics of PD include degeneration of neurons of the *substantia nigra* in the brain. PD is considered a complex disease, and both genetic and environmental factors are relevant to its etiology. Several genes associated with PD have been identified by linkage analysis in multi-case families. *LRRK2* is the gene most recently identified and, among identified genes, it seems to be the gene most often mutated in the dominant form of PD. *LRRK2* codes leucine-rich repeat kinase, a huge protein containing 2527 amino acids. The protein has several functional domains, but its role in PD is unknown. We sequenced exons 32 and 44 and flanking regions of *LRRK2* in the DNA of 60 unrelated Iranian PD patients. One variation was observed in exon 32 (c.C4624T causing P1542S) and another in intron 32 (IVS32+347). These variations are thought not to be associated with disease. We also found five variations in exon 44, four of which are intronic and have been previously reported. The fifth variation was G6523C, which was found in the heterozygous state in one patient and causes the substitution of aspartic acid 2175 by histidine (D2175H). This substitution occurs at the N-terminal of the WD40 domain of *LRRK2* which is thought to be a protein-protein interaction domain. The variation was not observed in 218 controls and in 110 additional patients as assessed by ARMS-PCR. Further analysis is needed to confirm the pathogenic effect of this mutation.

P05.156

Identification of two novel mutations in *LRRK2* among Iranian Parkinson's Disease patients

Z. Fazlali^{1,2}, S. Shojaei³, N. Farboodi¹, F. Ghazavi¹, G. Shahidi⁴, F. Sina⁴, B. Zaman⁵, H. Sadeghi⁶, K. Parsa⁵, E. Elahi^{1,6};

¹School of Biology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran, ²Iranian National Elite Foundation, Tehran, Islamic Republic of Iran, ³Department of Biotechnology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran, ⁴Iran University of Medical Sciences, Hazrat Rasool Hospital, Tehran, Islamic Republic of Iran, ⁵Neurosurgery, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran, ⁶Center of Excellence in Biomathematics, School of Mathematics, Statistics and Computer Science, College of Science, University of Tehran, Tehran, Islamic Republic of Iran.

Parkinson's Disease (PD) is one of the most common progressive neurodegenerative disorders. It is characterized by selective loss of nigrostriatal dopaminergic neurons. Five genes associated with PD have been identified by linkage analysis of affected families: *α-synuclein*, *parkin*, *DJ-1*, *PINK-1* and *LRRK2*. Mutations in the *Leucine-rich repeat kinase 2 (LRRK2)* gene have been most often observed in autosomal dominantly inherited PD, a form of the disease which has pathological features most closely resembling those seen in idiopathic forms of PD. Among the approximately 80 exonic variations so far observed in *LRRK2*, less than 10 are definitively thought to cause PD. In this study, we sequenced exons 36 and 37 of *LRRK2* in 60 PD Iranian PD patients. Two novel heterozygous variations, c.G5174A in exon 36 and c.C5467A in exon 37 were observed. Each variation was observed in only one patient. The first causes substitution of arginine by glutamine at position 1725 (R1725Q), and the second causes substitution of glutamine by lysine at position 1823 (Q1823K). Both affected residues are located in the COR (carboxy-terminal of Ras) domain, where at least one pathogenic mutation has been previously identified. To assess the presence of c.G5174A and c.C5467A in other PD patients and in controls, an ARMS-PCR assay was set up for each of the variations. Neither variation was observed among 230 healthy controls and 115 additional unrelated PD patients. Although these observations suggest that both variations may be disease associated mutations, this conclusion is presently not conclusive.

P05.157

A Yeast Two hybrid screen for *LRRK2*

S. Jain^{1,2}, E. Greggio², A. Kaganovich², P. Heutink¹, M. Cookson²;

¹CNCR, Amsterdam, The Netherlands, ²NIA, Bethesda, MD, United States.

Mutations in *Lrrk2* cause autosomal dominant Parkinson's Disease. *LRRK2* (DARDARIN) belongs to a newly identified family of proteins referred to as ROCO proteins that contain two conserved domains (i) a ROC (Ras in complex proteins) domain that and ii) a COR domain (C-terminal of ROC). In addition *LRRK2* also contains a WD40 and a leucine rich repeat domain, as well as a predicted tyrosine kinase catalytic domain. A yeast two hybrid was performed to help elucidate the function of *LRRK2*.

LRRK2 was found to interact with fasciculation and elongation factor zeta 2 (FEZ2), a mammalian orthologue of the *Caenorhabditis elegans* UNC-76 protein, which is involved in the axonal outgrowth and synaptic organization. FEZ2 is ubiquitously expressed in mammalian tissues with the majority of information about its function being inferred from studies of its homolog, FEZ1. FEZ1 appears to be involved in neurogenesis upon phosphorylation by PKC ζ . Knockout of UNC-76 from *C. elegans* leads to locomotion and axonal transport defects. Given the role of FEZ1 in axonal outgrowth and normal synaptic function, FEZ2 and *LRRK2* may co-operate in maintaining SN neuritic length and branching, and makes FEZ2 a good functional interactor for *LRRK2*. In support of this hypothesis, recent evidence has suggested that *LRRK2* plays a role in maintaining neuronal morphology in vitro and in vivo.

Effect of overexpression of PKD2 in a murine model

E. Ribe¹, S. Burtey¹, M. Riera¹, R. Rance¹, E. Passage¹, P. Pennekamp², B. Dworniczak², M. Fontés¹;

¹INSERM U491, Marseille, France, ²Institute for Human Genetics, Muenster, Germany.

Polycystin-2 (PC-2), a cation channel of the Trp family, is involved in autosomal dominant polycystic kidney disease (ADPKD) type 2 (AD-

PKD2). This protein has recently been localized to the primary cilium where its channel function seems to be involved in a mechanosensory phenomenon. However, its biological function is not totally understood, especially in tubule formation. We describe a mouse model for human PC-2 overexpression, obtained by inserting a human BAC containing the PKD2 gene. Three lines were generated, expressing different levels of PKD2. One line, PKD2-Y, has been explored in more details and we will present physiological and molecular exploration of this transgenic animals. Our data demonstrate that transgenic animals older than 12 months present tubulopathy with proteinuria and failure to concentrate urine. The kidney cortex has been found disorganized. Moreover, we observe that extracellular matrix protein expression is downregulated in these animals. Overexpression of human PKD2 leads to anomalies in tubular function, probably due to abnormalities in tubule organogenesis. Surprisingly, PKD2-Y FISH analysis showed that a significant number of metaphases presented with more than a single Y chromosome. Transgenic nucleus size is larger compared to non-transgenic cells suggesting problems during cell division. Likewise we show that fibroblasts from transgenic mouse present with mitotic instability. It remains to be determined what is the relationship between PC-2 and cell division.

P05.159

Gene expression in 2-3 somite stage WT and Pkd2 mutant mouse embryos

P. Pennekamp, M. Dahmer, G. Randau, N. Koo, B. Dworniczak; University Clinics Muenster, Muenster, Germany.

The development of an invariant left-right (LR) asymmetry of the visceral organs is a fundamental feature of vertebrate embryogenesis. Failure to establish the normal organ position (*situs solitus*) may result in a mirror-image reversal (*situs inversus*), in left or right isomerism or in heterotaxia (*situs ambiguus*). While the complete *situs inversus* does not have adverse impact on the organisms, heterotaxia frequently is accompanied by fatal malformations and complex cardiac and cardiovascular defects. Increasing evidence based on research on genetically modified animals including our *Pkd2* knockout mouse suggest, that the disturbance of proper LR axis development and thus misalignment of the developing heart tube is one of the major causes for the development of congenital heart disease (CHD) resulting in early prenatal death in most cases and it is very likely that the same mechanisms are responsible in large part for early abortions in the first trimester of pregnancy in humans.

To identify and to characterize novel genes and mechanisms which influence LR axis development in vertebrates and thus might be involved in the development of congenital cardiac defects we performed a gene expression analysis of right and left body halves of 2-3 somite stage male WT and *Pkd2* mutant mouse embryos using Affymetrix Gene Chips. We identified and validated by in situ hybridization (ISH) analyses several genes which are either already known or highly suggestive to influence LR axis development. Data obtained during this analysis will be presented.

P05.160

Genetic mechanisms involved in the pathogenesis of premature ovarian failure: study of *FMR1*, cryptic anomalies (especially small deletions) in the Xq27-Xqter region and other causative genes, in 122 women from the Basque Country.

M. I. Tejada¹, E. Beristain¹, C. Martinez-Bouzas¹, N. Puenta¹, N. Viguera¹, M. Artigas², M. A. Ramos-Arroyo², B. Prieto¹, S. González³, J. Peña⁴, R. Matorras^{1,3};

¹Hospital de Cruces, Barakaldo-Bizkaia, Spain, ²Hospital Virgen del Camino, Pamplona, Spain, ³IVI-Bilbao, Leioa-Bizkaia, Spain, ⁴Instituto Ginecológico Elcano, Bilbao, Spain.

Premature Ovarian Failure (POF) is characterized by secondary amenorrhea, elevated level gonadotropins and sex steroid deficiency in women less than 40 years old. It is well known that some of the Premutation (PM) carrier women of Fragile X Syndrome (FXS) develop POF. More recently, it has been identified a common region responsible for ovarian development -Xq27-Xqter-, where the *FMR1* gene lies and interestingly, so lie other X-linked genes for MR. Furthermore, there are other genes in the pathogenesis of POF, the results being that it is heritable in up to 30% of cases.

We studied all of these genetic mechanisms in peripheral blood sam-

ples of three groups of women: 42 known PM females from families of FXS, 25 with POF and 17 without; and 80 females with POF, and normal FMR1. The following genes were analysed: FMR1; BMP15; GDF9; INHA; NOBOX and FOXE1 polyaniline tract length. Two kits of MLPA for the X chromosome were also studied.

Our results revealed 3 new PM carrier women without history of MR (3/80=3.75%) which confirms that FMR1 gene is the first cause of POF. Furthermore, we found a microdeletion by MLPA (Xq28-Xqter) (1/80=1.25%) in a woman with POF and a family history of POF. In the group of previously known PM carrier women no differences were found except for the number of CGG repeats that is higher than 100 in the group without POF.

As a conclusion, our work demonstrates the need of performing genetic analysis in women with POF.

P05.161

Acute intermittent porphyria: impact of mutations in the porphobilinogen deaminase gene on the protein structure

D. Ulbrichova, J. Zeman, P. Martasek;

1st School of Medicine, Prague 2, Czech Republic.

Acute intermittent porphyria (AIP) is an autosomal dominantly inherited disorder, classified as acute hepatic porphyria. It is characterized by a deficiency of porphobilinogen deaminase (PBGD, EC 4.3.1.8), the third enzyme in heme biosynthesis. Expression of the disease is highly variable, determined in part by environmental, metabolic and hormonal factors. Clinical expression of AIP is associated with an acute neurologic syndrome, which includes both neuropsychiatric symptoms and neurodegenerative changes. Autonomic neuropathy may underlie severe abdominal pain, the most typical symptom of acute attack. Porphobilinogen deaminase is monomeric protein with a single catalytic active site and is organized in three domains approximately equal in size. Several crystallographic structures of PBGD from *E. coli* have been determined.

To establish the effects of newly found mutations on the protein structure of PBGD, we expressed mutant constructs with the described mutations in *E. coli*, and we analyzed their biochemical and enzymatic properties. All purified enzymes carrying causative mutations had relative activities dramatically decreased according to the average level expressed by the normal allele.

E. coli and human PBGD amino acid sequences have 35% homology and more than 70 % similarity, and considering this fact, it is possible to extrapolate structure/function relationships for human mutations leading to simple amino acid substitution based on comparative *E. coli*/human analyses. These analyses together with the kinetic studies of existing mutations can help predict the impact on the enzyme function in the living organism and further improve our understanding in this field. (Supported by Grants MSM0021620806, 1M6837805002, GAUK 257540 54007)

P05.162

Molecular characterization of Premature Ovarian Failure associated with FMR1 premutation

N. Locatelli¹, K. Camelin², B. Bodega¹, S. Bione³, D. Toniolo⁴, C. Santoro², E. Ginelli¹, A. Marozzi¹;

¹Dept. of Biology and Genetics for Medical Sciences - University of Milan, Milan, Italy, ²Dept. of Medical Sciences - University of Piemonte Orientale, Novara, Italy, ³Institute of Molecular Genetics-CNR, Pavia, Italy, ⁴Dibit-San Raffaele Scientific Institute, Milan, Italy.

Premature Ovarian Failure (POF) is defined as secondary hypergonadotropic (FSH ≥ 40 IU/l) amenorrhea occurring before the age of 40, and affects ~1% of females. Women who carry the FMR1 premutation are at an increased risk for ovarian insufficiency. To precisely define the range of FRAXA expansions and its incidence in POF manifestation 209 POF and 200 control women were sized for the CGG tract. We found a significant association (10%, $P < 1 \times 10^{-6}$) between POF and FRAXA premutation (range 60-163 repeats), and a significant enrichment (5,7%, $P = 0.006$) of POF carriers of intermediate expansions (range 41-58 repeats). The results obtained strengthen the correlation between FMR1 expansion and POF. The molecular pathogenesis this association is still unclear. As for FXTAS patients, a toxic RNA-mediated gain of function model for POF women carrying the FMR1 premuted allele was hypothesized. The POF condition might be a consequence of a toxic effect of FMR1 expanded mRNA

on ovarian target tissue (e.g. oocytes or granulosa cells), leading to increased atresia/apoptosis of follicles. To determine the possible interaction between premuted FMR1 RNA and ovarian proteins, gel shift assay were set up incubating the nuclear extracts of the granulosa cell line COV434 with premuted FMR1 RNA. A specific interaction between granulosa nuclear proteins and FMR1 premuted RNA were observed, suggesting that rCGG-repeated binding protein are present in granulosa cells. To identify and characterize rCGG-repeat-binding proteins, pull-down assays will be set up.

P05.163

Novel type of mutation in Pseudohypoparathyroidism type Ia

E. Fernández-Rebollo¹, R. Barrio², G. Pérez-Nanclares¹, A. Carcavilla², I. Garrin¹, L. Castaño¹, G. Pérez de Nanclares¹;

¹Endocrinology and Diabetes Research Group, Hospital de Cruces, Barakaldo, Spain, ²Pediatric Endocrinology, Hospital Ramón y Cajal, Madrid, Spain.

Individuals with AHO and resistance to PTH, TSH, and often, additional hormones are referred to as having PHP-Ia. These patients carry heterozygous inactivating mutations, including translation initiation mutations, amino acid substitutions, nonsense mutations, splice site mutations and small insertions or deletions, in one of the 13 *GNAS* exons encoding the α -subunit of the stimulatory G-protein (G_{α}). *GNAS* has been described as one of the most complex gene loci as several different transcript variants have been detected.

Objective: We sought to identify the molecular defect in a patient apparently suffering from PHP-Ia.

Methods and results: The *GNAS* gene of a 5-yr-old boy with brachydactyly, mental retardation, pseudohypoparathyroidism, and congenital hypothyroidism was investigated. Sequencing analysis of DNA extracted from peripheral blood revealed a heterozygous mutation in exon 2, consisting in an inversion of de novo origin and maternal inheritance, that was explained by the analysis of the SNP located in exon 5.

Molecular studies of cDNA prepared from blood RNA demonstrated that both the normal and the mutant variants were stable. The anomalous RNAs were generated by new splice-sites in intron 1, that produced a protein of only 59 aminoacids due to the creation of a premature stop codon in the processed intron 1.

Conclusion: This report demonstrates for the first time an inversion at the *GNAS* gene responsible of pseudohypoparathyroidism type Ia.

P05.164

Deficient inhibitors of calcification act as common final pathway in PXE and the PXE-like syndrome

O. M. Vanakker¹, L. Martin², L. J. Schurgers³, P. J. Coucke¹, C. Vermeer³, I. Pasquali-Ronchetti⁴, A. De Paep¹;

¹Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, ²Department of Dermatology, Angers University Hospital, Angers, France, ³Department of Biochemistry (VitaK), University of Maastricht, Maastricht, The Netherlands, ⁴Biomedical Sciences Department, University of Modena and Reggio Emilia, Modena, Italy.

Pseudoxanthoma elasticum (PXE) is an autosomal recessive disorder, characterized by oculocutaneous and cardiovascular manifestations, due to mineralization and fragmentation of elastic fibres. The causal *ABCC6* gene encodes a transmembrane transporter; however, the pathogenetic link with the elastic fiber abnormalities remains unknown.

We recently identified a novel PXE-like syndrome - resembling PXE -, associated with a vitamin K (VK)-dependent clotting factor deficiency. We identified causal mutations in *GGCX*, encoding a gamma-carboxylase. Together with phosphorylation by the Golgi casein kinase, carboxylation represents an important posttranslational modification necessary for activation of VK-dependent proteins, such as matrix gla protein (MGP) and osteocalcin (OC), known to be calcification inhibitors. Hence, this disorder provides novel possibilities to unravel the pathogenetic events causing PXE.

In PXE-like patients, immunohistochemistry on skin tissues and serum ELISA tests revealed increased levels of uncarboxylated (inactive) MGP and OC, as a result of the *GGCX* mutations. In PXE patients, similar results were obtained. An important difference in PXE patients was however an increase of the phosphorylated fraction of inactive MGP, whereas the phosphorylated/unphosphorylated MGP ratio in PXE-like samples was normal. This suggests that in PXE not only the carboxylase activity is downregulated but also an upregulation of the

Golgi casein kinase occurs.

We demonstrated that dysfunction of (VK-dependent) calcification inhibitors forms a common pathway in the PXE-like syndrome and PXE. Our findings suggest that ABCC6 dysfunction does not merely lead to decreased serum levels of its substrate but causes a chain of intracellular events involving carboxylation and phosphorylation of calcification inhibitors.

P05.165

Characterization of a novel mutation in the CTSK Gene in a family with PYCD

J. Toral-Lopez¹, L. M. Gonzalez-Huerta², S. A. Cuevas³;

¹Centro Medico ISSEMYM, Ecatepec, Mexico, ²Hospital General de Mexico, Mexico D.F., Mexico, ³Hospital General de Mexico, Fac Medicina, UNAM, Mexico D.F., Mexico.

Pycnodysostosis is an inborn error of metabolism due to the deficient activity of cathepsin K, a lysosomal cysteine protease from the papain family of proteases. The autosomal recessive disorder is consequence of the diminished capacity of osteoclasts to degrade organic bone matrix. Pycnodysostosis is clinically characterized by short stature, osteosclerosis, delayed cranial suture closure, hypoplastic mandible, acro-osteolysis, hypoplastic clavicle and dental anomalies. The spine may be affected with kyphosis, scoliosis or lumbar lordosis. Pathological fractures, nonunion of fractures and spondylolisthesis are frequent complications in pycnodysostosis. The gene of the pycnodysostosis (*CTSK*) has been mapped on the human chromosome 1q21. A few *CTSK* gene mutations have been identified in several non-related families with pycnodysostosis. In the present study, we analyzed the *CTSK* gene in three members of a family with pycnodysostosis and identified a novel missense mutation. The parents agreed to participate. Whole blood was obtained from each patient as well as from the parents and 100 normal controls. Genomic DNA was extracted from whole blood samples. All exons of the *CTSK* gene were amplified and sequenced from genomic DNA of the patients, parents and controls by PCR and DNA sequencing analysis. We found a novel mutation in the carboxyl extreme of the cathepsin K. This mutation, and previous data, show that affection of carboxyl-terminus of the enzyme is important in the genesis of pycnodysostosis phenotype.

P05.166

Copy Number Variations and Long-QT Syndrome

J. Barc¹, S. Schmitt^{1,2}, F. Briec¹, M. Le Cunff¹, C. Vieyres³, C. Le Caignec^{1,2}, F. Kyndt^{1,2}, H. Le Marec^{1,4}, V. Probst^{1,4}, J. Schott^{1,2};

¹INSERM U915, l'institut du thorax, Nantes, France, ²Laboratoire de génétique CHU, Nantes, France, ³Cabinet de cardiologie, Angoulême, France, ⁴Clinique cardiologique CHU, l'institut du thorax, Nantes, France.

Long-QT Syndrome (LQTS) is an inherited cardiac arrhythmia characterized by a prolonged QT interval on the surface ECG associated with syncope and sudden death caused by torsades de pointes polymorphic ventricular tachycardia. It is estimated to affect 1 in 5000 individuals. LQTS may be caused by mutations in 4 major genes encoding potassium channel pore forming (*KCNQ1*, *KCNH2*) and auxiliary (*KCNE1*, *KCNE2*) subunits and in the gene encoding the cardiac sodium channel *SCN5A*. Approximately 25% of patients diagnosed with LQTS have no mutation in one of five LQTS genes. Genetic testing detection failures due to large genomic rearrangements are one explanation. The purpose of this study was to determine the relative copy number in the 5 major LQTS genes in 100 mutation-negative LQTS probands. A MLPA approach was used and aberrant exon copy numbers were confirmed using Agilent 244K CGH array.

This study identified 2 large deletions in *KCNH2* gene in 2 probands with QTc intervals of 478 ms and 554 ms. The first patient carries an estimated 145 Kb deletion including *KCNH2*, and *ABP1* genes. The second deletion spanning 650 Kb includes *KCNH2* exon 4 to 15, *ABP1* and 18 additional genes. Familial investigations identified 3 additional affected individuals carrying the *KCNH2* deletion. Both deletions are expected to be non functional, decreasing I_{Kr} current in ventricular cardiomyocytes, suggesting haploinsufficiency as the most likely mechanism leading to LQTS.

The identification of 2% large deletions in LQTS genes strongly suggests screening for copy number variants in mutation negative LQTS probands.

Mitochondrial DNA mutations and recurrent miscarriage

M. Kaare¹, V. Ulander², R. Kaaja², K. Aittomäki^{1,3};

¹Folkhälsan Institute of Genetics, Helsinki, Finland, ²Department of Obstetrics and Gynecology, Helsinki University Central Hospital, Helsinki, Finland, ³Department of Clinical Genetics, Helsinki University Central Hospital, Helsinki, Finland.

The mitochondrias are involved in ATP production and apoptosis. These processes are important in early development and may be disturbed by mutations in mtDNA, thereby leading to spontaneous miscarriage. Phenotype causing mutations are usually heteroplasmic and cause a phenotype when the proportion of mutant mtDNA increases beyond a threshold. This proportion can shift at cell division/when inherited and therefore the phenotype often shows remarkable variation within a family. Accordingly, such a shift can occur from a mother with mild or no phenotype to an embryo with significant enrichment of mutated mtDNA causing fetal demise and possibly recurrent miscarriage (RM).

To study the role of mtDNA mutations in RM we screened 48 women with RM for mitochondrial mutations using dHPLC, a sensitive method which can detect ~5% heteroplasmy. So far, 10 different heteroplasmic variations have been detected. By screening placental samples available from 3 women with different variations we have been able to show that the variations have been inherited by the fetus, and are in some cases present in a higher proportion of mtDNAs in the fetus compared to the mother. So far, we have been able to determine the exact sequence change of three variations. Two changes are previously reported in the Mitomap database as normal variations. One variation is not reported in the database and is predicted to be a synonymous change in the mtND6 gene. Further studies are ongoing to define the remaining variations to determine if the variations may be the actual cause of miscarriages.

Validating the role of RET in the CNS: discovery of novel interactors

D. Fusco¹, M. Vargiolu¹, E. Bonora¹, L. F. Pennisi¹, R. Baumeister², G. Romeo¹;

¹U.O. Genetica Medica, Bologna, Italy, ²Bio3/Bioinformatics and Molecular Genetics, Albert-Ludwigs University of Freiburg, Freiburg, Germany.

RET encodes a tyrosine kinase receptor mainly expressed in neural crest derived and urogenital cells. Two major isoforms of RET are produced by alternative splicing: RET51 and RET9.

Mutations of RET protooncogene have been associated with both neoplasia (MEN2A, MEN2B and FMTC) and Hirschsprung disease.

The precise role of RET in the maturation of the peripheral nervous system, in kidney morphogenesis and in spermatogenesis has been established. RET is responsive to signals induced by neurotrophic factors of the GDNF-family ligands.

Recent studies have shown that RET binds the neurotrophin NGF. This suggests a functional role of RET in the Central Nervous System (CNS). Nonetheless, no signaling pathway involving RET is known in the CNS. Hence we developed a strategy aimed at identifying novel interactors that may help us to reconstruct the pathway connecting RET and NGF. To accomplish this task, we applied to RET51 the technique of the yeast two hybrid split ubiquitin system, that allows detection of interacting molecules belonging to the cytoplasm and the membrane. A first screening for RET 51 interactors has revealed 10 candidates. Among these we focused on a neurotrophic factor. Validation of the interaction was carried out through a co-immunoprecipitation assay in HEK293 cells. We either ascertained that this interaction occurs via a specific amino acid residue activated after binding of NGF.

On the basis of these preliminary results, we are currently testing the hypothesis that RET 51 might have a central role in the growth and the trophism of CNS cells.

P05.169

A high-resolution RNA expression atlas of Retinitis Pigmentosa genes in the human and mouse retinas

D. Trifunovic¹, M. Karali¹, D. Camposampiero², D. Ponzir², V. Marigo³, S.

Banfi¹;

¹TIGEM, Naples, Italy, ²Fondazione Banca degli Occhi del Veneto, Venice, Italy,

³Department of Biomedical Sciences, University of Modena and Reggio Emilia,

Modena, Italy.

Retinitis Pigmentosa (RP) is one of the leading causes of visual handicap in the world population and is characterized by high genetic heterogeneity. The study of the disease mechanisms and the development of efficient therapeutic approaches have mostly relied on the availability of animal models for this condition, so far. Nevertheless, little information is available about the RNA expression profiles of RP genes in the human retina. To overcome this lack of information, we generated an expression atlas of 34 known RP genes in human and murine retinas. The atlas can be freely accessed at <http://www.tigem.it/RPexp/>. The vast majority of the genes analyzed displayed similar patterns between human and mouse retina. We observed different expression patterns for the CNGB1, USH2A and FSCN2 genes with respect to previously reported profiles. Additionally, we detected different expression profiles for the RPGR, CA4, PAP1, RGR and RLBP1 genes in human and mouse retina. The differences observed in the expression patterns of some genes in human and mouse will open new perspectives on the function of these genes and on their putative roles in disease pathogenesis.

P05.170

Overexpression of CERKL, a Retinitis Pigmentosa gene, protects cells from apoptosis under oxidative stress conditions

A. Garanto^{1,2}, M. Tuson^{1,3}, R. González-Duarte^{1,2}, G. Marfany^{1,4};

¹Dept. de Genètica; Universitat de Barcelona, Barcelona, Spain, ²CIBERER. Instituto de Salud Carlos III, Barcelona, Spain, ³Sloan-Kettering Institute, New York, NY, United States, ⁴IBUB. Universitat de Barcelona, Barcelona, Spain.

Retinitis Pigmentosa (RP) is a highly heterogeneous genetic disease, where more than 30 causative genes have been already reported. RP is characterised by progressive retinal neurodegeneration due to photoreceptor apoptosis. Our group identified a previously unannotated gene, CERKL, as responsible for this disease in 3 different spanish families. CERKL encodes a presumptive lipid kinase that shares similarity to the human ceramide kinase. Ceramides are sphingolipids, a group of membrane lipids that have been increasingly involved in the regulation of relevant cellular and physiological processes, such as cell growth, differentiation, apoptosis and inflammation. Therefore, we hypothesised that CERKL would play a key role in controlling photoreceptor survival/death. Overexpression of the CERKL enzyme in transiently transfected cultured cells clearly protects cells from apoptosis under oxidative stress conditions. This protection starts as early as 4 hours, but becomes more prominent at 24 hours post-treatment, where apoptosis is reduced two-fold by CERKL expression. We are now actively searching for its retinal substrate. Our in vitro and in vivo preliminary results do not support that ceramide/s are the direct substrate for this enzyme. Subcellular localisation of CERKL shows that it is associated to membranes, such as endoplasmic reticulum, Golgi and Trans-Golgi vesicles, although it can also be found in the nucleus in some cells, pointing to shifts in localisation depending on the cellular state. Dissecting the function of CERKL will provide new clues on the sphingolipid role on photoreceptors and unveil new targets for therapeutical approaches.

Mutational analysis of RHO and RDS genes in patients with autosomal dominant form of retinitis pigmentosa from Volga-Ural region of Russia

E. R. Grinberg¹, L. U. Dzhekmileva¹, I. S. Zaidullin², E. K. Khusnutdinova¹;

¹Institute of biochemistry and genetics, Ufa, Russian Federation, ²Research Institute of Eye Diseases, Ufa, Russian Federation.

Purpose: To identify mutations in the RHO and RDS genes in patients with autosomal dominant form of retinitis pigmentosa (adRP) from Volga-Ural region of Russian Federation. Retinitis pigmentosa, the most common hereditary cause of blindness, comprises a clinically and genetically heterogeneous group of retinal disorders. It affects about one in 5 000 individuals worldwide

Methods: 37 patients with adRP confirmed by pedigrees were examined clinically and with visual function tests. The 5 exons of RHO and 3 exons of RDS genes were analyzed for sequence changes by single-strand conformation polymorphism analysis (SSCP) and further sequencing.

Results: We detected known mutation Pro347Leu, novel mutation Arg-252Pro and two polymorphisms IVS1+10g>a, IVS3+4c>t in RHO gene.

There were statistically significant differences in allele and genotype frequencies of sequence change IVS3+4c>t of RHO gene in affected patients with adRP and in controls. According to our data, this polymorphism might be pathogenic. Recently were reported 16 possible combinations of the exon 3 RDS gene four SNPs and detected four from 16 possible combinations (minihaplotypes): G¹¹⁴⁷A¹¹⁶⁶G¹²⁵⁰C¹²⁹¹ (I), C¹¹⁴⁷A¹¹⁶⁶A¹²⁵⁰C¹²⁹¹ (II), C¹¹⁴⁷G¹¹⁶⁶A¹²⁵⁰C¹²⁹¹ (III) and G¹¹⁴⁷A¹¹⁶⁶G¹²⁵⁰T¹²⁹¹ (IV). Sequencing results for variant positions in exon 3 RDS gene in adRP patients from Volga-Ural region revealed all four minihaplotypes described above and minihaplotype C¹¹⁴⁷A¹¹⁶⁶A¹²⁵⁰T¹²⁹¹ (V). Minihaplotype C¹¹⁴⁷A¹¹⁶⁶A¹²⁵⁰C¹²⁹¹ (II) was revealed only in patients and it might be linked with RP.

Conclusions: To optimize the DNA diagnostics of retinitis pigmentosa, it is necessary to analyze patients from various ethnic groups. Our study helps in molecular characterization of RP in Russia.

P05.172

Knock-down of Cox5a in HEK293 cells

D. Formuskova, L. Stiburek, J. Zeman;

Faculty of Medicine, Prague 2, Czech Republic.

Cox5a is one of 13 structural subunits of cytochrome c oxidase (COX), the terminal enzyme of respiratory chain. We used RNA interference (RNAi) to down-regulate steady-state level of Cox5a subunit and analyzed impact of its knock-down on COX assembly.

We constructed seven derivatives of pCMV-GIN-ZEO plasmid coding for hairpins aimed at different positions of COX5A mRNA. A Cox5a protein has a long half-life (a level of the protein is 48 hours post-nucleofection unchanged using immunoblotting). Therefore we introduced COX5A coding sequence into the maxFP-Red - N plasmid to encode fusion protein. The marker plasmid was co-transfected with RNAi-mediating plasmid derivatives (the higher the level of fusion protein the higher the leakage of individual hairpin-mediated RISC systems). A fluorescence of fusion protein was found rapidly lower compared to maxFPRed marker thereby complicating a setting of FACS measurements, but Western Blot of fusion protein with COX5A antibody gave an acceptable result. To optimize the detection of RNAi-potential through fluorescence by FACS, we re-cloned COX5A coding sequence into 3' UTR of maxFPRed marker. The final transcript contains target sequence for RNAi but leads to translation of merely maxFPRed marker. Fluorescence intensities were comparable with that obtained at empty plasmid.

Based on the above-mentioned methods, we chose three candidate shRNAs and prepared stable cell lines, where depletion of Cox5a was confirmed using SDS immunoblotting. Also specific activity of COX was revealed decreased. BN-PAGE showed diminished level of COX holoenzyme and its assembly intermediates.

Supported by GACR 305/08/H037 and GAUK 1/2006/R.

P05.173

The challenges encountered in diagnostic screening of the RYR1 gene

S. M. Lillis¹, T. Lepre¹, H. Zhou², F. Munton², H. Jungbluth¹, S. Abbs¹;

¹Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom, ²Neuromuscular Unit, Hammersmith Hospital, London, United Kingdom.

Mutations in the skeletal muscle ryanodine receptor gene (*RYR1*) are implicated in a number of congenital myopathy phenotypes including central core disease, multi-minicore disease and centronuclear myopathy.

We have developed a high throughput 384-well sequencing approach for screening the 106 exons of *RYR1*. This method uses tagged primers and robotics to overcome the practical challenges faced by screening such a large gene. To date we have tested over 44 patients and here we report on the complexities which have arisen.

Certain *RYR1* related disorders may exhibit both autosomal dominant and recessive modes of inheritance; it is not always certain whether we are searching for one or two mutations. The identification of missense changes of unknown pathological significance complicates this.

Our mutation screening is further complicated due to the marked phenotypic variability: mutations in *RYR1* can manifest in a wide range of clinical phenotypes whilst similar phenotypes may result from mutations in a number of different genes excluding *RYR1*. Additionally there are reports of *RYR1* mutations that only exhibit symptoms on a mono-allelic background.

One particularly interesting case involves a patient with a clinical diagnosis of autosomal recessive multi-minicore disease in whom we found three RYR1 mutations - two missense mutations previously reported as pathogenic and one previously unreported three base pair deletion.

In addition to causing congenital myopathy, mutations in certain regions of the RYR1 gene are also associated with malignant hyperthermia susceptibility (MHS) and it is important that the implications of this are clearly explained to other family members.

P05.174

Role of ATTCT repeat interruptions in spinocerebellar ataxia type 10

I. Alonso¹, T. Almeida¹, L. B. Jardim², O. Artigalas², M. L. Saraiva-Pereira², T. Matsuura³, J. Sequeiros⁴, I. Silveira¹;

¹UniGENe - IBMC, Univ. Porto, Porto, Portugal, ²Hosp. Clinicas de Porto Alegre, Porto Alegre, Brazil, ³Center for Neurological Diseases and Cancer, Nagoya University Graduate School of Medicine, Nagoya, Japan, ⁴ICBAS, Univ. Porto, Porto, Portugal.

Spinocerebellar ataxia type 10 (SCA10) is a dominant neurological disease, caused by the expansion of an (ATTCT)_n in intron 9 of *ATXN10*, of still unknown function. SCA10 was first described in Mexican families with ataxia and seizures. We have previously described an expansion of the ATTCT repeat in two Brazilian families presenting ataxia without seizures. We found reduced penetrance alleles of 360-370 repeats, in elderly asymptomatic subjects.

To investigate a previous hypothesis of interruptions in the (ATTCT)_n tract, functioning as a disease modifier, we assessed the interruption in another family with ataxia and seizures, and more than 2000 ATTCT units.

By a modified PCR technique, an abnormal discontinuous ladder, exceeding the range observed for normal alleles, was detected in this Brazilian family, presenting progressive cerebellar ataxia with associated seizures and onset during or after the 3rd decade. This suggested the presence of interruptions within the ATTCT expansion. Modified PCR products of patients showing an interrupted pattern were agarose-gel purified and cloned with TOPO TA cloning kit for sequencing analysis and determination of the interrupted motif.

In this family, the ATTCT repeat seems to be interrupted by a large stretch, unrelated to the repeat sequence, and patients show progressive cerebellar ataxia with associated seizures. In contrast, the previous SCA10 families identified by us, showed cerebellar ataxia without seizures, caused by the expansion of uninterrupted ATTCT tracts. This newly identified family reinforces the hypothesis that interruptions in the (ATTCT)_n tract function as a disease modifier.

P05.175

Ribosomal frameshifting on expanded *ATXN3* transcripts: a *Drosophila* model

C. Gaspar¹, S. Stochmanski¹, J. Laganière¹, M. Therrien¹, D. Rochefort¹, D. Van MeyeF, G. A. Rouleau¹;

¹Centre of Excellence in Neuroomics, Université de Montréal, Montreal, QC, Canada, ²Centre for Research in Neuroscience, McGill University, Montreal, QC, Canada.

Background: Spinocerebellar ataxia type 3 (SCA3) is caused by the expansion of a coding CAG repeat in the *ATXN3* gene. We have previously shown that the expanded CAG repeat in SCA3 is prone to -1 ribosomal frameshifting, leading to the production and aggregation of proteins containing polyalanine stretches. These frameshifted molecules confer increased toxicity to cells when compared to constructs containing expanded CAA repeats, which code for polyglutamine in the main frame but lack the ability to frameshift into an alanine frame. Anisomycin (a ribosome interacting antibiotic that reduces -1 frameshifting) decreases frameshifting in expanded CAG tracts and ameliorates the cellular toxic phenotype.

Aims: To model expCAG repeat -1 frameshifting *in vivo*; to assess the contribution of -1 frameshifting to expCAG toxicity in the fly.

Methods: Full-length *ATXN3* *Drosophila* transgenic lines carrying either wtCAG, expCAG or expCAA constructs containing epitope tags in the three possible reading frames were generated and comparatively analysed.

Results: We show that: (1) transgenic expression of expCAG *ATXN3* constructs is deleterious in the fly; (2) transgenic expression of exp-

CAA *ATXN3* constructs, despite adequate levels of protein expression, is not toxic; (3) -1 frameshifting occurs in *Drosophila* and is restricted to the expanded CAG transgenic lines.

Conclusions: We propose that -1 ribosomal frameshifting is a major contributor to the toxicity observed in expanded CAG repeat diseases. This novel pathological mechanism may open new therapeutic opportunities for these diseases.

Mutation analysis of the *SCN1A* gene and genotype-phenotype correlations in Bulgarian epilepsy patients

I. Yordanova^{1,2}, L. Claes³, I. Ivanov⁴, A. Suls³, I. Litvinenko⁵, P. Dimova⁶, D. Hristova⁶, V. Bozinova⁶, I. Kremensky^{1,2}, P. De Jonghe³, A. Jordanova^{2,3};

¹National Genetics Laboratory, Sofia, Bulgaria, ²Molecular Medicine Center, Medical University, Sofia, Bulgaria, ³VIB Department of Molecular Genetics, University of Antwerp, Antwerpen, Belgium, ⁴Department of Pediatrics, Medical University, Plovdiv, Bulgaria, ⁵Department of Pediatrics, Medical University, Sofia, Bulgaria, ⁶Department of Neurology, Medical University, Sofia, Bulgaria.

Epilepsy is a common neurological disease, affecting more than 1% of people from any age, gender and ethnical origin. Mutations in the alpha1-subunit ($\alpha 1$) of the neuronal voltage gated sodium channel Na_v1.1, are associated with generalized epilepsy with febrile seizures plus (GEFS+) and severe myoclonic epilepsy in infancy (SMEI). It is encoded by 26 exons of the *SCN1A* gene on chromosome 2q24.

We performed a mutation analysis of *SCN1A* in 28 patients with GEFS+, 20 with SMEI and 62 with other types of infantile epilepsy. Genomic DNA was extracted from peripheral blood lymphocytes using a standard sodium chloride precipitation method. The *SCN1A* point mutation screening included PCR analysis followed by direct sequencing of all exons and exon-intron boundaries of the gene. In addition, all patients were analyzed for exonic deletions and duplications by MAQ assay.

We identified 11 disease-causing mutations, including 6 missense, 2 nonsense, 1 splice-site mutation and 2 single base deletions. Two missense and all truncating mutations were found in SMEI patients, consistent with the severity of the epilepsy phenotype. Four GEFS+ patients carried a missense mutation. All mutations we identified had not been reported in the literature. This is the first large scale study of *SCN1A* gene analysis in Bulgarian epilepsy patients.

In our sample, a mutation was identified in 23% of patients with GEFS+ or SMEI, and none in the other epilepsy patients. This nicely illustrates that GEFS+ and SMEI are part of a continuous spectrum of fever associated epilepsy phenotypes caused by mutations in *SCN1A*.

P05.177

KPQ del in *SCN5a* gene in two different types of SCD in one family

S. Saber¹, K. Banihashemi¹, M. Eftekharzadeh², M. Khosroheidari¹, m. a. SadrAmeli³, A. F. Fazelifar³, M. Haghjoo³, m. Houshmand⁴, E. V. Zaklyazminkaya⁵;

¹Special medical center genetic lab ward, Russian Academy of Science DNA lab, Tehran, Islamic Republic of Iran, ²Tehran clinic arrhythmia center, Tehran, Islamic Republic of Iran, ³Heart center shahid Rajaei hospital electrophysiology ward, Tehran, Islamic Republic of Iran, ⁴Special medical center genetic lab ward, Tehran, Islamic Republic of Iran, ⁵Russian Academy of Science DNA lab, Moscow, Russian Federation.

Cardiac action potentials are generated and propagated through the coordinated activity of multiple ion channels, including voltage-gated sodium channels, calcium channels and potassium channels. Mutations in genes encoding these channels cause familial arrhythmias. Heart rhythm disturbances constitute some inherited syndromes any kind of genetic nature

Many kinds of arrhythmia caused SCD (sudden cardiac death) and the prevalence of SCD is 1: 1000 individuals. Some of SCDs were caused by Na channelopathy such as LQT3 and Brugada Syn these are two of main caused of sudden cardiac death in young people with out any detectable cardiac abnormality with routine tests and we know that Brugada syndrome was caused by loss of function of Na channel and LQT3 was caused by gain of function Na channel in heart.. We can check *SCN5a* gene for ruling out of this gene as a main gene of Na channelopathy in heart arrhythmias. We check by SSCP and Sequencing this gene. We checked *SCN5A* in a family with 11 affected person that approved by ECG and EPS study and some persons

had Brugada Syn and some had LQT3 .we checked SCN5a and we can find KPQ del 1505-1507 in all patients.As you know this del was caused only LQT3.so it was very interesting that we can find this del in Brugada syndrome. So we are working in other hypothesis for solving this situation

P05.178

Seckel-syndrome like phenotype associated with a 550 kb microdeletion of the long arm of chromosome 5 characterized by array comparative genome hybridization (aCGH)

P. M. Kroisel¹, A. C. Obenaus¹, B. Plecko², K. Wagner³, M. R. Speicher¹, T. Schwarzbraun¹;

¹Institute of Human Genetics, Graz, Austria, ²Department of Pediatrics, Graz, Austria.

Primordial dwarfism and Seckel-syndrome are rare genetically heterogeneous disorders. Several subtypes of these severe growth retardation syndromes have been described mainly based on clinical features, growth characteristics, presence or absence of particular skeletal anomalies and further criteria. During the last years a remarkable progress in identification of genes involved was achieved. Seckel-syndrome and primordial dwarfism can be genetically caused following an autosomal recessive mode of inheritance. Genes involved in cell division, cell cycle control pathways or related to DNA repair have recently been identified and characterized to be responsible for some forms of these disorders when a homozygous loss of function mutation is present. Here we report on a 3 ½ year old male patient resembling phenotype features of Seckel-syndrome associated with a 550 kb microdeletion 5q33 detected by high resolution aCGH. The patient is the fifth child of young healthy non-consanguineous parents. Birth weight was 800 g, length 37 cm. No precise information about gestational week at birth was available. Weight at 3 ½ years is 4.450 g, length 62.4 cm and head circumference 39.8 cm. He shows a beaked nose, low set ears, micro- and retrognathia, transverse palmar creases, fifth finger clinodactyly, general hirsutism and darker skin pigmentation than relatives. Psychomotor development is good, however he is unable to speak because he has a tracheostoma since more than two years. Investigation of those less than 20 genes deleted and the molecular rearrangement could allow identifying a gene responsible for a variant form of primordial dwarfism or Seckel syndrome.

P05.179

Severe Combined Immunodeficiency (SCID) caused by R235Q homozygous mutation in adenosine deaminase (ADA) gene

F. Mora, J. F. Rodríguez-Gutiérrez, M. Bernal, J. A. Brieva, A. Nieto, A. Samalo;

Hospital Puerta del Mar, Cádiz, Spain.

Inherited deficiency of ADA accounts for approximately 17% of SCID and 50% of autosomal recessive SCID.

Patient: a two months old boy from Morocco with a suspicion of SCID (severe infections, diarrhea, failure to thrive, profound lymphopenia). Parents were consanguineous (first cousins). Erythrocyte ADA enzyme activity was assayed: ADA activity in patient was nearly undetectable while in his parents it was about 50% of a control. In his healthy brother activity was normal.

Molecular diagnosis: nearly 70 different mutations have been described in ADA gene causing SCID; half of them are "private". Most patients are heteroallelic and homozygosity is mostly restricted to consanguineous families.

Mutational analysis of ADA gene was performed. We designed primers for PCR amplification of the 12 exons comprising the gene. PCR products were purified and sequenced with the amplification primers using BigDye Terminator Cycle Sequencing kit in an ABI 310 Genetic Analyzer.

Results: The patient was homozygous for R235Q (704G>A) missense mutation in exon 8. Both parents were heterozygous for this mutation. His healthy brother was also heterozygous, in spite of his normal ADA activity. It is the first time that R235Q mutation is detected in homozygosity in a SCID patient, and the first time this mutation is detected outside of Japan.

Patient was also homozygous for D8N (22G>A) polymorphism in exon 1; parents and brother were carriers. This polymorphism is not related to SCID but it causes decreased enzyme activity and can contribute to the low level of ADA activity in the patient.

P05.180

Mutations in SHOX2 do not appear to be involved in Léri-Weill dyschondrosteosis (LWD) and idiopathic short stature (ISS)

M. Aza-Carmona¹, D. Gorbenko del Blanco¹, S. Benito-Sanz¹, P. Lapunzina^{2,3}, J. Argente^{1,4}, K. E. Heath¹;

¹Hospital Infantil Universitario Niño Jesús, Universidad Autónoma de Madrid, Madrid, Spain, ²Hospital Universitario La Paz, Universidad Autónoma de Madrid, Madrid, Spain, ³CIBERER Instituto de Salud Carlos III, Madrid, Spain, ⁴CIBER (CB06/03) Instituto de Salud Carlos III, Madrid, Spain.

SHOX encodes a transcription factor involved in determining stature in humans. Mutations/deletions of SHOX and a downstream region result in Léri-Weill dyschondrosteosis (LWD), Langer mesomelic dysplasia and idiopathic short stature (ISS). However, no molecular defect has been detected in a variable proportion of LWD/ISS cases. SHOX has a human homolog, SHOX2, located on chromosome 3q25.32, which function is unknown. The Shox2^{-/-} mouse presents a cleft palate phenotype with shortened limbs, suggesting that SHOX2 may participate in limb development.

In order to investigate if SHOX2 is implicated in LWD/ISS, we have analyzed 35 LWD/ISS families and 89 ISS individuals, without a known molecular defect. SHOX2 mutation screening was performed by dH-PLC and DNA sequencing of the exons and intron/exon boundaries. Large deletions were analyzed in the familial cases using previously described (D3S3692) and novel microsatellites (D3S4638, D3S4639 and D3S4640) flanking SHOX2.

Two variants were identified in exon 1 of SHOX2 in two familial cases: a missense mutation E21K and a duplication of three glycines Gly77-Gly78dup (c.232_233dupGAGGAGGTG). We subsequently screened exon 1 in 50 healthy individuals. The E21K mutation was not observed in controls but it did not cosegregate with the short stature phenotype. Insertions and deletions of the glycine repeat in SHOX have been described in patients with LWD/ISS but the insertion in the glycine repeat of SHOX2 appears to be polymorphic as we observed duplications of this region in three normal controls.

These results suggest that SHOX2 is not the molecular cause of the LWD/ISS in the cases studied.

P05.181

Pathways of SOD1 and TAU-induced motor neuron degeneration

L. C. Kudo, L. Parfenova, J. Pomakian, H. V. Vinters, M. Wiedau-Pazos, S.

Karsten;

David Geffen School of Medicine at UCLA, Los Angeles, CA, United States.

Amyotrophic Lateral Sclerosis (ALS) is a devastating neurodegenerative disease that selectively affects motor neurons. To identify early molecular triggers of selective motor neuron degeneration, we applied microarray technology to investigate gene expression profiles of motor neurons and glia isolated with laser capture microdissection from two distinct transgenic mouse models of ALS: SOD1-G93A and TAU-P301L. The analysis was performed prior to the development of neurodegeneration reducing the number of false positives due to the possible reactive changes in the course of the disease. The majority of identified genes are model specific, indicating that TAU and SOD1 induced neurodegeneration have distinct molecular pathways and therefore, may require specific treatments. Several genes were consistently altered in the motor neurons of both models. One of them, Dynein, points to the early dysfunction of retrograde axonal transport. To investigate the relevance of microarray identified gene expression changes for human sporadic disease, immunohistochemical experiments were carried out using a specific ALS tissue microarray (TMA) consisting of ALS, FTD and control human postmortem CNS tissues.

P05.182

Alu-related 5q35 microdeletions in Sotos syndrome

N. Matsumoto¹, J. Mochizuki^{1,2};

¹Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan, ²Department of Obstetrics and Gynecology, Kitasato University School of Medicine, Sagami-hara, Japan.

Haploinsufficiency of the NSD1 gene due to 5q35 microdeletions or intragenic mutations causes Sotos syndrome (SoS). In 46 of the 49 Japanese deletion-cases, common deletion breakpoints were located at two flanking low copy repeats (LCRs), implying that non-allelic homologous recombination (NAHR) between LCRs is the major mechanism for the common deletion. In the remaining three cases of atypical

deletions, the mechanism(s) of deletions remains unanswered. We characterized the atypical microdeletions using fluorescence in situ hybridization (FISH), quantitative real-time PCR (qPCR), and Southern blot hybridization. All the deletion breakpoints in the three cases were successfully determined at the nucleotide level. Two deletions are 1.07 Mb (SoS19) and 1.23 Mb (SoS109) in size, and another consisted of two deletions with sizes of 28 kb and 0.72 Mb, intervened by an intact 29-kb segment (SoS44). All deletions were smaller than a typical 1.9-Mb common deletion. *Alu* elements were identified in both deletion breakpoints in SoS19, one of deletion breakpoints in SoS109, and both deletion breakpoints of the proximal deletion in SoS44. *Alu*-mediated NAHR is strongly suggested at least in two of atypical deletions. Finally, qPCR is a very useful method to determine deletion breakpoints even in repeat-related regions.

Introduction. Sotos syndrome (SS) is a rare genetic condition characterized by overgrowth, macrocephaly, large forehead, large hands and feet, accelerated bone age, typical gestalt, mental retardation of variable degree and a slight predisposition to develop tumours. This condition is due to an abnormality of the *NSD1* gene caused by deletions or spontaneous mutations.

Material and methods. From November 2003 to November 2007, we evaluated 215 patients with presumed diagnosis of SS, referred to the Spanish Overgrowth Syndrome Registry. The patients were evaluated in their local hospitals and referred by geneticists, paediatricians, neurologists and other health professionals. An initial study by microsatellite genotyping, a MLPA specific for the *NSD1* critical region and neighbouring genes and analysis of the coding regions of *NSD1* by dHPLC and/or bi-directional direct sequencing were made in all of them.

Results. We completed all the studies in 186 out of the 215 patients referred. One hundred and twelve presented complete clinical data or a clear phenotype of SS, evaluated by 2 clinical geneticists trained in SS patients. We found 76 genetic alterations, 17 of them *NSD1* deletions and 59 point mutations; a detection rate of about 68%. Some of these mutations are novel and others are recurrent.

Comments. The detection rate of mutations in patients with clear clinical-neurobehavioural phenotype of SS is nearly 70%. Our figures are similar to that reported in other series. The finding of several recurrent mutations suggests that there are "hot spots" in *NSD1*, meaning common molecular mechanisms responsible for the disease.

Hereditary spastic paraplegias (HSPs) are genetically and phenotypically heterogeneous disorders with various clinical profiles and modes of transmissions. The *SPG15* locus was first reported to account for a rare form of complicated autosomal recessive spastic paraplegia variably associated with mental impairment, pigmented maculopathy, dysarthria, cerebellar signs, distal amyotrophy and thinning of the *corpus callosum*, sometimes designated Kjellin syndrome. Here, we report the refinement of the *SPG15* locus to less than 3 Mb on chromosome

14q23-q24 and the identification of 6 different truncating mutations that were found to segregate with the disease in 8 families with a phenotype that included, variably, some of the clinical features of Kjellin syndrome. The *SPG15* mRNA was widely distributed in human tissues and in rat embryos as well. In adult rodent brain, its expression profile closely resembled that of *SPG11*, another gene responsible for complicated HSP. The identification of the *SPG15* gene is a starting point for the elucidation of the mechanisms underlying axonal degeneration in this complicated form of HSP.

Sebastiao, Santa Maria da Feira, Portugal.

Hereditary spastic paraplegias (HSP) are neurodegenerative disorders mainly characterized by lower limb spasticity associated, in complicated forms, with additional neurological signs. Recently, we identified the *SPG11*, as the responsible gene for a complex autosomal recessive (AR) HSP. We have analyzed 76 index ARHSP patients for mutations in the *SPG11* gene. We found 22 mutations segregating in 13 (30%) families and 7 (21%) isolated cases. Two mutations were recurrent suggesting founder effects. Nineteen mutations were novel. The highest frequency of patients with *SPG11* mutations (41%) was found in HSP patients presenting with a thin *corpus callosum* (TCC); however, these mutations were rare in patients with mental impairment without TCC (4.5%). Disease onset occurred during the first to the third decade mainly by problems with gait and/or mental retardation. Overall, the phenotype of the 38 examined *SPG11* patients was severe. After a mean disease duration of 14.9 ± 6.6 years (range: 2-35), 53% of patients used a wheelchair or were bedridden. At the time of examination, in addition to mental retardation, 80% of the patients showed cognitive decline with executive dysfunction. The phenotype also frequently included lower motor neuron degeneration (81%) with wasting (53%). Slight ocular cerebellar signs were also noted in patients with long disease durations. In addition to TCC (95%), brain MRI revealed white matter alterations (69%) and cortical atrophy (81%), which worsened with disease duration. Our study reveals the high frequency of *SPG11* mutations in patients with HSP associating TCC and cognitive impairment and also extends the associated phenotype.

P05.186

SPG4 mutations and phenotype of hereditary spastic paraplegia in Estonia

R. Tamm^{1,2}, M. Braschinsky³, E. Raukas^{2,4}, S. Lüüs³, K. Gross-Pajuf⁵, C. Boillot⁶, F. Canzian⁷, A. Metspalu^{4,8}, S. Haldre⁹;

¹IMCB, University of Tartu, Tartu, Estonia, ²Department of Genetics, United Laboratories, Tartu University Clinics, Tartu, Estonia, ³Neurological department, Tartu University Clinics, Tartu, Estonia, ⁴Estonian Biocenter, Tartu, Estonia, ⁵Neurological department, West Tallinn Central Hospital, Tallinn, Estonia, ⁶International Agency for Research on Cancer, Lyon, France, ⁷German Cancer Research Center (DKFZ), Heidelberg, Germany, ⁸University of Tartu, Tartu, Estonia.

Hereditary spastic paraplegia (HSP) is a clinically and genetically heterogeneous disorder, which is classified clinically into "pure" (pHSP) and "complex" (cHSP) forms. Great inter- and intrafamilial variations are very typical. Autosomal dominant hereditary spastic paraplegia (AD-HSP) is the most common form due to the mutations in the spastin gene (*SPG4*). The aim of this study was to describe phenotype

and to detect new sequence variants within SPG4 gene in 51 HSP patients in Estonia. Fifty healthy individuals were used as controls. The majority of patients had pHSP and only five patients had cHSP form of the disease. cHSP was the most frequent in sporadic cases. All 51 samples were screened with DHPLC and abnormal elution profiles were sequenced. Nine changes (G609A, A810G, 1299-1g>c, 1310delA, 1370+215g>c, 1370+202delG, C1503A, 1477-1481del-GAGAA, 1966insA) in SPG4 gene were detected showing no gender predisposition. Seven were new and only found in 11 HSP patients, but two (one new - 1370+215g>c and other previously described - 1370+202delG) were detected both in patients and controls. Only two mutations (1299-1g>c, C1503A) showed familial segregation, in which three and two family members were affected, respectively. Other mutations were found in individuals from different families. In conclusion we associate above-mentioned seven new mutations with 11 AD-HSP cases, since new sequence variants were found only in patients compared to healthy controls. The rest of the patients must be checked for other changes (larger INDELs) in SPG4 and other genes involved in this disease should be considered for further analysis.

P05.187

In depth investigation of -1 frameshifting in expanded CAG repeat tracts using time-lapse live cell imaging

S. J. Stochmanski¹, C. Gaspar¹, D. Rochefort¹, J. Laganier¹, P. Hince¹, G. Di Cristo², G. A. Rouleau¹;

¹Centre of Excellence in Neuromics, CHUM Research Centre, Montréal, QC, Canada, ²Centre de Recherche, Hôpital Ste-Justine, Montréal, QC, Canada. Spinocerebellar ataxia type 3 (SCA3) results from an expansion of a polyglutamine-encoding CAG tract in the *ATXN3* gene. We have previously demonstrated that this expanded CAG tract is subject to -1 ribosomal frameshifting into the alanine frame, which seems to confer an increased toxicity, and that the antibiotic anisomycin reduces both -1 frameshifting and cell toxicity. Currently, dual-tagged *ATXN3* reporter constructs were created to express DsRED in the main (glutamine) frame and EGFP in the -1 (alanine) reading frame, and these reporter constructs contained either 14 CAG repeats, 89 CAG repeats, or 92 CAA repeats. Constructs were transfected into COS-1 cells as well as mouse cortical organotypic slice culture preparations, and were monitored for the production of red or green fluorescence signals using time-lapse live-cell two-wave fluorescent microscopy. Employing this technique, we have confirmed the occurrence of -1 frameshifting for the CAG89 construct, whereas the constructs bearing wild-type CAG or expanded CAA repeats did not show significant frameshifting. We also determined that there is a marked time delay between the onset of glutamine-containing protein expression and the production of frameshifted species, as well as a correlation between frameshifting and cell death. These findings argue in favour of local glutamine codon starvation, followed by a shift in the reading frame to resume translation of the protein in the alanine frame and seem to confirm the implication of -1 ribosomal frameshifting in the pathogenesis of SCA3.

P05.188

Quantitative analysis of *SMN1* gene based on real-time PCR

M. Šimáková¹, H. Poláková², L. Kádaš^{1,2};

¹Comenius University, Faculty of Natural Sciences, Department of Molecular Biology, Bratislava, Slovakia, ²Institute of Molecular Physiology and genetics Slovak Academy of Science, Bratislava, Slovakia. Spinal muscular atrophy (SMA) is an autosomal recessive disorder, caused by the homozygous absence of the survival motor neuron gene (*SMN1*) in approximately 94% of patients. Since most carriers have only one *SMN1* gene copy, several quantitative analyses have been used for the SMA carrier detection. We performed a *SMN1* quantitative real-time PCR analysis using an allele specific primer for the carrier detection of SMA. We compared the sensitivity, specificity, advantages and disadvantages recently described in the quantitative method, using TaqMan probes and a newly developed Plexor™ technology, which had not previously been used for identifying heterozygotes. Using a comparative threshold cycle ($C_{t,c}$) method and the DNA fragment of human beta globine gene as a reference gene, the gene copy number of *SMN1* was quantified. The sensitivity and specificity of the TaqMan and Plexor™ technologies were similar; moreover, the assay efficiency was almost ideal when using the Plexor™ technology. The incidence of SMA (1:6000-10000) and the notable carrier

frequency (1:35-50) as well as the severity of disease, and the lack of effective treatment may justify the implementation of such analysis in DNA diagnostic laboratories.

Molecular Genetics and Epidemiology in Spanish Spinocerebellar Ataxia

H. San Nicolás¹, J. Corral¹, I. Banchs¹, L. De Jorge¹, O. Combarros², J. Berciano², C. Serrano³, M. Calopa⁴, A. Matilla⁵, D. Genís⁶, V. Volpini¹;

¹Center for Molecular Genetic Diagnosis of Hereditary Diseases (CDGM)- IDI-BELL, Hospitalet de Llobregat, Spain, ²Dep of Neurology. Hosp Univ Marqués de Valdecilla, Santander, Spain, ³Dep of Neurology. Hosp Sant Joan de Deu, Martorell, Spain, ⁴Dep of Neurology. Hosp Univ De Bellvitge. IDIBELL, Hospitalet de Llobregat, Spain, ⁵Health Sciences Research Institute Germans Trias i Pujol, Badalona, Spain, ⁶Dep of Neurology. Hosp Univ Josep Trueta, Girona, Spain.

Autosomal dominant cerebellar ataxias (ADCA) are a clinically and genetically heterogeneous group of neurodegenerative disorders in which several spinocerebellar ataxia (SCA) genes have been cloned: SCAs1-3, SCAs6-7, SCA12 and SCA17; sharing a CAG repeat expansion mutations which generally encodes a polyglutamine tract. In SCA8 the mutation is an untranslated CTG repeat. We have analyzed 340 unrelated familial and 1,013 sporadic and idiopathic cases of SCA. Over the familial cases 6.04% were SCA1; 26.85% SCA2; 32.89% SCA3; 7.38% SCA6; 6.71% SCA7; 14.77% SCA8; and 1.34% SCA17. In 22 familial index cases with SCA8 expansions the allele range goes from 85 to 470 repeats ($129.36\% \pm 67.55\%$; Pearson Coef. = -52.22%). Maternal transmissions presented elongations of the CTG combined sequence ranging from +2 to +13 repeats (7.50 ± 5.5 ; Pearson Coef. = 73.33%). In contrast, paternal transmissions presented contractions ranging from 1 to -17 repeats (-6.83 ± 7.51 ; Pearson Coef = -109.93%). Several giant SCA8 expansions ranges from 401 to 1,126 (N= 9), carried by unaffected adult individuals and being originated from homozygous SCA8 females with alleles of moderate size. In contrast, the homozygous males have transmitted contracted alleles, as in heterozygous cases occurs. We have tested 90 individuals from general population and the distribution of SCA8 alleles could be classified in two groups: 15 to 34 CTGs, with frequency 98% and 77 to 86 CTGs, with frequency 2%. About 60% of familial ADCA cases remained genetically unclassified. No SCA mutations were detected in the 1,013 isolated and idiopathic cases of spinocerebellar ataxia.

Novel mutations found in *ABCA4* in Spanish families

J. Aguirre-Lamban^{1,2}, R. Riveiro-Alvarez^{1,2}, D. Cantalapiedra^{1,2}, M. Garcia-Hoyos^{1,2}, E. Vallespin^{1,2}, A. Avila-Fernandez^{1,2}, J. Gallego-Merlo^{1,2}, M. Lopez-Martinez^{1,2}, M. Trujillo-Tiebas^{1,2}, C. Ramos^{1,2}, C. Ayuso^{1,2};

¹Fundacion Jimenez Diaz, Madrid, Spain, ²Centro de Investigacion Biomedica en Red de Enfermedades Raras (CIBERER), ISCIII, Madrid, Spain. Introduction: *ABCA4* mutations have been associated with Stargardt disease (STGD). A few cases with autosomal recessive cone-rod dystrophy (arCRD) and autosomal recessive retinitis pigmentosa (arRP) have also been found to have *ABCA4* mutations. Comparative genetic analyses of *ABCA4* variation and diagnostics have been complicated by substantial allelic heterogeneity. Subjects and Methods. 31 unrelated families, were previously studied with the ABCR400 genotyping microarray. In patients with either none or only one mutant allele were analysed by dHPLC, sequencing and multiplex ligation-dependent probe amplification (MLPA). Haplotype analysis was also performed. Results. 27 *ABCA4* mutations were found in 31 Spanish patients with the ABCR400 microarray. We confirmed that the p.Arg1129Leu mutation is the most frequent in Spanish patients. dHPLC allowed us to find eleven novel mutations and were not found in the 100 chromosomes. Using both tools, the mutation detection rate obtained was incremented in a 24.2% with respect to the use of the microarray alone. We detected 1.6 % of false positives and 1.6 % of false negatives. In 17/31 patients (54.8%) in which the second or neither mutation was found by these methodologies, they were studied with MLPA; however no deletion or duplication was found in these samples. No mutation was found in 4/31 patients (12.9%). Conclusions. The ABCR400 microarray is a comprehensive screening tool for genetic variation in patients with *ABCR*-associated retinal pa-

thology. We consider that the combination of microarray, dHPLC and MLPA is the optimal screening strategy for mutation analysis in this huge gene in Spanish patients.

Genomic Structural Variation in patients with Multiple Sclerosis

E. Docampo^{1,2}, R. Rabionet^{1,2}, M. García^{1,2}, J. E. Martínez³, E. Munteis³, J. Roquer³, L. Armengol^{1,2}, X. Estivill^{1,2};

¹Center for Genomic Regulation, Barcelona, Spain, ²Public Health and Epidemiology Network Biomedical Research Center (CIBERESP), Barcelona, Spain, ³Neurology Service, Hospital del Mar-IMAS, Barcelona, Spain.

Multiple sclerosis (MS) is a chronic inflammatory demyelinating disease that affects the central nervous system. Several studies provide evidence that MS is a complex disorder involving genetic and environmental factors. Several different approaches have been undertaken to elucidate the genetic causes of MS, including linkage and association studies. These have consistently shown association to the major histocompatibility complex (MHC) region, specifically the DR15 haplotype. Other MS genes have been more elusive, and only ILR7 has shown up as a clear risk factor. The aim of this study was to evaluate a possible contribution of genomic structural variation to MS susceptibility. Forty relapsing-remitting MS samples were divided into two pools and comparative genomic hybridization (CGH) against a pool of 50 control samples was performed using Agilent 244K arrays. With the initial selection criteria (three consecutive probes with a log₂ ratio above 0.29), only the chromosome 6 MHC region, spanning four to six probes (depending on the pool), showed differential hybridization between cases and controls. Relaxing the criteria to only two consecutive probes, five additional regions showed a difference in cases versus controls and were selected for follow-up by RTqPCR experiments. In addition, based on the association shown by the MHC region, a SNPlex experiment with 48 SNPs from HLA class II region was designed, including SNPs from potential CNV regions and SNPs not analyzed by other platforms, and three of these SNPs were shown to be significantly associated to MS.

P05.192

Analysis of raw data from MLPA-based assays: development of a new web-based software „eMLPA“

J. Camajova, M. Krhounek, M. Hancarova, J. Vejvalka, M. Macek, M. Macek Jr;

Department of Biology and Medical Genetics, Charles Univ.-2nd Med. School and Univ. Hospital Motol, Prague, Czech Republic.

MLPA allows detection of large deletions/duplications that would otherwise remain undetected by standard PCR-based techniques. MLPA is based on relative quantification of PCR-multiplexed specific sequences, and for interpretation, computerized analysis of data is necessary. Available commercial, proprietary or freely distributed software packages differ in user friendliness, diagnostic utility, sensitivity and specificity. Usually, these software applications also do not allow optimization of utilized algorithms by long-term “feedback learning” from stored data.

Our “eMLPA” software aims to provide a universal computational interface for all MLPA-based assays. While other software packages use defined algorithms for data analysis, eMLPA allows selection of variant methods for e.g. probe normalization. As none of the individual steps (peak discrimination, e.g.) is a trivial task, instead of rigid computations our approach suggests solutions to be verified, corrected or rejected in interaction with users. Data transformation via independent procedures allows for flexibility and comparison of results at various analytical steps. Data manipulation (management of users, probes, samples and results) is implemented in a web-based system, with no other requirements than a browser. To support the logistics of teamwork properly, eMLPA allows users to create, manage and collaborate on defined projects. eMLPA also offers long-term storage of anonymized intermediary data for evaluation of different numerical methods, for data quality control or for assessment of variance of results of specific probes within a given MLPA mix.

Supported by VZFNM 000064203 and Medigrd 1ET202090537.

Gene expression signature of adrenaline biosynthesis and inflammatory pathways in women with left ventricular apical ballooning syndrome

N. Marziliano¹, M. Grasso¹, A. Repetto¹, E. Porcu¹, A. Pilotto¹, M. Diegoli², M. Tagliani¹, E. Disabella¹, A. Eloisa¹;

¹Fondazione IRCCS Policlinico San Matteo, PAVIA, Italy, ²University of Pavia, PAVIA, Italy.

Marked elevation of plasma catecholamine levels has been reported in transient left ventricular apical ballooning syndrome (LVABS).

Using quantitative PCR (Q-PCR), we investigated the expression profiles of inflammatory and adrenergic pathways in the RNA isolated from peripheral leukocytes, and from lymphocyte and monocyte subsets of 16 female patients with LAVBS, and compared with 7 age-matched women with acute myocardial infarction (AMI) and 17 presenting with chest pain and angiographically normal coronary arteries. Three of the 351 genes belonging to the adrenaline biosynthesis pathway [DAT (Neurotransmitter transporter, dopamine), AT (Sodium-dependant amino acid transporter) and NET (Norepinephrine transporter)] were over-expressed in LVABS than in AMI, whereas COMT (Catechol-O-methyltransferase) and PMNT (Phenylethanolamine N-methyltransferase) were under-expressed. Similarly 3 of the 343 genes of the inflammatory pathway [IL1 β (Interleukin 1 β), TNF α (Tumor necrosis factor-alpha), IL10 (Interleukin-10)] were overexpressed in AMI while TBX21 (T-cell-specific T-box transcription factor) in LVABS; although higher in LVABS, MAD-homolog was underexpressed in both AMI and LVABS than in controls; CCR5 (Chemokine receptor 5) was underexpressed in AMI than in LVABS and controls. In addition 3 of 178 genes of the angiogenesis pathway [AT1R (Angiotensin receptor 1), AT2R (Angiotensin receptor 2) and HIF2A (Endothelial-pas domain protein 1)] were overexpressed in the AMI than in LVABS and controls, while iNOS was more expressed in controls than LVABS and AMI. The lymphocytes did not express DAT, NET, AT, DOPA and COMT.

Our gene expression results suggest an overactivity of adrenergic and inflammatory pathways in LVABS and replicate the biochemical profile documented previously in LVABS.

P05.194

Research Report: Analysis of the TCR transcriptome by TcLandscape: a tool for T cell immune response characterization and patient follow-up

C. Ruiz¹, P. Miqueu¹, L. Xu², S. Jankowski²;

¹TcLand Expression, Nantes, France, ²Applied Biosystems, Foster City, CA, United States.

The understanding of T cells during the immune response follow-up is a crucial step in the development and improvement of immunotherapy treatments. TcLand has developed a new workflow and tool: the TcLandscape. This method provides a global and detailed analysis of the T Cell Receptor (TCR) β -chain transcriptome. The TcLandscape consists of a quantitative analysis of TCR β -chain mRNA expression by real-time PCR, followed by a qualitative diversity study and T cell selection based on the collection of the TCR Complementarity Determining Region 3 (CDR3) length distribution (CDR3-LD) with a capillary electrophoresis sequencer. An integrated analysis is then performed to assess the contribution of each V β chain length with the total T cell repertoire. The result is displayed in a 4-dimensional visualization graph. Novel dedicated statistical analysis methods, including specific signal treatment algorithms and multidimensional data reduction methods, allow the identification of significant differences between the different groups of patients.

The ability to analyze whole T cell populations, as well as specific T cells, such as CD4+/CD8+ or Treg cells, provides a powerful tool to highlight sub-populations of interest in order to understand autoimmune diseases, transplantation, vaccination and other immune responses. In this presentation, we will outline the workflow to conduct a TcLandscape study.

P05.195

Characterization of a spontaneous, recessive, missense mutation arising in the Tecta gene

M. Moreno-Pelayo^{1,2}, R. Goodyear³, A. Mencía^{1,2}, S. Modamio-Høybjørn^{1,2}, K. Legan³, **L. Olavarrieta Scappini**^{1,2}, F. Moreno^{1,2}, G. Richardson³;

¹Unidad de Genética Molecular-Hospital Ramón y Cajal, Madrid, Spain, ²Centre

for Biomedical Research on Rare Diseases (CIBERER), Madrid, Spain, ³School of Life Sciences, University of Sussex, Falmer, Brighton BN1 9QG, United Kingdom.

The *TECTA* gene encodes alpha-tectorin (TECTA), a major non-collagenous component of the tectorial membrane (TM). In humans, mutations in *TECTA* lead to either dominant (DFNA8/A12) or recessive (DFNB21) forms of non-syndromic hearing loss. All missense mutations in *TECTA* that have been reported thus far are associated with the dominant subtype, whereas those leading to recessive deafness are all inactivating mutations. Here we characterize a spontaneous missense mutation (c.1046C>A, p.A349D) arising in the mouse *Tecta* gene that is, unlike all previously reported missense mutations in *TECTA*, recessive. The morphological phenotype of the *Tecta*^{A349D/A349D} mouse resembles, but is not identical to, that previously described for the *Tecta*^{AENT/AENT} mouse. As in the *Tecta*^{AENT/AENT} mouse, the TM is completely detached from the surface of the organ of Corti and spiral limbus, lacks striated-sheet matrix, and is deficient in both beta-tectorin (Tectb) and otogelin. A significant amount of Tecta is, however, detected in the TM of the *Tecta*^{A349D/A349D} mouse and numerous, electron-dense matrix granules are seen interspersed amongst the disorganised collagen fibrils. Mutated *Tecta*^{A349D} is therefore incorporated into the TM but presumably unable to interact with either Tectb or otogelin. The *Tecta*^{A349D/A349D} mouse therefore reveals that missense mutations in *Tecta* can be recessive and lead to TM detachment, and suggest that similar mutations arise in the human population, they would likely cause deafness.

P05.196

Molecular genetic analysis of the Wiskott-Aldrich syndrome in four Russian families

V. V. Zabnenkova, I. G. Sermyagina, A. V. Polyakov;

Research Centre for Medical Genetics, Moscow, Russian Federation.

The Wiskott-Aldrich syndrome is a rare X-linked recessive immunodeficiency disorder caused by mutations in the *WASP* gene.

WASP gene located at Xp11.22-p11.23, has 12 exons containing 1823 base pairs.

A search for *WASP* gene mutations was performed by direct DNA sequencing analysis of all exons and exon-intron junctions.

Four different *WASP* gene mutations were found in the four unrelated families with Wiskott-Aldrich syndrome.

In the first case only biological material of an affected proband's mother was available for searching for mutations. The frameshift mutation (p.Phe36fs44) was found in the exon 1 of *WASP* gene in heterozygosity. Also, the prenatal diagnosis of Wiskott-Aldrich syndrome was carried out for this family. In the second case the missense mutation (p.Asp224Gly) was found in the exon 7. Proband's mother was heterozygous for the mutation. In the third and fourth families the splice site mutations were found in the intron 8 of *WASP* gene - IVS 8 + 1nt G → C and IVS 8 + 1nt G → A, respectively. Proband's mothers were heterozygous for found mutations. Also, in the last case proband's brother had the same mutation and maternal aunt and grandmother were non carriers of this mutation.

One novel mutation p.Asp224Gly was found in this molecular investigation, the others have been reported. We supposed the mutations "hot spot" in intron 8 of *WASP* gene.

P05.197

Hereditary forms of thrombophilia in patients with fetal loss in the Kazakh population

G. S. Svyatova, G. K. Rapilbekova;

The Scientific Centre of obstetric, gynecology and perinatology, Almaty, Kazakhstan.

The aim of this research is to detect hereditary forms of thrombophilia in patients with syndrome of loss of fetus in the Kazakh population.

We investigated the genotype frequencies of the C677T mutation of the MTHFR gene, the G20210A mutation of the prothrombin gene and the Factor V Leiden mutation in 100 Kazakh patients with a history of fetal loss and 200 healthy female as controls. The hereditary thrombophilias were found in 53% of patients. The C677T mutation was present in 41% of patients, 35% women were heterozygous and 6% patients were homozygous. This mutation was found in isolation in 28% of patients, and in combination with other mutations in 13%. The C677T mutation was found in 22% of controls, from them 21%

are heterozygotes and 1,5% were homozygous. The Leiden mutation was found in 9% of patients and all were heterozygotes. In 4% of patients the Leiden mutation was the only abnormality. It was present in combination with other mutations in 5%. In contrast, the factor V Leiden mutation was found in only 1,3% of controls. The G20210A mutation of the prothrombin gene was found in 4% of patients, and all are heterozygotes. The mutation was the only abnormality in 2% of patients and it was present in combination with other mutations in a further 2%. In controls this mutation was not found. The combination of two and even of three defects of thrombophilia were found in 18% of patients whereas in the control group we found only isolated defects of thrombostasis.

P05.198

Screening for the C46T polymorphism in the F12 gene by melting point analysis with the Light Cycler system: atypical results, detection of the variant G47A

I. Tirado, I. Coll, E. Martínez-Sánchez, A. Santamaria, J. Soria, J. Fontcuberta; Hospital Sant Pau Lab. Hematologia Unitat Hemostàsia i Trombosi, Barcelona, Spain.

The C46T in the F12 gene is a novel genetic risk factors for thromboembolic disease. Thus we designed a method, based on melting peak analysis using fluorescence hybridization probes (Real Time PCR-Lightcycler, Roche), to genotype the C46T as a routine analysis. We report the results of one case that showed atypical melting curves in the LightCycler analysis.

The patient was a 53-year-old man with cerebral ischemia diagnosed by computed tomography. A genetic analysis showed that he was heterozygote for the prothrombin G20210A mutation and showed atypical melting curves when the C46T polymorphism was analyzed. The family study revealed that his father, his sisters and one son were also carriers of the G20210A and they showed the same atypical melting curves for C46T. Subsequent sequencing revealed a G47A heterozygous variant. This variant was not detected in 250 healthy controls indicating that this variant is extremely rare.

Although the G47A variant is rare, its position adjacent to the C46T polymorphism imposes some diagnostic limitations in that C46T might be undetectable. In addition individuals with C46T exhibit low levels of FXII because this variant generates an alternative initial methionine and as consequence a stop codon resulting in the synthesis of a premature protein. The presence of both, G47A and C46T in such close positions prevents the generation of an alternative methionine and consequently cancels the effect of C46T.

This study was supported by the Ministerio Sanidad y Consumo, Instituto de Salud Carlos III, RECAVA (03/01) and by PETRI (PET-2006-0361).

A transporter of the thyroid hormone T3 (MCT8) is implicated in X-linked dysmyelination (Pelizaeus-Merzbacher Like Disease / Spastic Paraplegia Type 2)

C. Vaurs-Barrière^{1,2}, M. Deville³, C. Sarret^{1,2}, G. Giraud^{1,2}, V. Des Portes⁴, O. Boespflug-Tanguy^{1,5}, R. Touraine⁶;

¹GrReD INSERM U931, Clermont-Ferrand, France, ²Université de Clermont, UFR Médecine, Génétique Médicale, Clermont-Ferrand, France, ³Service de génétique clinique chromosomique et moléculaire, CHU, St Etienne, France, ⁴Centre de référence des déficiences intellectuelles de causes rares, Service de neurologie pédiatrique, Lyon, France, ⁵Centre de référence des leucodystrophies, Service de Génétique Médicale, CHU, Clermont-Ferrand, France.

Among the numerous genes implicated in X-linked mental retardation, the one coding for the specific thyroid hormone T3 transporter, i.e. monocarboxylate transporter 8 (MCT8, SLC16A2, MIM 300095), has been initially implicated in boys presenting a severe delay of psychomotor development and secondly in a syndromic mental retardation affection characterized by a progressive spasticity, the Allan-Herndon-Dudley syndrome (MIM 300523). In those clinical pictures, abnormal relative concentrations of thyroid hormones (total T4 decreased, TSH borderline and total T3 increased) suggest the implication of this gene. The identification of a MCT8 missense mutation in one of our patients presenting a diffuse hypomyelination on MRI imaging until the age of 3 years old has inclined us to test the implication of this gene in X-linked early dysmyelination suggestive of Pelizaeus-Merzbacher Like disease or spastic paraplegia type 2. MCT8 coding sequences have

been analyzed by DHPLC in a cohort of 37 boys presenting a hypomyelination without mutation in the PLP1 gene. A MCT8 mutation has been identified in 4 patients from 4 independent families. These results demonstrate the interest of MCT8 mutation screening in hypomyelinating leukodystrophies of unknown origin and suggest, at least in humans, a new role of MCT8 in oligodendrocyte maturation.

Alopecia areata: Association with resistance to thyroid hormones

R. Bircan¹, T. Güran², T. Akçay², S. Turan², A. Berekeç²;

¹Namik Kemal University, Faculty of Arts and Sciences, Department of Molecular Biology and Genetics, Tekirdag, Turkey, ²Marmara University, School of Medicine, Dept. of Pediatric Endocrinology, Istanbul, Turkey.

Context : Resistance to thyroid hormone (RTH) syndrome is a rare genetic disorder, generally characterized by the absence of the usual symptoms and metabolic consequences of thyroid hormone excess. Mostly it is caused by thyroid hormone β receptor mutations. Up to date 124 mutations in the TR β gene identified in 500 different families. Besides, alopecia areata (AA) is an autoimmune disease of the hair follicle, frequently associated with other autoimmune disorders, one of the most common of which are thyroid diseases like hashimoto thyroiditis and Graves' disease.

Objective: we described a family having RTH syndrome, caused by a novel TR β mutation, coexisted with diffuse, patchy alopecia without autoimmune thyroid disease in affected members

Design: For the precise diagnosis of RTH, genetic testing was carried out on the index patient, two siblings, his mother and father. Genomic DNAs were extracted from peripheral blood samples by using standard protocols. Exon 7-10 of the thyroid receptor beta (TR β) were amplified by PCR and possible candidate mutations screened by using direct DNA sequencing.

Main Outcome: A novel TR β mutation (I353V) was found in a 9 1/3 years old boy having both RTH syndrome and alopecia areata. This mutation was also detected in his father and elder brother who were affected by RTH and also have alopecia areata. It could be Speculated that alopecia areata might be a novel sign of RTH either coexisted with the other distinctive clinical and phenotypical characteristics of the syndrome.

Functional characterisation of single nucleotide polymorphisms in the coding region of the human tryptophan hydroxylase gene TPH2

K. Bokelmann, M. V. Tzvetkov, M. Sedej, J. Brockmöller;
University Medicine, Göttingen, Germany.

The tryptophan hydroxylase isoenzyme 2 (TPH2) catalyzes the rate-limiting step of serotonin synthesis in the human brain. Reduced serotonin synthesis may be linked with neuropsychiatric disorders like major depression or bipolar disorder or with the success or failure in therapy of these diseases. Several genetic variants in the coding region of the TPH2 gene have been reported but, thus far, only few of them have been functionally characterized. Here we present functional analysis of the TPH2 variants L36Q, P206S, P312P, A328V and D479E.

The enzyme variants were heterologously expressed in PC12 and HEK293 cells. Enzyme activity of the protein variants was assessed as amount of intracellular serotonin or 5-hydroxy-tryptophan measured by HPLC. The expression rates were controlled by qRT-PCR and Western blot.

The 328V variant showed significantly decreased activity both in PC-12 (only 28% of the wild type activity, $P < 0.002$ Mann-Whitney U test) and HEK293 cells (16%, $P < 0.05$). The P206S substitution led to decrease of the TPH2 activity in HEK293 cells (32%, $p < 0.05$), but not in PC-12 cells. The L36Q and D479E substitutions showed no effect on the enzyme activity in both cells tested. The common silent variant P312P did not effect enzyme expression or activity. Furthermore, no effect of the P312P variant on the TPH2 splicing could be shown in an exon-trapping assay.

In conclusion, the A328V substitution leads to significant reduction of the TPH2 activity *in vitro*. The role of this variant in the susceptibility or in the therapy of serotonin-related neuropsychiatric disorders reminds to be elucidated.

P05.202

Analysis of the TSC1 and TSC2 genes in patients with Tuberous Sclerosis from Spain

C. Vidales, I. Zubillaga;

Policlínica Gipuzkoa, San Sebastian, Spain.

Tuberous Sclerosis is a multisystemic disorder characterised by hamartomas frequently found in brain, skin and kidney. Convulsions, seizures and mental retardation are also common features of the entity. TS is caused by mutations in TSC1 (9q34) and TSC2 (16p13) genes. Both are tumour suppressor genes and encode the hamartin (TSC1) and tuberlin (TSC2) proteins. We report here our findings after the TSC1/TSC2 genetic study of patients coming from several hospital spanish services. Mutational analysis were performed by DNA sequencing. Our results are discussed in basis of the relation between clinical data of patients and the gene mutation variant associated. We have familial and sporadic cases and in both we also try to establish the number of minimum criteria for candidate selection to genetic testing.

P05.203

What about UMOD gene involvement in renal development? A novel UMOD mutation associated with immature renal structures

E. Benetti¹, G. Caridi², M. Della Vella³, L. Rampoldi⁴, A. Zucchini⁵, G. Ghiggeri², L. Artifoni⁶, L. Murer^{1,6};

¹Pediatric Nephrology, Dialysis and Transplantation Unit, Department of Pediatrics, University of Padua, Padua, Italy, ²Laboratory of Pathophysiology of Uremia, Istituto Gaslini, Genoa, Genoa, Italy, ³Laboratory of Nephrology, Department of Pediatrics, University of Padua, Padua, Italy, ⁴DIBIT San Raffaele, Milan, Milan, Italy, ⁵Pediatric Unit, Hospital of Faenza, Faenza, Italy, ⁶Laboratory of Pediatric Nephrology, Department of Pediatrics, University of Padua, Padua, Italy.

Mutations of the UMOD gene, encoding uromodulin, have been associated to medullary cystic kidney disease (MCKD), familial juvenile hyperuricemic nephropathy (FJHN) and glomerulocystic kidney disease (GCKD).

We report on an 13-year-old boy, presenting with moderate chronic renal failure, a family history (father) of an undefined renal-transplantation-requiring nephropathy and a personal history of hyperuricemia and urine concentrating ability impairment preceding the onset of renal failure. Renal ultrasonography demonstrated slightly reduced bilateral kidney volumes and cortical hyper-echogenicity, with two tiny cysts in the left kidney. Renal biopsy showed up to 60% of glomeruli featuring an enlargement of Bowman's space (glomerular cysts), with mild interstitial fibrosis (α SMA-positive), inflammatory infiltrate and focal tubular atrophy at the cortical level. At the cortico-medullary junction, immature tubules (some dilated), with PAX2-positive immunostaining, surrounded by a vimentin-positive mesenchymal tissue. Unlike previously reported cases, no uromodulin positive globular aggregates within the cytoplasm of tubular cells were observed.

Genetic analysis revealed a novel heterozygous mutation of UMOD gene (c.149 G>C;p.Cys50Ser), involving the first EGF-like domain of the protein, both in the boy and his father.

This novel UMOD mutation, associated with an immunohistochemical pattern different from the previous reports and a histological picture characterized by immature renal structures, opens up new issues about UMOD possible role in renal development.

P05.204

PDZK7 does not participate in the usher protein network

E. Aller^{1,2}, E. van Wijk³, T. Jaijo^{1,2}, C. Nájera⁴, F. Palau^{5,2}, J. M. Millán^{1,2}, H. Kremer³;

¹Hospital Universitario La Fe, Valencia, Spain, ²Center for Biomedical Research on Rare Diseases (CIBERER). ISCIII, Valencia, Spain, ³Department of Otorhinolaryngology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, ⁴Departamento de Genética, Universidad de Valencia, Valencia, Spain, ⁵Instituto de Biomedicina de Valencia, CSIC, Valencia, Spain.

Introduction: Usher syndrome (USH) is an autosomal recessive genetic disease defined by the association of sensorineural hearing loss and visual impairment due to retinitis pigmentosa (RP), with or without vestibular affection. USH is clinically and genetically heterogeneous. Nine genes have been identified which codify for proteins that are integrated in a protein network known as Usher interactome. The central core of the interactome is formed by the PDZ domain containing homologues harmonin and whirlin with the rest of USH proteins assembling

to this core. Additional interacting proteins assembling to the USH protein network are candidates to be responsible for Usher syndrome, non-syndromic hearing loss or retinal dystrophies.

Hypothesis: The protein product predicted for PDZK7 (NM_024895) shows high homology to both harmonin and whirlin and could have a similar function. Thus, it is a candidate member for the Usher interactome.

Objective: The aim of the present work was to determine the existence of interactions between PDZK7 and the proteins of the Usher interactome: usherin, NBC3, VLGR1, cadherin 23, protocadherin 15 and SANS.

Methods: Interactions were tested by yeast two hybrid (Y2H) assays and by co-expression and co-localization in cos-1 cells studies.

Results: No interaction was found between PDZK7 and USH proteins.

Conclusions: The absence of interactions between PDZK7 and USH proteins indicates that it is not part of the USH interactome.

P05.205

Assessment of hearing loss in French patients diagnosed with pathogenic genotypes in usherin

C. Abadie¹, L. Larrieu¹, D. Baux¹, C. Blanchet², S. Gerber³, J. Kaplan³, M. Claustres^{1,4}, A. Roux¹;

¹Laboratoire de génétique moléculaire, Inserm U827, Montpellier cedex 5, France, ²Centre de référence des affections génétiques sensorielles, Montpellier cedex 5, France, ³Inserm U393, Hôpital Necker-Enfants Malades, Paris, France, ⁴Université Montpellier I, Montpellier, France.

Usher syndrome is an autosomal recessive disorder characterised by hearing impairment, retinitis pigmentosa (RP) and variable vestibular dysfunction. Usher syndrome presents both genetic and clinical heterogeneity, and is divided into 3 subtypes caused by at least 9 genes. Usher syndrome type II (USH2) is the most frequent clinical group. Affected patients show moderate to severe hearing loss (HL) and variable evolution of RP. Typical USH2 audiograms have a gently down-sloping configuration from moderate in the low frequencies to severe or profound in the high frequencies. High variability is recognised and clinical diagnosis of USH2 can be missed suggesting that USH2 is likely to be more frequent than estimated. USH2A is the overwhelmingly involved gene in USH2 and encodes two isoforms of the protein called usherin (a short isoform of 1546 residues and a long isoform of 5202 residues).

Audiograms were collected in a french cohort of 30 patients presenting with pathogenic genotypes in usherin. ISO 7029 norm-based calculation was used to abolish age-related and gender bias. For a third of these patients, audiograms could be collected over several decades in order to assess the progression of HL. Preliminary results tend to show a homogeneous range of hearing deficiency, either considering the affected isoform, or the type of mutations (truncating, missense or splice variants). However, some audiograms did not fit within the defined range; some of them could be explained by the presence, on one allele, of the controversial p.Cys759Phe variant.

P05.206

New mutations in VWF Gene, from mexican patients with „Von Willebrand Disease“

R. Peñaloza, H. Benitez, V. Rojas, M. Espinosa, A. Cervantes, M. Flores, D. Arenas, F. Salamanca;

IMSS, Mexico City, Mexico.

We analyzed exon 28 of VWF gene from 20 Mexican Mestizo index cases with von Willebrand disease, using DNA amplification by polymerase chain reaction and direct sequencing using Big Dye (Applied Biosystem, USA). They have high frequency of blood group type O (80%), and normal or low aPPT, VWF:Ag, VWF:RCo, and FVIII:C. We found two novel mutations: (insT3706) and (delG4911) in patients with VWD type 1. Both produce an early stop with a short putative protein. The first one corresponding to a woman with menorrhagia, and the second one to a male with mucocutaneous bleeding to require hospitalization. Moreover, we found other polymorphisms previously informed. This is the second part of molecular study of VWF gene where we informed other three new mutations, previously.

P05.207

The study of the WFS1 gene is useful in non syndromic hearing loss, with ascending or U-shape audiometric curve

L. Jonard¹, D. Feldmann¹, S. Marlin¹, C. Koval¹, M. Louha¹, K. Olszewski¹, R. Couderc¹, H. Dollfus², V. Drouin-Garraud³, D. Lacombe⁴, F. Fellmann⁵, C. Francannet⁶, G. Lina-Granade⁷, C. Petit⁸, F. Denoyelle¹;

¹AP-HP, Paris cedex 12, France, ²Génétique médicale, Strasbourg, France, ³Génétique clinique, Rouen, France, ⁴Génétique médicale, Bordeaux, France, ⁵Génétique médicale, Besançon, France, ⁶Génétique clinique, Clermont-Ferrand, France, ⁷ORL Hôpital E.Herriot, Lyon, France, ⁸INSERM U587, Paris, France.

Introduction: Wolfram syndrome or DIDMOAD is characterized by the association of diabetes, optic atrophy and hearing impairment. This autosomal recessive syndrome is due to WFS1 gene mutations. Some dominant mutations of the same WFS1 gene have been associated with nonsyndromic deafness, preferentially affecting low frequencies (DFNA6/14/38). Unlike the Wolfram's mutations, the dominant mutations are essentially located in the exon 8 of the WFS1 gene.

Methods: We have analysed exon 8 of the WFS1 gene in a cohort of 64 unrelated individuals affected by nonsyndromic hearing loss (HL). 23 individuals presented with an ascending audiometric curve and 41 presented with a U-shape curve.

Results: In four different families, we identified a heterozygous mutation: c.923C>G (p.Ser308Cys), c.1079G>A (p.Cys360Tyr), c.2141A>G (p.Asn714Ser) and c.2421C>A (p.Ser807Arg). These new WFS1 variations segregate perfectly with the HL, are missense mutations affecting highly conserved residues, and are absent from 100 control DNA samples.

These 4 French families are affected with isolated autosomal dominant HL. In a same family, a mutation can cause an HL characterised by an ascending curve or a U-shape curve, and evolution between these two shapes has been observed. The exhaustive audiological and clinical examination of the 17 affected patients allowed us to precise DFNA6/14/38 phenotype.

Conclusion: The molecular screening of WFS1 gene is useful for patients presenting with sporadic or familial non syndromic hearing loss, with an ascending or U-shape audiometric curve. Moreover, our study leads to clarify the spectrum of WFS1 mutations and the related phenotype in non syndromic hearing impairment DFNA6/14/38.

P05.208

DNA repair efficacy determines the severity of XPB associated progeroid Cockayne syndrome

J. Andressoo^{1,2}, G. Weeda³, J. de Wit⁴, J. R. Mitchell⁴, R. B. Beems⁴, H. van Steeg⁴, J. H. Hoeijmakers³, G. T. J. van der Horst³;

¹Institute of Biotechnology, Helsinki, Finland, ²Former address: Erasmus Medical Center, Rotterdam, The Netherlands, ³Erasmus MC, Rotterdam, The Netherlands, ⁴National Institute of Public Health and Environment, Bilthoven, The Netherlands.

Mutations in the basal transcription and nucleotide excision repair (NER) helicase XPB associate with a mild form of the combined cancer and premature aging syndrome xeroderma pigmentosum / Cockayne syndrome (XPCS). Due to the dual role of XPB and absence of animal models, the underlying molecular mechanisms of XPB-XPCS have remained obscure. Here, with the first Xpb mouse models we demonstrate that severe alterations in Xpb are lethal, providing explanation to the relative scarcity of XPB associated disease. Furthermore, we show that knock-in mice with an XPCS-patient-derived XPB mutation mimic the UV-sensitivity typical for XP, but fail to show CS features and age normally. However, further ablation of DNA repair capacity by crossing the Xpb mutant mice to other NER mutants causes appearance of CS-like features such as premature aging and increase in cellular sensitivity to chronic oxidative stress, demonstrating the causative role of DNA repair defect in the onset of XPB-associated accelerated aging. The Xpb/Xpa double mutants display a novel NER phenotype, with intermediate severity of ageing symptoms and remarkable inter-animal variance. This large variance provides experimental evidence to the hypothesis that stochastic DNA damage accumulation is an important determinant of clinical variance in NER syndromes. Based on our results, we suggest a model of NER phenotypes in which the inter-individual variation first increases and then decreases as a function of the degree of DNA repair deficiency.

P05.209**A novel frame-shift mutation of the EDA gene in a Spanish family with X-linked hypohidrotic ectodermal dysplasia**

M. Núñez Lozano¹, S. Ciria Abad¹, J. Cañueto Álvarez², M. I. Zafra Cobo², M. Morán Estefanía², A. Santos-Briz Terrón², P. Unamuno Pérez², R. González Sarmiento¹;

¹Unidad de Medicina Molecular-Departamento de Medicina, Universidad de Salamanca, Salamanca, Spain, ²Departamento de Dermatología, Hospital Universitario de Salamanca, Salamanca, Spain.

X-linked hypohidrotic ectodermal dysplasia (XLHED) is characterized by defects in the development of ectodermal structures as sweat glands, hair and teeth. Mutations in EDA gene, which codes for ectopasin-A, cause alterations in the protein and seems to be responsible for this disorder. In the present study, we analyse, by PCR, heteroduplex analysis and automatic sequencing, the full coding region and the exon-intron boundaries of the EDA gene in DNA from peripheral blood of one Spanish family with XLHED.

We found an alteration in the EDA gene in two members of the studied family. This alteration consists in a duplication of 2bp (c.974-975ins-GA) in the 5 exon that produces a change in the DNA sequence of collagen like domain rich in Gly-X-Y motifs. This domain is important for multimerization of the protein. Furthermore this duplication produces a truncation of the last exon that codes for a part of a TNF-like domain, which can affect the NF- κ B and c-Jun kinase pathway.

The two affected members of the family show remarkable phenotypic characteristics on skin, teeth, eyebrows, lips and head hair, but aggravated in one of them. This phenomenon is explained by inheriting of the mutation and epigenetics mechanisms of anticipation of the disease across generations.

This results show a novel mutation in the EDA gene in a Spanish family with XLHED syndrome which introduces a new reading frameshift and a premature stop codon. This extends our knowledge of pathogenic mutations in EDA gene.

P05.210**X-linked juvenile Retinoschisis (XLRs) in Spanish patients: common ancestries, hot spots and incomplete penetrance**

R. Riveiro-Alvarez^{1,2}, M. Trujillo-Tiebas^{1,2}, M. Garcia-Hoyos^{1,2}, D. Diego-Alvarez^{1,2}, D. Cantalapiedra^{1,2}, E. Vallespin^{1,2}, J. Aguirre-Lamban^{1,2}, A. Avila-Fernandez^{1,2}, A. Gimenez^{1,2}, C. Ramos^{1,2}, C. Ayuso^{1,2};

¹Fundacion Jimenez Diaz, Madrid, Spain, ²Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), ISCIII, Madrid, Spain.

Purpose: X-linked juvenile Retinoschisis (XLRs) is one of the most common causes of juvenile macular degeneration in males, characterised by myocystic changes, splitting within the inner retinal layer ("schisis") and presence of vitreous veils. The aim was to describe the genotype-phenotype correlation in Spanish XLRs families with mutations in the *RS1* gene.

Methods: The study was performed in 31 Spanish XLRs families, comprising 46 affected males and two symptomatic women. Molecular analyses included direct sequencing, haplotype construction and determination of the X inactivation pattern.

Results: 18 different *RS1* mutations were identified; eight of them were novel ones. These new changes included missense (p.Gln154Arg, p.Leu137Pro, p.Glu215Val, p.Arg197Ser, p.Pro192Leu, p.His207Asp), nonsense (p.Gln80Ter) and frameshift substitutions (p.Thr138fsX). 2 out of 31 "de novo" mutational events were detected. The most common mutation (p.Gln154Arg; 6/18) presented a common haplotype. The symptomatic women showed a normal X inactivation pattern. Interestingly, a healthy male presenting the p.Arg209His mutation was identified.

Conclusions: A prevalent mutation in Spanish XLRs patients (p.Gln154Arg) has been first reported in this work and presented a common origin. The frequency of "de novo" mutations was 6%, which mainly rise in CG dinucleotides (hot spots). Further analyses showed that the retinal affectation in both women could be due to mutations in another gene. Nevertheless, the possibility of incomplete penetrance for *RS1* variants or a gain-of-function alteration in a different interacting gene might be suspected. Despite the mutation spectrum is large and the phenotype variable, there was no correlation between mutation type and severity of disease.

P05.211**Hierarchical analysis of 28 Y-chromosome SNP's in the population of the Republic of Macedonia**

P. Noveski, S. Trivodalieva, G. D. Efremov, D. Plaseska-Karanfilska; Macedonian Academy of Sciences and Arts, Research Centre for Genetic Engineering and Biotechnology, Skopje, The former Yugoslav Republic of Macedonia.

Analysis of Y-chromosome haplogroups, defined by single nucleotide polymorphisms (SNP's), has become a standard approach for studying the origin of human populations and measuring the variability among them. Furthermore, Y-SNP's represent a new forensic tool, because their population specificity may allow to determine the origin of any male sample of interest for forensic purposes. The aim of this study was to develop a strategy for rapid, simple and inexpensive Y-chromosome SNP's typing in the population of R. Macedonia. We have studied a total of 343 DNA male samples; 211 Macedonians, 111 Albanians and 21 of other ethnic origin (Roma, Serbs and Turks). Methodology included multiplex PCR and single nucleotide extension reaction by SNaPshot multiplex kit. The set of 28 markers has been grouped in 5 multiplexes in order to determine the most frequent haplogroups using only 1 or 2 multiplexes. Twenty different Y haplogroups were determined among 343 male DNA samples. The finding that five haplogroups (E3b1, I1b1, J2b1a, R1a and R1b) comprise more than 70% of the Y chromosomes is consistent with the typical European Y chromosome gene pool. The distribution of the Y-haplogroups differs between Macedonians and Albanians. The most common Y haplogroup among Macedonians is I1b1 (27.5%), followed by three haplogroups present with similar frequencies E3b1 (15.6%), R1a (14.2%) and R1b (11.4%). Among Albanians the most frequent Y haplogroup is E3b1 (28.8%), followed by R1b (18.0%), J2b1a (13.5%) and R1a (12.6%).

P05.212**Elucidating the molecular function of ZFYVE27 (Protrudin)**

K. Pantakani D.V., T. Khromov, J. Wolter, G. Tomasik, H. Hühn, **A. U. Mannan**; Institute of Human Genetics, University of Göttingen, Göttingen, Germany.

ZFYVE27 is a member of the FYVE-finger family of proteins. The FYVE-finger domain is suggested to be responsible for endosomal localization of these proteins and the majority of the FYVE-finger proteins serve as regulators of endocytic membrane trafficking. ZFYVE27 was identified as a spastin interacting protein and previously, we characterized its interaction with spastin in mammalian cells. More importantly, we identified a German family in which mutation in ZFYVE27 causes autosomal dominant form of hereditary spastic paraplegia (HSP). A comprehensive expression analysis of ZFYVE27 in mouse revealed a high level of expression primarily in the HSP affected tissues such as brain, cerebellum and spinal cord. Immunohistochemical analysis of tissue sections from various subdivisions of brain and spinal cord showed expression in both cell soma and axons of the motor-neurons. To elucidate the molecular function of ZFYVE27 in vivo, we are generating a loss of function mouse model by knockout strategy. Conceivably the phenotype of these mouse models might mimic the pathological features of HSP, therefore will provide us with a valuable model system to study the underlying cause for HSP etiology.

P05.213**Pitfalls of mapping a large Turkish consanguineous family with vertical Monilethrix inheritance**

F. Celep¹, A. Uzunclu², F. M. Sonmez³, O. Uyguner², Y. Isik Balci⁴, S. Bahadir⁵, A. Karaguzel¹;

¹Karadeniz Technical University, Faculty of Medicine, Department Medical Biology and Genetics, Trabzon, Turkey, ²Istanbul University, Istanbul Medical Faculty, Department of Medical Genetics, Istanbul, Turkey, ³Karadeniz Technical University, Faculty of Medicine, Department of Pediatrics Neurology, Trabzon, Turkey, ⁴Pamukkale University Faculty of Medicine, Department of Pediatrics Haematology, Denizli, Turkey, ⁵Karadeniz Technical University, Faculty of Medicine, Department of Dermatology, Trabzon, Turkey.

Monilethrix, a rare autosomal dominant disease characterized by hair fragility and follicular hyperkeratosis, is caused by mutations in three type II hair cortex keratins. The human keratin family comprises 54 members, 28 type I and 26 type II. The phenotype shows variable penetrance and results in hair fragility and patchy dystrophic alopecia. In our study, Monilethrix was diagnosed on the basis of clinical characteristics and microscopic examination in a family with 11 affected members. Haplotype analysis was performed by three Simple

Tandem Repeat markers (STR) and *KRT86* gene was sequenced for the identification of the disease causing mutation. In the results of this, autosomal dominant mutation (E402K) in exon 7 of *KRT86* gene was identified as a cause of Moniltherix in the large family from Turkey.

P05.214

PEX7 gene mutation in infant with Rhizomelic Chondrodysplasia Punctata Type 1

M. G. Oğur¹, C. Has², A. Yıldırım¹, P. Baysal¹, H. R. Waterham²;

¹Ondokuz Mayıs University Medical Faculty, Samsun, Turkey, ²Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.

Rhizomelic chondrodysplasia punctata (RCDP) is an autosomal recessive peroxisomal disorder. Clinically patients present dwarfism due to symmetrical shortening of proximal long bones, ataracts, periarticular calcifications, multiple joint contractures, and psychomotor retardation. So far three subgroups have been defined due to different genes involved. The most common of these is RCDP Type 1 which is caused by mutations in *PEX7* gene.

Here we report a 4 year 6/12 month-old male infant diagnosed as RCDP due to distinct clinical manifestations: short stature, rhizomelic shortening of proximal long bones, multiple joint contractures, and psychomotor retardation. There was notable frontal bossing, depressed profile, a flat nasal bridge, dysplastic external ears, and small nares. Roentgenological studies included abnormalities such as severe shortening of the femur and humerus, irregular and broad metaphyses, calcific stippling of the epiphyses (humerus). Bilateral cataract was diagnosed later. Plasma phytanic acid levels were elevated. Mutation analysis for *PEX7* gene revealed a homozygous mutation for 370_396del127bp (del G124_S132).

The parents were consanguineous and the family history yielded another similarly affected and deceased female child. After mutation analysis family was informed and data given for possibilities of a prenatal diagnosis in any subsequent pregnancy.

P05.215

Identification of a novel mutation in *DKC1* in Russian family with Dyskeratosis Congenita

M. Kurnikova¹, I. Shagina¹, M. Maschan², A. Maschan², L. Khachatryan², D. Shagin^{1,3};

¹Evrogen Joint Stock Company, Moscow, Russian Federation, ²Federal Research Clinical Center for pediatric hematology, oncology and immunology, Moscow, Russian Federation, ³Shemyakin and Ovchinnikov Institute of Bioorganic Chemistry, Moscow, Russian Federation.

Dyskeratosis congenita (DC) is a rare congenital syndrome characterized by the triad of reticular skin pigmentation, nail dystrophy and mucosal leukoplakia, and the predisposition to bone marrow failure and malignancies. Mutations in *DKC1* gene encoding dyskerin are responsible for the X-linked DC. We found novel mutation in *DKC1* in Russian family with X-linked DC. The proband was a 10-y-old boy with skin lesions, nail dystrophy, oral mucosa erosions, epiphora and blood marrow failure, and his 8-y-old brother had identical signs of ectodermal dysplasia without bone marrow failure. Their 2-y-old sister had no clinical signs of DC. Each of the 15 coding exons of the *DKC1* gene and their flanking regions were amplified from genomic DNA by PCR and screened for mutations by SSCP analysis, and the shift detected on the SSCP gel was re-amplified, cloned and sequenced. The novel mutation is a 2-bp inversion in exon 3: NM_001363:c.166_167invCT (L55S). It was found in the proband and his brother; their mother was a carrier and the sister was not. This is the first report of *DKC1* mutation analysis in Russian patients.

The Human Developmental Biology Resource (HDBR) is a unique resource, funded by the Wellcome Trust and UK-MRC to provide human embryonic and fetal tissue to the research community for gene expression studies. The HDBR is based at the Institute of Child Health, University College London and the Institute of Human Genetics, Newcastle University. The HDBR collects material from terminations of pregnancy. This valuable material is used primarily to study the ex-

pression of developmentally significant genes including genes implicated in birth defects and inherited metabolic disorders.

The HDBR has ethical approval for the collection, storage and distribution of material between 4 and 12 weeks of development. Ethics Committee approval and a laboratory Risk Assessment is required before material can be supplied. The HDBR can provide fresh, frozen or sectioned material. In addition the HDBR administers the Fetal Tissue Bank (FTB) collection, previously at the Hammersmith Hospital. The FTB collection is composed of material between 8 and 19 weeks of gestation and is either frozen or cryopreserved for the generation of cell lines. A significant proportion of the HDBR material is karyotyped and normal karyotyped material is provided for research but karyotypically abnormal material can be provided on request.

In addition the HDBR offers an in-house gene expression service for the analysis of RNA or protein using *in situ* hybridisation or immunohistochemistry respectively. The HDBR provides electronic images for publication and advice on interpretation of results. Data is deposited, in a public database.

Data from recent HDBR studies will be presented.

Renal damage triggers cyst formation in an inducible *Pkd1*-deletion model

H. Happé¹, A.M. van der Wal², I.S. Lantinga-van-Leeuwen¹, W.N. Leonhard¹, M.H. Breuning¹, E. de Heer² and D.J.M. Peters¹;

¹Human Genetics, Leiden University Medical Center, ²Pathology, Leiden University Medical Center

Autosomal Dominant Polycystic Kidney Disease (ADPKD) is caused by a mutation in the *PKD1* or *PKD2* gene. This disease is characterized by large fluid-filled kidney cysts and a progressive deterioration of renal function eventually leading to renal replacement therapy.

We generated a tamoxifen-inducible, kidney epithelium-specific *Pkd1*-deletion mouse model. Deletion of the *Pkd1* gene in adult mice resulted in a mild cystic phenotype. However, in newborn mice, this results in massive cyst formation. In young mice, tubular cell proliferation still takes place to elongate the nephron, in contrast to the adult kidney. Therefore, we hypothesized that renal injury followed by a tissue repair response, including epithelial cell proliferation, accelerates cyst formation in adult *Pkd1*-deletion mice.

Inducible *Pkd1*-deletion mice were treated with the nephrotoxicant DCVC upon *Pkd1*-gene inactivation. 10-14 weeks after DCVC treatment, renal function rapidly declined in DCVC treated *Pkd1*-deletion mice, as determined by blood urea concentration. Kidney-to-body weight ratios were increased in DCVC treated animals compared to controls. Histopathological analysis revealed numerous cysts mainly of proximal tubular origin. Cyst formation was absent in DCVC treated *Pkd1*^{+/+} mice while non-treated *Pkd1*-deletion mice only showed few focal cysts. Renal proliferation indexes were determined by Ki-67 staining at 1 wk after injury and were increased in *Pkd1*-deletion animals compared to DCVC treated *Pkd1*^{+/+} mice.

In conclusion, these data provide evidence that injury-induced enhanced proliferation of renal epithelium in the absence of wild type polycystin-1 is a trigger for cyst formation. Since polycystin-1 localizes in the basal-body/centrosome, we hypothesize that aberrant planar cell polarity of the newly formed cells plays a role in ADPKD.

Identification of novel variants in the Arylalkylamine N-acetyltransferase (AANAT) human gene and their contribution to Mood Disorders susceptibility

V. Soría¹, M. Gratacòs², È. Martínez-Amorós¹, J. Valero³, C. García², J. R. González⁴, A. Gutiérrez-Zotes⁵, E. Saus², M. Bayés², J. M. Crespo¹, L. Martorell⁶, E. Vilella³, A. Labad³, J. Vallejo^{1,5}, J. M. Menchón^{1,5}, X. Estivill⁶, M. Urretavizcaya^{1,5};

¹Mood Disorders Clinical and Research Unit, CIBER-SAM, Psychiatry Department, Bellvitge University Hospital, Barcelona, Spain, ²CIBERESP (CIBER en Epidemiología y Salud Pública), Genes and Disease Program and CeGen Barcelona Genotyping Node, Center for Genomic Regulation (CRG), Barcelona, Spain, ³Grup d'Investigació en Psiquiatria. Hospital Universitari Institut Pere Mata, Rovira i Virgili University, Reus, Spain, ⁴CREAL, Center for Research in Environmental Epidemiology, Barcelona, Spain, ⁵Department of Clinical Sciences, Bellvitge Campus, Barcelona University, Barcelona, Spain, ⁶Experimental and Health Sciences Department, Pompeu Fabra University, Barcelona, Spain.

Disruption of circadian rhythms, including abnormalities of circadian phase position and melatonin secretion, have been described in mood disorders (MD) but the molecular mechanisms underlying their pathology are largely unknown. Arylalkylamine N-acetyltransferase (AANAT) is a key enzyme involved in circadian oscillations of melatonin levels. In order to assess the possible contribution of AANAT gene variability to the susceptibility to MD, we systematically investigated common and rare variation in the AANAT gene through a sequential sequencing and single nucleotide polymorphisms (SNP)-based genotyping approach. Our sample consists of 445 unrelated patients with MD (257 unipolar major depressive disorder, 188 bipolar disorder) diagnosed according to DSM-IV criteria and 440 screened control subjects. The entire coding region, the exon-intron boundaries, the promoter and 3'UTR of the AANAT gene were directly sequenced in a subset of 360 MD patients by PCR, identifying 17 changes. Thirteen out of the 17 changes represent novel sequence variations and four had been described before: rs3760138, rs4238989, rs4646261 and rs8150. The novel and previously reported variants in dbSNP public database were genotyped in the rest of the MD sample and in the control sample using SNPlex genotyping system. Non-rare variants (MAF>2%) were further included in a case-control association study. The results showed significant differences in genotype distributions for two SNPs located in the promoter region of AANAT gene ($p=0.00006$; $p=0.004$), which remained significant after correcting for multiple comparisons. Our results suggest that genetic variability in the promoter region of AANAT gene contribute to the human susceptibility to mood disorders.

P06.002

Frequencies of four ABCG8 polymorphisms in patients with ischaemic vascular diseases

A. Szilvási¹, H. Andrikovics¹, E. Pongrácz², Á. Kalina³, Z. Komlósi⁴, I. Klein⁵, A. Tordai¹;

¹Hungarian National Blood Transfusion Service, Budapest, Hungary, ²Central Hospital of Ministry of Interior, Budapest, Hungary, ³Hospital of the National Railways, Budapest, Hungary, ⁴Semmelweis University, Budapest, Hungary, ⁵Hungarian Academy of Sciences, Budapest, Hungary.

Background. ABCG5 and ABCG8 mediate sterol absorption and excretion. It is still not clarified how the most common polymorphisms of these genes contribute to cholesterol plasma level changes, and whether polymorphisms are associated with multifactorial vascular diseases.

Methods. We investigated 241 unrelated, consecutively enrolled patients with ischaemic stroke, 148 patients with coronary heart disease (CHD) and 191 blood donors as healthy controls for allele frequencies (AF) of four common ABCG8 polymorphisms (D19H, Y54C, T400K, A632V).

Results. Linkage disequilibrium test revealed linkage between the respective neighbouring loci of ABCG8. Estimated haplotype frequencies were similar for the three investigated groups (stroke or CHD patients and healthy controls). AFs of the investigated polymorphisms in patient-groups showed no significant differences compared to con-

trols. There was a tendency toward reduced YY54 genotype frequency in the entire stroke group. Upon stratification by age at disease onset, male stroke patients under the age of 50 ($n=15$) showed significantly reduced frequency of YY54 compared to control males (24.2% vs. 41.3%; OR:2.205 [95%CI:1.079-4.504]; $p=0.0377$). No such associations were found in female cases. In healthy controls, cholesterol levels of individuals with YY54 genotype ($n=71$; median 4.51 [25th-75th percentiles, 4.19-5.43] mM) were significantly reduced compared to YC54 and CC54 individuals combined ($n=120$; median 4.95 [4.42-5.88] mM, $p=0.009$). In addition, we identified a new ABCG8 variant, T401S, in a healthy control.

Conclusions. According to our data ABCG8 YY54 may be a potential protecting factor against ischaemic stroke in young males; and Y54C polymorphism may influence cholesterol plasma levels in healthy individuals.

P06.003

Acetyl CoA carboxylase 2 (ACACB) promoter SNP -8414 C/T is associated with body fat in women and affects promoter activity

A. K. H. Lee¹, T. Kyriakou¹, D. Ge², G. Liu³, H. Snieder^{3,4}, T. D. Spector⁴, S. D. O'Dell¹;

¹Nutritional Science Division, King's College London, London, United Kingdom, ²Center for Population Genomics and Pharmacogenetics, Duke University, Durham, NC, United States, ³Unit of Genetic Epidemiology and Bioinformatics, University of Groningen, Groningen, The Netherlands, ⁴Twin Research and Genetic Epidemiology Unit, King's College London, St Thomas' Hospital Campus, London, United Kingdom.

Acetyl-CoA carboxylase (ACC) catalyses the formation of malonyl-CoA, an intermediate in fatty acid synthesis and a potent inhibitor of carnitine palmitoyltransferase (CPT1). CPT1 transfers long-chain fatty acyl-CoA (LCFA-CoA) to the mitochondria for β -oxidation, so ACC causes cytoplasmic accumulation of LCFA-CoA by increasing CPT1 inhibition. Elevated LCFA-CoA in the hypothalamus signals energy surfeit and leads to inhibition of feeding. We proposed that genetic variation influencing the level of expression of the ACC2 gene (ACACB) could be influential in determining body weight. We selected -8414 C/T (rs16939972), sited -368bp from the exon 1b transcription start site in ACACB promoter II, as a potential functional or marker site. We tested association with anthropometry, body fat, serum leptin, triglyceride and insulin sensitivity in 2633 healthy Caucasian females from the Twins UK cohort (mean age 47.3 \pm 12.6 y). Allele C was associated with higher total body fat ($P=0.014$). We then tested the activity of the promoter with respect to -8414 C/T alleles in transfected HepG2 hepatocytes. The constructs contained a 907bp region (from position -870 to +37 relative to the transcription start site) and were co-transfected with an SREBP-1a expression plasmid. Activity associated with allele C was 57.5 \pm 4.0% and with allele T 25.0 \pm 10.8% of that of an SREBP-1a control plasmid, i.e. allele C showed 2.3 times greater activity than allele T. ACACB could be influential in determining body weight.

P06.004

Polymorphisms in ACTN3, ACE and AMPD1 genes and physical performance in Bulgarian sub-elite athletes

S. A. Andonov¹, R. Saraeva², S. Andonova^{2,3}, R. Kaneva^{2,3}, V. Gigova¹, L. Stefanov¹, I. Kremensky^{2,3}, P. Atanasov¹;

¹National Sports Academy "Vassil Levski", Sofia, Bulgaria, ²Molecular Medicine Center, Medical University, Sofia, Bulgaria, ³University Hospital of Obstetrics, Sofia, Bulgaria.

The aim of this study was to analyse ACTN3 (R577X), ACE (I/D) and AMPD1 (34C>T) polymorphisms in sub-elite athletes ($n=70$, 57 males and 13 females) and controls ($n=44$, 15 males and 29 females). The correlations between genotypes and physiological and biochemical parameters at anaerobic conditions was investigated. Athletes were divided into three sport groups according to a power-time model of performance intensity. The physiological parameters were evaluated by standard Wingate Anaerobic Test and Ergospirometry. Spectrophotometry and Blood-Gas analysis were used for the estimation of the glycolytic enzyme activity of Lactate Dehydrogenase and Acid-Base Balance, respectively. DNA samples was genotyped by RFLP analysis followed by agarose gel-electrophoresis. Differences in the distribution of alleles and genotypes between the groups were assessed by χ^2 -test. Statistical analysis of variances was performed using one way ANOVA. No significant differences between the athletes and controls

was found according the allele and genotype frequencies of the investigated polymorphisms. AMPD1 heterozygous male athletes in the "Anaerobic" group showed greater Mean Power Output (Watts) in comparison to CC homozygous athletes (9,11 vs. 7,34 Watts). Significant correlation was observed also with the buffering capacity (HCO₃ and BE). No Individuals homozygous for the T-allele of AMPD1 were found. The ACTN3 genotype correlated with parameters relevant to exercise capacity such as oxygen uptake, saturation and Lean Body Mass in the male sub-groups of anaerobic sports and endurance sports, but not in the female sub-groups.

P06.005

Case-control study of six genes asymmetrically expressed in the two cerebral hemispheres: evidence of association of *BAIAP2* and *NEUROD6* with adulthood attention-deficit hyperactivity disorder

M. Ribases^{1,2}, **R. Bosch**¹, **A. Hervás**³, **J. Ramos-Quiroga**^{1,4}, **A. Bielsa**¹, **X. Gastaminza**¹, **M. Fernández-Anguiano**³, **M. Nogueira**¹, **N. Gómez-Barros**¹, **X. Estivill**^{5,6}, **M. Casas**^{1,4}, **M. Bayés**^{5,6}, **B. Cormand**^{7,8};

¹Department of Psychiatry, Hospital Universitari Vall d'Hebron, Barcelona, Spain, ²Research Group in Childhood Neurology and Psychiatric Genetics, Hospital Universitari Vall d'Hebron, Barcelona, Spain, ³Child and Adolescent Mental Health Unit, Hospital Mútua de Terrassa, Barcelona, Spain, ⁴Department of Psychiatry and Legal Medicine, Universitat Autònoma de Barcelona, Barcelona, Spain, ⁵Genes and Disease Program, Center for Genomic Regulation (CRG), UPF, Barcelona, Spain, ⁶CIBER Epidemiología y Salud Pública, Instituto de Salud Carlos III (CRG), Barcelona, Spain, ⁷Departament de Genètica, Facultat de Biologia, Universitat de Barcelona, Barcelona, Spain, ⁸CIBER Enfermedades Raras, Instituto de Salud Carlos III, Barcelona, Spain.

Attention-deficit hyperactivity disorder (ADHD) is a common childhood-onset neuropsychiatric disorder that persists throughout lifespan in at least 30% of ADHD children. Different lines of evidence suggest that abnormal right-left brain asymmetries in ADHD patients may be involved in a variety of ADHD-related cognitive processes, including sustained attention, working memory, response inhibition and planning. Although the exact mechanisms underlying cerebral lateralization are unknown, left-right cortical asymmetry in humans has been associated with transcriptional asymmetry at early embryonic stages and a number of genes differentially expressed between hemispheres have been identified. Among these, we selected six functional candidate genes showing at least 1.9-fold differential expression between hemispheres (*BAIAP2*, *DAPPER1*, *LMO4*, *NEUROD6*, *ATP2B3*, *ID2*) and performed a case-control analysis in 531 ADHD patients (320 children and 211 adults) and 531 sex-matched unrelated controls. The single- and multiple-marker analysis provided preliminary evidence for the contribution of *BAIAP2* ($P=8.5e-06$; OR = 2.69 (1.74-4.17)) and *NEUROD6* ($P = 0.0053$, OR = 1.76 (1.18-2.61)) to adulthood ADHD. Additionally, association between both genes and performance deficits in the Conners Continuous Performance Test (CPT-II) was also identified. Our results support the participation of *BAIAP2* and *NEUROD6* in the continuity of ADHD across lifespan and suggest that genetic factors potentially influencing abnormal cerebral lateralization may be involved in the predisposition to this neurodevelopmental disorder.

P06.006

The genetic causes of sex differences in neurodevelopmental disorders

E. Stergiakouli, **H. Williams**, **K. Langley**, **A. Thapar**, **M. J. Owen**;
Department of Psychological Medicine, Cardiff University, Cardiff, United Kingdom.

ADHD and schizophrenia are heritable, neurodevelopmental disorders that are more prevalent in males. Both disorders also show sex differences in age of onset and severity. The Y chromosome is potentially an important influence on male susceptibility to neuropsychiatric disorders. Animal models have associated the Y chromosome with aggression and decreased levels of serotonin and dopamine in the brain. However, due to difficulties arising from the lack of recombination and widely accepted nomenclature, the Y chromosome has been largely excluded from genetic and genomic studies of neuropsychiatric disorders. In order to overcome this lack of knowledge we chose to study the Y chromosome in a sample of 210 cases with ADHD, 310 cases with schizophrenia and 700 U.K. controls. In total, 40 Y chromosome markers were selected to represent the main Y chromosome

haplogroups that are present in the U.K. according to data from the Y chromosome Consortium data and personal communication with Y chromosome researchers. Statistical analysis of Y chromosome haplogroup analysis revealed no significantly increased representation of any haplogroup in cases with ADHD or schizophrenia compared to controls. However, this is one of the few studies to have genotyped Y chromosome markers in such a large number of U.K. individuals and therefore our results provide an insight into the population structure of U.K. Y chromosome haplogroups.

P06.007

The influence of adiponectin G276T gene polymorphism on changes in adiponectin levels or its oligomer composition by exercise training

D. Ando¹, **Y. Hosaka**², **K. Suzuki**¹, **Z. Yamagata**¹;

¹School of Medicine, Chuo, Japan, ²Hosaka Clinic, Fujiyoshida, Japan.

Purpose: Exercise training improves glucose and lipid metabolism mediated by altered adiponectin oligomer composition. The purpose is to determine the effects of exercise training on total and high molecular weight (HMW) adiponectin and adiponectin oligomeric distribution and influence of adiponectin G276T gene polymorphism on changes in adiponectin levels or its oligomer composition by exercise training.

Subjects and Methods: A randomized parallel-design study (n = 53; 36 women and 17 men; aged 32-65 years) at a fitness club from April 2006 to July 2007 was conducted. Participants were randomly assigned to the exercise (n = 26) or control (n = 27) group and received exercise training for 70 min 2 times per week for 12 weeks and exercise advice at the baseline, respectively. Main outcome are muscle strength; body weight; body mass index; blood pressure; glucose and lipid parameter; circulating levels of total adiponectin and HMW adiponectin; and percentage of HMW adiponectin.

Results: After 12 weeks, there were no differences between the groups for the total adiponectin levels, HMW adiponectin levels, or percentage of HMW adiponectin. No significant difference in the change in the total and HMW adiponectin levels and the percentage of HMW adiponectin between the subjects with the G276G genotype and 276T allele carriers were found in either the exercise or control group.

Conclusion: In the absence of weight loss, Exercise training, does not change HMW adiponectin levels or the adiponectin oligomer composition. Adiponectin G276T gene polymorphism may not modify the adiponectin change response to exercise training.

P06.008

Genetic analysis of adult stature in Dutch isolated population

I. V. Zorkoltseva¹, **T. I. Axenovich**¹, **C. M. van Duijn**²;

¹Institute of Cytology and Genetics, Novosibirsk, Russian Federation, ²Department of Epidemiology & Biostatistics, Erasmus MC, Rotterdam, Netherlands.

We analysed a large complex pedigree from a Dutch genetically isolated population. About 2600 of 19700 pedigree members were phenotyped and genotyped for autosomal 5208 SNPs (Illumina 6K linkage panel). Complex segregation analysis of adult height was performed under mixed model including effects of biallelic major gene, polygene, age and sex. We used likelihood approximation based on breaking pedigree loops. The results confirmed large contribution of genes in the trait variance ($h^2 = 0.85$) and significance of major gene effect in accordance with Elston-Stewart test. Three genotypic means were estimated as 183.5, 178.3 and 174.6 cm in males at 40 years with average difference of male and female genotypic means about 13 cm. The putative major gene explained 18% of trait variance.

A genome-wide scan was performed by variance-components method using Merlin program. Prior to analysis, the pedigree was split into smaller non-overlapping fragments, with maximum bit-size of 18. No loci demonstrated significant linkage, however for 6 loci linkage was suggestive:

SNP	Chr	Position(cM)	LodScore
rs1993104	19	56.9	2.71
rs1873191	18	44.7	2.60
rs1019845	2	195.8	2.27
rs958883	5	123.3	2.15
rs936347	16	17.2	2.11
rs216223	17	2.1	2.11

Of these six loci, five were identified in previous linkage analyses, while locus at chromosome 16 (rs936347) was new.

P06.009**A candidate phenotypic modifier gene in fibrinogen deficient mice: beta-1,4-N-acetyl-galactosaminyl transferase 1 (galgt1)**R. J. Fish¹, D. Vu¹, A. Fort¹, S. Deutsch¹, J. Degen², M. Neerman-Arbez¹;¹Geneva University Faculty of Medicine, Geneva, Switzerland, ²Cincinnati Children's Hospital Research Foundation and University of Cincinnati College of Medicine, Cincinnati, OH, United States.

In humans the absence of circulating fibrinogen leads to a bleeding disorder with variable severity, afibrinogenemia. Fibrinogen alpha chain knock-out mice (FGA^{-/-}) are effectively afibrinogenemic and show a strain-specific bleeding phenotype in neonates. This variability implies that modifier genes exist in FGA^{-/-} mice and in humans with afibrinogenemia. About 70% of C57BL/6 FGA^{-/-} mice die in the neonatal period whereas survivors have normal longevity. Fewer (~20%) FVB/N FGA^{-/-} mice die as neonates but show high mortality at P30 to P60. To identify candidate FGA^{-/-} phenotypic modifier genes, we used microarray analysis on liver RNA from both mouse strains. Of the genes identified with variable expression between strains, one encodes a Beta-1,4-N-acetyl-galactosaminyl transferase (galgt1). A galgt1 paralog, galgt2, was identified as a modifier gene in a mouse model of another human bleeding disorder, von Willebrand's disease(1). By RT-PCR, we found that galgt1 expression increases in the liver of C57BL/6 mice from P0 to P30. In contrast, galgt1 expression is low in FVB/N mice at birth and declines with age. Using strain-specific polymorphisms and sequencing of RT-PCR products, we determined the expression of C57BL/6 and FVB/N galgt1 alleles in livers from F1 hybrid mice. Both alleles were expressed at P0, but only the C57BL/6 allele was detected at P30. Using pyrosequencing, the FVB/N allele expression was 22.8% at P0 and undetectable at P30. We are investigating the genetic basis for this differential allelic expression and whether it can explain strain-specific phenotypic variation in FGA^{-/-} mice. (1)Mohlke et al, (1999) Cell, 96, p111-120.

P06.010**Identification of susceptibility genes for Multiple sclerosis: a study of the genomic region 2q13-14 in an Italian population**I. Borzani¹, M. Tola¹, L. Caniati², G. De Santis¹, A. R. Collins³, C. Scapoli¹;¹University of Ferrara, Ferrara, Italy, ²St. Anna Hospital, Ferrara, Italy, ³University of Southampton, Southampton, United Kingdom.

Understanding the genetic basis of multiple sclerosis (MS) remains a major challenge, despite decades of intensive researches. Whole genome linkage studies were carried out in different populations and from these analyses the prediction of at least 38 potential non-MHC susceptibility regions emerged (Abdeen et al., 2006). Among these, chromosomal portions of specific interest to some populations came out: the region 2q14 in the Irish and English population (Heggarty et al., 2003; Mann et al., 2002), the region 2q36 in the Sardinians (Corradu et al, 2003) and the region 2p21-22 in Continental Italian population (Liguori et al., 2003).

The main objective of this study was to investigate the role of 2q13-14 region in the pathogenesis of MS. The investigation was conducted on 120 patients, with clinically defined MS, and on 249 healthy subjects collected from the North-Italian population. Using CHROMSCAN (Maniatis et al, 2002, 2005), a map in LD-units, under the Malécot model for multiple markers, was constructed. The block-step structure of the 2q13-14 region was based on 70 SNPs (validated in the Caucasian population) selected from the HapMap database, with rare variant frequencies higher than 10% and evenly covering a region of 1.2 Mb within the segment 2q13-14.

We tested the association with the disease through both allelic association and by association mapping with the Malécot Model (Morton et al. 2007).

The present results support a possible association between this candidate region and MS in the North-Italian population.

P06.011**Association between the N-acetyltransferase 2 (NAT2) gene polymorphisms and allergic rhinitis in Volga-Ural region of Russia**A. Khuzina¹, A. Karunas¹, A. Biktasheva², A. Yuldasheva³, E. Etkina², E. Khusnutdinova¹;¹Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Ufa, Russian Federation, ²Bashkir Medical State University,Ufa, Russian Federation, ³Pediatric polyclinic N1, Ufa, Russian Federation.

Allergic rhinitis (AR) is the result of an immunologically mediated hypersensitivity reaction of the nasal mucosa, initiated by exposure to specific allergens. The prevalence of AR in various countries ranges from 10-25%. It has been suggested in various studies that genetic defects in acetylation may be involved in the pathogenesis of allergic diseases and atopy.

The aim of this study was to examine the allele and genotype frequencies of three polymorphisms (481C>T, 590G>A, 857G>A) of the gene and analysed their combinations. The patient group consisted of 264 individuals with AR with different ethnic origins (Russians, Tatars, Bashkirs), the control group included 185 unrelated non-allergic individuals. The NAT2 alleles (*4, *5, *6, and *7) were determined by polymerase chain reaction-restriction fragment length polymorphism methods with DNA extracted from peripheral blood leucocytes by standard phenol/chloroform method.

The analysis has revealed that Tatars have significant higher frequency of *4 allele (wild type) of the NAT2 gene in control group than in patients (P=0,0007; OR=0,34; 95%CI=0,18-0,64). At comparison of group of patients with high total IgE level and the control group we have also determined increased frequency of *4 allele of the NAT2 gene in healthy donors (P=0,026; OR=0,53; 95%CI=0,3-0,93). Moreover, an association of *5*6 genotype of the NAT2 gene with AR at patients with high total IgE level has been found (P=0,012; OR=2,4; 95%CI=1,19-4,82).

Thus, we have determined statistically significant association between NAT2 gene polymorphisms and allergic rhinitis in Volga-Ural region of Russia.

P06.012**Inherited alopecia and ectodermal dysplasia in pakistani kindreds**

I. Ahmad, M. Tariq, A. Ali, M. Bakhtiar, A. Azhar, S. M. Baig;

National Institute for Biotechnology and Genetic Engineering (NIBGE), Faisalabad, Pakistan.

Inherited Alopecia (AP) is a rare autosomal recessive disease clinically characterized by total or partial hair loss soon after their birth and the development of papular lesions of keratin-filled cysts over extensive area of body. The inherited hypohidrotic and anhidrotic ectodermal dysplasia (ED) is characterized by the absence or hypoplasia of hair, teeth and eccrine sweat gland. Ectodermal dysplasias are highly heterogeneous with more than 200 distinct clinical forms reported so far. The X-linked hypohidrotic ectodermal dysplasia (XLED) is the most common form of ED. In this study, twelve consanguineous families with alopecia and seven with ectodermal dysplasia were ascertained from Southern Punjab and Northern areas of Pakistan having multiple affected members. Pedigrees were analyzed to determine the pattern of inheritance; in four families with AP the disease was inherited in the autosomal recessive pattern. Short Tandem Repeat Markers (STR) were used in the exclusion mapping for the ten most common loci reported. According to results, one family with AP was linked to the type 1 keratin genes (17q21.2locus) while other families are still undergoing exclusion analysis. In four families with ED exclusion to all known loci has been observed whereas one family is showing linkage to the type II keratin (KRT) genes (12q13.13 locus). Exclusion analysis is in process in two pedigrees with ED. The families excluded to all known loci will be subjected to genome wide scan by SNP (Single Nucleotide Polymorphism) analysis using Affymetrix 250K array system to find the homozygous regions to find out the locus having the disease gene. Statistical analysis such as LOD (log of odds) will be used to validate the data obtained.

P06.013**Alpha-synuclein in familial Parkinson's disease and Lewy Body Dementia**V. Greco¹, E. De Marco¹, F. Rocca¹, P. Tarantino¹, F. Annesi¹, D. Civitelli¹, G. Provenzano¹, V. Scornaienchi¹, I. Cirò Candiano¹, S. Carrideo¹, G. Squillace¹, G. Nicoletti^{1,2}, G. Annesi¹;¹Institute of Neurological Sciences, National Research Council, Mangone(Cosenza), Italy, ²Institute of Neurology, University Magna Graecia, Catanzaro, Italy.

Alpha-synuclein has been implicated in the pathology of certain neurodegenerative diseases, including Parkinson's disease (PD) and de-

mentia with Lewy bodies (DLB). Alpha-synuclein is the major component of the filamentous Lewy bodies and Lewy neurites that define these diseases at a neuropathological level. The point mutations A30P and A53T in alpha-synuclein gene (*SNCA*) cause familial forms of PD and DLB. Recently, a third missense mutation E46K in *SNCA* was described in a Spanish family with DLB and parkinsonism. Moreover the A53T alpha-synuclein mutation was found in an elder Greek man with DLB. These cases suggest that E46K and A53T mutations should be considered in the differential diagnosis of DLB. The aim of this study was to evaluate the role of E46K alpha-synuclein mutation as a risk factor in DLB and in familial PD. We analysed the E46K mutation in seventeen sporadic DLB patients and thirty-seven familial PD patients. The clinical diagnosis of DLB was based on the criteria proposed by the International Consortium on DLB. PD patients were diagnosed according to UK Brain Bank criteria. We conducted a genetic analysis by standard PCR and restriction digestion method. None of the subjects examined had the E46K alpha-synuclein mutation. These results do not support a role for this mutation in our patients with DLB or familial PD, in agreement with the emerging consensus that mutations in the *SNCA* are associated with PD in few families worldwide.

P06.014

Associations of Alpha-1 antitrypsin Pi*S allele with COPD

D. Serapinas, B. Sitkauskienė, R. Sakalauskas;

Department of Pulmonology and Immunology, Kaunas University of Medicine, Kaunas, Lithuania.

Chronic Obstructive Pulmonary Disease (COPD) is characterized by progressive airflow limitation and related to an abnormal inflammatory response of the lung that results from a gene-environment interaction. The best documented genetic risk factor is severe hereditary deficiency of Alpha-1 antitrypsin (AAT). The presence of Pi*Z allele (Glu³⁴²→Lys) in homozygote state, that is inherited in autosomal recessive way is already well proven factor for developing COPD. Data about Pi*S allele (Glu²⁶⁴→Val) influence for developing COPD are not ascertain yet. Current study analyzed 1000 COPD patients, that clinical diagnosis was confirmed by using GOLD spirometric criteria. AAT serum concentrations were measured by means of nephelometry, and phenotyping was carried out by means of isoelectric-focusing. We found Pi*S allele in 44 patients: 1 in homozygous state SS, 43 in heterozygous state: 40 MS and 3 SZ. AAT concentrations were significantly lower in SS and SZ group compared with normal AAT variant MM ($p=0,035$). Lung function parameter - forced expiratory volume in one second (FEV1) was also worse in SS and SZ patients ($p=0,043$) than in MM group. Clinical and biochemical characteristics of COPD patients with MS and MM phenotypes has no statistical differences. In conclusion, the results of the present study support the concept that Pi*S allele is genetic risk factor for COPD for carriers of phenotypes SS and SZ, but not SM.

⁴UNIFESP, Sao Paulo, Brazil.

Interleukin-6 is a multifunctional cytokine produced by immune and non immune cells and act as an inflammatory mediator as well as endocrine and metabolic regulator. The IL-6 human gene is located in chromosome 7p21 and present many polymorphisms. The IL-6 rs 1800795 (-174G>C) polymorphism has been associated with Alzheimer's disease (AD) in some populations, however these findings have not been replicated in other studies. The IL-6 rs 1800796 (-572G>C) polymorphism has been considered as a risk factor for cardiovascular diseases and the IL-6 rs 00797(-597G>A) showed an association with systemic sclerosis, an autoimmune disease. To our knowledge, both polymorphisms have not been investigated in AD. DNA was extracted from blood samples of 302 subjects with similar ethnic origins, being 137 patients with AD, 130 elderly controls and 107 young controls. Subjects were genotyped concerning the three IL-6 polymorphisms using PCR-RFLP technique. AD patients were diagnosed according to NINCDS-ADRDA criteria. Association study was performed using Chi Square tests with $p=0.05$. No significant genotype distributions related

to -174 and -597 polymorphisms were observed among groups. However GG genotype and G allele of rs 1800796 polymorphism occurred more frequently in patients than in young controls ($p=0.045$, $p=0.031$, respectively). A tendency to a higher frequency of G genotype in elderly than in young controls was also detected ($p=0.06$). In our study G allele excess among AD patients of rs 1800796 is due to either a problem of the control sample or associated to a AD susceptibility. Financial Support: FAPESP, CNPq, CAPES

Association analysis of SNPs in PLAU and IDE genes with late-onset Alzheimer's disease in a sample of Mexican patients

C. Venegas¹, N. Najera¹, F. Mena¹, F. Garcia¹, L. Gutiérrez², M. López³, S. Kofman¹;

¹Hospital General de Mexico, Servicio de Genética. Facultad de Medicina, Universidad Nacional Autónoma de México, Mexico. D.F, Mexico, ²Servicio de Geriatria, Instituto Nacional de la Nutrición y Ciencias Médicas, Mexico. D.F, Mexico, ³Secretaria de Enseñanza Clínica Internado y Servicio Social, Facultad de Medicina, Universidad Nacional Autónoma de México, Mexico. D.F, Mexico.

Background: Urokinase-type plasminogen activator (PLAU) and insulin-degrading enzyme (IDE) genes represented strong positional and biologic candidates for late-onset Alzheimer disease (LOAD) susceptibility. PLAU and IDE are located on chromosome 10q22.2-23.3 close to a region of linkage for LOAD. In addition, many studies have identified a possible role of PLAU and IDE genes in the degradation of different forms of Amyloid β -peptide. Several polymorphisms of these genes have been analyzed, however a systematic meta-analysis of this SNPs of previous association studies; suggested that only (PLAU_1=rs2227564) and (IDE_9=rs1887922), are true allele risk with $OR>1.10$. Materials and Methods: A case-control study was design to evaluate the possible association between these SNPs with LOAD of Mexican patients. Data collection was performed from 55 patients with LOAD and 55 sex and age-matched controls subjects. We analyzed alleles and genotype distributions for APOE ($\epsilon 2/\epsilon 3/\epsilon 4$), one (C/T) polymorphism in exon 6 of the PLAU (rs2227564), and one (C/T) SNP in intron 20 of the IDE (rs887922). Results: We found different allele and genotype frequencies for all SNPs analyzed between cases and controls. Association was observed for the APOE $\epsilon 4$ allele ($OR=2.42$), TT genotype of PLAU ($OR=2.20$), and CC genotype of IDE ($OR=1.18$). Conclusions: These data suggest a genetic association between APOE ($\epsilon 4$), PLAU (TT), and IDE (CC) genotypes with LOAD in Mexican population. Absence of Association between APOA1 Polymorphism and Alzheimer's disease

M. L. Varlese^{1,2}, C. Babalini¹, C. Patrono^{1,3}, Z. Esposito^{1,2}, A. Borreca^{1,2}, P. Montieri^{1,2}, G. Sancesario², A. Orlacchio³, G. Bernardi^{1,4}, T. Kawara⁵, A. Orlacchio^{1,2};

¹Laboratorio Neurogenetica CERC-IRCCS Santa Lucia, Rome, Italy, ²Dipartimento di Neuroscienze, Università degli Studi di Roma "Tor Vergata", Rome, Italy, ³Dipartimento di Medicina Sperimentale e Scienze Biochimiche, Università degli Studi di Perugia, Perugia, Italy, ⁴Dipartimento di Neuroscienze, Università degli studi di Roma "Tor Vergata", Rome, Italy, ⁵Department of Neurology, Hyogo Brain and Heart Center, Himeji City, Japan.

Apolipoprotein A1 (APOA1) is the major apolipoprotein of the high-density lipoprotein, involved in reverse cholesterol transport. Alterations in cholesterol homeostasis influence the risk for Alzheimer's disease (AD). Vollbach et al. (2005) suggested that variation in the APOA1 might influence the function of the protein, and thus brain cholesterol metabolism, leading to an increased risk for AD. They identified two polymorphisms, a G/A substitution at position -75bp and a C/T and G/A base substitution at position -83bp or -84bp, or both, in the APOA1 promoter and investigated the effect of these polymorphisms on the risk for AD in 427 AD patients and 500 controls of German and English descent. They found that the A allele of the APOA1 -75bp G/A polymorphism was significantly associated with an increased risk for AD in subjects with an age at onset of 66 years or younger. In order to confirm these data we analysed the presence of this association in the Italian population recruiting 203 patients ($n 75 \leq 66$ and $128 > 66$ years old) affected by sporadic AD and 232 controls ($n 100 \leq 66$ and $132 > 66$ years old). In agreement with Vollbach et al. (2005), our analysis didn't

show any statistically significant association in LOAD group. On the other hand, we didn't find any association between APOA1 -75bp G/A polymorphism and the EOAD group ($\chi^2=0,084$, $df = 2$, $p = 0,959$). In opposition to Vollbach et al. (2005) our results show that variants of APOA1 don't influence the onset and the risk for Italian AD sample.

Paraoxonase gene polymorphism association with ALS in the French, Quebec and Swedish populations

P. N. Valdmánis^{1,2}, E. Kabash³, J. Bouchard³, F. Salachas⁴, V. Meininger⁴, P. Andersen⁵, W. Camu⁶, N. Dupre^{3,2}, G. A. Rouleau²;

¹McGill University, Montreal, QC, Canada, ²Center of Excellence in Neuromics, University of Montreal, CHUM-Notre-Dame Hospital, Montreal, QC, Canada, ³Department of Neurological Sciences, CHAUQ Enfant-Jesus, Quebec City, QC, Canada, ⁴Fédération des maladies du système nerveux, Hôpital de la Salpêtrière, Paris, France, ⁵Department of Neurology, Umeå University hospital, Umeå, Sweden, ⁶Unité de Neurologie Comportementale et Dégénérative Moléculaire Unit, Institute of Biology, Montpellier, France.

Amyotrophic lateral sclerosis (ALS) is an adult-onset neurodegenerative disease that results in the loss of upper and lower motor neurons. The disease is 90-95% sporadic in nature which suggests that multiple subtle genetic effects may lead to the development of ALS. One primary threat to motor neurons is oxidative stress. As such, an association has been observed between paraoxonase (PON) gene variants and ALS susceptibility. The PON cluster consists of three adjacent genes on chromosome 7q21.3 that aid in the detoxification of organophosphate insecticide and prevent the oxidation of lipoproteins. We sought to examine the frequency of coding and intronic PON polymorphisms in a set of 1197 ALS case and 1076 control samples from France, Sweden, and the founder French Canadian population of Quebec. Twenty SNPs that span the three paraoxonase genes were selected for Taqman genotype analysis. While individual SNPs were not considered associated on their own, a haplotype of SNPs at the C-terminal portion of *PON2* that includes the PON2 C311S amino acid change was significant in the French (p-value 0.0075) and Quebec (p-value 0.026) populations as well as all three populations combined (p-value 1.69×10^{-6}). Thus, we have identified two populations where susceptibility to ALS is significantly associated with variants in the PON gene cluster. The functional consequence of the variants identified with respect to motor neuron degeneration will provide insight into the role of these genes in susceptibility to ALS.

Identification of TDP-43 variants in amyotrophic lateral sclerosis (ALS) patients

E. Kabashi, P. N. Valdmánis, P. Dion, G. A. Rouleau;

Centre de Recherche de l'Université de Montréal, Montréal, QC, Canada.

Recently, TDP-43 was identified as a major component of ubiquitinated aggregates in amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). We have screened 200 ALS patients, 120 sporadic (SALS) and 80 familial (FALS) cases and we have identified several missense variants in the TDP-43 gene. None of these variants were present in 360 unaffected controls. We are currently aiming to determine the causative effect of TDP-43 mutations in ALS pathogenesis and motor neuron degeneration. We will sequence further ALS cases for mutations, perform functional assays to determine what could be the gain or loss of function of TDP-43 and test whether this leads to selective vulnerability of motor neurons. Finally, we are generating three in vivo models, including transgenic mice, which will determine whether mutations in TDP-43 induce a motor neuron disorder and motor neuron pathology in other species. This project will contribute greatly to our understanding of ALS pathophysiology and the functional role that TDP-43 plays in this disease.

Analysis of association of Apo E gene with placental insufficiency at habitual non-carrying of pregnancy

N. Mamedaliev, G. Svyatova, T. Nurbayeva;

Scientific Center of Obstetric, Gynecology and Perinatology, Almaty, Kazakhstan.

Both non-carrying of pregnancy and placental insufficiency are the basis of many kinds of heavy obstetrical pathology which causes unfavorable outcome for the fetus.

The aim of this research is to study features of distribution of alleles of Apo E Gene at pregnant women of Kazakh population with clinical placental insufficiency and habitual non-carrying of pregnancy in anamnesis.

Materials and Methods of Research. By the method of PDRF analysis on the basis of PCR-mediated and site-directed mutagenesis, an analysis of frequencies of alleles of Apo E Gene was held at 12 pregnant Kazakh women with diagnosed placental insufficiency and habitual non-carrying of pregnancy in anamnesis. Examples of DNA, taken from 32 sound non-related pregnant Kazakh women with physiologically going pregnancy, were used as control examples.

Results. The analysis of frequency of detecting polymorphism of Apo E Gene made known that favorable genotype E2E3 was really detected more frequently at patients of the control group (75%) than at those of the basic group (50%). Frequency of genotypes E3E3 and E3E4 was 33.3% and 8.3% in the researched pathology group against 6.25 and 0% in the sound group. The revealed data are in accordance with data taken from publications, and they are proof of its possible genetic relation with unfavorable allele E3E4 of Apo E Gene at development of placental insufficiency during habitual non-carrying of pregnancy. The further research of molecular-and-genetic markers will allow us to get more objective information about the nature and mechanisms for rise of placental insufficiency.

A second candidate gene causing aniridia? : preliminary results

F. Bayraklı¹, D. Ceyhan², Y. Bayrı³, I. Güney⁴, T. Cankaya⁵, K. Bilguvar³, S. Bayraklı⁶, M. Güneş⁶;

¹Marmara University, Department of Neurosurgery, Istanbul, Turkey, ²Van Military Hospital, Department of Ophthalmology, Van, Turkey, ³Yale University, Department of Neurosurgery, New Haven, CT, United States, ⁴Marmara University, Department of Medical Genetics, Istanbul, Turkey, ⁵Istanbul Surgery Hospital, Division of Genetics, Istanbul, Turkey, ⁶Istanbul University, Department of Family Practice, Istanbul, Turkey.

Aniridia can range from a readily visible, almost complete absence of the iris, through enlargement and irregularity of the pupil mimicking a coloboma, to small slit-like defects in the anterior layer seen only on transillumination with a slit-lamp.

Approximately one third of all cases of aniridia are sporadic and these are often found to have cytogenetically detectable deletions involving 11p13, besides balanced chromosomal translocations and single chromosomal breaks.

Aniridia can also be caused due to six different categories of *PAX6* mutations including nonsense, splicing, frame-shifting insertions or deletions, in-frame insertions or deletions, missense, and run-on mutations.

We found a large kindred with aniridia that have 10 live affected patients with autosomal dominant trait. While ophthalmological examinations of the affected patients revealed total aniridia, cranial magnetic resonance imaging studies showed no abnormalities in brain tissue.

Karyotype analysis (550 bands) revealed normal male (46, XY) and sequencing of translated and untranslated exons of *PAX6* gene were revealed no causative mutation. Chromosome 11 specific array-CGH for micro unbalanced translocation, deletion or amplification detection in or around the *PAX6* gene is underway.

This preliminary results suggest that there can be another causative gene for aniridia. Whole genome linkage analysis is the next step to identify responsible chromosomal locus.

P06.022

APO E epsilon genetic polymorphism and foot ulceration severity in peripheral vascular complications of type 2 diabetes mellitus

V. V. Petrova¹, M. A. Bogdanova², A. N. Voitovich², Y. A. Spesivcev², V. I. Larionova²;

¹St. Petersburg State University, Saint-Petersburg, Russian Federation, ²St. Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation.

Peripheral vascular disease (PVD) includes inflammatory process that leads to cell damage and impaired regeneration within a vessel wall resulting in the formation of foot ulcers. PVD is a common and severe complication of type 2 diabetes mellitus. Many investigations show that polymorphisms in apolipoproteins genes can be associated with PVD.

Therefore, they may play a role in genetic predisposition of diabetic foot ulcers. In this study, 100 diabetic patients with PVD (age 55-75, disease manifestation 5-15 years) were divided into three groups using the Wagner ulcer classification system: the first group consisted of patients with 1-2 grade of ulceration, the second group with 3-4 grade of ulceration and the third group with 5 grade of ulceration. The allelic and genotype frequency distribution of *APO E epsilon* genetic polymorphism was estimated in these groups using the chi-squared test. We found out the allele and genotype frequencies in the second and the third group differed significantly from the same in the first group ($p=0.05$). The diabetic PVD patients with 3 to 5 grade of ulceration had a significantly higher E4-allele frequency in comparison with the group of patients with 1-2 grade of ulceration.

Apolipoprotein A5 gene IVS3+G476A allelic variant confers susceptibility for development of ischemic stroke

A. Maasz¹, P. Kisfalai¹, Z. Szolnok², L. Jaromi¹, F. Hadarits³, B. Melegh¹;

¹Department of Medical Genetics and Child Development, University of Pecs, Pecs, Hungary, ²Department of Cerebrovascular Diseases, Pándy Kálmán County Hospital, Gyula, Hungary, ³Central Laboratory, Markosovszky County Hospital, Szombathely, Hungary.

Background: The T-1131C, T1259C and IVS3+G476A are naturally occurring variants of the apolipoprotein A5 gene; the aim of this study was to investigate the possible impact of these variants in the development of ischemic stroke. **Methods:** PCR-RFLP assays were used to determine the distributions of the apolipoprotein A5 gene alleles in small-, large-vessel and mixed subgroups of 378 patients and in 131 stroke-free control subjects. **Results:** Increased triglyceride levels were found in subjects carrying -1131C, 1259C, IVS3+476A alleles in all stroke groups and in controls. The -1131C and IVS3+476A alleles, but not the T1259C variant showed significant accumulation in all stroke subgroups. Logistic regression analysis adjusted for age, gender, BMI, total cholesterol levels, ischemic heart disease, hypertension, diabetes mellitus, smoking-and drinking habits revealed, that the IVS3+476A allele represent independent susceptibility factor for stroke (ORs for small-vessel: 4.748; large-vessel: 3.905; mixed: 2.926; overall: 3.644 at 95% CI; $p<0.05$); we could also confirm the previously verified pathogenic role of -1131C variant. **Conclusions:** Our results suggest that while all of the three apolipoprotein A5 gene variants are associated with elevated triglycerides; only the -1131C and the IVS3+476A alleles confer risk for all types of ischemic stroke; such association could not be detected for 1259C allele.

P06.024

APOA5 gene S19W polymorphism and atherogenic dyslipidemia in patients with type 2 diabetes

A. N. Voitovich¹, A. A. Bystrova², V. L. Stepanova², B. I. Smirnov³, O. A. Berkovich², E. V. Shliakhto², V. I. Larionova¹;

¹St. Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation, ²St. Petersburg State Medical University, Saint-Petersburg, Russian Federation, ³St. Petersburg State Electrotechnical University, Saint-Petersburg, Russian Federation.

Atherogenic dyslipidemia (AD), characterized by increased plasma levels of triglycerides or combined hyperlipidemia (hypertriglyceridemia and low plasma HDL level), is the most common in patients with type 2 diabetes (DM2). Apolipoprotein (apo) A5 gene S19W polymorphism has been shown to associate with increased plasma TG levels. So, the goal of this study was to define types of AD in patients with DM2 and to estimate the allele and genotype frequencies distribution of S19W APOA5 in groups of patients with different types of AD. A total of 232 patients with DM2 (168 women and 64 men, mean age 57±7) were classified as belonging to a group with isolated hypertriglyceridemia (62 subjects), a group with isolated hypoalphalipoproteinemia (13 subjects), a group with combined hyperlipidemia (27 subjects) and a normolipidemic group (118 subjects). APOA5 S19W genetic polymorphism was studied using the PCR-RFLP method. For statistical analysis of the allele and genotype frequencies distribution, the AD groups were compared with a normolipidemic group using the chi-squared test or the Fisher's exact test. We found out the allele and genotype frequencies in the group with isolated hypertriglyceridemia differed significantly from the same in the normolipidemic group ($p<0.001$). At the same time there was a statistically significant difference in allele and

genotype frequencies between the patients with combined hyperlipidemia and the normolipidemic group ($p=0.01$). The DM2 patients with hypertriglyceridemia both isolated and combined have significantly higher 19W-allele frequency in comparison with normolipidemic group of patients with DM2.

Autozygosity mapping in a large cohort of consanguineous Iranian families reveals three frequent loci for autosomal recessive intellectual disability

A. W. Kuss¹, M. Garshasbi¹, L. Abbasi-Moheb^{1,2}, M. M. Motazacker¹, K. Kahriz², S. Abedin², S. Esmaeli-Nieh¹, F. Behjat², A. Tzschach¹, H. Ropers¹, H. Najmabad²;

¹Max Planck Institute for Molecular Genetics, Berlin, Germany, ²Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Teheran, Islamic Republic of Iran.

There is reason to believe that autosomal recessive intellectual disability (ARID) is more common than X-linked intellectual disability, but it has so far received considerably less attention. This is partly due to small family sizes and low consanguinity rates in industrialized societies, both of which have hampered gene mapping and identification. To shed more light on the causes of ARID and as a prerequisite for diagnosis, counselling and therapy, we have set out in 2003 to perform systematic clinical and molecular studies in large consanguineous Iranian families with several mentally retarded children. This has already led us to the discovery of 12 novel ARID loci, eight of which had a LOD score above three, and in one of them we were recently able to identify a mutation in GRIK2. Contrary to previous observations which prima facie argued against the existence of frequently mutated genes, investigations in our expanding cohort of more than 200 families have now led to the identification of three loci (on chromosomes 1, 5 and 19), that show overlapping autozygosity regions of three, four and six families, respectively. At each of these loci a minimum of two overlapping linkage intervals were solitary in the respective family and showed a significant LOD score of or above three. Mutation screening in order to elucidate the underlying gene defects is ongoing and likely to reveal frequent ARID genes. The outcome of our project will broaden the basis for genetic counselling and provide insight into the molecular basis of brain function.

P06.026

Association of the methylenetetrahydrofolate reductase gene C677T polymorphism with unipolar depression

T. G. Noskova, E. K. Khusnutdinova;

¹Institute of Biochemistry and Genetics Ufa Scientific Centre RAS, Ufa, Russian Federation.

Unipolar depression (UD) is a complex disorder thought to result from multiple genes interacting with environmental and developmental components. The 5,10-methylenetetrahydrofolate reductase gene (MTHFR) is considered to be an important candidate gene of MDD. A single base mutation C677T results in production of a mildly dysfunctional thermolabile enzyme. The MTHFR 677T/T genotype and, to a lesser extent the 677C/T genotype, is associated with a significant elevation in the circulating concentrations of the homocystein and a decrease in serum folate concentrations, which may be parallel a similar reduction in 5-methyltetrahydrofolate in CNS and may lead to reduction in monoamine neurotransmitter function and greater risk of UD. This study examined association of the MTHFR gene C677T polymorphism with UD in Russian and Tatar patients. Samples of 174 patients and 331 healthy volunteers were investigated using PCR method and subsequent enzyme digestion. There were significant differences in distribution of genotype ($\chi^2 = 6.006$, $P = 0.05$) and allele ($\chi^2 = 4.603$, $P = 0.03$) frequencies between depressive patients and controls in total samples. For the Tatars the MTHFR**T*/**T* (OR = 3.21, 95%CI =1.04-9.93) and the MTHFR**T* (OR = 1.87, 95%CI =1.19-2.94) are risk markers; the MTHFR**C*/**C* (OR = 0.51, 95%CI = 0.29-0.90) and MTHFR**C* (OR = 0.53, 95%CI = 0.34-0.84) are protective markers. For the Russians only MTHFR**T*/**T* genotype (OR = 2.56, 95%CI = 1.01-6.48) is a possible risk marker for development of UD. Our results confirm the role of MTHFR C677T polymorphism in susceptibility to unipolar depression in patients of Russian and Tatar descents.

P06.027

The role of cytokine gene polymorphisms in the pathogenesis of childhood asthmaY. Fedorova¹, A. Karunas¹, N. Ramazanova², E. Etkina², E. Khusnutdinova¹;¹Institute of Biochemistry and Genetics, Ufa, Russian Federation, ²Bashkir Medical State University, Ufa, Russian Federation.

Asthma is a complex genetic disease characterized by increased airway responsiveness, reversible airway obstruction, and airway inflammation. Cytokines have important pathogenic role in this inflammation. In the present study, we analyzed associations between polymorphic variants of cytokine and cytokine receptor genes (*IL4*, *IL4RA*, *IL10*, *IL1B*, *IL1RN*) and asthma. The patient group consisted of 150 children with atopic asthma; the control group included 183 unrelated non-atopic individuals from Volga-Ural region of Russia. Genotyping was performed by polymerase chain reaction with specific primers followed by restriction digestion and gel electrophoresis.

A significant difference was observed in the allele and genotype frequencies of -627C>A polymorphism of the *IL10* gene and -590C>T polymorphism of the *IL4* gene between children with asthma and non-atopic control ($p < 0,05$). The frequency of CC genotype of the *IL10* gene was higher in asthma patients (58,0%) compared with control groups (42,1%; OR=1,9). Increased frequencies of TT genotype and T allele of the *IL4* gene were found in asthma patients (17,3% vs 7,7%; OR=2,5 and 46,0% vs 33,5%; OR=1,7, accordingly).

The analysis of -511C>T and 3953C>T polymorphisms of the *IL1B* gene, VNTR-polymorphism of the *IL1RN* gene, *Ile50Val* polymorphism of the *IL4RA* gene revealed that there are no significant differences in the frequencies of allele and genotype between asthma patients and control group ($p > 0,05$).

In summary, these results provided evidence for a role of *IL4* (-590 C>T) and *IL10* (-627 C>A) polymorphisms in susceptibility to childhood asthma in Volga-Ural region of Russia.

P06.028

IL4RA and IL12B gene polymorphisms with atopic asthma and opisthorchosisI. Saltykova¹, A. Simakina¹, E. Bragina², M. Freidrin², L. Ogorodova¹, V. Pusyrev²;¹Siberian State Medical University, Tomsk, Russian Federation, ²Institute of Medical Genetics of Tomsk Scientific Center of Siberian Branch of Russian Academy of Medical Science, Tomsk, Russian Federation.

Two common polymorphisms of the human *IL4RA* (I50V) and *IL12B* (1188A/C) genes were studied in 150 Russian patients with atopic bronchial asthma (BA), patients with *Opisthorchis felinus* helminth invasion, patients co-affected by these two diseases, and 150 healthy controls from Tomsk (Russia). Unlike the previous studies, no association with any disease was found for *IL4RA* gene polymorphism. The 1188A/C exchange in the *IL12B* gene was not associated with BA as well; however, the 1188C/C genotype prevalence was significantly higher in opisthorchosis patients as compared to the controls ($p < 0,05$). These data suggest a possible involvement of common polymorphism of the *IL12B* gene in pathogenesis of opisthorchosis.

P06.029

Association between genetic polymorphisms in transforming growth factor beta-1 (TGFβ1) and asthmaH. W. Lin¹, G. G. Yang², L. Y. Wang³, M. W. Lin^{1,4};¹Institute of Public Health, National Yang-Ming University, Taipei, Taiwan, ²Department of Respiratory and Critical Care, Buddhist Tzu Chi General Hospital, Hualien, Taiwan, ³Institute of Aboriginal Health, Tzu Chi University, Hualien, Taiwan, ⁴Department of Medical Research & Education, Taipei Veterans General Hospital, Taipei, Taiwan.

Asthma is a complex disease resulting from a combination of multiple genetic and environmental factors. Transforming growth factor beta-1 (TGF-β1) is expressed in many cell types including inflammatory cells and structural cells, such as airway epithelial and smooth muscle cells. TGF-β1 may modulate airway inflammation and remodeling, therefore TGF-β1 is a plausible candidate gene for asthma.

To investigate association between asthma and polymorphisms of the TGF-β1 gene, we conducted an age-sex matched case-control study including 283 asthmatic patients and 285 healthy controls in Taiwan. We selected 4 SNPs (rs1800469 C/T, rs1982073 T/C, rs2241715 T/G, rs2241716 G/A) on the TGFβ1 gene and performed genotyping

using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) method or TaqMan assay.

There were significant differences in the genotype and allele distribution of rs1800469 and rs2241715 polymorphisms of the TGF-β1 between asthmatic patient and controls. The combination of TC and TT genotypes of rs1800469 were also associated with a significantly increased risk of asthma as compared with the CC genotype [OR=1.697, 95%CI= 1.151-2.503]. The G allele of rs2241715 was associated with an increased risk of asthma as compared with the T allele [OR=1.331, 95%CI=1.051-1.684], however, only borderline significant genotypic difference was found between asthma and control group. Significant difference in the observed haplotype frequencies between cases and controls was also found. Those subjects with haplotype TCTG have increased risk of asthma.

Our results suggest that the two polymorphisms of the TGF-β1 gene are significantly associated with asthma in Chinese population of Taiwan.

P06.030

Association between ABCA1 transporter mRNA level and atherosclerosisE. Demina¹, T. Rodygina¹, A. Sheydina¹, A. Denisenko², A. Shvarcman¹;¹Petersburg Nuclear Physics Institute of RAS, Gatchina Leningradskaya oblast', Russian Federation, ²Saint-Petersburg Institute of Experimental Medicine, Saint-Petersburg, Russian Federation.

ABCA1 transporter is known to play important role in the cholesterol transport from peripheral tissues. However its influence on atherosclerosis development remains not studied completely.

According to our hypothesis ABCA1 gene expression level may influence on metabolism of antiatherogenic high density lipoproteins (HDL) and contribute to atherosclerosis development.

For ABCA1 gene expression level analysis banks of cDNA, isolated from leukocytes and macrophages of controls and patients with atherosclerosis diagnosed using angiography, were created. A significant reduction of ABCA1 mRNA level in leukocytes of patients with atherosclerosis when compared with controls was discovered. Mean ABCA1 expression levels in leukocytes for the group of patients and for the control group are 0.63±0.28 and 0.92±0.13 ($p = 0,02$). In the same time we detected a significant increase of ABCA1 mRNA level in macrophages of patients when compared with controls. Mean ABCA1 expression levels in macrophages for the group of patients and for the control group are 1.32±0.11 and 0.90±0.16 ($p = 0,003$).

In the group of patients with atherosclerosis 2-fold increase of ABCA1 gene expression level in macrophages when compared with the one in leukocytes was discovered. Mean levels of ABCA1 gene expression in macrophages and leukocytes of patients are 1.32±0.11 and 0.63±0.28, respectively, ($p = 0,000026$). In the control group ABCA1 gene expression level in macrophages did not differ from the one in leukocytes.

The study was supported by Russian Foundation for Basic Research (grant 06-04-49609).

Study of heme oxygenase 2 gene mutation as risk factor for CAD in Iranian patients with Atherosclerosis

S. Raoufzadeh, M. Zamani, S. Aleyasin;

National Institut for Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran.

Heme oxygenase 2 (HMOX2) enzyme is important in oxidative stress found in endothelial cells and adventitial nerves of blood vessels. This enzyme in collaboration with heme oxygenase 1 enzyme metabolizes heme molecules into ferrous iron, carbon monoxide (CO) and biliverdin which is further reduced to bilirubin. Both of biliverdin and bilirubin are potent antioxidants and reduce the chance of atherosclerosis. HMOX2 induces endothelial relaxation by synthesizing CO. This is the first study to investigate heme oxygenase 2 gene mutations in 137 patients with premature CAD affected with atherosclerosis and 100 normal controls. Pairs of primers have been designed to amplify exons 2, 3 and 4 of HMOX2 gene. All products have been analyzed by SSCP analysis and shifted fragments were separated for further sequencing. Two new sequence variations were observed among 13 patients with atherosclerosis consisted of C to A substitution in codone A70D (GCC to GAC) and A to G substitution in codone K89E (AAG to GAG). Levels of total direct and indirect bilirubin were determined in patients and

control groups. Statistical analysis showed significant association between A to G mutation and risk of atherosclerosis ($P = 0.01$). No significant alteration in the level of total bilirubin was observed between case and control groups ($P = 0.6$). This is the first report on the association between HMOX2 and atherosclerosis among Iranian CAD patients. This finding presences the importance of this mutation in development of atherosclerosis. More study would show the importance of hemoxy-genase 2 gene mutation in other populations.

P06.032

Large scale association study of gene-gene interaction within the filaggrin pathway

E. Rodríguez¹, H. Baurecht¹, N. Novak², N. Klopp³, T. Illig³, S. Wagenpfeil¹, A. D. Irvine⁴, S. Weidinger¹;

¹Technical University Munich, Munich, Germany, ²University of Bonn, Bonn, Germany, ³Helmholtz Zentrum München, Neuherberg, Germany, ⁴Our Lady's Children's Hospital, Dublin, Ireland.

Filaggrin deficiency due to null mutations in the *FLG* gene has been established as risk factor for atopic eczema (AE). Processing of pro-filaggrin to biologically active filaggrin monomers involves several dephosphorylation and proteolytic steps, and their impairment might also disturb skin barrier function. Among the proteases suggested to be implicated in profilaggrin processing is the stratum corneum chymotryptic enzyme (SCCE), which is possibly regulated by *SPINK5*-derived serine proteinase inhibitor LEKTI. An insertion in the 3' untranslated region of the kallikrein 7 gene (*KLK7*) encoding SCCE as well as a *SPINK5* variant have been reported to be associated with AE, but could not be replicated so far.

In our study we aimed at clarifying the role of these genetic variants for AE. Considering the potential biological interactions between filaggrin, SSCE and LEKTI, we also examined gene-gene interactions.

Association analysis was carried out in a cohort of 486 German families as well as in a cohort of 773 cases and 2924 supernormal controls. Whereas the strong effect of *FLG* polymorphisms was confirmed, no association of the *KLK7* insertion could be detected. Concerning the *SPINK5* polymorphism rs2303067 A-allele, weak association was observed in the family collection only, with a strong maternal effect. There was no evidence for epistatic effects between *FLG*, *KLK7*, and *SPINK5* variants that significantly predict AE risk. Thus, our data confirm the impact of filaggrin deficiency due to *FLG* loss-of-function mutations on AE risk, but do not support the hypothesis that this effect is dependent on *KLK7* or *SPINK5*.

Linkage and linkage disequilibrium scan for autism in an extended pedigree from Finland

H. Kilpinen¹, T. Ylisaukko-oja^{1,2}, K. Rehnström^{1,2}, E. Gaál¹, J. A. Turunen¹, E. Kempas¹, L. von Wendt³, T. Varilo^{1,2,4}, L. Peltonen^{1,2,4};

¹Department of Molecular Medicine, National Public Health Institute, Helsinki, Finland, ²Department of Medical Genetics, University of Helsinki, Helsinki, Finland, ³Unit of Child Neurology, Hospital for Children and Adolescents, Helsinki, Finland, ⁴Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

As a part of the genetic study of autism spectrum disorders (ASDs) in the Finnish population, an extensive genealogical search was conducted to find out whether a substantial fraction of the families would share the same ancestral lineage. Based on this search back to the 17th century, 18 ASD families (33 affected) were merged into one extended pedigree.

We hypothesized that this pedigree could expose rare ASD gene(s) enriched to this internal subisolate, and performed a genome-wide scan using 1107 STS-markers (intermarker spacing ~3.4cM). A joint analysis of linkage and linkage disequilibrium was performed with Pseudomarker statistics and a traditional multipoint linkage analysis with Simwalk2.

Nine loci exceeded the chosen significance level of $-\log(p) > 2.5$. Of these, 1q21-23 ($p = 0.00082$) is one of the best loci in our previous genome-wide scans for autism and Asperger syndrome in Finland, while 15q11-13 ($p = 0.00081$) is a well-recognized site for cytogenetic abnormalities associated with autism. Best multipoint linkage was observed at 19p13 [$-\log(p) = 3.57$].

Regional candidate genes were chosen from these best loci at 1q23, 15q12 and 19p13, and analyzed with SNPs using additional 126 families with ASDs (281 affected). Most significant association was

observed with five consecutive SNPs of *ATP1A2* (1q23; $p = 0.00055$) and with eight consecutive SNPs within a *TLE*-gene cluster (19p13; $p = 0.000078$). This association evidence was not detected using the nationwide sample, suggesting enrichment of these loci to our pedigree. We are currently performing a high-resolution analysis of the extent of shared chromosomal regions among the members of the pedigree with Illumina 317k platform.

P06.034

The BDNF receptor gene *NTRK2* is a susceptibility gene for autism

C. Correia^{1,2}, I. Sousa², I. Peixeiro², L. Lourenço², J. Almeida³, R. Lontro³, L. Gallagher^{4,5}, M. Gil^{4,5}, S. Ennis⁶, G. Oliveira³, A. M. Vicente^{1,2};

¹Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisboa, Portugal, ²Instituto Gulbenkian de Ciência, Oeiras, Portugal, ³Hospital Pediátrico de Coimbra, Coimbra, Portugal, ⁴Department of Genetics, Smurfit Institute, Trinity College, Dublin, Ireland, ⁵Department of Psychiatry, Trinity College, Dublin, Ireland, ⁶School of Medicine and Medical Sciences, University College, Dublin, Ireland.

Autism is a complex neurodevelopmental disorder likely determined by multiple genes. The *NTRK2* gene encodes a receptor, TrkB, for neurotrophin 4/5 and Brain-Derived Neurotrophic Factor (BDNF), which promotes neuronal differentiation and regulation of synaptic function in the developing and adult nervous system. Intriguing observations, such as increased BDNF levels in autistic children and *NTRK2* mutations in children with developmental delays, raise the hypothesis that an abnormal function/expression of *NTRK2* might be involved in autism. 38 tag SNPs, spanning the *NTRK2* gene, were tested for association with autism in 323 Portuguese trios. We found significant transmission disequilibrium of alleles at three markers in introns 5-6 and 15-16 ($0.011 < P < 0.041$). Given this evidence for association, we genotyped these markers in a second population sample of 168 Irish trios. In the combined sample ($N = 491$) we found an association of the same three SNPs at a more stringent P -level ($0.006 < P < 0.015$), and found nominal associations with four additional markers in intron 22-23 ($0.0211 < P < 0.043$). Previously we have described a significant increase of plasma BDNF levels in approximately 30% of our patients. We therefore screened *NTRK2* exons encoding ligand-binding and catalytic regions (exons 6, 7, 12, 18, 20-24) for mutations in 20 autistic individuals with increased BDNF levels and 10 controls. No mutations were identified in these individuals, and there was no evidence for association of *NTRK2* with plasma BDNF distribution. The overall results therefore suggest that *NTRK2* may be a susceptibility gene for autism, but its impact on autism is not mediated by the increased BDNF levels.

A large-scale systematic search for causal variants involved in autism and schizophrenia: resequencing of X chromosome synaptic genes

A. Piton, G. Julie, S. 2. D. team, G. A. Rouleau;

Center for the study of brain diseases, CR CHUM Hospital Notre-Dame, Montreal, QC, Canada, Montreal, QC, Canada.

Autism (AUT) and schizophrenia (SCZ) are two common neurodevelopmental disorders, which result from the combination of genetic and environmental factors. Linkage studies on the whole genome and association studies with candidate genes have failed to clearly identify the genes involved in the pathogenesis of these two diseases. We hypothesize that several different rare variants in numerous genes, including *de novo* variants, could lead to these diseases.

Therefore, we decided to directly sequence, in 285 AUT and SCZ patients, genes coding for proteins involved in the synapse, as defects in synaptic processes can lead to impairment in cognitive function. We decided to focus on the X chromosome, as evidence supports its implication in the predisposition to AUT especially, but also to SCZ.

Using various methods and sources, we established a complete list of 183 synaptic and potentially synaptic genes located on this chromosome and we ranked them according to their relevance for the diseases. We selected in this way 104 X-linked candidate genes that have been sequenced in our patient cohort. We have already identified more than hundred rare non-synonymous variants in AUT and SCZ patients. Some of them are particularly interesting due to their inheritance mode and their potential effect on the protein.

The screening of synaptic genes located on the X chromosome has led

to the identification of deleterious variants that could be responsible for AUT or SCZ in our patients. We are currently performing functional validation of these variants using animal models (zebrafish, fruitfly, worm or mice neurons).

P06.036

Association between polymorphisms of immune defense modifier genes and autoimmune diseases in Tomsk population

A. A. Rudko¹, E. I. Kondratieva², N. V. Tarasenko², E. V. Loshkhova², G. N. Yankina², N. P. Stepanenko², V. P. Puzyrev¹;

¹Research Institute of Medical Genetics, Tomsk, Russian Federation, ²Siberian State Medical University, Tomsk, Russian Federation.

The results of an investigation of the influence of immune defense modifier genes polymorphism [*IL1B* (+3953A1/A2), *IL1RN* (VNTR), *IL4* (3'-UTR G/C), *IL4RA* (I50V), *IL12B* (A1188C) and *VDR* (F/f and B/b)] on the development and presentation of type 1 diabetes, celiac disease (CD), and autoimmune thyroiditis (AT) are presented. The study was performed in 49 families with 139 patients affected by CD, 110 families with 350 type 1 diabetes patients, 119 patients with AT, and 129 unaffected controls of Russian ethnicity from Tomsk. We discovered various potential associations. The first was between +3953A1/A2**IL1B* and type 1 diabetes ($p=0.040$), and the second between the VV genotype of I50V**IL4RA* and AT ($p=0.032$). Family-based studies revealed association between 3'-UTR G/C**IL4* and CD ($p=0.024$), and between I50V**IL4RA* with type 1 diabetes ($p=0.018$), and additionally with complications of the disease: diabetic retinopathy ($p=0.050$), nephropathy ($p=0.026$) and neuropathy ($p=0.050$). Furthermore, the association with clinical course of the CD (typical form) was obtained for I50V**IL4RA* and F/f**VDR* polymorphisms ($p=0.001$ and $p=0.009$, respectively). The combination of type 1 diabetes and AT was associated with allele A2 of the VNTR**IL1RN* polymorphism ($p=0.018$), whereas combination of CD and AT was associated with allele C of G/C 3'-UTR**IL4*. Thus, in this investigation we detected associations of the studied phenotypes mainly occurred in polymorphic variants of the Th2-immunity genes.

Genetic analysis of pedigrees with autosomal dominant Premature Graying of hair

S. Ari¹, A. K. Maiti², J. V. Solanki³, R. Uppala¹, U. Radhakrishna¹;

¹Green Cross Blood Bank & Genetic Centre, Ahmedabad, India, ²Sealy Center for Molecular Medicine, University of Texas Medical Branch, Galveston, TX, United States, ³Department of Animal Genetics & Breeding, Veterinary College, Gujarat Agriculture University, Anand-388001, India.

Whiteness of hair is one of the most recognizable early signs of aging. This is also termed 'Canities'. It is caused by the gradual decrease of pigmentation that occurs when melanin ceases to be produced in the hair root, and new hairs grow without pigment. The change naturally occurs as people age, usually turning hair from its natural color to gray, then to white. Premature-graying of hair (MIM 139100) or whiteness of the hair is a phenotypic change that appears as early as at teens and twenties, for some, even in childhood. The causes of this relatively common condition are largely unknown, although genetic, medical and other environmental factors all are suspected. The phenotype is frequently associated with many known genetic disorders such as Book syndrome, Waardenburg syndrome and Lison syndrome. The most common factors that could trigger the condition were tobacco smoking. We have studied six large Indian families with premature-graying of hair. The phenotype in these families is constituent with autosomal dominant mode of inheritance. The pedigrees consist of 290 individuals including 57 affecteds (25 males 32 females). The age of onset ranged from early childhood to teenage with a graying range from 20-40% hair and it increased with the advancement of age. Skipping of a generation was observed in three pedigrees. Cytogenetic analysis of two affecteds in each family did not show any anomaly. Systematic genome-wide association or high density linkage studies with microchips could be initiated in these families to identify the genetic loci. Email: u_c_rao@hotmail.com

A strong association of axillary osmidrosis with genotype of the ABCC11 gene defining the earwax type

M. Tsuda^{1,2}, N. Miwa^{1,2}, M. Nakashima^{1,3,2}, M. Nakano⁴, M. Nakashima⁵, K. Yoshiura^{1,2}, T. Ohta^{6,2}, N. Niikawa^{6,2};

¹Department of Human Genetics, Atomic Bomb Disease Institute, Nagasaki University, Graduate School of Biomedical Sciences, Nagasaki, Japan, ²Solution Oriented Research of Science and Technology, Japan Science and Technology Agency, Tokyo, Japan, ³Department of Reconstruction and Plastic Surge, Atomic Bomb Disease Institute, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, ⁴Department of Reconstruction and Plastic Surgery, Atomic Bomb Disease Institute, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, ⁵Tissue and Histopathology Section, Atomic Bomb Disease Institute, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, ⁶Research Institute of Personalized Health Sciences, Health Sciences University of Hokkaido, Hokkaido, Japan.

Two types of cerumen are known in humans: the wet type with brownish sticky earwax, and the dry type lacking or reducing ceruminous secretion. The wet type is predominant in populations of European and African origin, while the dry type is often seen in Eastern Asian populations. An association of axillary odor with the wet earwax type among the Japanese was reported about 70 years ago. However, the data of the two traits were based on phenotypical analysis by researchers or on self-declaration by the subjects examined, because of lacking of definite diagnostic methods. We recently found that a SNP (rs17822931) of the ABCC11 gene is the determinant of the earwax types. In the present study, a total of 79 individuals with axillary osmidrosis (AO), who received a surgical operation to remove bilateral axillary apocrine glands, were examined for their earwax types by genotyping at the rs17822931 polymorphic locus. The earwax-type frequency among them was compared with that in the general Japanese population. The result showed a strong association between AO and the wet earwax type ($c^2 = 90.00$, $p < 2.5 \times 10^{-21}$). In addition, immunohistochemical study of the axillary and ceruminous apocrine gland tissues using an anti-ABCC11-protein antibody revealed that ABCC11 is strongly expressed and localized in the apical membrane of the both gland cells. The result indicates that ABCC11 protein (MRP8) functions in the axillary apocrine gland as well as in the ceruminous gland, and supports the association between axillary odor and earwax type.

P06.039

BCL1 glucocorticoid receptor gene polymorphism and bone mineralisation and metabolism in juvenile idiopathic arthritis

M. M. Kostik¹, A. A. Kozyreva², D. N. Baranov¹, N. N. Slizovskaya¹, V. I. Larionova¹;

¹State Pediatric Medical Academy, Saint-Petersburg, Russian Federation,

²Federal heart, blood and endocrinology center, named by V.A. Almazov, Saint-Petersburg, Russian Federation.

Juvenile idiopathic arthritis (JIA) is group of chronic inflammatory joint disease with different complications, such as osteopenia. Some patients receive only nonsteroid anti-inflammatory drugs (NSAID) and other patients receive glucocorticoides.

The aim of our study was whether *Bcl1* glucocorticoid receptor (GCR) gene polymorphism associated with bone mineralization and metabolism disturbances in JIA children.

Objectives: we included in our study 122 JA children, 43 boys (35,2%) and 79 girls (64,8%). Glucocorticoides were administered 30 children (24,6%), 3 boys and 27 girls. Another 92 JIA children were treated with NSAID.

Methods: *Bcl1* GCR polymorphism was detected by polymerase chain reaction with restriction assay [Fleury I. et al, 2003]. Osteopenia was detected by dual-energy X-ray absorptiometry L1-L4 (Hologic QDR 4500C), with national pediatric referent database (Schepliyagina L.A., 2005 et al). Bone metabolic markers, such as total Ca, Ca⁺⁺, phosphate, and total alkaline phosphatase, osteocalcine, β -CrossLabs and parathyroid hormone also were detected in our patients.

Results: We haven't differences between genotypes and alleles distribution between children, who received NSAID and glucocorticoides. Girls with osteopenia (Zscore<-1,0 SD) had significantly higher GG genotype and G allele GCR gene. Girls, carriers G allele had significantly low bone mineralization parameters: bone mineral density (BMD) - Z score ($p=0,003$) and tendency: bone mineral content ($p=0,07$) and BMD, measured in gsm² ($p=0,06$) and significantly high

osteocalcine level ($p=0,05$) when girls with CC genotype.

Conclusion: in our study we have revealed that GG genotype and G allele *BclI* GCR was associated with osteopenia in JIA girls with high osteocalcine level.

P06.040

S2G (Syndrome to Gene): Novel software for the identification of genes associated with human genetic syndromes

A. Gefen, R. Cohen, O. S. Birk;

National Institute for Biotechnology in the Negev, Beer-sheva, Israel.

The identification of genomic loci associated with human genetic syndromes has been significantly facilitated through the generation of high density SNP arrays. However, the identification of the specific disease-associated genes within such loci is still a tedious labor-intensive bottleneck. Optimal selection of candidate genes from within a defined genomic locus is a crucial step in the process.

We have generated novel software that selects optimal candidate genes, using a two step procedure. For any given syndrome, the software seeks all genes associated with syndromes containing similar phenotypes. It then searches through the entire human genome for other genes that are associated with these reference genes. This search takes into account interacting biochemical pathways, protein-protein interactions, transcription factor cascades, etc. A gene list is generated with an order of priority (degree of possible interaction with the reference gene(s)). This list is then filtered for the specific genomic locus in question - and a prioritized list of candidate genes is generated.

S2G can be used also in clinical genetics: when S2G gets a query for related syndromes of a given one, the score vector of the given syndrome is sorted creating a list of syndromes starting with the closest related syndrome. The result of the query is a list of syndromes with their known causing genes, so one can view and explore which genes are associated with similar phenotypes to those of the query syndrome.

P06.041

Dystrobrevin binding protein 1 gene (*DTNBP1*) in a Bipolar Case-Control Study (BACCS)

D. Gaysina^{1,2}, S. Cohen¹, P. C. Chow¹, L. Martucci¹, A. Schosser^{1,3}, H. A. Ball¹, F. Tozzi⁴, J. Perry⁵, P. Muglia⁴, I. W. Craig¹, P. McGuffin¹, A. Farmer¹;

¹MRC SGDP, Institute of Psychiatry, London, United Kingdom, ²Institute of Biochemistry and Genetics, Ufa, Russian Federation, ³Medical University Vienna, Vienna, Austria, ⁴GSK Research & Development, Verona, Italy, ⁵GSK Research & Development, Greenford, United Kingdom.

Background: Recent studies suggest a substantial degree of overlap in genetic susceptibility across the traditional categories of schizophrenia and bipolar disorder. There is consistent evidence for an association of the *DTNBP1* gene with schizophrenia, and thus this gene has also become a focus of further investigation in bipolar disorder (BD).

Methods: The aim of our study is to explore the association of *DTNBP1* gene with BD and with a sub phenotype such as presence/ absence of psychotic symptoms in a sample of 465 patients with BD (ICD10/DSMIV) and 478 ethnically matched control subjects recruited from the UK. Seven SNPs of the *DTNBP1*: rs2743852 (SNP C), rs760761 (P1320), rs1011313 (P1325), rs3213207 (P1635), rs2619539 (P1655), rs16876571 and rs17470454 were investigated using SNPlex genotyping system.

Results: We report significant differences in genotypic and allelic frequencies of rs3213207 and rs760761 of *DTNBP1* gene between the bipolar patients and controls. We also show a global haplotypic association and an association of a specific haplotype within this gene with BD.

Conclusions: Our results are consistent with previous studies in term of a general association between the dysbindin gene and bipolar disorder and provide additional molecular genetic evidence that a portion of the genotypic overlap between schizophrenia and bipolar affective disorder is attributable to this gene.

A 7 Mb region within 11q13 is candidate to contain a high penetrance gene for breast cancer

J. M. Rosa Rosa¹, G. Pita¹, A. González-Neira¹, V. Fernández¹, R. Oldenburg², P. Devilee³, J. Benítez¹;

¹Human Cancer Genetics Programme, Madrid, Spain, ²Dept. of Clinical Genetics, Leiden, The Netherlands, ³Dept. of Human Genetics, Leiden, The Netherlands.

Familial breast cancer represents up to 5% of the total breast cancer cases. Only a fraction of families affected by breast cancer is explained by mutation in *BRCA1* and *BRCA2*. Recently, our group has performed a new SNP-based linkage study in 19 non-*BRCA1/2* families from Spain, Netherlands and USA. We found that a single family was linked to two different chromosomes (regions 11q13 and 14q21), and showed a non-parametric LOD score of 11.5 in both regions. The regions spanned 28 and 14.5 Mb respectively. We ruled out any possible translocation between both chromosomes using cytogenetic techniques. We used both a panel of STRs and an indirect approach based on HapMap data to narrow down these two regions from 28 to 7Mb in chromosome 11 and from 14.5 to 8.5 Mb in chromosome 14. We selected the 11q13 region to perform a mutational screening on some candidate genes (*NUMA1*, *FGF3*, *CCND1*, *RAD9A*, *RNF121*, *FADD* and *has-mir-192*). Although we have not found any deleterious mutation in the coding sequence of these genes, data from infrequent markers located in different genes confirms 11q13 as a candidate region to contain a breast cancer susceptibility gene. A larger study involving new families could limit their size and facilitate a more extensive mutational screening.

PPP3R1 and NFATC4 polymorphisms have no influence on cardiac parameters in healthy individuals and related to cardiac remodeling in patients with cardiovascular disease

O. G. Ivanova¹, O. A. Makeeva¹, I. V. Tsimbal'uk², K. V. Puzryev², O. Y. Byichkova¹, A. A. Lezhnev³, V. A. Kazakov³, V. M. Shipulin³, V. P. Puzryev^{1,2};

¹Research Institute of Medical Genetics, Tomsk, Russian Federation, ²Siberian State Medical University, Tomsk, Russian Federation, ³Research Institute of Cardiology, Tomsk, Russian Federation.

Numerous data appeared supporting the notion about an important role which calcineurin pathway plays in myocardial hypertrophy, cardiac remodeling and human heart failure. Though only few studies had been reported to date which demonstrate an association of calcineurin pathway genes polymorphisms with cardiac parameters or other cardiovascular measurements.

In this study we analyzed association of two calcineurin pathway genes polymorphisms (5-base pair deletion in calcineurin B promoter - *5I/5D PPP3R1* gene polymorphism and SNP rs2228309 in exon 2 of *NFATC4* gene - *G160A*) with echocardiographic parameters in 216 healthy individuals. Two polymorphisms under study had previously been shown by us to be associated with left ventricular (LV) remodeling in patients with arterial hypertension.

In healthy subjects we did not find association of those two polymorphisms with LV myocardium mass index, wall thickness, LV remodeling index, end diastolic size, ejection fraction or other cardiovascular parameters.

To further analyze the role of two functional genetic variants we collected a group of patients with ischemic heart disease and ischemic cardiomyopathy ($n=104$). We had revealed that patients differed from healthy subjects in *A160G NFATC4* gene allele frequencies ($p=0,046$).

Our data supports the assumption that calcineurin pathway components may be involved in pathological types human heart remodeling.

P06.044

Study of genetic risk factors for cardiovascular disease in São Miguel Island population (Azores)

T. Pereirinha¹, C. C. Branco^{1,2}, P. R. Pacheco^{1,2}, R. Cabral^{1,2}, L. Mota-Vieira^{1,2};

¹Mol Genetics & Pathology Unit; Hospital of Divino Espírito Santo of Ponta Delgada, EPE, Azores, Portugal, ²Instituto Gulbenkian de Ciencia, Oeiras, Portugal.

Several genetic variants – factor V Leiden (G1691A), prothrombin (G20210A) and *MTHFR* (C677T and A1298C) – were found to be associated with cardiovascular disease (CVD), a frequent cause of death in many populations. The aim of this study is to investigate the preva-

lence of CVD risk mutations in São Miguel Island (Azores). From this population, 87 healthy individuals were analysed for the following variants: factor V Leiden, *MTHFR* (C677T and A1298C) by PCR-RFLP, and prothrombin by real-time PCR (FACTOR II Q - PCR Alert Kit, Nanogen Advanced Diagnostics). The allelic and genotypic frequencies of these polymorphisms were estimated and their values were compared with other populations. The results demonstrate that values of the mutant alleles *MTHFR* 677T (38.5%) and 1298C (23.6%) were relatively similar to those found in other populations. However, in São Miguel Island population, factor V Leiden shows a value of 1.7% for the 1691A allele, one of the lowest in Europe. Whereas, prothrombin (20210A) is present at a frequency of 3.4%, being one of the highest. Genotype frequencies of the genetic polymorphisms analysed showed similar values to other European populations. Furthermore, thirteen genetic profiles were identified in the study group: 13 individuals (14.94%) had none of the variants, 37 (42.53%) only one, 33 (37.93%) two, and 4 (4.60%) had three or more polymorphisms. The joint analysis of these polymorphisms represent a valuable contribution to further understanding the CVD in São Miguel Island. Funded by Azorean Government (M1.2.1./I/003/2005). lmotavieira@hdes.pt

P06.045

Analysis of sequence variants and splice isoforms in *IL18RAP* in celiac disease

G. Trynka¹, A. Zhernakova², K. A. Hun³, G. A. R. Heap³, L. Franke², J. Romanos¹, A. Szperl¹, M. Bruinenberg¹, M. C. Wapenaar¹, P. Deloukas⁴, R. McManus⁵, D. A. van Hee⁶, C. Wijmenga^{1,2};

¹University Medical Center Groningen, Groningen, Netherlands, ²University Medical Center Utrecht, Utrecht, Netherlands, ³Queen Mary University of London, London, United Kingdom, ⁴Wellcome Trust Sanger Institute, Cambridge, United Kingdom, ⁵Trinity Centre for Health Science, Dublin, Ireland.

Celiac disease (CD) is a common autoimmune disorder of the small intestine induced by the ingestion of gluten protein in genetically susceptible individuals. CD is a complex genetic trait in which presence of the HLA-DQ2/8 genotype is necessary but not sufficient for the disease development. Previously a genome wide association study (GWAS) in the UK celiac cohort initially identified a new non-HLA locus on chromosome 4q27. In a more extensive follow-up study, 1020 UKGWAS top associated SNPs were independently genotyped in three additional European celiac cohorts (2,410 celiac cases, 4,828 controls) and seven novel celiac loci were identified. One of the associated regions (P overall=8.49x10⁻¹⁰) maps to a 350-kb block on the chromosome 2q11-2q12. This block contains four genes including two *IL-18* receptors (*IL18R1* and *IL18RAP*). The strong correlation between the *IL18RAP* mRNA expression and associated SNP was observed in a group of treated celiac patients ($p < 0.0001$). Since the associated SNP is an intronic variant we sequenced the coding regions of *IL18RAP* in 23 celiac disease patients and 8 controls, and found 19 variants, 17 of which were already in dbSNP. One novel variant (c.1210+17A>G) was observed in a single control and the other one (c.1384+70_1384+71insT) was found in two celiac individuals. We are now genotyping the 19 SNPs in a large cohort of Dutch, UK and Irish celiac samples. *IL18RAP* is known to express two splice variants. Using quantitative real-time PCR we are currently testing for correlation between the genotypes and the expression of *IL18RAP* splice isoforms.

Relationship between Beta (3) Integrin (ITGB3) Leu 33 Pro Polymorphism and cerebral infarction

S. K. N. Lee E.Y, S. K. N. Lee E.Y;

Medical Institution, Almaty, Kazakhstan.

Objective: To explore the distribution of B beta 3 integrin (ITGB3) polymorphism in Kazakh population and the association of the polymorphisms with the occurrence of different types cerebral infarction. Methods: The B beta 3 integrin - Leu 33 Pro polymorphism was identified by polymerase chain reaction and restriction fragment length polymorphism in 37 patients with different cerebral infarctions (CI) and 87 healthy controls matching on age and sex..

Result : Distribution of genotypes ITGB3 basic group (LL 37,8%, LP 56,8%, PP 5,4%),in control group (LL 55,2%, LP 44,8%) ($p=0,2880$).

Frequency 33Pro allele provided of above that control group (33, 8% and 22, 4% accordingly) ($p < 0,05$).

Conclusion: The study demonstrated that 33 Pro allele of the B beta

(3) integrin gene (ITGB3) -Leu33Pro polymorphism may be a susceptible predictor different types of the cerebral infarctions in Kazakh population.

P06.047

Analysis of N-acetyltransferase 2 gene polymorphism in cervical cancer

I. Novakovic¹, D. Vusurovic¹, N. Maksimovic¹, T. Damjanovic¹, B. Jekic¹, B. Popovic², L. Lukovic¹, R. Papovic¹, V. Kesic³;

¹Institute of Human Genetics, School of Medicine, Belgrade, Serbia, ²Institute of Human Genetics, School of Dentistry, Belgrade, Serbia, ³Institute of Gynecology and Obstetrics, CCS, Belgrade, Serbia.

Cervical cancer (CC) is one of the most common causes of morbidity and mortality in women. Although the HPV is a major factor associated with CC the other risk factors have been indicated including smoking, oral contraceptive usage, lack of awareness for preventive care as well as genetic risk factor.

In our research N-acetyltransferase 2 (NAT2) gene polymorphism was estimated as a possible genetic risk factor. NAT2 has an important role in the metabolism of carcinogens and "slow acetylator" phenotype has been considered as risk factor for malignancy.

Our study included 51 women with diagnosis of CC and control group of 51 healthy women. Alleles determining fast acetylation (F1) or slow acetylation (S1, S2, S3) at NAT2 loci were detected by PCR-RFLPs method. The other risk factors were collected by questionnaire. It was calculated the frequency of gene polymorphisms, possible link with CC, frequency of other risk factors as well as combination of all estimated risk factors.

The most common genotypes in the CC and control group was F1S1 and S2S3, respectively, both in the same percentage of 27.45%. Genotype S2S3 has been significantly frequent in CC women what is considered as a predisposition for disease. Protective role of F1 allele for CC was not established. Smoking, rare gynecological checks, as well as lack of knowledge of CC prevention are confirmed as important risk factors for disease.

The research indicated role of NAT2 polymorphism in CC and confirmed that regular gynecological check through well organised screening is still best preventive method.

P06.048

The TaqIB Polymorphism of CETP Gene is Associated with Risk of Coronary Atery Disease (CAD) in Men in Russian Population

M. A. Bogdanova¹, A. N. Voitovich¹, O. S. Romashkina¹, N. Moroshkina², O. Ignateva², V. Isakov¹, A. Y. Anisenkova¹, B. I. Smirnov³, Y. R. Kovalev¹, O. A. Bercovich², V. I. Larionova¹;

¹St.Petersburg State Pediatric Medical Academy, St.Petersburg, Russian Federation, ²St. Petersburg Pavlov State Medical University, St.Petersburg, Russian Federation, ³St. Petersburg Electrotechnical University, St.Petersburg, Russian Federation.

CETP plays a central role in the metabolism of lipoproteins and might therefore alter the susceptibility to atherosclerosis. The TaqIB polymorphism of the *CETP* had been shown to be associated with its effect on lipid-transfer activity and on HDL cholesterol (HDL-CH) concentrations.

This study was undertaken to investigate genotype distribution and allele frequencies of *CETP* Taq B1 polymorphism in CAD patients of different age and sex and healthy individuals and to reveal its influence on HDL-CH concentration in these groups of patients.

594 patients were included in our study: 227 men who survived myocardial infarction (MI) under the age of 45 (group I), 95 men with MI after 60 years (group II) and 115 healthy men (group III); 73 angiographically diagnosed CAD women (group IV) and 84 women (age > 80 years) without CAD (group V), all originated from Saint-Petersburg, Russia. Genotypes were determined by PCR-RFLP, statistic: χ^2 tests, SPSS. In group I levels of total cholesterol, LDL-CH and triglycerides was significantly higher, and levels of HDL-CH lower in comparison with group II. We found that frequency of B1B2 genotype was significantly higher among patients from group I than among patients from group II and group III ($p=0,02$ and $p=0,04$ respectively; OR=2). There was no difference in B1 and B2 allele frequency in groups of CAD and healthy men. Our results allow to suggest that B1B2 genotype of *CETP* is a risk factor of CAD in men but not in women in analyzed groups.

P06.049

Analysis of CFTR gene in Italian patients with idiopathic normocalciuric calcium nephrolithiasis

M. Gabaldo¹, C. Bombieri¹, A. Fabris², A. Lupo², P. F. Pignatti¹, G. Gambaro²;

¹Section of Biology and Genetics, Dpt. of Mother and Child and of Biology-Genetics, University of Verona, Italy, ²Division of Nephrology, Dpt. of Biomedical-Surgical Sciences, University Hospital of Verona, Italy.

Idiopathic calcium nephrolithiasis (ICN) is a multifactorial disease, whose pathogenesis involves a complex interaction of environmental and individual factors, possibly genetic. A growing body of evidence shows an association between Cystic Fibrosis (CF) and calcium nephrolithiasis. Of patients with CF, 3.0 to 6.3% are affected with nephrolithiasis, generally with calcium oxalate stones, a percentage greater than that of age-matched healthy controls (1-2%). CFTR mutations may be responsible for abnormal kidney development or may affect some steps of renal crystallization processes, thus favouring stone formation. Aim of this project was to investigate whether idiopathic normocalciuric calcium renal stone formers are associated with CFTR gene mutations or polymorphisms. A group of 44 Italian normocalciuric ICN patients and presenting no story reminding of CF were selected. Clinical and laboratory test to determine renal function were performed to exclude other causes of nephrolithiasis. The complete coding sequence and the intronic flanking regions of the CFTR gene were analysed by DGGE and sequencing. A total of 5/44 (11%) patients had a mutation in the CFTR gene, all in heterozygosis (2 F508del, 1 D1152H, 1 R110H, 1 R75Q). This results is not statistically different from that found in a previous study on the general population (HumGenet, 106:172-178, 2000). The frequency of other common polymorphisms of the CFTR gene is also not different from the general population. These results show that the CFTR gene carrier status is not a risk factor for normocalciuric ICN.

MTHFR gene polymorphisms as a risk factor for congenital heart disease in São Miguel island, Azores (Portugal)

R. Cabral^{1,2}, F. Tejero¹, L. de Fez¹, P. R. Pacheco^{1,2}, C. C. Branco^{1,2}, C. P. Duarte³, R. Anjos⁴, L. Mota-Vieira^{1,2};

¹Mol Genetics & Pathology Unit; Hospital of Divino Espírito Santo of Ponta Delgada, EPE, Azores, Portugal, ²Instituto Gulbenkian de Ciencia, Oeiras, Portugal, ³Pediatric Department; Hospital of Divino Espírito Santo of Ponta Delgada, EPE, Azores, Portugal, ⁴Pediatric Cardiology Department; Hospital of Santa Cruz, Carnaxide, Portugal.

Congenital heart defects (CHD) are among the most common birth defects worldwide, occurring in São Miguel Island with a prevalence of 9.16 per 1000 live births (Cymbron T *et al. Community Genet*, 9: 107-112, 2006). Several studies demonstrate that the intake, by the mothers, of periconceptional folic acid reduces the risk of congenital anomalies, including CHD. This fact led to the search of candidate genes involved in folate metabolic pathways. Methylene tetrahydrofolate reductase (MTHFR), a regulating enzyme of this metabolism, is responsible for the availability of active folate. Our main goal is to test the C677T and A1298C MTHFR polymorphisms as risk factor for CHD. We analyzed these two variants in a control population of 469 healthy blood donors from São Miguel and in the CHD group of 95 patients. For 677CC, 677CT and 677TT, we observed 28 (29.5%), 54 (56.8%), and 13 (13.7%) CHD cases, respectively. Similar proportions were found in the control individuals, that is, 162 (34.5%) were CC, 223 (47.6%) were CT and 84 (17.9%) were TT. Genotype frequencies of 1298AA, 1298AC and 1298CC were 56 (58.9%), 38 (40%) and 1 (1.1%) among cases and 264 (56.3%), 177 (37.7%) and 28 (6%) among control population, respectively. These values reveal no significant differences between both groups (odds ratio, 95% confidence interval). Because we have evidences of familial aggregation in CHD cases, this study is being concluded with the transmission/disequilibrium test in order to analyse the transmission distortion in the 89 nuclear families. Funded by Azorean Government (M1.2.1/003/2005). ritacabral@hdes.pt

P06.051

Peripheral Gene Expression Profiling of CCK-4-Induced Panic in Healthy Subjects

K. Kallassalu^{1,2}, E. Maron^{3,4}, A. Tammiste¹, R. Kolde⁵, I. Tõru⁴, V. Vasar⁴, J. Shlik⁶, A. Metspalu^{7,2};

¹IMCB, Tartu, Estonia, ²Estonian Biocentre, Tartu, Estonia, ³Research Department of Mental Health, The North Estonian Regional Hospital, Psychiatry Clinic, Tallinn, Estonia, ⁴Department of Psychiatry, University of Tartu, Tartu, Estonia, ⁵Institute of Computer Science, University of Tartu, Tartu, Estonia, ⁶Department of Psychiatry, University of Ottawa, Ottawa, ON, Canada, ⁷University of Tartu, Tartu, Estonia.

Panic attacks are anxiety-related phenomena defined as discrete periods of abruptly escalating intense fear or discomfort with multiple somatic and cognitive symptoms. Panic-induction or challenge tests in healthy subjects provide certain advantages in the investigation of genetic mechanisms of panic. Understanding why some, but not all, healthy subjects demonstrate panic response to a challenge test may advance knowledge about the pathogenesis of panic attacks and panic disorder.

In the present study we used the Illumina Human-6 v2 Beadchips for whole genome expression profiling in healthy subjects (n=31) participating in a cholecystokinin-tetrapeptide (CCK-4) challenge test. We aimed to explore the association between gene expression signatures, the occurrence of panic attacks, and the influence of the CCK-4 challenge on peripheral transcriptional activity.

The results showed that, after summarizing gene expression profiles before and after CCK-4 provocation, 16 genes were differently expressed between panickers and non-panickers (p<0.05). Considering the higher susceptibility to panic attacks in females, we also performed separate analyses by gender. The transcriptional levels of 8 genes distinguished female panickers from female non-panickers. In males, 17 genes differed between panickers and non-panickers. Comparison of gene expression profiles in males and females revealed 5 genes expressed differently between genders. Gene expression profiling two hours post-CCK-4 challenge in all subjects, 78 genes showed significant changes in their transcriptional activity.

In summary, this study represents the first attempt to find associations between panic attacks and peripheral gene expression in humans using a challenge experiment design.

P06.052

Genetic polymorphism in the matrix metalloproteinases genes MMP1, MMP9, MMP12 and risk of chronic lung disease in children

O. Tselousova¹, G. Korytyna¹, L. Akhmadishina¹, T. Victorova^{1,2};

¹Institute of Biochemistry and Genetics, Ufa, Russian Federation, ²Bashkir State Medical University, Ufa, Russian Federation.

The matrix metalloproteinases (MMPs) are proteolytic enzymes that play an essential role in lung tissue remodeling and repair during the inflammatory response. MMP1 (interstitial collagenase), MMP9 (gelatinase B) and MMP12 (macrophage elastase) may be important in the development of chronic lung disease. In our study, we investigated the role of common polymorphisms within several MMP gene promoters in genetic predisposition to chronic lung disease in children. DNA samples from 235 children with chronic respiratory diseases were analyzed. The control group consisted of 323 conditionally healthy persons, living in the Republic of Bashkortostan, Russia.

We have shown that the alleles and genotypes distribution of MMP12 gene A(-82)G polymorphism was significantly differed between patients with chronic lung disease and controls ($\chi^2=5.45$, $df=1$, $P=0.02$ and $\chi^2=5.85$, $df=1$, $P=0.016$). The AA genotype was identified as a risk factor for chronic lung disease in children ($\chi^2=5.85$, $df=1$, $P=0.02$, $P_{cor}=0.04$; OR=2.02, 95%CI 1.13-3.62). Genotype AG was more frequent in healthy children, and was identified as a protective genotype ($\chi^2=5.85$, $df=1$, $P=0.02$, $P_{cor}=0.04$; OR=0.50, 95%CI 0.28-0.89).

However, the genotype and allele frequencies of polymorphisms G(-1607)GG of MMP1 gene and C(-1562)T of MMP9 gene do not significantly differ in groups.

Our results showed that the polymorphisms in several MMP genes may play a significant role in the development of chronic lung disease in children.

Association study of microsatellite markers of five candidate loci in the cleft lip and palate patients of Lithuania

L. Ambrozaitytė^{1,2}, A. Matulevičienė^{1,2}, V. Kučinskas^{1,2};

¹Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, ²Centre for Medical Genetics, Vilnius University Hospital Santariškių Klinikos, Vilnius, Lithuania.

The incidence of cleft lip and/or cleft palate (CL/P) in the population of Lithuania is 1 in 544 newborns; nonsyndromic CL/P cases are 74.1% part of it. Many different genes are considered as candidate loci for nonsyndromic CL/P responsible for this malformation. And the results by many study groups are still very inconsistent.

We have investigated five microsatellite markers D2S292 in TGFA gene, D14S61 in TGFB3 gene, D15S97 in GABRB3 gene, D17S1335 in RARA gene and BCL3 in BCL3 gene in 120 triads (child with nonsyndromic CL+/-CP and both parents) - 102 triads with a child with nonsyndromic cleft lip with or without cleft palate (NS-CL+/-P) and 18 triads with a child with nonsyndromic cleft palate only (NS-CPO). Association analysis was performed by using transmission disequilibrium test (TDT).

Allele-wise and genotype-wise analysis gave no statistically significant results ($p > 0.05$). Nevertheless transmission disequilibrium analysis of every marker allele separately showed significant association between three out of investigated five microsatellite markers and NS-CL+/-CP: allele 6 (182 bp) of D2S292 marker ($p = 0.024$), allele 11 (206 bp) of D14S61 marker ($p = 0.025$) and allele 3 (128 bp) of BCL3 marker ($p = 0.015$).

These results suggest the contribution of TGFA, TGFB3 and BCL3 genes to nonsyndromic CL/P as well as indicate that these genes are probably not the causal genetic risk factors.

P06.054

Intron region importance of BCL3 gene in the nonsyndromic cleft lip and/or cleft palate

I. Prane^{1,2}, B. Lace¹, L. Piekuse¹, J. Klovins², B. Barkane², I. Akota², A. Krumina¹;

¹Department of Molecular Biology and Genetics, Riga Stradins University, Riga, Latvia, ²Latvian Biomedical Research and Study Center, Riga, Latvia, ³Department of Oral and Maxillofacial Surgery, Institute of Stomatology, Riga Stradins University, Riga, Latvia.

Background: Orofacial clefts form as a result of interaction of environmental and genetic factors. Still up to now the exact mechanism of how the clefts form are not known. This is why it is so important to explore and investigate genes constituting to this process. It has been reported that *BCL3* (*B-cell leukemia/lymphoma-3*) on chromosome 19q13.1-q13.2, or a nearby gene may play a role in the etiology of nonsyndromic cleft lip and/or cleft palate (CLP/CP). There is possibility *BCL3* gene mutations increase affinity to transcriptional factors thus inhibited expression of genes, which are important in mesenchymal development process.

The aim of the study was to evaluate relevance of *BCL3* gene intron region in development of nonsyndromic orofacial clefts.

Materials and methods: Eight SNPs (rs7257231, rs1040117, rs8103315, rs2927457, rs11671085, rs1979377, rs2927456 and rs2306148) in the *BCL3* gene were analyzed with MALDI-TOFF technique for allelic association with the nonsyndromic CLP/CP in 75 trios (proband with both parents) from Latvia. Observed data were analyzed with transmission disequilibrium test (TDT).

Results: Three of eight SNPs (rs2927457, rs11671085 and rs2306148) were not polymorphic, five were found to be polymorphic - rs7257231, rs1040117, rs8103315, rs1979377 and rs2927456. TDT analysis revealed SNP rs10401176 ($\chi^2 = 5.143$, $P = 0.023$, df 1) in the CLP patient group and three SNPs rs10401176 ($\chi^2 = 5.444$, $P = 0.0196$, df 1), rs7257231 ($\chi^2 = 4.455$, $P = 0.034$, df 1), rs2927456 ($\chi^2 = 4.000$, $P = 0.045$, df 1) in the CP patient group showed statistically significant association.

Conclusion: Statistical analysis of obtained results showed *BCL3* gene intron 1 as a meaningful region for further studies.

P06.055

Role of the C1236T (rs1128503) polymorphism of the MDR-1 Gene on Clopidogrel Responsiveness

E. Trabetti¹, M. Zanon¹, P. Prandini¹, D. J. Angiolillo², E. Bernardo³, A. Fernandez-Ortiz³, C. Macaya³, T. A. Bass², P. F. Pignatti¹;

¹Department of Mother and Child and of Biology-Genetics, Section of Biology-Genetics, Verona, Italy, ²Division of Cardiology, University of Florida College of Medicine-Shands Jacksonville, Jacksonville, FL, United States, ³Cardiovascular Institute, San Carlos University Hospital, Madrid, Spain.

Background: Clopidogrel intestinal absorption and active metabolite formation are influenced by P-glycoprotein-mediated efflux. The functional activity of P-glycoprotein is under genetic control by the Multi Drug Resistance-1 (MDR-1) gene. If genetic variations of MDR-1 contribute to variability in clopidogrel response in patients with coronary artery disease remains poorly explored.

Methods: The C1236T (rs1128503) polymorphism of the MDR-1 gene was assessed in 62 patients. Patients were divided into 2 groups: carriers and non-carriers of the T allele. Platelet aggregation was performed before and 24 hours after clopidogrel administration. Standard (300mg; n=45) and high (600mg; n=17) loading dose regimens were used. All patients were on treatment with aspirin (100mg/day). Peak platelet aggregation was assessed by LTA using 6 $\mu\text{mol/L}$ ADP stimuli. Post-treatment platelet reactivity and percentage inhibition of platelet aggregation (IPA) were determined.

Results: 71% and 29% of the study population were T and non-T allele carriers, respectively. At baseline, there were no differences in platelet aggregation between the two groups. At 24 hours there were no differences in post-treatment platelet reactivity between groups following a 300mg loading dose administration. However, following a 600mg loading dose administration, post-treatment platelet reactivity was significantly higher in T allele carriers ($35 \pm 11\%$ vs $16 \pm 3\%$; $p = 0.006$). Accordingly, there were no differences in IPA following a 300mg dose and IPA was significantly lower in T allele carriers following a 600mg dose ($44 \pm 18\%$ vs $73 \pm 5\%$, $p = 0.001$).

Conclusions: The C1236T polymorphism of the MDR-1 gene modulates clopidogrel responsiveness in the acute phase of treatment when using high loading dose regimens.

P06.056

Association of cocaine dependence and neurotrophic factors: contribution of the Brain-Derived Neurotrophic Factor (BDNF) and the Neurotrophic Tyrosine Kinase Receptor 2 (NTRK2)

N. Fernandez-Castillo¹, M. Ribasés², B. Gonzalvo², M. Casas^{2,3}, C. Roncero^{2,3}, B. Cormand^{1,4};

¹Departament de Genètica, Facultat de Biologia, Universitat de Barcelona, Barcelona, Spain, ²Servei de Psiquiatria, Hospital Universitari Vall d'Hebron, Barcelona, Barcelona, Spain, ³Departament de Psiquiatria i Medicina Legal, Universitat Autònoma de Barcelona, Barcelona, Spain, ⁴CIBER Enfermedades Raras, Instituto de Salud Carlos III, Barcelona, Spain.

Drug addiction is a complex psychiatric disorder that results from the interaction of different genetic and environmental factors. Tolerance, sensitization, craving and abstinence are common features in drug addiction, and may be related to neuronal processes such as plasticity and remodeling. Animal and pharmacological studies suggest that neurotrophins may play an important role in cocaine addiction through their effect on these processes. To evaluate the contribution of the Brain-Derived Neurotrophic Factor (BDNF) and its specific receptor Neurotrophic Tyrosine Kinase Receptor 2 (NTRK2) we genotyped two SNPs in the *BDNF* gene and three SNPs in the *NTRK2* gene in a Spanish sample of 91 cocaine dependent patients and 91 sex and age-matched healthy controls. The single-marker analysis showed association between cocaine dependence and the Val allele of the p.Val66Met *BDNF* polymorphism (rs6265; $2p = 0.014$; OR = 2.14 (1.16-3.96)) and the c.2732T>C polymorphism of the *NTRK2* gene ($2p = 0.0062$). Additionally, the multiple-marker analysis supported an overrepresentation of the C/A/C haplotype (rs1187325/rs1047896/c.2732T>C) of the *NTRK2* gene in cocaine addicts ($2p = 0.005$; OR = 7.19 (1.77-29.2)). Our results, although preliminary, point out that the *BDNF* and *NTRK2* genes may contribute to the predisposition to cocaine addiction and suggest a potential participation of neurotrophic factors in drug dependence.

P06.057**Clinical and immunohistochemical pre-screening and RNA sequencing increase mutation detection rate for the Collagen VI genes**

T. P. Cullup¹, C. Jimenez-Mallebrera², L. Feng², S. Robb², F. Munton², S. Yau¹, S. Abbs¹;

¹DNA Laboratory, Guy's & St. Thomas' NHS Foundation Trust, London, United Kingdom, ²Neuromuscular Unit, Hammersmith Hospital, London, United Kingdom.

Ullrich Congenital Muscular Dystrophy (UCMD) and the milder Bethlem Myopathy (BM) are caused by mutations in COL6A1, COL6A2 and COL6A3 which collectively are comprised of 106 coding exons. Neither phenotypic nor immunohistochemical analyses are able to pinpoint which of these genes to target for mutation screening.

We have established a diagnostic mutation screening service for these three genes based on sequencing cDNA derived from fibroblast cultures. This requires only 26 overlapping cDNA fragments, compared with over 100 fragments needed to cover the genes using genomic sequencing.

Mutations have been detected in 14 out of an initial cohort of 16 patients; this 87.5% detection rate compares favourably with the 62% detection reported in Lampe et al. This higher rate of detection can be partly attributed to the sequential use of clinical and immunohistochemical screening prior to molecular analysis and partly to the RNA-based approach. In particular a change ten bases from the start of the exon in COL6A2 (c.1117-10A>G) is likely to be responsible for the splicing out of exon 13 in one patient, and in a second patient an absence of exon 10 at the cDNA level of the same gene has as yet no confirmed mechanism at the DNA level.

Surprisingly eight patients with a UCMD phenotype, previously thought of as a recessively-inherited form, have a single mutation; this reinforces current thinking that the two disorders represent either end of a phenotypic spectrum.

Lampe, A. K. et al; J Med Genet 2005;42:108-120

P06.058**A computational test for biological relatedness in genetic association studies using probabilistically inferred haplotypes**

L. Xumerle, G. Malerba, P. F. Pignatti;

Department Maternal Infantile and of Biology-Genetics. Section of Biology and Genetics, University of Verona, Italy.

An association between gene and disease may be incorrectly estimated if the allele frequencies differ among cases and controls depending on inbreeding or unrecognized population stratification.

A program (<http://medgen.univr.it/jenoware/>) was developed to compute the probability of genetic relatedness in pairs of individuals using a likelihood ratio test.

Using loci that are in LD decreases the accuracy of parentage assignments. Groups of SNPs in linkage disequilibrium (LD) were simulated to verify the effects of linkage on relatedness assignment. The probability of genetic relatedness was computed using the single SNPs and treating the SNPs as composite markers with different r^2 threshold values. Haplotypes were probabilistically inferred using the PHASE and Gerbil programs. False positive rate and power were assessed by simulation in unrelated individuals and in pedigrees.

As an example of results, in order to estimate the support for II degree relatedness with power 80%, and false positive rate 5%, the following was needed: 100 SNPs with no linkage; 275 SNPs having $r^2=0.4$; 20 probabilistically inferred haplotypes (100 SNPs having $r^2=0.4$); 40 probabilistically inferred haplotypes (200 SNPs having $r^2=0.8$).

In conclusion, if LD blocks are examined, the biological relatedness can be computed with a limited number of markers increasing test accuracy with probabilistically inferred haplotypes.

P06.059**A new gene for X-linked Congenital Ataxia maps to Xq25-q27.1**

G. Zanni^{1,2}, E. Bertini², C. Bellcross³, B. Nedelec¹, G. Froyen⁴, G. Neuhauser⁵, J. M. Opitz⁶, J. Chelly¹;

¹Université Paris Descartes, Institut Cochin, Département Génétique et Développement, Paris, France, ²Ospedale Pediatrico Bambin Gesù, Unit of Molecular Medicine, Rome, Italy, ³Dean Medical Center, Department of Perinatology, Madison, WI, United States, ⁴Human Genome Laboratory, Department of Human Genetics, Catholic University Leuven, Leuven, Belgium, ⁵Department of

Pediatrics, Justus Liebig Universität, Giessen, Germany, ⁶Department of Pediatrics, Medical Genetics, Human Genetics, Pathology, Obstetrics and Gynaecology, University of Utah, Salt Lake City, UT, United States.

We observed a large American family of Norwegian descent with X-linked nonprogressive congenital ataxia (XCA) and normal cognitive development in six affected males over three generations. Neuroimaging showed global cerebellar atrophy without evidence of supratentorial anomalies. Linkage analysis resulted in a maximum LOD score $Z=3.44$ for marker DXS1192 at $\theta=0.0$ with flanking markers DXS1047 and DXS1227 defining a region of 12cM in Xq25-q27.1. The clinical and neuroradiological findings in the present family are very similar to those described in two other reported X-linked families however, the newly identified locus does not overlap with the one defined previously in Xp11.21-Xq24, indicating that there are at least two genes responsible for this rare form of X-linked congenital cerebellar ataxia with normal intelligence.

P06.060**Autosomal dominant left atrial isomerism with suggestive linkage to chromosome 9q**

K. van Engelen, J. B. A. van de Meerakker, J. Lam, R. H. Lekanne dit Deprez, I. B. Mathijssen, M. J. H. Baars, B. J. M. Mulder, A. F. Moorman, A. V. Postma; Academic Medical Centre, Amsterdam, The Netherlands.

Background

Left isomerism is a laterality disorder, characterized by bilateral left sidedness including cardiovascular malformations, bilateral bilobed lungs and polysplenia. Autosomal dominant laterality disorders are infrequent and have only been reported in a few families. In this study, we analyzed a large three generation family with cardiac left isomerism.

Methods and results

We obtained phenotypic information, including physical examination, electrocardiography, echocardiography and blood samples of 22 family members. Thirteen individuals had a cardiac anomaly, with considerable variation between patients. Cardiac anomalies considered to be part of the left isomerism spectrum were, among others, bilateral left atrial appendages, septal defects, persistent left superior caval vein and specific electrocardiographic disturbances compatible with absence of the sinoatrial node. Other heart defects were present as well. The condition was inherited in an autosomal dominant pattern. Subsequent genome wide linkage analysis demonstrated linkage to a single locus on chromosome 9q shared by all affected individuals, with a multipoint maximum LOD score of 2.20 at marker D9S283. The shared locus was delineated by markers D9S167 and D9S1677, was 26 Mb in size and contained 218 genes. Sequence analysis of three candidate genes in this region (Inversin, TGFBR1 and IPPK) revealed no mutations.

Conclusions

The mapping of a suggestive locus for this autosomal dominant laterality disorder on chromosome 9q represents an important step toward the discovery of genes implied in laterality disorders. Further sequencing and investigation of genomic duplications/deletions of candidate genes will be the next steps in the identification of the susceptibility gene.

P06.061**Implication of HOXB9 and COL1A1 genes in congenital hip dislocation : a case-control association study in Brittany (Western-France)**

K. Rouault^{1,2}, V. Scotet¹, S. Autret³, F. Dubrana⁴, B. Fenolf⁵, F. Gaucher⁶, D. Tanguy⁷, C. Yaacoub⁸, C. Ferec^{1,2};

¹INSERM U613, BREST, France, ²Laboratoire de Génétique moléculaire, CHU Morvan, Brest, France, ³Université de Bretagne Occidentale, BREST, France, ⁴Department of orthopedic surgery, CHU La Cavale Blanche, BREST, France, ⁵Department of pediatric surgery, CHU Morvan, BREST, France, ⁶Department of orthopedic surgery, Hotel Dieu, Pont l'abbé, France, ⁷Department of physical medicine, Centre de Perharidy, ROSCOFF, France, ⁸Department of orthopedic surgery, CH Cornouaille, QUIMPER, France.

Congenital dislocation of the hip (CDH) is a complex disease which presents a mechanical component due to the pregnancy and delivery conditions and a genetic component linked to the ethnical predispositions and the familial aggregation. A case-control association study was set up in the area of Finistère (western Brittany, France) where CDH is frequent in order to study the implication of two candidate genes,

HOXB9 involved in the embryonic development of members and COL1A1 implied in the constitution of cartilaginous tissue. TagSNPs were selected using Haploview and Tagger softwares ($r^2=0.8$, $MAF=0.05$) and genotyped using SNaPshot method (HOXB9: $n=3$ and COL1A1: $n=12$). All SNPs were in Hardy-Weinberg equilibrium. Associations were tested using logistic regression analysis. Our cohort included 239 CDH patients and controls and CDH affected 91.2% of women and was bilateral in 60.8% of cases. Breech presentation was significantly associated with CDH (OR=10.10 [2.96-34.46], $p<0.0001$) and hyperlaxity was also more frequent in cases (OR=6.74 [2.31-19.71], $p<0.0001$). On genetic aspects, no significant association was observed between CDH and the markers of HOXB9 gene. The analysis of COL1A1 gene revealed significant association for two markers: rs1107946 (genotype AA+AC vs CC: $p=0.0379$) and rs2857396 (genotype TT+TC vs CC: $p=0.0426$). These findings were not confirmed after Bonferroni correction. An interaction between primiparas and rs1107946 was observed ($p=0.0491$). A replication study (TDT) and a haplotype analysis are still in process and will better explain the role of this two genes in CDH. This work was supported by a grant from PHRC and PRIR.

Endothelial nitric oxide synthase polymorphism in children with connective tissue dysplasia in Saint-Petersburg

I. A. Kostik¹, M. L. Chukhlovina², V. I. Larionova², T. I. Kadurina¹;

¹Medical Academy Postgraduate Studing, Saint-Petersburg, Russian Federation,

²State Pediatric Medical Academy, Saint-Petersburg, Russian Federation.

Connective tissue dysplasia (CTD) is a group of heterogeneous diseases with hereditary and inborn collagen synthesis disturbance. These patients have risk of vascular disorders. Previous studies have suggested an influence of gene endothelial nitric oxide synthase (eNOS) on vascular disorders (VD) in adults and children.

The aim of our study was to detect distribution polymorphic eNOS genotypes and alleles in CTD children and healthy children in Saint-Petersburg.

101 CTD children (38 girls, 63 boys) and 146 healthy Saint-Petersburg children (70 girls and 76 boys) were included in our study. The mean age of CTD patients was 12.71 ±4.88 years. We detected 4a/4b gene polymorphism eNOS (4a with 27-bp repeats, 393 bp total; 4b with five tandem repeats, 420 bp total), eNOS gene promoter T-786C SNP and glu298-to-asp polymorphism eNOS in these children by PCR.

The distribution of 4a/4b polymorphism has revealed significant differences ($p=0,025$) in genotypes frequency between CTD and healthy boys.

The distribution of eNOS T-786C SNP polymorphism has revealed significant differences ($p=0,015$) in genotypes frequency between CTD and healthy girls.

The distribution of glu298-to-asp polymorphism eNOS has revealed significant differences ($p=0,015$) in genotypes frequency between all groups. (Dates in table)

Conclusion: allele C of eNOS T-786C and allele T of glu298-to-asp eNOS, associated with vascular disturbances were frequent in children with CTD.

Copy number variation (CNV) is likely to be a substantial source of human genetic diversity, influencing the variable susceptibility to multifactorial disorders. However, the relatively high cost and false positive rate of genome wide methodologies have still precluded large scale association studies in patients and controls. Schizophrenia is a complex illness thought to be caused by a number of genetic and environmental effects, few of which have been clearly defined. We have used a multiplex-ligation-PCR-amplification based method to target previously reported and putatively relevant gene-containing CNV regions. A total of 122 genes were studied in 451 schizophrenic patients and 304 matched controls for association studies. Most genotyped CNVs (84%) showed very low (<1%) population frequency, while only few were common variants whose frequency did not differ between groups. A few rare variants were only present in patients suggesting a possible pathogenic involvement. We found two patients with amplification of two consecutive probes in 22q11.23 that were further characterized. Both patients showed 1.2 Mb overlapping duplications spanning 24 genes, being *de novo* in the case for whom the parents were available. A specific assay targeting this complex 22q11.23 region revealed two additional CNVs significantly associated with increased risk for schizophrenia, the duplication of the *DDT* gene and the positive genotypes of the *GSTT2* gene (Fisher, $p<0.01$). Our data provide complementary evidence for chromosome 22q11.23 as a susceptibility locus for schizophrenia, and suggest that CNV within this region may influence risk.

P06.064

A new type of hereditary corneal recurrent erosions with late subepithelial fibrosis - Dystrophia Helsingiensis

E. Björck¹, K. Lagerstedt¹, B. Hammar², P. Fagerholm², A. Dellby², H. Lind³;

¹Karolinska Institutet, Molecular medicine and surgery, Stockholm, Sweden,

²Department of Ophthalmology, Faculty of Health Sciences, University Hospital, Linköping, Sweden,

³Department of Ophthalmology, Hudiksvall, Sweden.

We describe the phenotype of a large family with an autosomal dominant inherited corneal dystrophy characterized by recurrent corneal erosions and late subepithelial fibrosis. The disorder was not linked to any known gene causing autosomal dominant corneal dystrophies with a clinical resemblance. The pedigree consisted of 342 individuals of whom 85 were affected by the disorder. The affected family members had erosive symptoms that usually lasted from 1 to 10 days. By the age of 7 almost all of the affected individuals suffered from recurrent corneal erosions. The attacks generally declined in frequency and intensity, but all individuals had developed subepithelial fibrosis by the age of 40. The fibrosis generally started in the midperiphery and were followed in some family members by the development of gelatinous masses or keloid-like formations. Nevertheless, only a marginal reduction of visual acuity was seen, and thus no one received corneal grafts. The affected individuals did not share haplotypes for genetic microsatellite markers surrounding the known genes (*COL8A2*, *TGFBI*, *GSN*, *KRT3*, *DCN*, *KRT12*) causing autosomal dominant corneal dystrophies with a similar phenotype and thus we conclude that the family had a previously not describe of corneal dystrophy. A genome wide scan is now being performed to locate the disease causing gene.

P06.065**Frequency, significance and association of ACE I/D and MTHFR C677T gene polymorphisms in Turkish patients with early onset coronary artery disease**

K. Ulucan¹, H. S. Ozturhan², D. Sevinc³, D. Agirbasli⁴, D. Kirac⁵, D. Javadova⁶, M. Agirbasli², A. I. Guney⁶;

¹Department of Medical Biology and Genetics, Faculty of Dentistry, Marmara University, Istanbul, Turkey, ²Department of Cardiology, Faculty of Medicine, Marmara University, Istanbul, Turkey, ³Department of Medical Biology and Genetics, Faculty of Medicine, Maltepe University, Istanbul, Turkey, ⁴Department of Medical Biology, Faculty of Medicine, Marmara University, Istanbul, Turkey, ⁵Department of Biochemistry, Faculty of Medicine, Yeditepe University, Istanbul, Turkey, ⁶Department of Medical Genetics, Faculty of Medicine, Marmara University, Istanbul, Turkey.

Introduction: Coronary artery disease (CAD) is a polygenic disease. A number of polymorphisms, including the insertion (I) or deletion (D) of a 287 bp Alu repeat sequence polymorphism of angiotensin I converting enzyme (ACE) gene and a point mutation (C677T) of 5,10-methylene-tetrahydrofolate reductase (MTHFR) gene have been implicated in the pathogenesis of CAD. We investigated ACE and MTHFR genotypes in patients with angiographically documented CAD in Turkish population.

Methods: 184 patients (aged between 23-72, mean 45 ± 7.5 years) were included in the study. DNAs from 89 patients with angiographically proven CAD (age <45 for male, <55 for female) and 95 controls without CAD were amplified.

Results: The ACE genotype DD was present in 32.6% of patients with CAD as compared to 37.9% in the controls (p = 0.45). Genotype frequencies in all groups for II, ID and DD were: 21.7%, 42.9%, 35.4% respectively. The overall frequency of the MTHFR genotypes were %70.7 (CC), %22.8 (CT) and %6.5 (TT). The MTHFR genotype TT was present in 4.5% of patients with CAD as compared to 8.4% in controls (p = 0.38). Subgroup analysis showed no significant differences between CAD and CAD free subjects. Also, the ACE DD and MTHFR TT genotypes were not found more common in patients having multi-vessel CAD when compared to single-vessel disease.

Conclusion: I/D polymorphism of ACE gene and C677T polymorphism of MTHFR gene are not independent risk factors for CAD in the studied Turkish population. Paraoxonase, PAI1 and e-NOS polymorphism detections are in progress for these patients.

P06.066**Quantitative Trait Mapping of Signaling Pathways in Human Primary Cells**

L. Cuninkova, S. A. Brown;

Institute of Pharmacology and Toxicology, Zurich, Switzerland.

Thousands of mammalian cell types each express a unique complement of receptors, ion channels, and enzymes. Nevertheless, the signaling pathways that transduce outside signals to the transcriptional machinery in these cells remain exquisitely conserved. Their downstream effector molecules are generally regulated by phosphorylation, and bind to conserved elements in hundreds of promoters to control a variety of processes. Such elements include CRE boxes, bound by CREB to mediate adenylyl cyclase-dependent transcription; SRE boxes, bound by SRF to mediate JNK- and ERK-family MAP kinase-dependent transcription; and E boxes, which are bound by CLOCK:BMAL1 heterodimers to mediate circadian transcription. We are generating a series of viral reporters for these pathways that are capable of infecting human primary cell cultures. The signals from these reporters can be used as quantitative traits in association and linkage studies to identify human modifier loci for these pathways. For example, using an E box reporter, we have been able to explore the molecular properties of the circadian clock in people of early and late chronotype ("larks" and "owls"). We hope to use these cellular assays to map the genes that determine human differences in a variety of difficult-to-access behavioral phenotypes that might include daily behavior, mood, and memory.

P06.067**CARD15 gene polymorphisms in Serbian patients with Crohn's disease: Genotype-phenotype correlation**

B. Zukic¹, M. Protic², N. Jojic², A. Zivkovic¹, M. Godjevac¹, M. Radmilovic¹, M. Stojiljkovic¹, T. Karan-Djurasevic¹, S. Pavlovic¹;

¹IMGGE, Belgrade, Serbia, ²Department of Gastroenterology, Zvezdara Clinical Center, Belgrade, Serbia.

Capsase activation and recruitment domain 15 (CARD15) has been identified as the pivotal gene associated with Crohn's disease (CD). Several studies have shown that CARD15 polymorphisms increase susceptibility for CD and are associated with ileal location and fibrostenotic behaviour of the disease. The aim of this study was to evaluate the prevalence of CARD15 polymorphisms and their phenotypic correlation in Serbian patients with CD. 131 patients with well defined CD and 88 healthy controls were genotyped for three common polymorphisms (R702W, G908R and Leu1007insC) by PCR-RFLP. CARD15 variant was found in 46/131 (35.11%) patients with CD and 13/88 (14.77%) of healthy controls (p= 0.001). The frameshift polymorphism (L1007fs) showed a significant association with CD (15.27%) compared to control group (0.00%) (p<0.0001). The frequency of R702W was remarkably higher in control group (14.77%) and almost equal to occurrence of this particular polymorphism in patients with CD (20.63%). Polymorphism G908R was observed significantly more frequent in patients with CD (5.3%) than in control group (0.00%) (p=0.043). Univariate analysis established that carriers of CARD15 common polymorphisms had a significantly higher risk of isolated ileal location (p= 0.042; OR 1.650; 95% CI 1.04 -2.60), fibrostenotic behaviour (p< 0.0001; OR 3.143; 95% CI 1.58-6.25) and surgical resection (p=0.036, OR 2.2; CI 1.046-4.626). This study confirms that carriers of CARD15 polymorphisms have an increased risk of CD. The data show that polymorphisms are associated with ileal, fibrostenosing disease and a higher risk of surgery.

P06.068**Prevalence of IGR2230a_1 genotypes in Hungarian Crohn's disease and ulcerative colitis patients**

L. Magyari, G. Talián, V. Csöngéi, J. Bene, K. Komlósi, L. Járomi, E. Sáfrány, C. Sipeky, B. Melegh;

Department of Medical Genetics and Child Development, University of Pécs, Pécs, Hungary.

Two main clinical presentations of inflammatory bowel disease are Crohn's disease and ulcerative colitis. IBD is caused by a combination of genetic, environmental and immunological factors. Association has been repeatedly demonstrated between IBD and the IBD5 locus on chromosome 5q31 (Silverberg et al; Eur J Hum Genet. 2007 Mar;15(3):328-35.). The aim of the study was to examine the prevalence of the IGR2230a_1 intronic nucleotide polymorphism of the SL-C22A5 gene (coding for the OCTN2 carnitine transporter protein) in Hungarian IBD patients and controls. We examined 200 patients with CD (97 males, 103 females, mean age 39.4 ± 14.6 years) and 246 patients with UC (108 males, 138 females, mean age 44.0 ± 15.1 years). A group of 187 carefully selected, clinically healthy subjects (106 males, 81 females, mean age 37.7 ± 10.7 years) were collected for the study. For genotyping we used PCR/RFLP methods. The prevalence of the mutant allele A of IGR2230a_1 was 48.5 % in the CD and 47.1 % in the UC patients, while it was 44.6 % in the controls. The frequency of the homozygous AA genotype was similar in all three groups, and the wild type GG genotype was the most frequent in the controls (31.6 %), less in the UC cohort (28.4 %) and the least among the CD patients (23.5 %). None of the reasonable comparisons of genotypes resulted in statistically significant difference between patients and controls.

P06.069**Interaction of IL23R 3'-UTR and ATG16L1 T300A in Hungarian Crohn's disease patients**

V. Csöngéi¹, L. Magyari¹, E. Sáfrány¹, B. Faragó¹, L. Járomi¹, C. Sipeky¹, I. Takács², P. Orosz², B. Melegh¹;

¹Department of Medical Genetics and Child Development, University of Pécs, Pécs, Hungary, ²2nd Department of Internal Medicine and Haematology, Semmelweis Teaching Hospital, Miskolc, Hungary.

Recently, we found significant association between Crohn's disease (CD) and rs10889677 (3'-UTR C2370A) of the interleukin-23 receptor (IL23R) gene in Hungarian patients (Faragó et al.; Ann Rheum

Dis. 2008 Feb; 67(2):248-50. Epub 2007 Jul 2.). The aim of this study was to investigate the statistical interaction of this CD susceptibility factor and rs2241880 (A1338G, T300A) of the autophagy-related 16-like 1 (ATG16L1) gene (Hampe et al.; Nat Genet. 2007; 39:207). 198 Hungarian patients with CD and 225 healthy controls were genotyped by PCR-RFLP methods. We found significantly higher frequency for the ATG16L1 G allele and GG genotype in the CD cohort compared to controls ($p=0.008$, OR=1.454, 95% CI: 1.106-1.910; $p=0.0001$, OR=3.460, 95% CI: 2.086-5.740). The frequencies and odds ratios of rs10889677 genotypes were stratified by rs2241880 genotypes. The ATG16L1 AG genotype significantly increased the risk for CD on the background of IL23R 3'-UTR CA and AA ($p_{CA}=0.043$, OR=2.522, 95% CI: 1.043-6.097; $p_{AA}=0.013$, OR=4.550, 95% CI: 1.464-14.145). The ATG16L1 GG genotype significantly increased the risk for CD with the susceptibility alleles of IL23R 3'-UTR ($p_{CA}=0.004$, OR=4.000, 95% CI: 1.553-10.306; $p_{AA}=0.0001$, OR=32.500, 95% CI: 3.59-294.216). The significantly highest relative odds ratios for rs2241880 were detected on the background of the IL23R AA genotype, suggesting the risk alleles of these two disease-associated loci have an additive effect.

P06.070

IL1RL1-IL18R1-IL18RAP-SLC9A4 and CARD9 loci are susceptibility factors for both Crohn's disease and ulcerative colitis

E. A. M. Festen¹, A. Zhernakova², L. Franke², G. Trynka¹, C. C. van Diemen¹, M. Bevova², R. M. Nijmeijer², R. Heijmans³, H. M. Boezen¹, D. A. Van Heel⁴, A. A. van Bodegraven⁵, P. C. F. Stokkers⁵, C. Wijmenga¹, B. A. Crusius³, R. K. Weersma¹;

¹University Medical Centre Groningen, Groningen, The Netherlands, ²University Medical Centre Utrecht, Utrecht, The Netherlands, ³VU Medical Centre, Amsterdam, The Netherlands, ⁴Queen Mary's School of Medicine and Dentistry, London, United Kingdom, ⁵Academic Medical Center, Amsterdam, The Netherlands.

The two main phenotypes of inflammatory bowel disease (IBD) - Crohn's disease (CD) and ulcerative colitis (UC) - are chronic intestinal inflammatory disorders with a complex genetic background.

We performed a functional candidate gene analysis within the innate immune pathway in IBD using a three-stage design. In phase I, 354 SNPs from 85 innate immunity genes were typed in a cohort of 520 Dutch IBD patients (284 CD, 236 UC) and 808 controls. In phase II, 9 SNPs showing association at $p<0.006$ in phase I were replicated in a second independent cohort of 545 Dutch IBD patients (326 CD, 219 UC) and 360 controls. In phase III, 3 SNPs with $p<0.01$ in the combined phase I and phase II analysis were genotyped in an additional cohort of 786 Dutch IBD samples (452 CD, 334 UC) and 768 independent controls. Joint analysis of 1,851 IBD patients (1062 CD, 789 UC) and 1936 controls demonstrated strong association to the *IL18RAP* gene for both CD and UC ($p_{IBD}=1.9E-8$, OR 1.35). Association in CD is independently supported by the Crohn's disease dataset of the Wellcome Trust Case Control Consortium. In addition, an association of the *CARD9* variant to CD and UC was observed ($p_{IBD}=3.25E-5$, OR 1.21). Both genes are located in extended haplotype blocks on 2q11-2q12 and 9q34.3, respectively. Our results indicate two novel IBD loci and further support the importance of the innate immune system in the predisposition to both CD and UC.

P06.071

Prevalence of IGR2198a_1 and IGR2096a_1 genetic variants in Hungarian patients with Crohn's disease and ulcerative colitis

L. Járomi¹, V. Csöngéi¹, L. Magyari¹, G. Talián¹, E. Sáfrány¹, C. Sipeky¹, L. Lakner², B. Melegh¹;

¹Department of Medical Genetics and Child Development, University of Pécs, Pécs, Hungary, ²Department of Medicine and Gastroenterology, Markusovszky Hospital, Szombathely, Hungary.

Two major forms of inflammatory bowel disease (IBD) are Crohn's disease (CD) and ulcerative colitis (UC). The development of these diseases is caused by both environmental factors and complex genetic predisposition. Genetic association was found between IBD and IBD5 on chromosome 5q31. Our goal was to analyse the possible influence of two variants in this region IGR2096a_1 (rs12521868) and IGR2198a_1 (rs11739135) in Hungarian IBD patients. PCR/RFLP methods were used for detecting the various genotypes. We examined 226 patients with CD (105 males, 121 females, age: 40.5 ± 14.5 mean

± S.D.), and 260 patients with UC (112 males, 148 females, mean age: 48.7 ± 15.9). 156 carefully selected clinically healthy, age-, sex-, weight- and height-matched control subjects (85 males, 71 females, mean age: 45.9 ± 10.2) were collected for the study. The IGR2198a_1 C allele and the IGR2096a_1 T allele was present in a significantly higher frequency in both CD (45.1%, $p=0.004$, OR 1.554, 95% CI 1.154-2.093; 46.5%, $p=0.01$, OR 1.639, 95% CI 1.217-2.207) and UC (42.3%, $p=0.028$, OR 1.385, 95% CI 1.035-1.853; 42.1%, $p=0.028$, OR 1.394, 95% CI 1.042-1.866) cohorts compared to controls (34.6% and 33.6% respectively). The IGR2198a_1 CC and IGR2096a_1 TT genotype frequencies were also increased, comparing the CD group to the controls (18.6%, $p=0.043$, OR 1.865, 95% CI 1.019-3.415; 22.1%, $p=0.009$, OR 2.178, 95% CI 1.216-3.902). We concluded that IGR2096a_1 and IGR2198a_1 SNPs mean susceptibility to both CD and UC in the Hungarian population.

P06.072

49A/G and CT60 polymorphisms of the CTLA-4 gene associated with Graves' disease but not with Hashimoto's thyroiditis and postpartum thyroiditis

A. Bicek¹, B. Krhin¹, K. Zaletel¹, S. Hojker¹;

¹University Medical Centre Ljubljana, Department of nuclear medicine, Ljubljana, Slovenia.

Single nucleotide polymorphisms in the CTLA-4 gene have been suggested as genetic factors in susceptibility to autoimmune thyroid disease (AITD). In our case-control study Graves' disease (GD), Hashimoto's thyroiditis (HT), postpartum thyroiditis (PPT) patients and control subjects from the Slovenian population were genotyped for two A/G single nucleotide polymorphisms (49A/G and CT60) of the CTLA-4 gene. The 49A/G polymorphism was genotyped by polymerase chain reaction-restriction fragment length polymorphism (RFLP) analysis using BseXI. CT60 was genotyped using a real-time polymerase chain reaction (RT-PCR) and results were analyzed by the χ^2 test.

We found no significant difference, for either polymorphism, between the frequencies of AA and AG genotypes in control versus AITD patients. However, the frequency of the GG genotype was significantly higher in AITD patients versus controls for 49A/G ($p<0.005$; 102 controls, 301 AITD patients), and for CT60 polymorphism ($p=0.0096$; 150 controls, 345 AITD patients). Comparing frequencies of the GG genotype in GD, HT and PPT with controls, a significant association of 49A/G and CT60 polymorphism was shown for GD whereas association of these polymorphisms with HT and PPT could not be confirmed. In 123 GD patients the frequency of GG genotype (13.8%) was significantly higher ($p=0.0452$) versus 102 controls (4.9%). The frequency of the GG genotype at CT60 was significantly higher in the group of 150 GD patients (42%; $p=0.0113$), versus 150 control subjects (27.3%). We conclude that 49A/G and CT60 polymorphism contributes to predisposition to GD, but not for HT and PPT.

P06.073

Sequencing the steroid-21-hydroxylase gene and linkage analysis of the detected polymorphisms

A. Szilagyí¹, B. Blaskó¹, Z. Banlaki¹, G. Gyapay², M. Sasvari-Szekely³, G. Füst¹;

¹3rd Department of Internal Medicine, Semmelweis University, Budapest, Hungary, ²Genoscope - Centre National de Séquençage, Evry, France, ³Institute of Medical Chemistry, Molecular Biology and Pathobiochemistry, Semmelweis University, Budapest, Hungary.

The steroid-21-hydroxylase enzyme (CYP21) plays a crucial role in the synthesis of steroid hormones. Its gene is located in the MHCIII region in a strongly linked modular structure. This region referred to as RCCX contains four genes: RP, complement C4A or C4B, CYP21 and TNX. The number of RCCX modules may vary from 1 to 3 on a chromosome. Our previous results showed that individuals with 0 or 1 C4B gene (i.e. C4B*Q0) have higher risk for myocardial infarction and stroke; moreover they were selected out from the healthy elderly population. The aim of the present study was to reveal the possible molecular genetic background of these observations. We assumed that C4B*Q0 carrier state may result in impaired function of the neighboring CYP21 gene, associated with inadequate mobilization of steroid hormones during stress in critical situations. The CYP21 gene was sequenced in 96 healthy individuals, in whom the copy number of C4 genes and the genotype of three SNPs located in the MHCIII region

(RAGE -429T/C, HSP70-2 1267A/G and TNF α -308G/A) were also determined. We identified 53 polymorphisms in the CYP21 gene; ten SNPs were previously not reported. C4B*Q0 was found to significantly linked to two intronic SNPs (1106C/A and 1113T/C) of CYP21. Analysis of 34 families confirmed that the haplotype block involving the variant form of the SNPs has no C4B gene. These results indicate that the SNPs may contribute to the higher morbidity and mortality rate of C4B*Q0 carriers, presumably by influencing the expression of the CYP21 protein.

P06.074

Bisphosphonate related Osteonecrosis of the jaw is associated with polymorphisms of the Cytochrome P450 2C8 in Multiple myeloma: a genome wide single nucleotide polymorphism analysis

M. E. Sarasquete¹, R. Garcia-Sanz^{1,2}, L. Marin¹, M. Alcoceba¹, M. C. Chillón¹, A. Balanzategui¹, C. Santamaria¹, J. Bladé², J. de la Rubia², J. Peti¹, M. T. Hernandez², J. J. Lahuerta², M. Gonzalez^{2,1}, J. F. San Miguel^{1,2};
¹Hospital Universitario de Salamanca, Salamanca, Spain, ²Grupo Español de Mieloma. Red Española de Mieloma (G03/136), Spain, Spain.

Osteonecrosis of the jaws (ONJ) is an adverse side effect of bisphosphonate (BP) therapy. Patients with multiple myeloma (MM) usually receive BPs for the treatment of bone destruction. ONJ could be caused by a combination of environmental and genetic risk factors. Our aim was to assess the role of genetics in ONJ development. We performed a genome wide association study using 500.568 SNPs in two series of MM patients included in the same therapeutic protocol receiving the same BP therapy: 22 cases (MM with ONJ) and 65 matched controls (MM without ONJ).

Clinical and biological characteristics, response to treatment and survival rates were similar in both subsets of patients. Regarding the polymorphisms, we identified four SNPs (rs17110453, rs1934951, rs1934980 and rs1341162) mapped within the Cytochrome P450-2C8 gene (*CYP2C8*) with a singular distribution among cases and controls. Rs1934980, rs1341162 and rs17110453 showed a significant correlation with ONJ ($p=4.231e^{-6}$, $p=6.22e^{-6}$ and $p=2.15e^{-5}$ respectively), although the association was not significant after Bonferroni correction. The SNP rs1934951 kept its statistical significant association with ONJ (P -value= $1.07e^{-06}$, P corrected value= 0.02). Genotyping results displayed an overrepresentation of the T allele in cases vs. controls (0.475 vs. 0.125). Thus, individuals homozygous for the risk allele had a likelihood of ONJ increased by 12.75 (95% confidence interval 3.7 to 43.5).

Our data suggest that the rs1934951 polymorphism may play a role as a risk factor for developing ONJ in MM patients receiving BPs therapy.

P06.075

CYP2D6 polymorphism in patients with Parkinson's disease

M. Lisak, M. Stefanović, M. Roje Bedeković, Z. Trkanjec, E. Topić, V. Demarin; University Hospital Sestre milosrdnice, Zagreb, Croatia.

Aim: CYP2D6 is an enzyme of cytochrome P-450 system that metabolizes some of endogenous substances in central nervous system, including metabolism of dopamine and drugs used for Parkinson's disease (PD) treatment. Decreased metabolic capability of this enzyme could be associated with increased risk of morbidity and of higher risk for side effects of antiparkinsonian medication. The aim of this study was determination of the incidence and comparison of non-functional alleles with the intention of detecting increased risk for PD in individuals with damaged function of enzyme CYP2D6.

Materials and methods: Multiplex allele-specific polymerase chain reaction (PCR) the incidence of non-functional alleles CYP2D6*3, *4, *6, *7, and *8 was determined in healthy volunteers (n=145) and in patients with PD (n=41).

Results: In a group of healthy volunteers the incidence of CYP2D6 alleles was: CYP2D6*3=1.4%, CYP2D6*4=11.0%, CYP2D6*6=1.0%, CYP2D6-wt=86.6%.

In a group of PD patients the incidence of CYP2D6 alleles was: CYP2D6*3=1.2%, CYP2D6*4=20.7%, CYP2D6*6=1.2% and CYP2D6-wt=76.8%. Statistically significant difference was found only for allele CYP2D6*4 (relative risk=2.10; 95% CI: 1.113-3.994).

The relation of genotype distribution was *3/wt 2.8% and 2.4%; *4/wt 18.6% and 26.8%; *4/*4 1.4% and 7.3%; *6/wt 1.4% and 2.4%; *4/*6

0.7% and 0.0%; wt/wt 75.2% and 61.0% in healthy volunteers and PD patients, respectively). There was no statistically significant difference between these distributions.

Discussion: Results of this study indicate that the allele CYP2D6*4 could be considered as a weak risk factor for PD, but similar study should be carried out on larger sample group.

P06.076

Contribution of gene sequence variant CYP3A4*1B of the hepatic cytochrome P450 3A4 enzyme to variability in individual response to clopidogrel

A. N. Stolyarova, O. V. Sirotkina;

Petersburg Nuclear Physics Institute Russian Academy of Science, Saint-Petersburg, Russian Federation.

Clopidogrel is an inactive pro-drug that requires oxidation by hepatic cytochrome CYP3A4 to generate active metabolite. Because genetic variations are the major determinant of heterogeneity in metabolic activity of enzyme, we hypothesize that polymorphism of CYP3A4 gene may influence platelet aggregation in patients treated with clopidogrel. We examined platelet aggregation in 100 patients with acute coronary syndrome treated by clopidogrel 75mg/day according to variant CYP3A4*1B. Aggregation was induced by ADP 20mkM and measured in two points - before and on day 7 after clopidogrel treatment as level of light transmission (LT,%) determined by optical aggregometry. For detection of the CYP3A4*1B the PCR and original endonuclease digestion with PstI was used and results in patients were compared with 83 healthy persons. Our study showed that the frequencies of CYP3A4*1B genotypes were 89%, 10% and 1% in patients and 90.5%, 8.5% and 1% in controls for wild, heterozygous and homozygous genotypes, respectively, and these frequencies didn't differ in two groups. The LT was significantly lower in patients in second measuring point compared to first point - $20.59\pm 1.58\%$ and $34.03\pm 1.96\%$, respectively ($p<0.0001$). The wild genotype CYP3A4*1B was associated with significant reductions in platelet aggregation after clopidogrel treatment - LT was $33.41\pm 2.06\%$ versus $19.81\pm 1.65\%$ in first and second measuring point respectively ($p<0.0001$). In carriers of CYP3A4*1B mutant allele the reduction of platelet aggregation was poorly effective and LT was $37.96\pm 6.26\%$ versus $25.59\pm 4.95\%$ in first and second measuring point respectively ($p>0.1$). In conclusion, the CYP3A4*1B polymorphism may contribute to poorly clopidogrel effect on platelet aggregation.

P06.077

Association of CYPs, GSTs, CAT, GPX1, SODs genes polymorphisms with chronic lung disease in children

G. F. Korytina, C. Olga, A. Leysan, V. Tatyana;

Institut of biochemistry and genetics, Ufa, Russian Federation.

To assess the role that polymorphisms of cytochrome P450 and antioxidant-related genes play in genetic predisposition to severe chronic lung disease of children, the allele and genotype distributions of CYP1A1(2455A/G, 3801T/C), CYP1A2 (-2464T/delT, -163C/A), CYP2E1 (-1053C/T), GSTM1 (Del), GSTT1 (Del), GSTP1 (Ile105Val, Ala114Val), CAT (-262 C/T, 1167 C/T), GPX1 (Pro197Leu), SOD1 (3intron+35 A/C), SOD3 (Arg213Gly) genes were studied in children with chronic lung disease (N=188) and healthy children (N=300), living in the Republic of Bashkortostan in environment with air pollutions.

Genotypes of cytochrome P450 and antioxidant genes that associated with susceptibility to chronic lung disease of children were determined. The frequency of 1A2C genotype of CYP1A1 gene was significantly higher in cases of chronic lung disease patients than in healthy control group (15.43% vs 8.67%; $X^2=4.626$, $df=1$, $P=0.0318$, $P_{cor}=0.0636$; $OR=1.922$ 95%CI 1.055-3.507). The patients with chronic lung disease showed significantly elevated frequencies of the GSTT1 gene deletion (38.83% vs 21.33% in control; $X^2=16.66$, $df=1$, $P=0.0006$; $OR=2.305$ 95% CI 1.512-3.515). The distribution of the GSTP1 gene alleles was significantly differed from that of chronic lung disease patients and controls, there was a higher frequency of the Ile/Ile genotype in the patients than in healthy group (76.06% vs 60.0%; $X^2=12.629$, $df=1$, $P=0.0011$, $P_{cor}=0.0022$; $OR=2.119$ 95%CI 1.383-3.25). The CC genotype of CAT -262C/T locus were associated with higher risk of chronic airway disease in children (70.74% vs 56.67% in control; $X^2=9.143$, $P=0.0034$ $P_{cor}=0.0068$; $OR=1.85$ 95%CI 1.23-2.78).

P06.078

The association between gene polymorphism of cytochrome P450 2D6 and behavioral characteristicsV. A. Shleptsova¹, J. Shchegolkova², A. G. Tonevitsky³;¹Faculty of basic medicine, Moscow State University, Moscow, Russian Federation, ²Biological faculty, Moscow State University, Moscow, Russian Federation, ³Russian research institute of sport and physical education, Moscow, Russian Federation.

The cytochrome P450 2D6 (CYP2D6) enzyme is involved in the hepatic metabolism of many drugs and other exogenous substances. There are a little evidences that CYP2D6 involves in metabolism of endogenous psychoactive substances and expresses not only in liver but also in the brain. Therefore it may influence on psychological process. It has been shown that there are significant differences in personality between extensive and poor metabolizers.

In our investigation we investigated an association of gene polymorphism of CYP2D6 and personality traits. 160 healthy subjects took part in the study (women - 82, men - 78). There were tested by different psychological questionnaires which examine aggression, impulsivity, anxiety and others and also by psychophysiological measurements. We genotyped with PCR-method any gene variations of CYP2D6: CYP2D6*1, CYP2D6*2 (C2850T), CYP2D6*4 (G1934A), CYP2D6*10 (C100T) We showed that CYP2D6 poor metabolizers (CYP2D6*4, CYP2D6*10) had significantly higher level of verbal aggression ($p=0.04$) and inability of stopping aggression ($p=0.04$) and had more pleasure of aggression ($p=0.02$) than extensive metabolizers (CYP2D6*1, CYP2D6*2). Furthermore, this relationship expressed to the same extent both at men, and at women.

Association between CYP2D6 gene polymorphism and personality characteristics can indicate on influence cytochrome activity on neuromediator's metabolism in brain.

P06.079

Cytokine genes polymorphisms are associated with essential hypertension in Tatars from Bashkortostan, RussiaY. R. Timasheva¹, T. R. Nasibullin¹, A. N. Zakirova², O. E. Mustafina²;¹Institute of Biochemistry and Genetics, Ufa, Russian Federation, ²Bashkir State Medical University, Ufa, Russian Federation.

Cardiovascular disease is the leading cause of death in the Western world. Recently inflammation was proved to be the main substrate underlying the development atherosclerosis. Cytokines mediate interactions of all cells participating in atherogenesis. However, the role of certain cytokines genetic variants on disease risk is not well understood. We tested the hypothesis that specific genetic polymorphisms of some cytokines are associated with increased risk of essential hypertension (EH) and its cardiovascular complications.

355 patients with EH and 343 unrelated normotensive individuals without family history of cardiovascular disease were enrolled in the study. Both patients and control originated from Tatar ethnic group from Bashkortostan, Russia. DNA was isolated from peripheral venous blood. Genotyping was performed using polymerase chain reaction and restriction analysis. Statistical analysis was performed using Fisher's exact test. Odds ratios with 95% confidence interval were also calculated.

We have shown that *IL-10* -627**C/C* genotype is associated with decreased hypertension risk (OR=0.53, CI: 0.22-0.78). *TNFA* -308**G/G* was found to be protective against stroke in hypertensive patients (OR=0.48, CI: 0.24-0.97). *1159*A/A* *IL12B* genotype was also associated with lower stroke risk (OR= 0.43, CI: 0.21_0.9).

We demonstrate that common genetic variants of *IL10*, *TNFA* and *IL12B* genes are associated with the risk of EH and its complications. Our data suggest a role for cytokine genes polymorphisms in cardiovascular disease.

Strong linkage disequilibrium for the frequent GJB2 35delG mutation in the Greek populationH. Kokotas¹, L. Van Laer², M. Grigoriadou¹, V. Iliadou³, J. Economides⁴, S. Pomoni¹, A. Pampanos¹, N. Eleftheriades⁵, E. Ferekidou⁶, S. Korres⁶, A. Giannoulia-Karantana⁷, G. Van Camp², M. B. Petersen¹;¹Institute of Child Health, Athens, Greece, ²University of Antwerp, Antwerp, Belgium, ³AHEPA Hospital, Thessaloniki, Greece, ⁴'Aghia Sophia' Children's Hospital, Athens, Greece, ⁵St. Loukas Hospital, Thessaloniki, Greece, ⁶Athens

University, Athens, Greece, ⁷Athens University Medical School, Athens, Greece. Approximately one in 1,000 children is affected by severe or profound hearing loss at birth or during early childhood (prelingual deafness). Up to forty percent of autosomal recessive, congenital, severe to profound hearing impairment cases result from mutations in a single gene, *GJB2*. The 35delG mutation accounts for the majority of *GJB2* mutations detected in Caucasian populations and represents one of the most frequent disease mutations identified so far. Some previous studies have assumed that the high frequency of the 35delG mutation reflects the presence of a mutational hot spot, whilst other studies support the theory of a common founder. Greece is amongst the countries presenting high frequency of the 35delG mutation (3.5%), and a recent study raised the hypothesis of the origin of this mutation in ancient Greece. We genotyped 60 Greek deafness patients homozygous for the 35delG mutation for six single nucleotide polymorphisms (SNPs) and two microsatellite markers, mapping within or flanking the *GJB2* gene, as compared to 60 Greek hearing controls. A strong linkage disequilibrium was found between the 35delG mutation and markers inside or flanking the *GJB2* gene, at distances of 34 kb on the centromeric and 90 kb on the telomeric side of the gene, respectively. Our study supports the hypothesis of a founder effect and we further propose that ethnic groups of Greek ancestry could have propagated the 35delG mutation, as evidenced by historical data beginning from the 15th century BC.

P06.081

Detoxification system gene variants and small-for-gestational-age birthsN. Nabieva¹, T. Ivashchenko², N. Shabalov¹, V. Baranov²;¹Medical Pediatrics Academy, St.Petersburg, Russian Federation, ²Ott's institute of Obstetrics and Gynecology, St.Petersburg, Russian Federation.

Small-for-gestational-age (SGA) is defined as birth weight below the 10th percentile according to gestational age and sex based on national standards. Little is known about the role of detoxification system gene variants as risk factors for SGA births. Only a few studies have considered the direct role of polymorphic xenobiotic-metabolizing genes in fetal growth. GSTM1 and GSTT1, in the GST family, are both involved in the biotransformation of a wide range of reactive toxic and mutagenic compounds, including ROS oxygen species and components of tobacco smoke. GST enzymes are present in large amounts in the placenta in early pregnancy and are expressed early in embryonic development. The polymorphisms of xenobiotic-metabolizing genes (GSTM1, GSTT1, NAT2) responsible for xenobiotics conjugating enzymes of Phase II detoxification system were studied by PCR-RFLP in SGA infants and control group newborns.

The genotypes distribution for NAT2 gene was identical in controls group and in group of SGA patients. The analysis of genotypes distribution for polymorphism and GST M1 in patients and in controls has not revealed significant differences.

The frequency of GSTT10/0 genotype was significantly higher in group of patients compared to controls (34% versus 10% respectively, $p=0.003$). Concordance of both GSTT1 0/0 and NAT2 S/S genotypes were found in 17.2% of patients and was almost 4 times more compared to only 4% in control ($p=0.01$). The 37% of patients had at least two functionally impaired genotypes for studied genes.

The study provides new information on the role of polymorphic detoxification genes in development of SGA.

P06.082

Analysis of the association between LECAM-1 P213S polymorphism and ESRD in diabetic patients

C. M. Tecuceanu, D. Cimponeriu, P. Apostol, M. Stavarachi, M. Toma, L. Gavrilă;

Institute of Genetics, Bucharest, Romania.

Mutations in *lyam-1* gene (1 q23-q25) may predispose to phenotypes that can aggravate the evolution of vascular complications in diabetic patients, including renal disease.

The purpose of this case-control study was to estimate the association of LECAM P213S polymorphism with end-stage renal disease (ESRD) in diabetic patients.

Clinical information and biological samples were collected from dialyzed type I diabetic patients ($n=100$, M:F = 50:50) and healthy subjects ($n=200$, fasting glycemia 93.2 ± 8.2 mg/dl). Healthy subjects were

selected to be matched for age, gender and with subjects with T1DM patients. All subjects selected for this study were unrelated Romanian Caucasians. DNA samples were used for genotyping LECAM-1 P213S polymorphism using restriction of amplicons with Hph1 endonuclease.

The distribution of LECAM P213S in all lots is in agreement with Hardy - Weinberg equilibrium. When compare the distribution of LECAM genotypes in patients and control lots we observed only a trend of association with ESRD in T1DM patients. The sex or age at ESRD onset seems to not modify these observations. The lack of association with ESRD in T2DM seems to be not similar with results reported for other populations.

In conclusion, our study showed only a trend of association between LECAM P213S polymorphism and IRC in DM 1 patients.

P06.083

On the choice of an exposure to test for gene-environment interactions in type 2 diabetes: A new genotype-free method!

R. Kazma^{1,2}, C. Bonaiti-Pelli^{3,1}, J. M. Norris⁴, E. Génir^{2,1};

¹Univ Paris-Sud, Paris, France, ²INSERM U794, Paris, France, ³INSERM UMR-S535, Villejuif, France, ⁴Department of Preventive Medicine and Biometrics, University of Colorado Denver, Denver, CO, United States.

Gene-environment interactions might be involved in the susceptibility to multifactorial diseases but are difficult to detect. Available methods to test for gene-environment interactions usually concentrate on some particular genetic and environmental factors. Rather than focusing on a known genetic factor, we applied a new method to determine whether or not a given exposure is susceptible to interact with unspecified genetic factors, using the degree of familial aggregation as a surrogate. The Odds Recurrence Ratio (ORR) is an indirect measure of interaction since it contrasts recurrence risks in sibs of affected indexes when stratifying on the exposure of indexes. A Wald chi-square test based on the estimate of the ORR and its variance tests for the gene-environment interaction, while accounting for a possible confounding bias if indexes and their sibs are correlated for the exposure. An application on a sample of 588 nuclear families ascertained through one index affected with type 2 diabetes is presented where gene-environment interactions involving obesity, physical activity and dietary fat intake are investigated. An association with obesity is clearly evidenced and a potential interaction involving this factor is suggested ($p=0.06$). Multiple sibships have been used to increase sample size but a permutation procedure is needed to account for dependency of sibpairs. Results of this undergoing work will also be presented. The method proposed here might be of particular interest prior to genetic studies to help determine the environmental risk factors that will need to be accounted for and select the most appropriate samples to genotype.

P06.084

Compound heterozygosity in DJ-1 gene non-coding portion related to parkinsonism

P. Tarantino¹, D. Civitelli¹, F. Annesi¹, E. De Marco¹, F. Rocca¹, P. Pugliese², G. Nicolletti^{1,2}, I. Cirò Candiano¹, S. Carrideo¹, G. Provenzano¹, G. Annesi¹, A. Quattrone^{1,2};

¹Institute of Neurological Sciences, National Research Council, Mangone (Csenza), Italy, ²Institute of Neurology, Department of Medical Sciences, University Magna Graecia, Catanzaro, Italy.

Mutations in DJ-1 gene cause a clinically characteristic autosomal recessive juvenile onset form of Parkinson's disease (PD). We sequenced the DJ-1 gene in 40 sporadic patients with early onset Parkinson's disease and 100 appropriate controls, originated from southern Italy. We identified a single patient with age at onset of 38 years carrying two novel heterozygous mutations, both located in non coding regions. The first mutation (g. 159 C/G), located in the promoter region, was inherited from his mother whereas the second mutation, an insertion in the intron 4 splice site (IVS4+3 insA), was transmitted from his father. The DJ-1 cDNA level both in the patient and in a control subject was normalized with the GAPDH gene and a significant reduction ($P=0.027$) was found in the patient. Moreover, we obtained a single size of DJ-1 cDNA fragments in both wild type and mutated individuals. Of interest, no family member carrying only one of the two new mutations manifested symptoms of EOPD. Genomic rearrangements were excluded. Both mutations were absent in 200 control chromosomes.

In the remaining PD patients, we did not detect any pathogenic DJ-1 mutation. Our findings indicate that the mutant alleles are expressed at a lowered level, or that their corresponding mRNAs are partially degraded. Although the finding of a single size cDNA fragment is not suggestive of the activation of any alternative cryptic splice site, this cannot be fully excluded. Further studies are in progress.

P06.085

A genome-wide association study in schizophrenia using DNA pooling on 574 parent-offspring trios

G. Kirov¹, I. Zaharieva¹, L. Georgieva¹, V. Moskvina¹, I. Nikolov¹, M. Owen¹, M. O'Donovan¹, S. Cichon², A. Hillme², D. Toncheva³;

¹Cardiff University, Cardiff, United Kingdom, ²University of Bonn, Bonn, Germany, ³University Hospital "Maichin Dom", Sofia, Bulgaria.

We conducted a genomewide association study (GWAS) on schizophrenia with DNA pooling in order to reduce the cost of the project. We used a parent-offspring trios design in order to avoid the potential problems of population stratification. We constructed pools from 605 unaffected controls, 574 SZ patients and a third pool from all the parents of the patients. We hybridised each pool 8 times on Illumina Human-Hap550 arrays. We estimated the allele frequencies of each pool from the averaged intensities of the arrays. The significance level of results in the trios sample was estimated on the basis of the allele frequencies in cases and non-transmitted pseudocontrols, taking into account the technical variability of the data. We selected for individual genotyping the highest-ranked SNPs, after excluding poorly performing SNPs and those that showed a trend in the opposite direction in the control pool. We genotyped 63 SNPs in 574 trios and analysed the results with the transmission disequilibrium test (TDT). 40 of those were significant at $p<0.05$, with the best result at $p=1.2 \times 10^{-6}$ for rs11064768. This SNP is within the gene CCDC60, a coiled-coil domain gene. The most interesting result was for the third-best SNP: rs893703 ($p=0.00016$), within RBP1, a candidate gene for schizophrenia.

P06.086

DNase1 Exon2 analysis in Tunisian patients with Rheumatoid Arthritis, Systemic Lupus Erythematosus and Sjögren Syndrome and healthy subjects

S. Belguith-Maalej¹, H. Hadj Kacem¹, N. Kaddour², Z. Bahlouf¹, H. Ayadi¹;

¹Cibles pour le Diagnostic et la Thérapie, Centre de Biotechnologie de Sfax, Sfax, Tunisia, ²Service de Médecine Interne, CHU Hédi Chaker, Sfax, Tunisia.

Autoimmune Diseases (AID) are caused by the loss of immunological tolerance against self-antigens. The DNASE1 seems to participate in the genetic susceptibility of some AID, particularly the Systemic lupus erythematosus (SLE). Deficiencies in the normal rate of removal of chromatin or chromatin-protein complexes contribute to the development and severity of SLE. In fact, two mutations were reported among SLE patients from Japan and Spain (the 172 A→T mutation (K5X) and the 46-72 deletion respectively). In the aim to evaluate the DNASE1 contribution in the genetic susceptibility of Rheumatoid arthritis (RA), Sjögren syndrome (SS) and SLE in Tunisia, we studied these two mutations by PCR RFLP and by fragment size analyses on 3% agarose gel electrophoresis respectively. In order to achieve this work, DNA from 151 patients affected with RA, 55 patients affected with SS, 34 patients affected with SLE and 232 healthy control subjects were explored. Both mutations were absent among patient and control subjects. In addition, by direct sequencing, the DNASE1 exon 2 was analysed among 26 control subjects to identify a possible new polymorphic variations. Five known SNPs were explored (rs8176921, rs8176922, rs8176927, rs8176930, rs34907394). The 2113 G→T SNP (rs8176927:Arg2Ser) is the only polymorphic functional nonsynonymous SNP. By PCR-RFLP, patient and healthy subjects DNAs were genotyped for rs8176927 for a case-control design. The statistical analysis showed no significant differences between patients and controls genotype data.

In conclusion, by analysing DNASE1 Exon2 gene, our study showed no particular genetic involvement of this gene in SLE, RA and SS development.

P06.087**Genetic effect of DAT1 and DRD2 gene polymorphisms on personality traits in healthy individuals from Russia**A. Kazantseva¹, D. Gaysina^{1,2}, E. Khushnutdinova¹;¹Institute of Biochemistry and Genetics Ufa Scientific Centre of Russian Academy of Sciences, Ufa, Russian Federation, ²MRC SGDP Centre, Institute of Psychiatry, King's College, London, United Kingdom.

Psychobiological model proposed by Cloninger supposes that sociability related personality traits are mediated by dopaminergic system functioning. We aimed to define a single genotype effect of *DRD2* TaqIA and *DAT1* MspI polymorphisms and to check possible epistatic effect between them and personality traits (assessed with the EPI and TCI questionnaires). 602 healthy individuals (men-206, women-396) of Caucasian origin (Russians-214, Tatars-388) were recruited from Russia (mean age±SD, 19.85±2.43 years).

MANOVA (carried out with gender and ethnicity as second factors) revealed the influence of *DRD2**gender interaction on Novelty Seeking (NS) ($p=0.017$; $F=5.734$) and Reward Dependence (RD) ($p=0.039$; $F=4.298$). Multiple comparisons explained this interaction by the differences in NS and RD scores between female carriers of A1-allele and male carriers of A2/A2-genotype ($p=0.001$; $F=11.208$ and $p=0.000$; $F=16.464$ correspondingly); in NS scores between females with A2/A2-genotype and males with A1-allele ($p=0.000$; $F=18.678$). Demonstrated effect could be partly due to higher NS and RD in women compared to men ($p=0.000$; $F=26.643$ and $p=0.001$; $F=21.102$). Moreover, association of A1-allele with lower NS ($p=0.040$; $F=4.278$) and higher RD ($p=0.029$; $F=4.814$) was demonstrated in men.

The effect of *DAT1**ethnicity interaction was observed on RD ($p=0.018$; $F=5.615$) caused by the differences in RD of G/G-genotype carriers from Tatar and Russian population ($p=0.001$; $F=10.752$). Association between *DAT1* A-allele carriers and higher extraversion ($p=0.045$; $F=4.030$) and NS ($p=0.042$; $F=4.148$), lower Persistence ($p=0.020$; $F=5.401$) was demonstrated.

Our findings suggest single *DAT1* gene effect on extraversion and Persistence, while differences in NS and RD are caused by *DRD2**gender and *DAT1**ethnicity interaction.

This work was supported by RSCI grant 06-06-00163à and «Russian Science Support Foundation» (to A.Kazantseva, D.Gaysina).

P06.088**The T-Allele of the Dopamine Transporter Core Promoter Polymorphism and Risk of Attention-Deficit Hyperactivity Disorder**M. Ohadi¹, A. Aghajani Refahi¹, E. Shirazif², N. Moghimi¹, H. Najmabadi¹;¹Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, ²Iran University of Medical Sciences, Mental Health Research Center, Tehran, Islamic Republic of Iran.

Pharmacological and genetic findings implicate the DAT1 gene in the development of attention-deficit/hyperactivity disorder. In this study, we examined whether either allele of the DAT1 core promoter -67 functional polymorphism is associated with ADHD in a case/control study. The allele and genotype frequencies of the polymorphism were studied in 110 patients and 120 controls, which were matched on the basis of sex, age and ethnicity. The genotype frequencies in the patients group were as follows: AA 19.2%; AT 65.2%; TT 15.4% vs. the genotype frequencies in the control group: AA 47.5%; AT 43.3%; TT 9.2% [$\chi^2=20.73$, $df=2$] The T-allele of the -67A/T polymorphism revealed a ~1.56-fold excess in the patients group comparing with the controls [$\chi^2=14.50$, $df=1$]. For the first time, these findings provide tentative evidence of the contribution of the DAT1 gene core promoter polymorphism to the etiopathophysiology of ADHD at least in the Iranian population that we have studied. Further work is warranted to confirm this finding and to assess its generalization to other ethnic groups.

P06.089**Origin of nondisjunction in trisomy 21 Down syndrome**

S. K. Dey, S. Ghosh;

West Bengal University of Technology, Kolkata, India.

Down syndrome due to trisomy 21 is the most common human chromosomal abnormality. In order to gain further insight into the mechanism underlying nondisjunction, we investigated the association between reduced recombination and nondisjunction. We genotyped 12 microsatellite markers spanning along 21q from centromere to telo-

mere in 122 individuals with free trisomy 21 and in their parents. Our DNA marker studies of parental origin were informative in 119 families with overwhelming majority 89.91% being maternal and 10.09% is paternal. Only cases of maternal origin were included in our analysis. The distribution of nondisjunction in maternal meiotic I and meiotic II stages were 81.19% and 19.81% respectively. The mean maternal age of nondisjunction in our Indian population sample is 27.58±6.4 which is significantly lower than that of Caucasians. We created a genetic map, using maternal meiotic I nondisjunction data. The female genetic map was restricted to 21q. The distribution of chiasma shows a difference throughout the length of chromosome arm(21q) with more recombination towards telomeric end in comparison to control data. The telomeric exchange is a significant risk factor for meiotic I nondisjunction, irrespective of the age of the mother. Analysis of crossover events indicates that in younger mother (< 29) there was an increase in both zero and one exchange events, suggesting reduction of recombination. The linkage map of 21q(39.58cM) was significantly shorter than the control female linkage map, indicating an overall reduction of recombination. Thus, reduced recombination may be responsible, at least in part, for the etiology of nondisjunction in trisomy 21.

P06.090**Identification of a new locus for autosomal recessive Dyschromatosis universalis hereditaria on chromosome 12q21-q23**K. Brakensiek¹, H. C. Hennies², I. A. Bukhari³, G. Nürnberg², C. Becker², J. Huebener¹, M. Cabrera Miranda¹, H. Frye-Boukhriss¹, S. Knothe¹, J. Schmidtke¹, E. A. El-Harith¹, M. Stuhmann¹;¹Institute of Human Genetics, Hannover Medical School, Hannover, Germany,²Cologne Center for Genomics, University of Cologne, Cologne, Germany,³Department of Dermatology, King Faisal University, Dammam, Saudi Arabia.

Background: Dyschromatoses are a group of pigmentary dermatoses characterized by the presence of small and irregularly shaped hyper- and hypopigmented maculae. There are two major forms of the disease: Dyschromatosis symmetrica hereditaria (DSH), where the maculae are restricted to the dorsal aspects of the extremities, and Dyschromatosis universalis hereditaria (DUH), where patients are affected by a generalized distribution of the maculae over most of their body. Usually, both disorders show autosomal dominant inheritance, but in some cases autosomal recessive inheritance was reported. Autosomal dominant DSH was mapped to chromosome 1q21.3, and mutations in the ADAR- (*DSRAD*-) gene were identified. A second dyschromatosis locus was mapped on chromosome 6q24.2-q25.2, but the two analyzed families, which were initially reported to be affected with DSH, were later suggested to have autosomal dominant DUH.

Patients and methods: We investigated whether one of the two known Dyschromatosis-loci is involved in the development of DUH in a consanguineous family from Saudi Arabia (four siblings were affected, three siblings and the parents were unaffected).

Results: After confirmation that neither of the two known loci is linked to the disease in this family, a SNP-based genome-wide linkage analysis was performed and a new locus for dyschromatosis was identified on chromosome 12q21-q23. The candidate region (LOD score of 3.4) contains 125 known or predicted genes.

Conclusion: We have identified a new locus for DUH, and obtained evidence that DUH and DSH are distinct disorders with different genetic origins.

P06.091**Frequency of the coding polymorphisms in the PARK2 gene - characterization of the polish group with Parkinson disease of the early onset**D. Hoffman-Zacharska¹, D. Kozirowski², J. Bal¹, A. Friedman²;¹Institute of Mother and Child, Dept. of Medical Genetics, Warsaw, Poland,²Faculty of Health Science, Medical University in Warsaw, Dept. of Neurology, Warsaw, Poland.

Parkinson disease (PD; OMIM 168600) is the second most frequent neurodegenerative disease in the elderly. Among the PD patients there is less common group of age of onset before 50 years classified as a early-onset PD (EO-PD) with mutations in parkin gene (PARK2; OMIM 62544) as a common cause. The prevalence of this form of PD is not known. However, in Europe, parkin type of EO-PD accounts for approximately 50% of autosomal recessive parkinsonism and 18% of

individuals without a family history with onset before age 45 years. A variety of deletional and point mutations has been described in PARK2 gene as well as a few coding polymorphism being a possible risk factors for sporadic and familial PD. The role of this polymorphisms is still unclear and published results contradictory.

We present the analysis of the frequency of the four coding polymorphism detected in the group of EO-PD sporadic patients of Polish origin (Ex4 S167N, Ex10 V380L, Ex 11 D394N and R402C) in comparison with the group of control subject.

Presented results are preliminary as the groups are not big enough to be conclusive (70 EO-PD patients, 100 control subjects) but they indicate no difference in frequency of analysed polymorphisms in both of them. We can conclude there is no association of any of polymorphism under consideration with sporadic EO-PD form.

P06.092

Genetic association of single SNPs and a LD-Haplotype at PSORS6 in patients with early onset psoriasis and evidence for epistasis with PSORS1 risk locus

U. D. Hüffmeier¹, J. Lascorz¹, T. Becker², A. Ekici¹, S. Endele¹, C. Thiel¹, F. Schürmeier-Horst³, R. Mössner⁴, K. Reich⁵, W. Kurraf⁶, T. F. Wienker², H. Traupe³, A. Reis¹;

¹University of Erlangen, Erlangen, Germany, ²University of Bonn, Bonn, Germany, ³University of Münster, Münster, Germany, ⁴University of Göttingen, Göttingen, Germany, ⁵Dermatologikum Hamburg, Hamburg, Germany, ⁶Asklepios Klinik, Westerland/Sylt, Germany.

Psoriasis is a genetically complex, chronic inflammatory skin disease. We have previously performed a genome wide linkage study in a set of psoriasis families and have identified a susceptibility locus on chromosome 19p13 (PSORS6). In a follow-up linkage disequilibrium (LD) study in an independent family based cohort, we found evidence for association to two newly discovered microsatellites at this locus (D19SPS20: $P < 2.7 \times 10^{-2}$, D19SPS21: $P < 5.3 \times 10^{-5}$). An association scan in 300 trios, based on the LD structure of the region, revealed association to several single SNPs in one LD block. When we stratified this cohort for carrying the PSORS1 risk allele at the HLA-C locus on chromosome 6p, evidence for association became much stronger at single SNP and haplotype levels (p -values between 2.0×10^{-4} and 9.0×10^{-4}). In a population based replication study of 1,114 psoriasis patients and 937 control individuals, evidence for association was observed again after stratification to the PSORS1 risk allele. In both study groups, logistic regression showed evidence for interaction between the risk alleles at PSORS1 and PSORS6. The associated LD block did not comprise any known genes. Interestingly, an adjacent gene, *MUC16*, coding for a large glycosylated protein expressed in epithelia, could be shown to be also expressed in tissues relevant for pathogenesis of psoriasis such as skin and thymus. In summary, we confirmed and refined the susceptibility locus at PSORS6 which seems to be restricted to patients with early onset psoriasis carrying the PSORS1 risk allele.

P06.093

Parkin, DJ-1 and PINK1 mutations in Dutch patients with early-onset Parkinson's disease

M. G. Macedo¹, D. Verbaan², Y. Fang¹, B. Anar¹, A. Uras¹, J. L. Groen¹, P. Rizzu¹, J. J. van Hilten², P. Heutink¹;

¹VU University Medical Center, Amsterdam, The Netherlands, ²Leiden University Medical Center, Leiden, The Netherlands.

Objectives Recessively inherited early-onset Parkinson's disease (EOPD) has been associated with mutations in the *Parkin*, *DJ-1* and *PINK1* genes. In order to assess the genetic contribution of all known recessive genes in EOPD in the Dutch population we investigated the prevalence and nature of mutations in the PROPARK (PROfiling PARKinson's disease) patient cohort. **Methods** A total of 186 unrelated Dutch EOPD patients (mean age at onset: 41.1 ± 6.6 years, 130 sporadic, 56 familial) with an age at onset (AAO) ≤ 50 years were studied. The genetic screening was performed by direct sequencing and dosage analysis of the three genes. **Results** Mutations were found in 9% (16/186) of the patients however PD may be explained in only six (3%) patients who carried homozygous or heterozygous compound mutations in *Parkin* ($n=5$) or *DJ-1* ($n=1$). No homozygous or compound heterozygous mutations were detected in *PINK1* gene. In addition, 6 (3%), 3 (2%) and 2 (1%) patients carried a single heterozygous mutation in *Parkin*, *DJ-1* and *PINK1* genes, respectively. Interestingly, two

novel mutations were found in one patient in heterozygous state but not in 700 ethnically matched control chromosomes. **Conclusions** *Parkin* was the most frequently mutated gene in EOPD, followed by *DJ-1* and *PINK1*. The low overall mutation frequency observed indicates that caution has to be taken with the extrapolation of mutation frequencies found in other studies and populations and suggests that other genes and risk factors for PD remain to be discovered.

P06.094

DNER, a neuronal transmembrane protein is dispensable for gross cellular morphology and sensory nerve fiber excitability

U. Brandt-Bohne^{1,2}, D. R. Keene³, B. Erdmann⁴, G. Lewin⁴, M. Koch²;

¹Center for Genomic Regulation, Barcelona, Spain, ²Institute for Biochemistry II University Clinics Cologne, Cologne, Germany, ³Shriners Hospital for Children Research Center, Portland, OR, United States, ⁴Max Delbrueck Center for Molecular Medicine, Berlin-Buch, Germany.

DNER is the first transmembrane protein expressed in the brain containing only multiple epidermal growth factor (EGF) - like repeats in its extracellular domain. DNER further contains a signal peptide, a serine rich stretch, a transmembrane domain and a cytoplasmatic C-terminus. Since its close relation to Notch and Delta it has been named Delta/Notch-like-related receptor. Structural homology to other EGF-bearing proteins involved in extracellular signalling events and in neuronal development, point out a possible involvement of DNER in such processes.

The extracellular domain of DNER was cloned and recombinant protein was used for polyclonal antibody production. Recombinant and full length protein is larger than the theoretical calculated mass and glycosidase digestion indicate that DNER is glycosylated. Distribution analysis by semi quantitative RT-PCR show that almost no mRNA was present in non-neuronal tissues. In mouse embryos, DNER mRNA is detectable at day 9.5 of gestation in the neural tube, dorsal root ganglia, ear placode, anterior and posterior zones of the developing forelimb, and in different cell types of the retina. The distribution of DNER protein is also mainly restricted to neuronal tissues and can also be detected in peripheral ganglia and nerves. A knock-out targeting vector was generated and the homozygote animals are being analyzed. In the homozygote knock out animals no DNER protein was detected. Surprisingly, the mice are viable and show no obvious phenotype. The gross cellular morphology appears unchanged and further analysis of the peripheral nerve functions, reveal no effects in excitability of specific A-fibers.

P06.095

Polymorphisms in ESR1 and ESR2 genes are associated with susceptibility to endometriosis

M. Lamp¹, M. Peters¹, H. Karro^{1,2}, Ü. Kadastik², E. Reinmaa³, K. Haller^{1,3}, A. Metspalu², A. Salumets^{1,3};

¹Department of Obstetrics and Gynaecology, University of Tartu, Tartu, Estonia,

²Tartu University Hospital's Women's Clinic, Tartu, Estonia, ³Department of Biotechnology, Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia.

Introduction. Endometriosis is defined as the presence of endometrial-like tissue outside the uterus. It affects about 5-10% of women of reproductive age and causes dysmenorrhoea, abdominal pain, dyspareunia and infertility. Endometriosis is considered to be an estrogen-dependent disease with a genetic background. The aim of this study was to evaluate possible associations between endometriosis and polymorphisms in the estrogen receptor α (*ESR1*) and β (*ESR2*) genes.

Materials and methods. 123 women (age: 18-44 years) with surgically confirmed endometriosis were enrolled in the study. 200 fertile women (at least two children; age: 30-50 years) from general population were used as controls. The 397 T/C polymorphism in the first intron of the *ESR1* gene was determined by PCR-RFLP analysis, using the restriction endonuclease *PvuII*. The number of CA repeats in the fifth intron of the *ESR2* gene was detected with fragment analysis.

Results. The distribution of *ESR1* TT/TC/CC genotypes was 17.9/54.5/27.6% among patients and 30.0/51.0/19.0% in the control group ($p=0.028$; χ^2 -test). The T/C allele frequencies were 45.1/54.9% and 55.5/44.5%, respectively ($p=0.008$). The number of CA repeats in the *ESR2* gene ranged from 14 to 26. The *ESR2* alleles were classified as short and long, with ≤ 21 and >21 repeats, respectively. Endome-

triosis patients had short (CA)_n alleles more frequently than healthy controls (61.4% vs 51.5%, $p=0.018$). This difference was even more remarkable in case of stage IV disease (80.8% vs 51.5%, $p=0.007$). Conclusions. The C-allele of *PvuII* polymorphism in *ESR1* gene and short *ESR2*-(CA)_n alleles could be associated with susceptibility to endometriosis.

P06.096

Genetic polymorphisms and physical performance in endurance sports

D. Varillas^{1,2}, J. J. Telleria^{1,2}, Á. Martín-Pastor¹;

¹Facultad de Medicina. Universidad de Valladolid, Valladolid, Spain, ²Instituto de Biología y Genética Molecular (UVa/CSIC), Valladolid, Spain.

Genes determine the potential for developing many of the structural and functional characteristics important in determining sports performance. So, the genetic constitution defines innate qualities. The genes also determine the speed and extent to which the performance characteristics of the individual respond to training, diet, and other environmental factors. The effects of genes on response to training to endurance sports seem to be moderate to large.

Here we study the correlation between endurance sports and the following polymorphisms: insertion/deletion in intron 16 (I/D) within *ACE* gene; p.C282Y and p.H63D in *HFE* (hemochromatosis) gene and p.R577X within *ACTN3* (alpha3-actinin).

We have genotyped samples of two groups of endurance sportsmen (runners $n=48$ and cyclists $n=60$) and control population ($n=66$).

We have observed that the D allele of the *ACE* gene were more frequent in sportsmen as a whole (72%) than in control population (42.4%) $p=0.0001$. For runners the frequency were 70.7% $p=0.003$, and for cyclist 72.9% with $p=0.004$.

p.63D allele of *HFE* was present in 60.3% of the cyclist and in 41.3% of the controls ($p=0.006$). There were no differences between runners and controls. The frequency of the p.282Y allele is very low in our population, nevertheless, it was more frequent in cyclist than in runners $p=0.015$.

The study of *ACTN3* gene did not show differences between the groups.

We conclude that genetic constitution contributes to the talent to practice endurance sports, and that the "predisposing" genes seem to be sport-specific.

P06.097

Analysis of ACE and eNOS gene polymorphisms in hemodialysis patients

T. M. Damnjanovic¹, I. Novakovic¹, B. Jekic¹, N. Maksimovic¹, V. Bunjevacki¹, S. Simic², L. Djukanovic², L. Lukovic¹;

¹Institute of Biology and Human Genetics, Belgrade, Serbia, ²Institute of Nephrology, CCS, Belgrade, Serbia.

Polymorphisms in genes encoding for angiotensin I converting enzyme (*ACE*) and NO synthase (*eNOS*) have been reported to be associated with increased susceptibility to renal failure. The aim of the study was to investigate allelic distribution of *eNOS* (4a4b, G894T) and *ACE* (I/D) gene polymorphisms in hemodialysis patients ($n=128$) and control group ($n=101$) and to find possible association of mutant allele with this disorder in Serbian population. The polymorphic variants were analysed using PCR-RFLPS and PCR-VNTR method.

The allele frequencies of two *eNOS* gene polymorphisms were: 0.27 894T, 0.21 4a, in the group of patients and 0.31 894T, 0.17 4a in control group. The frequencies of G894T polymorphism genotypes were 0.56 GG, 0.35 GT, 0.09 TT in the group of patients and 0.50 GG, 0.38 GT, 0.11 TT in the control group. The genotype frequencies of *eNOS* intron 4 polymorphism were 0.65 bb, 0.28 ba, 0.07 aa in the group of patients, and 0.70 bb, 0.26 ba, 0.04 aa in the control group. The difference between allelic and genotype frequencies (patients/control) is not statistically significant. The allele frequencies of *ACE* gene were 0.71 D (genotype: 0.58 DD, 0.28 ID, 0.14 II) in the group of patients and 0.62 D (genotype: 0.45 DD, 0.34 ID, 0.21 II) in the control group. The D allele frequencies in a group of patients is significantly higher than in control group ($\chi^2=3.96$, $DF=1$, $p<0.05$).

Thus, *ACE* D allele can be considered as genetic marker associated with renal failure, independently of alleles 4a or 894T.

P06.098

Genetic analysis of autosomal dominant nocturnal frontal lobe epilepsy (ADNFLE)

R. J. Camacho-García¹, D. Florea², T. Escobar Delgado³, A. Macaya⁴, M. Lucas⁵, M. L. Avendaño-Kunstmann⁶, J. Rodríguez Uranga³, A. Martínez-Mir¹;

¹Dept. of Medical Biochemistry and Molecular Biology. School of Medicine. University of Seville, Seville, Spain, ²Neurology and Neurophysiology, Hospital de Carabineros, Santiago, Chile, ³Neurology, Virgen del Rocío University Hospital, Seville, Spain, ⁴Pediatric Neurology, Vall d'Hebron University Hospital, Barcelona, Spain, ⁵Molecular Biology Service, Virgen Macarena University Hospital, Seville, Spain, ⁶Pediatric Neurology and Neurophysiology, Hospital de Carabineros, Santiago, Chile.

Epilepsy is a heterogeneous group of disorders affecting 0.5-1% of the population worldwide. Among them, autosomal dominant nocturnal frontal lobe epilepsy (ADNFLE) is an idiopathic epilepsy characterized by nocturnal motor seizures that typically begin during childhood. Familial cases follow an autosomal dominant pattern of inheritance with reduced penetrance. Disease-causing mutations have been described in the genes encoding the neuronal nicotinic acetylcholine receptor subunits *CHRNA2*, *CHRNA4*, and *CHRNA2*. A fourth locus has been identified on chromosome 15q24, and putative susceptibility loci mapped to chromosomes 3 and 8. These genes/loci account for only a minority of ADNFLE cases, indicating genetic heterogeneity.

We have ascertained two new pedigrees segregating ADNFLE. Family 1 is a five-generation pedigree originating from Chile, with twelve affected subjects and three obligate carriers. Patients present with focal, motor seizures or secondary generalized attacks. Family 2 is a three-generation Spanish family with four affected relatives, including one patient with concomitant early-onset Parkinson disease and a second patient with West syndrome. In order to identify the underlying disease-gene(s), we are currently performing cosegregation analysis using markers spanning all known ADNFLE loci. In addition, we are also studying other acetylcholine receptor genes (*CHRNA3*, *CHRNA5*, *CHRNA7* and *CHRNA4*), and loci on chromosomes 10 and 22, responsible for partial epilepsy with auditory features and familial partial epilepsy with variable foci, respectively. In the event that all loci are excluded as the underlying cause of disease, we will perform a genome-wide scan to identify a novel gene responsible for the ADNFLE phenotype in family 1.

P06.099

Association between genetic polymorphisms and pediatric essential hypertension

S. Stangler Herodez, B. Zagradiznik, K. Zerjavič, N. Marčun Varda, N. Kokalj Vokač, A. Gregorič;

University Medical Centre Maribor, Maribor, Slovenia.

Recent whole genome association studies identified a number of loci associated with the development of different complex trait life style diseases, i.e. coronary heart disease, diabetes type 2 and many others. Because these diseases increasingly affect children it can be assumed that similar genetic factors may contribute to their development in pediatric cases. This study presents association analysis for three common SNPs reported to be associated with coronary heart disease/obesity/diabetes type 2 in adults in a sample of children diagnosed with essential hypertension.

A total of 166 families were included in the study (514 individuals)... Allele specific PCR was adopted for the study. Polymorphism rs9939609 from the gene *FTO*, polymorphism rs7566605 from the gene *INSIG2* and polymorphism rs10757278 were selected for the analysis.

Weak association between polymorphisms rs10757278, rs9939609 and pediatric essential hypertension was observed. Also strong association for polymorphisms rs7566605 was present in our sample of families with children affected with pediatric hypertension.

Our results suggest that the three polymorphisms might be associated with the development of essential hypertension in children. The rs7566605 from the gene *INSIG2* may be involved in the pathogenesis of pediatric essential hypertension.

P06.100**An association between essential tremor and ETM2 locus in Latvian population**

I. Inashkina¹, I. Radovica¹, E. Vitols², L. Smeltēre³, E. Jankevics¹;

¹Latvian Biomedical Research and Study Centre, Riga, Latvia, ²Riga Stradins University, Department of Neurology, Riga, Latvia, ³Paul Stradins University Clinical Hospital, Riga, Latvia.

Essential tremor (ET) is one of the most common neurological disorders in humans. An autosomal dominantly inherited form of ET is genetically linked to two loci on chromosomes 3q13 (ETM1) and 2p24.1 (ETM2) in families from different parts of the world. Numerous of candidate genes for ET disorder - HS1-BP3, HCLS1, DRD3 - have been suggested during last years.

Here we report study analysing a group of 104 unrelated Latvian patients with ET for a genetic association with loci in candidate regions ETM1 and ETM2. Out of them, 52 were classified as familial on the bases of familial history. All patients were genotyped using sixteen informative STR markers within two loci associated with ET (9 markers for ETM2 and 7 for ETM1) and statistically analysed. Allele frequencies were estimated on 97 normal controls, matched by age and gender.

The one concrete allele frequencies were significantly different between familial ET samples in case of marker D2S220 ($p=0.0281$) and total ET samples in case of marker D2S2201 ($p=0.0385$) in comparison to control samples. Other loci did not show significant allele frequency differences between familial cases, total ET cases or control groups.

In addition, 7th exon of HS1-BP3 gene containing A265G substitution and 1st exon of DRD3 gene containing S9G substitution were analysed in all ET patients and control samples. Analysed data did not reveal any association between known variants of HS1-BP3 and DRD3 genes and ET phenotype.

Our data suggest an association between ETM2 locus and familial essential tremor in Latvian population.

P06.101**Lysyl Oxidase-like 1 gene Polymorphisms in Exfoliation Syndrome, Exfoliation Glaucoma and Primary Open Angle Glaucoma in the Finnish Population**

S. Lemmelä¹, E. Forsman², H. Nurmi¹, H. Laivuori¹, T. Kivelä³, P. Puska³, E. Vest³, A. Eriksson², H. Forsius², I. Järvelä¹;

¹Department of Medical Genetics, University of Helsinki, Helsinki, Finland,

²Population Genetics Unit, Folkhälsan Institute of Genetics, Helsinki, Finland,

³Department of Ophthalmology, University of Helsinki, Helsinki, Finland.

Exfoliation syndrome (XFS) is an age-related ocular disorder and a risk factor for the development of glaucoma. XFS is characterized by abnormal accumulation of greyish fibril-like material in the anterior segment of the eye. Similar material has also been found in extraocular tissues. XFS is prevalent worldwide but the prevalence varies widely in different populations; being even 20%-40% among individuals >80 years in Scandinavian countries. Familiar aggregation studies suggest genetic contribution to XFS. In a recent genome-wide association study, three SNPs, (rs2165241, rs1048661 (R141L) and rs3825942 (G153D)) on lysyl oxidase-like 1 (LOXL1) gene were found to be strongly associated with XFS and XFG, in Icelandic and Swedish patients. Together two non-synonymous SNPs accounted for 99% of XFG in this population. These two SNPs were in complete LD and three haplotypes were observed. Haplotypes G/G (OR=27.05) and T/G (OR=8.90) were risk haplotypes relatively to G/A with lowest estimated risk. In this study we investigate whether three LOXL1 SNPs are associated with XFS/XFG in Finnish population. SNPs are screened by direct-sequencing in XFS-, XFG- and POAG- patients (100/group) and as controls in ~120 individuals without any sign of XFS/XFG/POAG and ~300 Finnish blood donors. In preliminary results 59% (30/51) of XFS patients, 69% (40/58) of XFG patients and only 18% (10/55) of POAG patients were homozygous for the highest risk haplotype GG. Likewise in Icelandic and Swedish population about 25% (82/325) of general population in Finland were homozygous for the haplotype GG. Studies are ongoing and more XFS/XFG/POAG patients will be analyzed.

P06.102**FADS genotypes and desaturase activity estimated by arachidonic to linoleic acid ratio are associated with inflammatory and coronary artery disease**

E. Trabetti¹, G. Malerba¹, N. Martinelli², D. Girelli², P. Guarini², T. Illig³, M. Sandri², S. Friso², F. Pizzolo², L. Schaeffer³, J. Heinrich³, R. Corrocher², O. Olivieri², P. F. Pignatti¹;

¹Section of Biology and Genetics - Dept Mother & Child/Biol & Genet, Univ Verona, Verona, Italy, ²Dept Clinical and Experimental Medicine, Univ Verona, Italy, Verona, Italy, ³GSF-National Research Center for Environmental and Health, Institute of Epidemiology, Neuherberg, Germany, Neuherberg, Germany.

Background: The delta-5 and delta-6 desaturases, encoded by FADS1 and FADS2 genes, are key enzymes in the conversion of linoleic acid (LA) to arachidonic acid (AA). AA is the precursor of a cascade of mediators, such as eicosanoids, with inflammatory properties. Single nucleotide polymorphisms (SNPs) in FADS1 and FADS2 have been associated with different levels of AA and LA, with possible functional consequences on desaturase activity.

Methods and Results: Thirteen FADS SNPs and AA/LA ratio on red blood cell (RBC) membranes, a marker of desaturase activity, were evaluated in 876 subjects with (n=610) or without (n=266) angiographically documented coronary artery disease (CAD). AA/LA ratio was higher in CAD patients (2.17±0.41 versus 1.99±0.36; $P=2.5\times 10^{-10}$), and an increased AA/LA ratio resulted an independent risk factors for CAD (OR 2.22, 95%CI 1.37-3.61 for higher versus lower ratio tertile). Furthermore, hs-CRP levels increased progressively across AA/LA ratio tertiles. In a linear regression model including all the 13 SNPs analysed, 4 resulted to be independent predictors of AA/LA ratio variability. The subjects carrying the highest number of alleles associated with a raised ratio, as well as haplotypes with the highest number of such alleles, presented proportionally more elevated hs-CRP concentrations and an increased probability of having CAD.

Conclusions: An increased desaturase activity is associated with an elevated hs-CRP and, in turn, with an increased risk for CAD. Subjects carrying FADS genotypes associated with a higher desaturase activity may be prone to a proinflammatory response favouring atherosclerotic vascular damage.

P06.103**MLPA PCR-analysis for registration of the most frequent mutations in MEFV gene indigenous to Armenians**

V. A. Kadnikova, O. A. Schagina, A. V. Polyakov;

Research Centre for Medical Genetics, Moscow, Russian Federation.

Familial Mediterranean fever (FMF) is an autosomal recessive disease particularly common in several populations of Mediterranean extraction, and affecting mainly Turks, Jews, Armenians, and Arabs. It is characterized by recurrent short episodes of fever, sterile peritonitis, arthritis, and pleurisy. The gene responsible for FMF, *MEFV* (MIM# 608107), was identified by positional cloning in 1997. The product of the *MEFV* gene, named pyrin/marenostrin, is expressed in polymorphonuclear cells and monocytes and it is proposed that it regulates inflammatory responses at the level of leucocyte cytoskeletal organisation. Thirty six mutations located in the *MEFV* gene have been identified so far, mostly in exon 10, followed by exons 1, 2, 3, 5 and 9.

We elaborated the multiplex system for MLPA PCR-analysis for most frequent mutations indigenous to Armenians M694V, M680I, V726A, F479L, R761H, and E148Q in *MEFV* gene in exons 10, 5 and 2. The *MEFV* probe mix contains 18 different probes with amplification products between 82 and 145 bp. Length difference between consecutive amplification products is 3 or 4 bp.

DNA sample from 57 unrelated Armenian FMF patients were examined by this multiplex system. 83 chromosomes with different mutations were revealed. So, calculated informative of this system more than 73% for Armenians living on the Russian Federation territory.

Advantages of this method are: specificity; possibility to work with small quantity of researching material- method speed; for all mutation types used two universal ferments: ligase and polymerase; detection with help of PAAG or capillary electrophoresis; quantitative analysis genes copy or stripes of genes.

P06.104**Association study of candidate genes in the chromosome 5p13.1-q11.2 linkage region for familial primary cutaneous amyloidosis**

M. W. Lin^{1,2}, C. T. Hsu¹, C. C. Huang³, Y. F. Liu⁴, D. D. Lee⁵, T. T. Liu⁴, C. K. Wong⁶, S. F. Tsai⁶;

¹Institute of Public Health, National Yang-Ming University, Taipei, Taiwan,

²Department of Medical Research & Education, Taipei Veterans General Hospital, Taipei, Taiwan, ³Institute of Biomedical Informatics, National Yang-Ming University, Taipei, Taiwan, ⁴VYM Genome Research Center, National Yang-Ming University, Taipei, Taiwan, ⁵Department of Dermatology, Taipei Veterans General Hospital, Taipei, Taiwan, ⁶Division of Molecular and Genomic Medicine, National Health Research Institutes, Zhunan Town, Miaoli County, Taiwan.

Primary cutaneous amyloidosis (PCA) is a relatively common skin disorder in South America and Southeast Asia. The pathogenesis of PCA remains unclear. Most cases of PCA are sporadic but familial aggregation has been reported from South America and Taiwan. The different susceptibility among ethnic groups suggests that genetic factor may play an important role in its pathogenesis.

In our previous study, we performed genome-wide linkage analysis of familial primary cutaneous amyloidosis using both microsatellite and Affymetrix GeneChip[®] Human Mapping 10K Array and identified significant linkage evidence (maximum LOD=4.50) for a portion of FPCA families on chromosome 5. In the candidate region identified by SNP linkage mapping, there are 12 known genes.

To characterize the susceptibility genes for FPCA, we applied the Illumina GoldenGate[®] Assay to genotype large amounts of functional SNPs and tagSNPs selected from the HapMap project within or around candidate genes of significant linkage region on chromosome 5. A total number of 23 FPCA families with 75 affected and 72 phenotypically normal subjects and 94 normal control subjects were genotyped in the study. Several SNPs on NNT, FGF10, HCN1, ITGA1, ITGA2, NDUFS4, SNAG1 genes demonstrated statistically significant results (p-value <0.05).

In conclusion, our study found positive association between several candidate genes on chromosome 5 and FPCA. Independent study and functional study are required to confirm our findings.

P06.105**High prevalence of familial pulmonary fibrosis in Newfoundland suggestive of a novel genetic etiology**

L. A. Edwards, B. A. Fernandez, B. Noble, M. O. Woods;

Memorial University of Newfoundland, St. John's, NL, Canada.

Idiopathic Pulmonary Fibrosis (IPF) is a form of interstitial lung disease that is progressive and often fatal. This devastating disease is limited to the lungs, and the only treatment that improves survival is a lung transplant. It is usually diagnosed between ages 50-70 years. Without treatment, mean survival ranges from 2-4 years. Up to 3% of IPF patients have the familial form of the disease (familial pulmonary fibrosis or FPF). In 2001, autosomal dominant mutations in Surfactant Protein C (*SFTPC*) were shown to cause familial forms of lung disease, including FPF. Also, in 2006, mutations in genes encoding telomerase components, Telomerase Reverse Transcriptase (*TERT*) and an RNA component (*TERC*) were shown to increase susceptibility to FPF.

There is an unexpectedly high prevalence of FPF in Newfoundland. There are presently 14 identified FPF families with 54 affected individuals. The minimum prevalence of FPF in Newfoundland is 54 cases per 400,000, which is approximately 135 cases per 10⁶, compared to the FPF prevalence in the UK which is only 1.34 cases per 10⁶. Mutations in the *SFTPC* gene have previously been excluded in the FPF Newfoundland families. As well, mutations in the *TERT* and *TERC* genes have also been excluded in our 14 FPF families. In these families we are currently performing genome-wide scans to identify the causative gene(s) involved.

P06.106**Association of Fc gamma receptors (FcγRs) polymorphisms with susceptibility of Systemic Lupus Erythematosus (SLE) in Hong Kong Chinese**

P. Ng, Y. L. Lau, W. L. Yang;

Department of Paediatrics and Adolescent Medicine, University of Hong Kong, Queen Mary Hospital, Hong Kong, China.

Systemic Lupus erythematosus (SLE) is an autoimmune disease characterized by immune dysregulation, leading to high-level autoantibody production and immune complex deposition. Both genetic and environmental factors are known to contribute to the complex etiology of SLE. Fc gamma receptors, which constitute a clustered gene family located on chromosome 1q23, are low-affinity receptors for IgG and play important role in immune complex clearance. Abnormalities in FcγR mediated immune complex clearance could be involved in the disease and polymorphisms of FcγRs may affect the susceptibility and severity of SLE. In this study, we have examined SNP rs1801274 and SNP rs396991, two non-synonymous variations coding for amino acids located in the extracellular domain of FcγRIIa and FcγRIIIa, respectively. 430 SLE patients and 387 healthy controls of Hong Kong Chinese were genotyped for these two SNPs. The G allele of rs1801274 in FcγRIIa codes for R131, which was shown to have low-binding affinity to IgG. Our study found that the G/G genotype for this site was more frequent (14.2%) in SLE patients in our population compared to healthy controls (10.1%). No significant difference was seen in FcγRIIIa polymorphisms in Hong Kong Chinese. We are planning more extensive studies on this important locus and hypothesize that loss of balance among the receptors with opposing functions in this locus may confer disease susceptibility to SLE in Hong Kong Chinese.

P06.107**Study of linkage to FEB1 and FEB2 loci in Serbian families with febrile seizures**

N. Maksimovic¹, D. Perovic², M. Djuric², I. Novakovic¹, T. Damjanovic¹, B. Jekic¹, L. Lukovic¹, Z. Krcunovic¹;

¹Institute of Human Genetics, School of Medicine, Belgrade, Serbia, ²Mother and Child Health Care Institute of Serbia "Dr Vukan Cupic", Belgrade, Serbia.

Introduction: Febrile seizures (FS) represent the most common form of childhood seizure. It is well known that genetic factors play an important role in susceptibility to FS. Although specific genes that affect the majority of FS cases have not yet been identified, genetic loci for FS on chromosomes 8 (FEB1), 19 (FEB2), 2 (FEB3), 5 (FEB4), 6 (FEB5), and 18 (FEB6) have been reported recently. However, the mode of inheritance still remains unclear. Polygenic, autosomal dominant and autosomal recessive models have received support.

Aim: Our aim was to investigate the mode of inheritance in familial FS, to conduct the linkage analysis to FEB1 (8q13-21) and FEB2 (19p13.3) loci in Serbian population and to investigate the correlation between the specific locus and seizure type.

Methods: We investigated ten nonconsanguineous families with at least three members whose diagnosis of FS was established by the standard diagnostic criteria. The mode of inheritance was determined by pedigree analysis. In order to investigate the linkage of FS to FEB1 and FEB2 loci we analyzed microsatellite markers D8S1840, D8S530, D19S209, D19S216, D19S591. Alleles were determined after PCR and gel-electrophoresis and linkage was estimated by LOD score calculation.

Results: In ten investigated families we found the autosomal dominant mode of inheritance with reduced penetrance. Linkage analysis showed no significant correlation between febrile seizures and examined loci in our sample. Maximum LOD score of 0.98 at recombination fraction of $\theta=0.00$ was obtained at locus D19S209. That confirmed previously presumed genetic heterogeneity of the disorder.

P06.108**Familial Hemiplegic Migraine: linkage to chromosome 14q32 in a large Spanish kindred**

E. Cuenca-Leon¹, R. Corominas¹, M. Montfor^{2,3}, J. Artigas⁴, M. Roig¹, M. Bayés^{2,3}, B. Cormand^{5,6}, A. Macaya¹;

¹Grup de Recerca en Neurologia Infantil i Psiquiatria Genètica, Hospital Universitari Vall d'Hebron, Barcelona, Spain, ²Genes and Disease Program, Center for Genomic Regulation (CRG), UPF, Barcelona, Spain, ³CIBER Epidemiología y Salud Pública, Instituto de Salud Carlos III (CRG), Barcelona, Spain,

⁴Corporació Sanitària Parc Taulí, Sabadell, Spain, ⁵Departament de Genètica, Facultat de Biologia, Universitat de Barcelona, Barcelona, Spain, ⁶CIBER Enfermedades Raras, Instituto de Salud Carlos III, Barcelona, Barcelona, Spain.

Objective: To map the disease-causing gene in a large Spanish kindred with familial hemiplegic migraine (FHM), migraine with aura (MA) and migraine without aura (MO).

Methods: DNA samples from 20 family members were obtained. Patients were classified according to ICHD-II criteria for specific migraine subtypes. After ruling out linkage to known migraine genetic loci, a single nucleotide polymorphism (SNP)-based, 0.62 cM density genome-wide scan was performed.

Results: In 13 affected subjects, FHM was the prevailing migraine phenotype in six, MA in four and MO in three. Linkage analysis revealed a disease locus in a 4.15 Mb region on 14q32, with a maximum two-point LOD score of 3.1 and a multipoint parametric LOD score of 3.8. This genomic region does not overlap with reported migraine loci on 14q21-22. Several candidate genes map to this region. Sequence analysis of one of them, *SLC24A4*, encoding a potassium-dependent sodium/calcium exchanger, failed to show disease-causing mutations in our patients.

Conclusions: The finding of a new genetic locus in FHM underscores its monogenic character and hints to greater genetic heterogeneity than previously suspected. While several genes conferring increased susceptibility to migraine seem to reside on 14q, the underlying disease-causing gene in our family remains unidentified.

P06.109

Association study of TOR1A gene polymorphisms with the risk of primary focal dystonia

E. Sarasola¹, F. Sádaba², B. Huete², A. Rodríguez-Antigüedad², A. M. Pérez-Miranda¹, M. J. García-Barcina¹;

¹Unidad de Genética. Hospital de Basurto. Osakidetza - Servicio Vasco de Salud, Bilbao, Spain, ²Servicio de Neurología. Hospital de Basurto. Osakidetza - Servicio Vasco de Salud, Bilbao, Spain.

The most frequent cause of early-onset primary generalised dystonia, which is dominantly inherited, is a deletion of a GAG triplet from exon 5 of TOR1A gene (c.907delGAG). This gene encodes torsinA protein, whose role has been suggested to be involved in regulating nuclear envelope and endoplasmic reticulum organization. This 3-bp deletion removes a codon in the C-terminus of torsinA that normally encodes a glutamic acid residue, producing an altered protein, with reduced or no activity, which forms perinuclear inclusions.

A recent study described the effects of a new polymorphism in position c.646 (G>C) which causes the development of inclusions similar to those described for deltaGAG deletion. Moreover, this D216H amino acid change reduced the number of torsinA inclusions in cultured cells with deltaGAG deletion. Many groups have studied the implication of this and other polymorphisms in this gene in primary dystonia but results are controversial. In this work we will try to find a risk haplotype for primary focal dystonia.

We analyzed 6 different polymorphisms in individuals with focal dystonia (n = 60) and a control healthy population (n = 50). None of them presented the GAG deletion in TOR1A exon 5. For genotyping, real-time PCR followed by allelic discrimination or PCR and automated sequencing was performed. Statistical analysis was carried out using a haplotype-based approach.

P06.110

Molecular diagnosis of Friedreich's ataxia in Macedonian patients

S. A. Kocheva^{1,2}, S. Vlaski-Jekic³, M. Kuturec², G. D. Efremov¹;

¹Macedonian Academy of Sciences and Arts, Research Center for Genetic Engineering and Biotechnology, Skopje, The former Yugoslav Republic of Macedonia, ²Pediatric Clinic, Medical Faculty, Skopje, The former Yugoslav Republic of Macedonia, ³Department of Neurology, Medical Faculty, Skopje, The former Yugoslav Republic of Macedonia.

Friedreich's ataxia (FRDA) is a progressive neurodegenerative disorder of autosomal recessive inheritance, in which gait ataxia followed by upper limb ataxia, dysarthria, nystagmus, areflexia, loss of joint position sense, and spastic paraparesis develop from the second decade of life. It is the commonest hereditary ataxia, with a prevalence of 1 in 50 000 and a deduced carrier frequency in European populations of 1 in 120. Friedreich's ataxia has been associated with mutations of the

frataxin gene on chromosome 9 (X25 at 9q13). In this paper we present our results from the molecular analysis of frataxin gene (X25) gene in total of 40 patients with spinocerebellar ataxia from the Republic of Macedonia. Fifteen of the patients have an early onset of progressive ataxia (before 25 years), while 25 patient were more than 25 years old at the time of diagnosis. We amplified the FRDA associated expanded fragment using a long range PCR technique. PCR product were analyzed by agarose and/or PAG electrophoresis. Mutation analysis shown that 14/15 patient with typical early onset of the symptoms were homozygous for a GAA expansion in intron 1 of frataxin gene. No expansion of the GAA repeat were found in 25 patient with ataxia more than 25 years old. In 35 normal individuals the number of GAA repeat were in normal range.

P06.111

Molecular characterization of two variants of GATA4 in patients with Congenital Heart Defects

F. Giacomelli¹, M. Marini¹, E. Damato², A. Baban¹, G. Trocchio³, G. D'Annunzio², M. Lerone¹, G. Pongiglione³, R. Lorini², R. Ravazzolo¹;

¹Molecular Genetics and Cytogenetics Unit, Genoa, Italy, ²Pediatric Clinic, Gaslini Institute, Genoa, Italy, ³Unit of Cardiology, G. Gaslini Institute, Genoa, Italy.

Congenital Heart Defects (CHDs) are among the most common developmental anomalies that affect around 1% of newborns. One of the genes described as causative of CHD is GATA4, a zinc finger transcription factor, important regulator in heart development. Mice lacking this gene have defects in the formation of heart tube and are lethal. GATA4 mutations have been found in families with Atrial and Ventricular Septal Defects and rarely associated with Tetralogy of Fallot.

In this study we report two different variants in the non coding sequence of GATA4 gene found in two patients with Atrial Septal Defect: c784-3 C>T and c998-4C>G. Interestingly, in one of the two cases neonatal permanent diabetes was present in the patient and her mother.

These variants were not detected in more than 100 healthy controls, while one of the two was also detected in the apparently patient's unaffected mother. Both patients were screened also for TBX5 and NKX2.5 genes and no mutations were found.

These GATA4 variants are located at acceptor splicing sites in intron 3 and 5, respectively, and predicted to be potentially able to affect splicing on the basis of specialized software analysis.

Since the gene is not expressed in lymphocytes and fibroblasts, the effect on splicing cannot be directly tested on cDNA. Therefore an in vitro assay to verify the effect of both nucleotide variants using an exon trapping model has been set up.

The Health e Child IST-2004-027749 project is acknowledged.

P06.112

The distribution of S19W and -1131 T>C gene apolipoprotein A5 (ApoA5) polymorphism in children with innate risk factors of metabolic syndrome

A. P. Khmyrova¹, A. N. Voitovich¹, P. A. Sinicir², O. A. Kononova¹, M. Y. Scherbacova², V. I. Larionova¹;

¹State Pediatric Medical Academy, Saint-Petersburg, Russian Federation, ²Russian State Medical University, Moscow, Russian Federation.

The risk factors of cardiovascular disorders there are in children and adolescence and sometimes may be cause of metabolic syndrome. One of metabolic syndrome criteria is atherogenic dyslipidemia with high level of triglyceride and low level of high density lipoprotein's cholesterol. The detecting of molecular markers of this dyslipidemia is one of the important problems.

The aim of our study was to investigate genotype and alleles distribution S19W and -1131 T>C ApoA5 gene polymorphism in children with risk factors of cardiovascular disorders and compare it with control group.

We included 187 children with risk factors of coronary artery disease (CAD) from 5 to 17 years old. Control group consisted of 150 children and adolescence with same age.

For detecting S19W and A-1131T>C ApoA5 gene polymorphism we used PCR with restriction assay by the method, described Talmud P. J. et al., 2002.

We have revealed significant differences in genotype distribution (SS-90,4% and 81,9%, SW - 9,6% and 16,8%, WW - 0,0% and 1,3%, p=0,05, relatively) and alleles distribution (S-95,2% and 90,3%, W-

4,8% and 9,7%, relatively, $p=0,025$) of S19W of *ApoA5* gene polymorphism between children with risk factors of CAD and control group. We haven't significant differences in genotypes and alleles distribution of A-1131T>C of *ApoA5* gene polymorphism in boys, girls and total group between children with risk factors of CAD and control group. **Conclusion:** children with risk factors of metabolic syndrome had more frequent SS genotype and S allele S19W of *ApoA5* gene polymorphism than in healthy children.

P06.113

Influence of *TNF* (G-308A) polymorphism on level of a *TNF*-alpha in blood at chronic diseases of lungs and liver

I. A. Goncharova¹, G. N. Seitova², E. V. Beloborodova², O. P. Bukreeva², I. L. Purilik², V. P. Puzyrev¹;

¹Scientific Research Institute of Medical Genetics, Tomsk, Russian Federation, ²Siberian State Medical University, Tomsk, Russian Federation.

Polymorphism in *TNF* (G-308A) gene was studied for association with tumor necrosis factor alpha level in blood of patients with chronic viral hepatitis (n=60) and chronic obstructive pulmonary disease (COPD) (n=72). The patients were from Tomsk population. It has been shown that level of *TNF*-alpha in patients with chronic viral hepatitis depends on *TNF* (G-308A) genotype: GG - 137.9±222.49; AG - 48.7±58.16; AA -31.0±1.41 ($p=0.018$). The finding suggests that in patients with chronic viral hepatitis allele A is associated with smaller intensity of an inflammation and fibrosis in a liver. In the patients with COPD, carriers of genotype AG had lower level *TNF*-alpha in blood at exacerbation (60,1±20,68) and during remission (75,1±16,56) in comparison with carriers of a genotype GG (193,8±50,65; 370,3±109,4) ($p=0,041$; $p=0,026$). Genotype AA has not been revealed. Thus, at patients with COPD allele A is associated with low level *TNF*-alpha in blood, like in patients with chronic viral hepatitis. These results are discordant with known data on association of allele A with increased level of production of *TNF*-alpha. There might be several explanations of the discrepancy, including population specificity of genetic predisposition to various diseases and different LD structure in adjacent regions of genome (including 3'-UTR region of the gene) in different populations, as well as different environmental factors that can influence realization of a "genetic background".

P06.114

Somatic genome structural variations

V. Sgaramella, J. L. Williams, F. Salamini;

CERSA, Lodi, Italy.

The notion that cells of common ancestry harbour genomes different from each other is strengthening. The differences may be either scheduled (e. g., immune response), or unscheduled (e.g., damage effects), and alter DNA structures. Simple repeats, interspersed sequences, (retro)transposons, pseudogenes, transgenes, etc., may assume unusual non-B conformations, affecting recognition by DNA-metabolizing enzymes. This may trigger a crescendo of variations, from base substitutions to aneuploidy. Epigenetics modifies chromatin and modulates transcription in somatic cells, but can be erased in germ cells. The resulting RNA may activate novel priming and retrotranscription thus concurring to genome rearrangements, competent to drive evolution and contribute to development. The resulting somatic genome structural variations (SGSV) may accelerate cell duplication and favour clonal amplification, occasionally optimizing some functions, but often deranging growth. Consequently, multicellular organisms are bound to be eventually genomic mosaic.

We report on: 1. the amplification of the genome of as few cells as possible of diverse somatic tissues, as a prerequisite for detecting SGSV; 2. their identification and characterization. For step 1, we have developed a modified isothermal whole genome strand displacement amplification based on the circularization of restricted genomes. For step 2, we are investigating two approaches, based on AFLP and differential 2D-gel electrophoresis; others are being considered such as mass sequencing and comparative genome hybridization. Benefits are expected in basic sciences (soma-germline-environment crosstalk, mechanisms of gene copy and chromosome number variations, evolution), as well as applications (diagnosis, therapy, stem cells, transgenetics, cloning, plant and livestock breeding).

P06.115

Cross-validation filtering for genome-wide association scan

Z. Vitezica^{1,2}, M. Martinez^{1,3};

¹INSERM U563, Toulouse, France, ²Université Paul Sabatier III, Toulouse, France, ³Université Paul Sabatier III, Toulouse, France.

Genome-wide association studies (GWAS) with hundreds of thousands of markers are now feasible. In a one-stage study design, stringent significance thresholds are used because of the multiple-test problem. Hence, GWAs have low power to detect uncommon disease genes with low effects, even in relatively large datasets (several thousands of cases and controls). Alternative approaches have been proposed (Satagopan et al., 2002; Skol et al., 2005). Briefly, the full set of markers is tested in a fraction of the dataset only. A set of "best" markers, to be followed-up in either an independent (two-stages design) or an increased (joint-analysis design) sample, is identified from pointwise P-values. Yet, relaxing the significance thresholds may not compensate decrease in power due to the sample size reduction in stage-1. Here, we propose to use the consistency in the "associated" allele as a new criterion to select the "best" markers. The Consistency Rate (CR) is the number of times that allele 1 is found to be the risk allele out of n sub-samples. Each marker is ranked according to its CR value. Non-disease markers are expected to have CR values of 50%. Thus, in our approach, the "best" markers are those with CR values significantly different from 50%. We study the statistical properties of our filtering approach by simulations, using a panel of 30,000 SNPs from HapMap data, and under different conditions (disease gene effects; sample sizes; number of sub-samples n). We report type I error and power rates of our filtering and of other approaches.

P06.116

Identification of novel susceptibility loci 7q31 and 9p13 for bipolar disorder in an isolated population

O. M. Palo¹, P. Soronen¹, K. Silander¹, T. Varilo¹, K. Tuononen¹, M. Perola¹, T. Kieseppä², T. Partonen², J. Lonnqvist^{2,3}, T. Paunio^{1,4}, L. Peltonen^{1,5};

¹FIMM, Institute for Molecular Medicine Finland and National Public Health Institute, Helsinki, Finland, ²Department of Mental Health and Alcohol Research, National Public Health Institute, Helsinki, Finland, ³Department of Psychiatry, Helsinki University Central Hospital, Helsinki, Finland, ⁴University of Helsinki and Helsinki University Central Hospital, Department of Psychiatry, Helsinki, Finland, ⁵Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom.

We performed a linkage analysis on 23 Finnish families with bipolar disorder and originating from the North-Eastern region of Finland, by using the Illumina Linkage Panel IV (6K) Array. The Panel IV had an average intermarker spacing of 0.64 cM across the entire genome. One phenotypic model, broad mood disorder including bipolar I disorder and recurrent depressive disorder, was used in the analyses. We found genome-wide significant evidence of linkage to chromosomes 7q31 (LOD = 3.20) and 9p13.1 (LOD = 4.02). Analyzing the best markers on the full set of 179 Finnish bipolar families supported the findings on chromosome 9p13 (maximum LOD score of 3.02 at position 383 Mb immediately upstream of the centromere. This region harbors several interesting candidate genes, including contactin associated protein-like 3 (*CNTNAP3*) and aldehyde dehydrogenase 1 (*ALDH1B1*). For the 7q31 locus, only one extended pedigree and seven families originating from the same late settlement region of Finland provided evidence of linkage, suggesting that a gene predisposing to bipolar disorder is enriched in that region of Finland. The loci on the centromeric region of 9p13 and telomeric region of 7q31 may represent novel susceptibility loci for mood disorder in the Finnish population.

P06.117

Mapping of a locus for Geroderma Osteodysplasticum to chromosome 1q23-q25

F. Brancati^{1,2}, V. Fodale³, G. Zampino⁴, M. Tartaglia³, B. Dallapiccola^{1,5};

¹IRCCS CSS Mendel Institute, Rome, Italy, ²Ce.S.I. e Dipartimento di Scienze Biomediche, Fondazione G. d'Annunzio, Chieti, Italy, ³Dipartimento di Biologia Cellulare e Neuroscienze, Istituto Superiore di Sanità, Rome, Italy, ⁴Istituto di Clinica Pediatrica, Università Cattolica del Sacro Cuore, Rome, Italy, ⁵Dipartimento di Medicina Sperimentale, Università La Sapienza, Rome, Italy. Geroderma Osteodysplasticum (GO; OMIM#231070) is a rare autosomal recessive condition described so far in less than 30 patients whose molecular defect is still unknown. GO is characterized by pre-

mature aging, skin laxity and generalised osteoporosis with spontaneous fractures. Craniofacial dysmorphism include a prominent forehead, ptosis, large protruding ears, droopy cheeks, flat malar region and prognathism.

We ascertained a Libanese family in which 3 individuals presented with GO. The proband aged 1 ½ years is born from sixth-degree consanguineous parents, while in his 2 maternal uncles (born from a maternal uncle who married his second-degree cousin) the diagnosis was posed at 21 and 18 years, respectively. A genome-wide search was performed by genotyping the 3 affected individuals for microsatellite markers spaced around 10-15 cM from the ABI PRISM® Linkage Mapping Set seeking for adjacent homozygous markers. Among 6 positive regions, haplotype reconstruction and genotyping of other family members allowed the identification of a unique informative 47 centimorgan region of homozygosity, shared only by the 3 patients. We generated 9 novel microsatellite markers in order to refine this region and outlined a locus for GO spanning from 155.15 to 174.71 megabases on the long arm of chromosome 1 (max Lod score 3.2). Sequencing of candidate genes within the linked interval is still in progress.

P06.118

Large deletions in 9q22.21-9q22.33 region of Gorlin syndrome patients

V. Musani¹, P. Gorry², A. Basta-Juzbašić³, S. Levanat¹;

¹Rudjer Boskovic Institute, Zagreb, Croatia, ²Laboratoire de Génétique, Développement & Cancer, Université V. Ségalen, Bordeaux, France, ³Department of Dermatovenereology, University School of Medicine, University of Zagreb, Zagreb, Croatia.

Gorlin syndrome, also known as Nevoid Basal Cell Carcinoma Syndrome (NBCCS) or Basal Cell Nevus Syndrome (BCNS), is an autosomal dominant disorder that is characterized by various developmental abnormalities, like cysts of the skin, jaw cysts, bone malformations and different tumors like basal cell carcinomas (BCC) as most frequent, and also medulloblastomas, meningiomas, fibromas of the ovaries and heart. The prevalence is estimated at one per 57000. Phenotypical and genotypical diversity in Gorlin syndrome is referring to inactivating mutations in only one gene, PTCH, the human homologue of the *Drosophila* segment-polarity gene *patched*. PTCH is a tumor suppressor gene, located at 9q22.3, encoding a 12-pass transmembrane glycoprotein that acts as an antagonist in the Hedgehog signaling pathway. The 34 kb gene contains 23 exons and there are several hundred mutations, spanning the whole gene. Although there are some recurring mutations, there are no apparent hot spots. Nonsense, frameshift, in-frame deletions, splice site, and missense mutations all have been described in the Gorlin syndrome patients. In some cases large deletions in PTCH region have been reported. We developed semi-quantitative fluorescent multiplex PCR with polymorphic markers surrounding PTCH and analyzed the whole 9q22 region in 50 Gorlin syndrome cases from France and Croatia. In three cases we found large deletions from 4-7 megabases in length, giving some depth and additional indications for phenotype diversity of the Gorlin syndrome.

P06.119

Analysis of CTLA4 Gene Polymorphisms in spanish Graves' Patients

M. Piñeiro-Gallego¹, P. Álvarez-Vázquez², L. Constela³, R. García-Mayor², D. Valverde¹;

¹Departamento de Bioquímica, Genética e Inmunología., Vigo, Spain, ²Complejo Hospitalario Universitario de Vigo., Vigo, Spain, ³Complejo Hospitalario Universitario de Vigo, Vigo, Spain.

Graves' disease (GD) is a common organ-specific autoimmune disease that affects 0.5%-1% of Western population. It is a multifactorial disease that develops as the result of a complex interaction between genetic susceptibility genes and environmental factors. GD is characterized by diffuse goiter, ophthalmopathy, and anti-thyroid-stimulating hormone receptor antibodies.

Numerous studies have demonstrated the linkage to several polymorphism of the CTLA4 gene. The CTLA4 gene is placed on chromosome 2q33 and codifies the T cell receptor, which negatively modulates the immune response disabling the T cells. The aim of the present work was to determinate the contribution of C/T dimorphism in the promoter at position -318, the A/G dimorphism at position + 49 in exon 1, and the C/T60 dimorphism in the 3'UTR of the CTLA4 gene to the severity

and manifestations of GD.

A cohort of 98 patients, and 50 healthy controls were used to genotype these three SNPs by PCR-RFLPs.

Results from +49A/G showed significant differences for the genotypes between Graves' patients and controls. The frequency of GG is higher than in controls, a 6% of the controls were homozygous for the G allele, while for the patients group we found 22%. Furthermore, significant increase in the frequency of the G allele was found in Graves' patients compared with controls ($X^2=6.04$, $P=0.0140$)

No statistically significant association has been found with the -318 A/G and CT60 3'UTR polymorphism ($X^2=17.8$, $P=0.1815$; $X^2=0.79$, $P=0.3729$ respectively).

P06.120

5 base pair deletions in Rab27a gene as hot spot in exon 6 in Griscelli Syndrome (type II)

S. Shahkarami¹, Z. Pourpak², M. Houshmand³, A. Hamidieh², M. Moir²;

¹Immunology, Asthma and Allergy Institute (IAARI), Tehran, Islamic Republic of Iran, ²Immunology, Asthma and Allergy Institute (IAARI), Tehran, Islamic Republic of Iran, ³National Institute of Genetic Engineering and Biotechnology, and Medical Genetic Lab, Special Medical Center, Tehran, Iran, Tehran, Islamic Republic of Iran.

Griscelli syndrome (GS), an autosomal recessive disorder, is characterized by a silver-gray sheen of the hair and the presence of large clusters of pigment in the hair shaft. GS can be associated to neurological impairment (GS1), immunodeficiency (GS2), or be isolated (GS3).

GS2 is caused by a mutation in the small GTPase RAB27A gene. The aim of this study was to investigate mutations in RAB27A gene, in a 3 year-old boy who was referred to our center with immunodeficiency and silver gray sheen of the hair.

Material and method: Genomic DNA was extracted from peripheral blood cells by salting out method. Five coding exons were amplified by PCR-Sequencing methods and sequenced to detect probable mutations in RAB27A gene.

Result: A homozygote deletion was found in exon 6 of the RAB27A gene.

Discussion: This deletion leads to a frame shift mutation in exon 6 and a premature stop codon. Clinical manifestations and immunodeficiency help physician to suspect diagnosis of GS II. As molecular analysis has provided an exact way to investigate mutations in immunodeficient patients like GS, it can be considered as a very useful method for definite diagnosis.

Because of an amino acid deletion and frame shift in this exon, we conclude that this new deletion is pathogen. Other deletions were found and reported in the same exon as causative mutation. We believe that this region may be a hot spot for GS II and suggest that the first analysis for other patients must be done in this region.

Association study of the glycogen synthase kinase-3 beta (GSK3beta) gene with Mood Disorders

M. Gratacòs¹, V. Soria², E. Saus¹, F. Vivarelli¹, J. R. González², J. Valero⁴, É. Martínez-Amorós², M. Bayés¹, A. Gutiérrez-Zotes⁴, J. M. Crespo^{2,5}, L. Martorell⁴, E. Vilella⁴, A. Labad⁴, J. M. Menchón^{2,5}, J. Vallejo^{2,5}, X. Estivill^{1,6}, M. Urretavizcaya^{2,5};

¹CIBERESP (CIBER en Epidemiología y Salud Pública), Genes and Disease Program and CeGen Barcelona Genotyping Node, Center for Genomic Regulation, Barcelona, Catalonia, Spain, ²Mood Disorders Clinical and Research Unit, CIBER-SAM, Psychiatry Department, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, Catalonia, Spain, ³CREAL, Center for Research in Environmental Epidemiology, Barcelona, Catalonia, Spain, ⁴Grup d'Investigació en Psiquiatria. Hospital Universitari Institut Pere Mata, Rovira i Virgili University, Reus, Tarragona, Catalonia, Spain, ⁵Department of Clinical Sciences, Bellvitge Campus, Barcelona University, Barcelona, Catalonia, Spain, ⁶Experimental and Health Sciences Department, Pompeu Fabra University, Barcelona, Catalonia, Spain.

Glycogen synthase kinase-3beta (GSK3beta) is a key component of the Wnt signaling pathway and is known to regulate such critical cellular functions as structure, gene expression, mobility and apoptosis. Recent findings support that GSK3beta may play a role in the pathophysiology and treatment of Mood Disorders (MD). We hypothesize that genetic variants, including SNPs and CNVs (Copy Number Vari-

tions) in the GSK3beta gene could partially underlie the susceptibility to mood disorders, just as much to unipolar major depression as to bipolar disorder. We performed a genetic case-control study including 440 screened control subjects and 445 patients with MD (257 Unipolar Major Depressive Disorder, 188 Bipolar Disorder). First, we selected a set of 11 TagSNPs polymorphisms representative of the patterns of common variation identified in European population in the genomic region containing the GSK3beta gene and genotyped them using SNPlex Genotyping System. Moreover, we are replicating the experiment of Lachman et al. in our Spanish sample of MD patients. They found a statistical significant increased number of gains in a CNV partially overlapping GSK3beta in bipolar patients compared with control individuals. All the results were analyzed using SNPAssoc package, from R software. Regarding TagSNPs analyses, nominal associations were found once stratified by polarity, even though they did not remain significant after correction for multiple comparisons. Overall, although genetic variants in GSK3beta gene might be a contributing factor to the development of mood disorders, further studies in larger samples are needed to obtain more conclusive results.

P06.122

Study of an association of deletion/insertion polymorphisms of *GSTM1* and *GSTT1* genes with a risk of development of endometriosis

E. Kamenev¹, O. A. Schagina¹, L. F. Kurilo¹, L. M. Michaleva², A. V. Polyakov¹;

¹Research Centre for Medical Genetics, Moscow, Russian Federation, ²Institution of Human Morphology RAMN, Moscow, Russian Federation.

Endometriosis is a common disease defined as a growth of endometrial tissue outside the uterine cavity that often results a vast array of gynaecological problems including dysmenorrhoea, pelvic pain, infertility. Endometriosis is regarded as one of the multifactorial diseases caused by an interaction between the environment and multiple genes.

Glutathione-S-transferases (GSTs) are enzymes involved in the phase II detoxification process of xenobiotics including carcinogens and mutagens. Gene polymorphisms of members of the GSTs family might impair detoxification function and increase the risk of the disorder. The present study was carried out to investigate if deletion/insertion polymorphisms of *GSTM1*, *GSTT1* and there combination are useful markers for predicting endometriosis susceptibility.

DNA was extracted from blood of 40 patients with reliable diagnosis of endometriosis and 50 healthy women (control group). DNA samples were amplified by polymerase chain reaction and detected by electrophoresis. The relative frequencies of the *GSTM1* wild/null and the *GSTT1* wild/null genotypes between both groups were compared.

The proportion of individuals with *GSTM1* null mutation was 45% in the endometriosis group and 30% in the control group ($P > 0.05$), the proportions of *GSTT1* wild/null alleles in both groups were 22.5%/18% accordingly ($P > 0.05$). The proportions of *GSTM1*(null/null) + *GSTT1*(null/null) genotype were 12.5%/2% ($P > 0.05$). The distribution of the polymorphisms and there combination was not significantly different between the two groups. These results suggest that the *GSTM1* and the *GSTT1* null mutations aren't associated with a risk of the development of endometriosis in Russian women.

P06.123

Risk Factors of Inhibitors Development in Haemophilia Patients

M. Mihailov, M. Serban, D. Savescu, S. Arghirescu, C. Petrescu, M. Puiu; University of Medicine and Pharmacy "Victor Babes" Timisoara, Romania, Timisoara, Romania.

Introduction. FVIII inhibitors appearance in haemophiliacs is related to several factors, like substitution with native plasma products, frequent changing of FVIII concentrates, high rate of HBV and HCV infection, pseudotumours and other massive muscular haematomas, etc.

Objective. Starting from particularities of haemophilia treatment in our country, we evaluated the variables impact on inhibitors development. We assessed frequency and inhibitors titer, in correlation with risk factors.

Material and method: retrospective single center study based on 219 haemophilia patients registered and treated in the IIIrd Pediatric Clinic Timisoara, using Bethesda assay. We evaluated the influence of some parameters on frequency and inhibitors titer: haemophilia severity, gene mutations, family history, type of substitutive product used, hepatitis C or B infection, Interferon alpha therapy, surgical interventions,

and bolus vs. intravenous infusion of FVIII.

Results. Between January 1997- 2002, inhibitors frequency was 47.5%, whereas after January 2002 only 19.19% of patients had inhibitors due to reactants and methodology change. The majority of inhibitors were in severe haemophilia (78.95%), 15 of these patients being positive for intron 22 inversion.

Family history and exposure to FVIII were important risk factors of inhibitors development. Hepatitis C or B infection, Interferon alpha therapy, surgical interventions and intravenous infusion of FVIII haven't been significantly correlated with inhibitors' development.

Conclusions. In our patients, we found only the following risk factors for inhibitors development: exposure to FVIII, type of FVIII gene mutations and familial predisposition. Accuracy of technique and experience of laboratory technician is decisive for inhibitor evaluation.

P06.124

Association of the IL4R single-nucleotide polymorphism S411L with Hand Osteoarthritis

M. Vargiolu¹, T. Silvestri², E. Bonora¹, P. Dolzan², L. Punzi³, A. Fioravanti⁴, G. Romeo¹, R. Meliconi^{2,5};

¹U.O. Genetica Medica, Policlinico S. Orsola-Malpighi via Massarenti, Bologna, Italy, ²Laboratorio di Immunologia e Genetica, Istituti Ortopedici Rizzoli, Bologna, Italy, ³Rheumatology Unit, University of Padova, Italy, Padova, Italy, ⁴Rheumatology Unit, Policlinico "Le Scotte", Siena, Italy, ⁵Rheumatology Unit, Istituti Ortopedici Rizzoli, Bologna, Italy.

Primary osteoarthritis (OA) is a common late-onset arthritis that demonstrates a complex mode of transmittance with both joint-site and gender-specific heterogeneity. In OA anti-inflammatory and anabolic cytokines which are usually responsible for the control of cartilage homeostasis are altered or inadequate. Hitherto, functional study had been mainly focused on the IL13/IL-4/IL-4R system which has a strong chondroprotective role and it is reasonable to speculate that polymorphism within these genes may be risk factors for OA. We therefore investigated polymorphisms in these genes as potential OA susceptibility loci by genotyping fifteen SNPs using TaqMan® Technology in 413 patients (26 male, 387 female) with hand OA and 326 healthy controls (14 male, 312 female). Although the majority of these SNPs had already shown an association with OA in previous studies, in our case-control study only one SNP (dbSNP rs1805013) was associated with P -values of 0.0125. This association was attributable to an increased frequency in the probands of the minor T allele regardless of gender and disease severity. This SNP results in the substitution of a serine with a leucine in the codon 411 of IL4R and consequently of an aliphatic hydrophobic residue for a polar hydrophilic one, a change that could have effects on protein function. Further functional studies for the S411L substitutions will clarify the role of this SNP on osteoarthritis predisposition.

TMC1 but Not TMC2 Is Responsible for Autosomal Recessive Nonsyndromic Hearing Impairment in Tunisian Families

A. Tlili^{1,2}, I. Ben Rebeh², M. Aifa-Hman², J. Tlili-Chouchène¹, H. Dhoub³, J. Moalla³, M. Ben Said⁴, I. Lahmar⁴, Z. Benzina⁵, I. Charfedine³, N. Driss⁴, A. Ghorbel⁵, H. Ayad², S. Masmoudi²;

¹Laboratoire de Génétique Moléculaire Humaine, Sfax, Tunisia, ²Unité Cibles pour le Diagnostic et la Thérapie, Centre de Biotechnologie de Sfax, Sfax, Tunisia, ³Service d'O.R.L., C.H.U.H. Bourguiba de Sfax, Sfax, Tunisia, ⁴Service d'O.R.L., C.H.U. de Mahdia, Mahdia, Tunisia, ⁵Service d'Ophtalmologie, C.H.U. H. Bourguiba de Sfax, Sfax, Tunisia.

Hereditary nonsyndromic hearing impairment (HI) is extremely heterogeneous. Mutations of the transmembrane channel-like gene 1 (*TMC1*) have been shown to cause autosomal dominant and recessive forms of nonsyndromic HI linked to the loci *DFNA36* and *DFNB7/B11*, respectively. *TMC1* is 1 member of a family of 8 genes encoding transmembrane proteins. In the mouse, *MmTmc1* and *MmTmc2* are both members of *Tmc* subfamily A and are highly and almost exclusively expressed in the cochlea. The restricted expression of *Tmc2* in the cochlea and its close phylogenetic relationship to *Tmc1* makes it a candidate gene for nonsyndromic HI. We analyzed 3 microsatellite markers linked to the *TMC1* and *TMC2* genes in 85 Tunisian families with autosomal recessive nonsyndromic HI and without mutations in the protein-coding region of the *GJB2* gene. Autozygosity by descent analysis of 2 markers bordering the *TMC2* gene allowed us to rule

out its association with deafness within these families. However, 5 families were found to segregate deafness with 3 different alleles of marker D9S1837, located within the first intron of the *TMC1* gene. By DNA sequencing of coding exons of *TMC1* in affected individuals, we identified 3 homozygous mutations, c.100C→T (p.R34X), c.1165C→T (p.R389X) and the novel mutation c.1764G→A (p.W588X). We additionally tested 60 unrelated deaf Tunisian individuals for the c.100C→T mutation. We detected this mutation in a homozygous state in 2 cases. This study confirms that mutations in the *TMC1* gene may be a common cause for autosomal recessive nonsyndromic HI.

P06.126

Genome wide association analysis in human height of European-originated monozygotic female twins

J. A. Kettunen^{1,2}, I. Lindqvist³, S. Ripatti^{2,3}, T. D. Spector⁴, N. G. Martin⁵, L. Peltonen^{1,2}, M. Perola²;

¹Wellcome Trust Sanger Institute, Cambridge, United Kingdom, ²National Public Health Institute, Helsinki, Finland, ³Karolinska Institutet, Stockholm, Sweden, ⁴Twin Research and Genetic Epidemiology Unit, King's College, London, United Kingdom, ⁵Genetic Epidemiology Laboratory, Queensland Institute of Medical Research, Brisbane, Austria.

Stature (i.e. adult height) is a quantitative trait with high heritability. Various interesting regions in the human genome have been linked to adult stature but only few have been confirmed by later studies. Two genome wide association (GWA) studies have been published recently and they identified two loci (HMGA2 and GDF5-UQCC) to be strongly associated to stature after extensive replication studies. In this study we report a genome wide association analysis performed on 1631 European monozygotic female twin pairs from the GenomEUtwin consortium. One of each pair was genotyped with the Illumina Human-Hap300-duo chip. Whole genome association analysis was performed with the PLINK-program. Area of residence and age were used as covariates in all of the analyses. Our study had two goals: We wanted to reduce the environmental variance by using the mean of each pair as a phenotype. We observed an association ($p = 3.14 \times 10^{-6}$) on 8q24 locus underlying the linkage peak identified previously in our linkage scan on European dizygotic twins (LOD 3.28). The replication study is underway for the most significant findings in this GWA scan. Second, we analyzed whether we could pinpoint any regions in genome which would be associated to the difference within each pair. This approach was aiming to find genes responsible for increasing variance in human height, thus potentially indicating for example GxE interaction or imprinting/gene silencing. The most significant finding for variance in stature ($p = 1.22 \times 10^{-5}$) was identified on 6q14 region.

P06.127

Hepcidin gene in adult HFE-negative hemochromatosis

E. Marasco¹, V. Mantovani^{1,2}, P. Garagnani^{1,3}, D. Bastia¹, M. Cencè¹, G. Gerboni², D. Luiselli², G. Romeo²;

¹CRBA, University Hospital, Bologna, Italy, ²Medical Genetics Unit, University Hospital, Bologna, Italy, ³Dept. of Biology, Anthropology Unit, Bologna University, Bologna, Italy.

Hereditary Hemochromatosis (HH) is a disorder of iron homeostasis, characterized by increased iron absorption and tissue iron deposition, frequently related to HFE gene mutations. Hepcidin peptide (HAMP) down-regulates iron absorption; decreased HAMP expression is common in many HH forms and HAMP gene mutations are associated with juvenile HH.

Aim of this study was to investigate HAMP gene in 93 HH adult patients, negative for the most common HFE gene mutations, presenting >70% transferrin saturation.

Three exons and a promoter region of the gene were screened using DHPLC and sequencing. An additional upstream putative regulating region was also investigated.

The analysis did not show any classical mutations, but many previously undescribed variants were detected: 2 synonymous (L14L and T84T found in two patients), 5 variants in promoter and 5'UTR region, and one in the third intron. Interspecies comparison of HAMP sequences showed that 14 and 84 codons are highly conserved. The analysis of mRNA secondary structure, performed by MFOLD software, showed that the synonymous mutations here detected considerably modified the structure, particularly the 5' and 3'UTR regions. The novel promoter variant g.232C>T was found in 17% among patients and in 24%

among healthy controls ($p > 0.05$). The other promoter variants resulted sporadic in HH and absent in controls.

In conclusion, gene mutations causing defective HAMP peptide are not detected in our adult HFE-negative patients. However, HAMP variants might contribute to iron overload susceptibility, in addition to other genetic and/or environmental factors. Functional studies will be necessary to test this hypothesis.

P06.128

CSCE-based mutation analysis of NIPA1 gene revealed no mutations in Italian patients with autosomal dominant hereditary spastic paraplegia

A. Borreca^{1,2}, C. Patrono^{1,3}, C. Babalini¹, P. Montieri^{1,2}, M. L. Varlese^{1,2}, V. Moschella², G. Bernardi^{1,2}, T. Kawarai⁴, A. Orlandi^{1,2};

¹Laboratorio di Neurogenetica, CERC- IRCCS Santa Lucia, Rome, Italy, ²Dipartimento di Neuroscienze, Università degli Studi di Roma "Tor Vergata", Rome, Italy, ³Dipartimento di Medicina Sperimentale e Scienze Biomediche, Università degli Studi di Perugia, Perugia, Italy, ⁴Department of Neurology, Hyogo Brain and Heart Center, Himeji City, Japan.

We set up a new method based on Conformation Sensitive Capillary Electrophoresis (CSCE) to screen a cohort of 62 Italian families with autosomal dominant hereditary spastic paraplegia (ADHSP) for mutations in *NIPA1* gene (*SPG6*). Proband of all families were previously excluded for known mutations in the *SPG4* gene, *SPG3A*, *SPG13* and *SPG31* genes. CSCE adapts the technique of heteroduplex analysis on automated capillary array electrophoresis using the Applied Biosystems 3130 Genetic Analyzer. A previously published *SPG6* mutation in a Japanese ADHSP patient (Kaneko et al., 2006) was used as a positive control in the optimization of the analysis protocol. We analyzed the five coding exons and flanking intronic sequences of *NIPA1* gene and we didn't find any mutation in our cohort of patients. Up to now, only four different nucleotide changes have been reported in the *NIPA1* gene in populations from different geographic areas, two of them leading to the same aminoacidic change (G106R). Our negative result shows that *SPG6*-linked form is a rare cause of ADHSP in the Italian people, in confirmation of another study performed on European ADHSP families (Klebe et al., 2007). In this study, we provide a rapid, sensitive and effective protocol of automated mutation detection, also applicable to large genes and to high-throughput screening.

P06.129

HIF1A gene polymorphism is associated with power performance in athletes

A. M. Hakimullina, I. I. Ahmetov, V. A. Rogozkin;

St Petersburg Research Institute of Physical Culture, St Petersburg, Russian Federation.

Glycolysis is the central source of anaerobic energy in humans, and this metabolic pathway is regulated under low-oxygen conditions by the transcription factor hypoxia-inducible factor 1a (HIF-1a). HIF-1a controls a number of genes that are implicated in various cellular functions including cell proliferation (erythropoietin), glucose metabolism (glucose transporters and glycolytic enzymes), cell survival, and angiogenesis (vascular endothelial growth factor and VEGF receptors). A missense polymorphism, Pro582Ser, is present in exon 12 (C/T at bp 85). The rare T-allele is predicted to result in a proline to serine change in the amino acid sequence of the protein. This substitution increases protein stability and transcriptional activity, and therefore, improves glucose metabolism and angiogenesis. In this study, we investigated whether genetic variation at the locus encoding HIF1A is associated with elite athlete status in weightlifters, for which glycolysis is crucial for power performance. The study involved 53 Russian athletes (17 sub-elite, 32 elite and 4 highly elite) and 920 controls. HIF1A gene Pro582Ser polymorphism was determined by PCR-RLFP. The frequency of the rare Ser allele was significantly higher in weightlifters than in controls (17.9% vs. 8.5%; $P = 0.001$). Moreover, the frequency of Ser allele increased with growing skill level of athletes (sub-elite (14.7%) - elite (18.8%) - highly elite (25.0%)). Thus, HIF1A gene Pro582Ser polymorphism is associated with elite power athlete status, which suggests an important role for HIF-1a in skeletal muscle adaptation to power training.

P06.130**Association of the *RET* proto-oncogene to Intestinal Neuronal Dysplasia type B**

R. M. Fernandez^{1,2}, M. Ruiz-Ferrer^{1,2}, A. Sánchez-Mejías^{1,2}, M. López-Alonso^{1,2}, G. Antiñolo^{1,2}, S. Borrego^{1,2};

¹Unidad de Gestión Clínica de Genética, Reproducción y Medicina Fetal, Hospitales Universitarios Virgen del Rocío, Seville, Spain, ²Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), ISCIII, Seville, Spain. Hirschsprung disease (HSCR) is defined by the absence of intramural ganglia of Meissner and Auerbach along variable lengths of the gastrointestinal tract. Intestinal neuronal dysplasia type B (INDB) is characterized by the malformation of the parasympathetic submucous plexus of the gut. It seems to exist a connection between these two enteric nervous system abnormalities, supported by the fact that HSCR often includes a region of INDB-like character proximal to the aganglionic segment. Because of the major role played by the *RET* proto-oncogene in HSCR, we sought to determine if this gene was also related to INDB, by both a mutational screening in a series of patients, and the evaluation of its polymorphisms/haplotypes as susceptibility factors for this disease. We have used dHPLC techniques to screen the *RET* coding region in 23 patients presenting with INDB, and 30 patients with a combined HSCR+INDB phenotype. In addition, a total of 11 *RET* SNPs were strategically selected and genotyped by using Taqman technology. Distribution of such SNPs, as well as of the haplotypes generated by their combinations, was compared among the different groups of patients (INDB, HSCR+INDB, HSCR) and controls. As a result we have demonstrated the involvement of *RET* in the pathogenesis of intestinal neuronal dysplasia B, although by different molecular mechanisms to those leading to Hirschsprung disease. Further investigation is warranted in order to elucidate those precise mechanisms and to clarify therefore the genetic nature of INDB.

P06.131**First Dutch founder mutation in Hereditary Spastic Paraplegia**

W. A. G. van Zelst-Stams^{1,2}, S. G. M. Frints^{1,2}, M. Gerards^{1,2}, E. L. C. Jongen^{1,2}, R. G. Janssen¹, C. E. M. de Die-Smulders^{1,2}, C. T. R. M. Schrande-Stumpel^{1,2}, H. J. Smeets^{1,2};

¹department of clinical genetics, university hospital Maastricht, Maastricht, The Netherlands, ²The Netherlands Research Institute GROW, Maastricht University, Maastricht, The Netherlands.

Hereditary spastic paraplegia (HSP) is characterized by clinical and molecular heterogeneity. In autosomal dominant (AD) spastic paraplegia (SPG), *SPASTIN* (SPG4) and *ATLASTIN* (SPG3A) gene defects account for approximately 40% and 10%, respectively.

We performed parametric linkage analysis, using the Affymetrix 10K SNP array, to identify the SPG locus in a ten-generation Dutch pedigree. A maximum LOD score of 5.03 was obtained at the SPG31 locus (2p11-p12). Mutation analysis of the receptor expression-enhancing protein 1 gene (*REEP1*) was performed in 10 additional AD SPG families from the South-East part of the Netherlands. A truncating four basepair deletion in exon six (c.537_540delCGGC p.Ser179ArgfsX43) was identified which co-segregated with the disorder in the large linked family and in two other small unrelated families, suggesting a founder effect in our region. A founder effect was confirmed by haplotype analysis using polymorphic markers surrounding *REEP1*. The clinical features within these families ranged from normal to severe spasticity of legs and the age of onset varied from birth till >75 years of age. There was an inverse correlation between age at onset and severity and progression of symptoms. Further functional studies are needed to identify a major modifier in *REEP1* affected families.

In conclusion, we identified a founder *REEP1* mutation in 27% (3/11) of the AD pure SPG families investigated in the South-East part of the Netherlands. Thus *REEP1* gene defects in HSP seem at least as common as *ATLASTIN* (SPG3A).

P06.132**Quantitative trait locus mapping in complex human pedigrees with interpopulation origin**

G. R. Svischeva;

Institute of Cytology and Genetics, Novosibirsk, Russian Federation.

We perfected the variance-components method for quantitative trait locus (QTL) analysis of complex human pedigrees descended from interpopulation crosses between outbred parental lines with different

QTL allele frequencies in each population. Furthermore, dominance and inbreeding are allowed for. The updated method is based on the decomposition of trait variance into components with the consideration of the genetic effect conditioned by interpopulation origin and inbreeding of individuals. To estimate model parameters, namely additive and dominant effects, and the allelic frequencies of the QTL analysed, and also to define the QTL positions on a chromosome with respect to genotyped markers, we used the maximum-likelihood method. To detect linkage between the QTL and the markers we propose statistics with a noncentral chi-square distribution that provides the possibility to deduce analytical expressions for the power of the method and therefore, to estimate the pedigree's size required for 80% power. The method works for arbitrarily structured pedigrees and uses the phenotypic values and the marker information for each individual of the pedigree under observation as initial data and can be valuable for fine mapping purposes. The power of the method is increased if the QTL effects conditioned by interpopulation origin and inbreeding are enhanced.

P06.133**Clinical and genetic investigation of three kindreds with familial hyperparathyroidism**

G. Masi, L. Barzon, M. Iacobone, A. Porzionato, V. Macchi, G. Palù; University of Padova, Padova, Italy.

We investigated three Italian kindreds referred to our Surgery Unit for familial hyperparathyroidism. One kindred was diagnosed as affected by hyperparathyroidism-jaw tumor syndrome (HPT-JT), due to the occurrence of a maxillary ossifying fibroma, the other two kindreds were defined as familial isolated hyperparathyroidism (FIHP) because of the occurrence of hyperparathyroidism without other syndromic manifestations. Clinical investigation demonstrated that all kindreds shared other clinical features besides hyperparathyroidism, i.e., high frequency of uterine polyposis and thyroid neoplasms. Since germline *HRPT2* mutations are detected in HPT-JT kindreds, but also in 7% of FIHP kindreds, we tested patients for *HRPT2* mutations and performed immunohistochemical analysis of parafibromin, encoded by *HRPT2*, in all available tumor tissues. Germline *HRPT2* inactivating mutations were identified in the HPT-JT kindred and in both FIHP kindreds. A *HRPT2* somatic mutation was also demonstrated in a parathyroid adenoma from a FIHP patient, in agreement with *HRPT2* tumor-suppressor role. Moreover, loss of nuclear parafibromin expression was demonstrated in all parathyroid tumors, at variance with findings in biopsies from normal parathyroid glands. In addition, immunohistochemistry performed on a HPT-JT-related uterine polyp did not show any nuclear anti-parafibromin reactivity, as compared with five sporadic polyps in which almost all stromal cells exhibited nuclear parafibromin immunostaining. Overall, our results indicate that FIHP and HPT-JT associated with *HRPT2* mutations do not have a distinct genetic signature, but may represent variants of the same genetic disease. Loss of parafibromin expression in polyps supports the pathogenetic role for parafibromin in uterine polyposis associated with this syndrome.

P06.134**Investigation the role of -344C>T polymorphism in CYP11B2 gene among Bulgarian hypertensive patients**

R. Saraeva¹, J. Matrozova², R. Bogeska¹, I. Kremensky¹, S. Zacharieva², R. Kaneva¹;

¹Molecular Medicine Center, Medical University of Sofia, Sofia, Bulgaria, ²University Hospital of Endocrinology "Akad. Ivan Pentchev", Sofia, Bulgaria.

Background: The renin-angiotensin-aldosterone system is often investigated in relation to the pathogenesis of essential hypertension. The mineralocorticoid hormone aldosterone plays an important role in blood pressure homeostasis. A key factor for its synthesis is the enzyme aldosterone synthase, encoded by CYP11B2 gene. The -344C>T polymorphism in the 5' regulatory region of the CYP11B2, which disrupts a putative binding site for the steroidogenic factor 1, was reported to be associated with aldosterone excess and hypertension.

Objective: Our aim was to investigate the role of functional -344C>T polymorphism in the promoter region of CYP11B2 gene in the manifestation of hypertension, using case-control study design.

Methods: We included 185 Bulgarian hypertensive patients and normotensive control group. The -344C>T polymorphism was genotyped by RCR-RFLP method using HaeIII restrictase.

Results: The genotype and allele frequencies for -344C>T variant in

our normotensive control group were similar to these detected in other Caucasian populations. The genotype distribution of this polymorphism did not show statistically significant differences between the two explored groups ($p=0.822$). The comparison of the groups, divided by gender, also did not demonstrate significant differences in the genotype and allele distribution ($p>0.05$).

Conclusion: Our study does not support the involvement of the -344C>T polymorphism of CYP11B2 gene in the susceptibility to hypertension in Bulgarian patients. Due the small sample size, however, further studies in larger groups are warranted.

P06.135

Increased frequency of the IVS4+39C>T allele of PGHD-15 gene in group of patients with severe course of IBD

A. Nelke-Lozynska¹, M. Podralska², T. Banasiewicz¹, R. Slomski², W. Meisner¹, E. Czkwanianc³, I. Kubinska³, P. Krokowicz¹, A. Plawski²;

¹Karol Marcinkowski University of Medical Sciences, Poznan, Poland, ²Institute of Human Genetics, Poznan, Poland, ³Department of Pediatrics and Gastroenterology, Institute of Polish Mother's Memorial Hospital, Lodz, Poland.

Inflammatory bowel diseases (IBD) are autoimmune disorders (MIM #266600) with genetic background, characterized by chronic inflammation of the wall of gastrointestinal tract. IBD include two clinical entities: Crohn's disease and ulcerative colitis (MIM#191390). The incidence of these diseases in Western population ranges from 100 to 300 per 100 000. The symptoms of Crohn's disease may arise in any part of gastrointestinal tract, however most often the distal portion of the ileum and caecum is affected. Inflammatory process penetrates through the whole thickness of the bowel wall and skip lesions are typical. Continuous inflammatory lesions confined only to colonic and rectal mucosa are characteristic for ulcerative colitis. Fistulas are absent and the inflammation never adopts the granulomatous form.

In our research we examined the frequency of alleles in the NOD2 gene and 15-hydroxyprostaglandin dehydrogenase gene (PGDH-15) in 58 patients with severe postoperative relapses of inflammatory bowel diseases, 27 children with inflammatory bowel diseases and in control group (100 persons). The average age of onset was 31 years in the group of patients with severe disease course and 11 in the group of children. We observed the elevated frequency of the alleles 3019-3020insC and 802C>T of the NOD2 gene in comparison to the control group. The allele IVS4+39C>T of the PGDH-15 gene in the group of ill with the heavy course occurred two times more frequent than in the control group and three times more frequent in comparison with the group of affected children.

Bronchiectasis is a chronic infective and inflammatory disease characterized by dilatation of bronchi and sputum production. Although the pathogenesis of bronchiectasis is not fully understood, destruction of the bronchial wall that contributes to the development of airway dilatation may result from excessive extracellular matrix degradation. Matrix metalloproteinases (MMPs) are a family of proteolytic enzymes, which play an essential role in tissue remodeling and repair. Genetic variants of genes involved in extracellular matrix remodeling may drive the pathological processes that could lead to the development of bronchiectasis. The aim of this study was to analyse MMP1 G-1607GG and MMP9 C-1562T promoter polymorphisms in development of idiopathic bronchiectasis.

The genotypes of 37 patients with idiopathic bronchiectasis and 102 controls were determined by conformation sensitive gel electrophoresis for MMP1 G-1607GG gene variant and PCR-RFLP for MMP9 C-1562T polymorphism.

The distribution of -1607GG allele was significantly higher in patient group ($p=0.014$). Heterozygote carriers of -1607GG allele had a 5.3-

fold increased risk for bronchiectasis development (62.2% vs. 50%, $p=0.013$). The OR was even greater (8.7) for homozygous -1607GG genotype (29.7% vs. 18.6%, $p=0.006$) compared with homozygotes for 1G allele.

The MMP9 C-1562T allelic and genotype frequencies did not show significant differences between the groups.

According to our results MMP1 -1607GG variant might be involved in pathogenesis of idiopathic bronchiectasis. This polymorphism is associated with higher gene expression and may influence lung parenchyma damage and subsequent bronchial wall destruction and development of airway dilatation.

Novel differentiating genetic markers for CD and UC

Y. A. Nasykhova¹, N. V. Semenov², A. G. Kharitonov², T. E. Ivashchenko¹;

¹Ott's Institute of Obstetrics & Gynecology, St-Petersburg, Russian Federation,

²Medical Academy of Postgraduate Study, St-Petersburg, Russian Federation.

CD and UC belong to the inflammatory bowel diseases (IBD) with heterogeneous clinical manifestations, genetic factors and response to treatment. That provides increased interest for detection of differentiating factors valuable for precise early diagnostics of these diseases.

Five polymorphic variants of two genes (*Gly908Arg*, *Arg702Trp*, *Leu1007fs* of *NOD2/CARD15* gene and *-308G/A*, *-238G/A* of *TNFA* gene) were studied in CD patients ($n=102$), in UC patients ($n=71$) and also in control group ($n=100$). The frequency of *-308A* allele of the *TNFA* gene was increased in both groups of patients with CD and UC as compared to controls (15%, 11% and 4%, respectively). We have found an extremely significant difference for *Leu1007fs*, mutation of *NOD2/CARD15* gene which results in truncated protein. This mutation was revealed in 15% of patients with CD and only in 2% of patients with UC ($p=0.0055$). In control group the frequency of this mutation was 3%. The frequencies of carriers of two others genetic variants (*Gly908Arg*, *Arg702Trp*) were lower in UC patients (4% and 1%) as compared to these ones in CD patients (8% and 6%) but it was not significant.

Thus that mutation *Leu1007fs* of gene *NOD2/CARD15* plays a crucial role in pathogenesis of Crohn's disease and might be treated as a differentiation marker between patients with CD and UC. Consequently that may improve diagnostics of these diseases and provide appropriate treatment.

P06.138

Associations of CARD15, DLG5, OCTN1, TLR4, IL1, IL10 and TNFα genes variants with Inflammatory Bowel Disease

O. A. Schagina¹, P. V. Shumilov², A. A. Polyakov¹;

¹Research Centre for Medical Genetics, Moscow, Russian Federation, ²Russian Government Medical University, Moscow, Russian Federation.

Inflammatory bowel disease (IBD) is a multifactorial polygenic disease with probable genetic heterogeneity. It is characterized by chronic inflammation of the gastrointestinal tract.

64 unrelated patients from 6 to 14 years old with IBD and 52 controls children were investigated. The aim of our research was searching association between IBD and nine polymorphous variants of seven genes. The analysis for *CARD15* R702W, G908R, *Leu1007fs*, *DLG5* R30Q, *OCTN1* L530F, *TLR4* D2999G, *IL10* c.-1082 g>a, *TNFA* c.-308 g>a variants, and *IL1* VNTR polymorphism was performed by means of MLPA and AFLP analysis.

Results of genotyping are presenting in the table.

Thus it is not revealed associations between carriage of the variant alleles these genes and Inflammatory Bowel Disease at Russian children.

Allele frequencies of the minor alleles (%)

gene	CARD15	CARD15	CARD15	DLG5	OCTN1	TLR4	IL1	IL10	TNFA

CARD15, TNF-alpha, IL23R and ATG16L1 genes polymorphisms in Lithuanian patients with inflammatory bowel disease

J. Sventoraityte¹, A. Zvirbliene¹, R. Kwiatkowski², G. Kiudelis¹, L. Kupcinskas¹, S. Schreiber²;

¹Department of Gastroenterology, Kaunas University of Medicine, Kaunas, Lithuania, ²Institute of Clinical Molecular Biology, Christian – Albrechts – University, Kiel, Germany.

Background. Numerous genome-wide and linkage studies have identified and replicated significant association between inflammatory bowel disease (IBD) development and polymorphisms of genes attributed to recognition of bacterial products (CARD15), innate immune responses (TNF-alpha, IL23R), and autophagosome pathway (ATG16L1). Despite large number of studies accumulated in this field, there is only limited data on IBD genetic characteristics in East and Central Europe region.

Aim and Methods. This research aimed to analyze the frequency of the three CARD15 polymorphisms Arg702Trp (rs2066844), Gly908Arg (rs2066845) and Leu1007finsC (rs2066847); two TNF-alpha promoter polymorphisms -857C>T (rs1799724) and -308G>A (rs1800629); IL23R polymorphism Arg381Gln (rs11209026); and ATG16L1 polymorphism Thr300Ala (rs2241880) and their contribution to the development of IBD in a cohort of unrelated Crohn's disease (CD) (n=57), ulcerative colitis (UC) (n=123) patients and healthy controls (n=182) from the Lithuanian population.

Results. Carriage of CARD15 variants was more common in the CD patients than in controls and UC patients (40.4% CD versus 17.6% controls and 16.3% UC, p<0.0001). The single marker analysis of the CARD15 mutations revealed a strong association between Leu1007finsC rare variant and CD (p=3.687x10⁻⁸; OR=5.54, 95% CI: 2.85-10.75). No genetic association was detected between other two CARD15 variants (Arg702Trp and Gly908Arg), TNF-alpha promoter, IL23R and ATG16L1 polymorphisms and IBD in Lithuanian population.

Conclusion. Our study has revealed a strong association only between CARD15 gene variant Leu1007finsC and CD susceptibility in the Lithuanian population.

Understanding the role of IRAK-M in allergic asthma: replication in European children and functional analyses

S. Naitza¹, F. Anedda¹, N. Olla¹, G. Sole¹, L. Balaci¹, M. Zuncheddu¹, C. Caria¹, S. Sanna¹, M. Spada¹, E. Meloni², M. Wickman², G. Pershagen², A. Scheynius³, C. Söderhäll⁴, M. D'Amato⁴, J. Kere⁴, A. Cao¹, M. Uda¹;

¹Istituto di Neurogenetica e Neurofarmacologia (INN)-Consiglio Nazionale delle Ricerche (CNR), Monserrato (CA), Italy, ²Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, ³Clinical Allergy Research Unit, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden, ⁴Department of Biosciences and Nutrition, Karolinska Institutet, Stockholm, Sweden.

Asthma is a multifactorial disease influenced by genetic and environmental factors. Interest in finding etiologic factors has recently intensified, because of its increasing prevalence and associated mortality. Analysing a cohort of allergic asthmatics in the Sardinian founder population, where limited genetic and environmental heterogeneity facilitates the study of multifactorial traits, we recently identified IRAK-M as a new asthma susceptibility gene and replicated the association in a genetically distant Italian population. IRAK-M, a negative regulator of the TLR/IL-1R pathways and a master regulator of NF-κB and inflammation, is associated with early-onset persistent asthma and highly expressed in lung epithelia. Thus, our data suggest a link between hyperactivation of the innate immune system and chronic airway inflammation, indicating IRAK-M as a new target for therapeutic intervention against asthma.

To better understand the role of IRAK-M in the pathogenesis of asthma, we are carrying out a replication study in two European cohorts (the PARSIFAL and the BAMSE study groups), including children affected by asthma and/or its sub-phenotypes. In these samples we are evaluating the association of 6 SNPs defining the IRAK-M risk haplotype as well as gene-gene and gene-environment interactions in the predisposition to asthma. In parallel, we are analysing relevant IRAK-M variants identified by mutation screening in 314 Sardinians affected by allergic asthma and 200 controls. Experiments to evaluate the functional effect of the mutations on NF-κB activity and inflammation in monocyte- and

pneumocyte-derived cell lines as well as the regulation of IRAK-M expression are in progress.

Genetic polymorphisms of the insulin receptor substrate-1 (IRS-1) gene and profiles of clopidogrel-induced antiplatelet effects in type 2 diabetes mellitus patients with coronary artery disease

M. Zanoni¹, P. Prandini¹, D. J. Angiolillo², E. Bernardo³, A. Fernandez-Ortiz³, C. Macaya³, T. A. Bass², E. Trabetti¹, P. F. Pignatti¹;

¹Department of Mother and Child and of Biology-Genetics, Section of Biology-Genetics, University of Verona, Verona, Italy, ²Division of Cardiology, University of Florida College of Medicine-Shands Jacksonville, Jacksonville, FL, United States, ³Cardiovascular Institute, San Carlos University Hospital, Madrid, Spain.

Background: Patients with T2DM have reduced responsiveness to the platelet P2Y₁₂ receptor antagonist clopidogrel compared to non-diabetics. However, variability in clopidogrel-induced antiplatelet effects has been observed among T2DM and those with elevated platelet reactivity have a higher risk of atherothrombotic events. Since variation in insulin sensitivity modulates platelet P2Y₁₂ signaling, the aim of this study was to evaluate if SNPs of the insulin receptor substrate-1 (IRS-1) are associated with variation in the response to clopidogrel in T2DM patients.

Methods: A total of 7 tagSNPs (rs1801278, rs11683087, rs1801123, rs1896832, rs956115, rs2251692, rs6725330) were determined in 180 T2DM patients with coronary artery disease in a steady state phase of clopidogrel therapy. Patients were classified into carriers and non-carriers of the variant allele for each SNP according to a dominant model. In addition, haplotype distribution of IRS-1 genes within our population was assessed. Platelet function was determined by LTA following 20 μM adenosine diphosphate stimuli (ADP). Platelet aggregation according to genotype and haplotype was determined.

Results: The 7 tagSNPs were accountable for 93% of the haplotype distribution of the IRS-1 gene. Platelet aggregation was 55±15% in the overall population. Preliminary results showed an association between carriers of the variant C allele of the rs956115 SNP (n=34) and the highest degree of platelet reactivity (60±14%; p<0.05).

Conclusions: rs956115 polymorphism of IRS-1 gene is associated with lower clopidogrel-induced antiplatelet effects in T2DM patients with coronary artery disease.

P06.142

Polymorphism of insulin receptor substrate-2 gene in Turkish with type 2 diabetes mellitus

M. Hepdogru¹, A. Arslan², M. Gonen³, K. Gungor³, O. Dikbas³;

¹Department of Medical Biology, Selçuk University, Konya, Turkey, ²Department of Medical Biology, Gaziantep University, Gaziantep, Turkey, ³Department of Endocrinology, Selçuk University, Konya, Turkey.

Insulin receptor substrate-2 (IRS-2) is an endogenous substrate for the insulin receptor tyrosine kinase, which play a key role in insulin signaling. IRS-2 gene is potential candidate for development of type 2 diabetes mellitus. In this study, we have identified IRS-2 gene polymorphisms, evaluated their frequencies in Turkish subjects, and analyzed the contribution of these polymorphisms to the development of type 2 diabetes mellitus.

Study subjects were recruited from patients of Endocrinology Department, Selçuk University. We chose 122 unrelated, non-obese patients with type 2 diabetes mellitus and 35 unrelated, non-diabetic subjects with no family history of diabetes as age and body mass index matched control subjects. The coding and non-coding sequence of IRS-2 gene (divided into 15 overlapping fragments) was amplified by polymerase chain reaction and screened for the presence of single stranded conformational polymorphisms (SSCP).

Five missense (Thr⁸⁴⁹→Ser, Arg¹³⁰⁴→Gly, Lys¹²⁵³→Asn, Cys¹³¹⁸→Arg, Gly¹⁰⁵⁷→Asp) and six silent mutations (CCT→CCC encoding Pro⁴⁸³, GCT→GCC encoding Ala⁴⁸⁸, GGT→GGC encoding Gly⁴⁹⁷, CCC→CCT encoding Pro⁸²⁹, ACC→ACG encoding Thr⁸⁴⁵, TGT→TGC encoding Cys⁸⁰⁷) were detected in IRS-2 gene. The Thr⁸⁴⁹→Ser (6/122) and Gly¹⁰⁵⁷→Asp (8/122) mutations were more common in diabetic patients for these variants. Four novel amino acid variants were described and identified in the coding region of the IRS-2 gene. There was no significant association found with these variants and diabetes.

As a conclusion, IRS-2 Arg¹³⁰⁴→Gly, Lys¹²⁵³→Asn and Cys¹³¹⁸→Arg mutations rare and IRS-2 Thr⁸⁴⁹→Ser and Gly¹⁰⁵⁷→Asp mutations were

common in our population. But may not be major determinants in genetic susceptibility to type 2 diabetes.

P06.143

Association study of homocysteine metabolic regulatory genes with ischemic stroke risk in Singapore Chinese population

H. Low¹, K. Kasiman², C. Chen³, J. Liu⁴;

¹Department of Community, Occupational & Family Medicine, National University of Singapore, Singapore, ²Centre for Molecular Epidemiology, National University of Singapore, Singapore, ³Department of Neurology, Singapore General Hospital, Singapore, ⁴Genome Institute of Singapore, A*STAR (Agency for Science, Technology and Research, Singapore).

Moderately elevated plasma homocysteine level has been identified as an independent risk factor for vascular disease, including ischemic stroke. There are also substantial evidences for homocysteinaemia to be, at least partially, influenced by genetic factors. The focus of this study is to investigate the association between the 25 candidate genes of the homocysteine metabolic pathway and ischemic stroke risk in Chinese population. We genotyped 306 polymorphic SNPs from the 25 candidate genes in 376 stroke patients and 354 matched healthy controls from Singapore. Using genotype-based trend test, we identified 3 novel polymorphic loci from 3 genes (MTRR, SHMT1 and TCN2) which act as potential genetic risk factors for ischemic stroke. The effects of these loci are independent from each other as well as other known risk factors including age, gender, smoking, diabetes, hypertension and hyperlipidemia. We also found that the association of TCN2 variants with stroke appears to be more predominant in patients with lacunar infarction (LACI) than in other stroke subtype (non-LACI). In summary, the variants of these genes potentially affect individual susceptibility to ischemic stroke through the homocysteine metabolic pathway. Here, through genetic association study, our result supports the importance of B12 and folate cellular availability to prevent ischemic stroke in Chinese population. The growing evidence of importance of folate and B12 has significant implications for the inclusion of folic acid and B12 as supplement to prevent stroke. To our knowledge, this is the first comprehensive analysis of the homocysteine metabolic pathway in stroke.

Prevalence and phenotypic spectrum of known genes causative of Joubert Syndrome and Related Disorders: the experience of the International JSRD Study Group

E. M. Valente^{1,2}, F. Brancati³, L. Travaglini^{1,4}, M. Iannicelli^{1,4}, E. Bertin⁵, F. Emma⁶, E. Boltshauser⁷, A. Mazzotta¹, G. R. Stringin⁸, B. Dallapiccola^{1,4}, J. G. Gleeson⁹;

¹CSS-Mendel Institute, Rome, Italy, ²Dept. of Medical and Surgical Paediatric Sciences, University of Messina, Messina, Italy, ³CeSI, Aging Research Centre, and Dept. of Biomedical Sciences, G. d'Annunzio University Foundation, Chieti, Italy, ⁴Dept. of Experimental Medicine and Pathology, Sapienza University, Rome, Italy, ⁵Dept. of Laboratory Medicine, IRCCS Bambino Gesù Hospital, Rome, Italy, ⁶Dept. of Nephrology, IRCCS Bambino Gesù Hospital, Rome, Italy, ⁷Dept. of Neurology, Children's University Hospital, Zurich, Switzerland, ⁸Dept. of Neurosciences, University of California, La Jolla, CA, United States.

Joubert syndrome is an autosomal recessive condition characterized by hypotonia, ataxia, psychomotor delay, oculomotor apraxia, neonatal breathing abnormalities, and a complex midbrain-hindbrain malformation known as the “molar tooth sign” (MTS). The variable multiorgan involvement (mainly the retina and kidneys) defines several pleiotropic conditions (Joubert Syndrome Related Disorders, JSRDs) sharing the MTS. The nosological definition of JSRDs has long remained problematical, and a recently proposed classification is now based on the extent of retinal and renal involvement. Two loci (JBTS1-2) and five genes (NPHP1, AHI1, CEP290, MKS3, RPGRIP1L) have been identified so far. All genes encode for ciliary proteins, and JSRDs present clinical and genetic overlap with other ciliopathies, such as nephropthisis and Meckel syndrome.

Over the past 3 years, on behalf of the International JSRD Study Group, we have performed mutation screening of known genes in large cohorts of about 100-150 patients representative of all JSRD phenotypes. These allowed estimating the prevalence of gene mutations in different subgroups and drawing preliminary gene-phenotype correlates. Pure JS is mostly caused by AHI1 mutations (~10% of cases), and occasionally by MKS3. Cerebello-retinal phenotypes

are also mainly related to AHI1 (~20% of cases) although CEP290 can be rarely responsible. The genes most frequently causative of cerebello-renal phenotypes are NPHP1 and RPGRIP1L (~10% of cases each). Up to 50% of cerebello-renal cases are due to mutations in CEP290, while a minority relates to NPHP1 deletions. Overall, mutations in known genes are responsible of only 25-30% of JSRDs, supporting further genetic heterogeneity.

P06.145

Kir 4.1-KCNJ10 potassium channel gene polymorphisms in Type 2 diabetes

S. Oguzkan Balci¹, E. Akarsu², S. Aktaran², B. Gogebakan¹, M. Araz²;

¹University of Gaziantep, Faculty of Medicine, Department of Medical Biology, Gaziantep, Turkey, ²University of Gaziantep, Faculty of Medicine, Department of Endocrinology and Metabolism, Gaziantep, Turkey.

Potassium channels play an important role in insulin secretion. KCNJ10 channel protein is a member of Kir 4.1 potassium channel family. KCNJ10 gene is expressed in pancreatic beta cells. We therefore investigated whether polymorphisms in KCNJ10 gene are associated with type 2 diabetes in Turkish population.

In this study 166 individuals with type 2 diabetes and 100 age- and sex-matched healthy controls were tested for three single nucleotide polymorphisms (SNPs) in KCNJ10 gene. These SNPs were G to A transversion in intron 1 (SNP1) and G to A transversion in exon 2 (SNP2) and T to C transition in promoter (SNP3). All SNPs were genotyped by PCR-RFLP.

KCNJ10 gene SNP1 in intron 1 and SNP2 in exon 2 which were non-informative for Turkish population. The distribution of TT, TC, and CC genotypes for SNP3 in promoter was 56 %, 37% and 5 % in type 2 diabetes compared with 45 %, 51 % and 4 % in the controls ($\chi^2=4.352$, $p=0.113$). The allele frequency of T and C was 0.705, 0.295 in type 2 diabetes compared with 0.756, 0.244 in the controls ($\chi^2=1.676$, $p=0.195$). According to the “Hardy-Weinberg Equilibrium” TT genotype was found higher in type 2 diabetes than TC genotype ($\chi^2=4.07$, $p=0.04$).

We conclude that KCNJ10 gene SNPs were not associated with type 2 diabetes in Turkish population. However, further studies with larger samples are needed to address the exact role of KCNJ10 gene in type 2 diabetes and its complications such as diabetic retinopathy.

P06.146

Association of the CALM1 core promoter polymorphism with knee osteoarthritis in patients of Greek origin

M. Kalliakatos¹, M. Poulou¹, A. Tsezou², E. Kanavakis¹, K. Malizos², M. Tzetzis¹;

¹Department of Medical Genetics, Athens University, Athens, Greece, ²University of Thessaly, Medical School, Laboratory of Cytogenetics and Medical Genetics, University Hospital of Larissa, Larissa, Greece.

Osteoarthritis (OA) is characterized by focal areas of loss of articular cartilage in synovial joints, associated with varying degrees of osteophyte formation, subchondral bone change and synovitis. Calmodulin-1 gene (CALM1) encodes a ubiquitous eukaryotic Ca²⁺ binding protein and is the principal mediator of the calcium signal thus affecting the chondrocyte's response to mechanical load. A functional core promoter SNP -16C/T (rs12885713) was recently associated with HOA in the Japanese but not the British patients. In multifactorial genetic traits, each gene contributes to disease susceptibility to some extent, but such genes may also interact with each other. The aspartic-acid D14 repeat allele of the asporin gene (ASPN) is a susceptibility allele for both HOA and KOA in the Japanese and Caucasians. Our case-control study (158 KOA and 193 controls) focuses on genotyping Greek KOA patients for rs12885713, and investigating its role as a risk factor for the development of KOA. Our previous work on the same case-control group indicated that both the D14 and D15 alleles increased risk for KOA therefore we additionally investigate whether a combined effect of the ASPN D14/D15 alleles and CALM1 TT exists in Greek KOA patients. No significant differences were found in genotype frequencies for the -16T/C SNP of CALM1 gene between cases and controls ($p=0.581$). Our data implied that the -16TT (rs12885713) CALM1 core promoter genotype is not a risk factor for KOA etiology in Greek Caucasians on its own but associated with the ASPN D14 or D15 risk allele it could influence KOA susceptibility.

P06.147

A haplotype of the lipopolysaccharide-binding protein gene is associated with susceptibility to severe sepsis

C. Flores^{1,2}, E. Espinosa³, L. Pérez-Méndez^{1,2}, N. Maca-Meyer¹, R. Sangüesa³, A. Muriel⁴, J. Blanco^{2,4}, M. Muros^{2,5}, J. G. N. García⁶, J. Villar^{2,7};

¹Unidad de Investigación, Hospital Universitario N.S. de Candelaria, Santa Cruz de Tenerife, Spain, ²CIBER de Enfermedades Respiratorias, (CIBERes), Spain, ³Department of Anesthesia, Hospital Universitario N.S. de Candelaria, Santa Cruz de Tenerife, Spain, ⁴Intensive Care Unit, Hospital Universitario Río Hortega, Valladolid, Spain, ⁵Department of Clinical Biochemistry, Hospital Universitario N.S. de Candelaria, Santa Cruz de Tenerife, Spain, ⁶Pulmonary and Critical Care, Department of Medicine, University of Chicago, Chicago, IL, United States, ⁷Multidisciplinary Organ Dysfunction Evaluation Research Network, Research Unit, Hospital Universitario Dr. Negrín, Las Palmas de Gran Canaria, Spain.

The lipopolysaccharide-binding protein (LBP) is an acute phase protein that plays a dominant role in the genesis of sepsis by initiating signal transduction pathways leading to the activation of the inflammatory host response. A single nucleotide polymorphism (SNP) of the *LBP* gene has been previously associated with an increased risk for sepsis but gene-wide association studies are lacking. Here we evaluated the association of common variants across the entire *LBP* gene with susceptibility to severe sepsis by genotyping 10 selected SNPs, including a subset of tagging SNPs that efficiently captured common variation across the gene, in 176 severe cases of sepsis and 364 population-based controls. Although individual SNPs resulted non-significantly associated after adjusting for multiple testing, a haplotype extending ~1.2 kb in the 5'-flanking region of *LBP* gene, crucial for *in vitro* gene inducibility by cytokines, showed a significant association with susceptibility to severe sepsis ($p=0.001$, permuted $p=0.025$). Homozygous carrier patients of the haplotype had an elevated risk for severe sepsis (odds ratio: 2.21; 95% confidence interval: 1.39-3.51; $p=0.0006$) and this result was unaffected by covariate and population stratification adjustments. These patients also showed a consistent elevation of mean serum LBP concentrations across days examined. Taken together, these results support that common variation in *LBP* gene contributes to susceptibility to severe sepsis. Supported by grants from FUNCIS (37/02) and Ministerio de Educación y Ciencia, Spain (SAF 2004-06833)

P06.148

Effects of *LCAT* polymorphisms on HDL-C levels in Turkish population.

D. Agirbasli¹, M. A. Agirbasli², M. Sumerkar², C. Aral¹, S. Aksoy², S. Karabulut¹, B. Cirakoglu¹;

¹Department of Medical Biology and Genetics, Marmara University Medical School, Istanbul, Turkey, ²Department of Cardiology, Marmara University Medical School, Istanbul, Turkey, ³Siyami Ersek Cardiovascular Hospital, Istanbul, Turkey.

High density lipoprotein cholesterol (HDL-C) protects from vascular diseases. Genetic and environmental factors influence HDL-C levels. Low HDL-C is common among Turks. Nearly 50 % of the population has HDL-C levels below 35 mg/dl. Lecithin cholesterol acyltransferase (*LCAT*) takes part in reverse cholesterol transport and HDL-C maturation. The objective of our study is to evaluate the effects of 3 polymorphisms in *LCAT* gene on HDL-C levels. Study consists of 50 subjects with low HDL-C levels (<35 mg/dl) and 50 control subjects with high HDL-C levels (>65 mg/dl). We studied 511C/T polymorphism (exon 4), 4886C/T (exon 6), 608C/T (exon 5). Although single locus effects of the 3 polymorphisms of *LCAT* gene were not significantly related to the HDL levels, when combined effects are studied, the subjects with total of less than 2 high risk alleles had significantly higher HDL-C levels compared to subjects with 2 or more high risk alleles (56±27 vs 44±23, $p=0.04$). Multiple linear regression was performed to find the predictors of HDL-C. The variables were body mass index (BMI), glucose, age, smoking (number of pack years), number of high risk alleles. Age and smoking were the strongest predictors of HDL-C. However, after controlling for age and smoking, there was a negative correlation between the number of high risk alleles and HDL-C levels with borderline statistical significance ($p=0.07$).

These 3 genetic polymorphisms are susceptibility loci and are neither necessary nor sufficient for prediction of HDL-C, but co-existence of high risk alleles may contribute to low HDL-C levels.

P06.149

A study of LRRK2 mutations in Parkinson's disease patients from the Volga-Ural region of Russia

I. Gilyazova¹, E. Simons², E. Khusnutdinova¹, I. Khidiyatova¹, G. Breedveld², B. Oostr², R. Magzhanov¹, V. Bonifat²;

¹Institute of Biochemistry and Genetics, Ufa Science Centre, RAS, Ufa, Russian Federation, ²Erasmus MC Rotterdam, Rotterdam, Netherlands Antilles.

Mutations in the leucine-rich repeat kinase 2 (*LRRK2*) gene have been shown to cause both autosomal dominant and sporadic Parkinson's disease (PD). The common G2019S mutation shows wide geographical distribution while G2385R and I2020T variants are suggested to be risk factors for sporadic PD in Asian populations. The frequency of these mutations in the Volga-Ural region of Russia remained to be established. To determine the prevalence of G2019S, G2385R, I2020T mutations in the Volga-Ural region, we recruited 341 PD patients (129 Russians, 156 Tatars and 56 Bashkirs) and 360 controls (103 Russians, 131 Tatars, 126 Bashkirs) and conducted genetic analysis of these mutations. All patients exhibited at least two of the four principal signs of PD: resting tremor, rigidity, bradykinesia, or postural-reflex impairment. Exclusion criteria included prior history of multiple cerebrovascular events or other causes of parkinsonian symptoms. Controls were matched for age, ethnic origin and area of residence. Heterozygous G2019S was detected in one late-onset Bashkir patient with akinetic-rigid-trembling form (1.79%). Interestingly, that this patient doesn't carry a SNP in intron 13 (IVS13+104 G/A) which is in strong LD with the mutation and tags the commonest haplotype shared by all patients with this mutation in the Mediterranean populations.

The "Asian" risk factor, G2385R, was rare, but found in 2 Tatar PD patients (1.28%). We observed no I2020T mutations in this study sample. All mutations were confirmed by direct sequencing. These data have implications both for understanding the molecular mechanisms of PD, and for directing the genetic screening in clinical practice.

P06.150

Genetic Diagnosis and investigations of Disease LHON and CPEO

M. Houshmand;

NIGEB, Tehran, Islamic Republic of Iran.

Leber hereditary optic neuropathy (LHON) is a maternally inherited form of retinal ganglion cell degeneration leading to optic atrophy in young adults. To investigate any possible association between LHON primary mutations and

mtDNA haplogroups, the nucleotide sequence of the HVS-I region of mtDNA was determined in 30 unrelated Iranian patients with LHON harboring one of the primary mutations and 100 normal controls with the same ethnicity. Our analysis revealed a relatively high proportion of haplogroup J in LHON patients (53.3%) compared to normal controls (20%). In addition, a slightly significant increase of normal controls of haplogroup L has been confirmed (14% in normal controls vs. 0% in LHON patients at $p=0.03$), whereas other haplogroups did not show contribution to LHON contingency. We identified twelve nucleotide substitutions. Eleven of twelve nucleotide substitutions had already been reported as polymorphism. One of the nucleotide substitutions (A14290G) has not been reported. The A14290G nucleotide substitution does not change its amino acid. Different sizes of mtDNA deletions were detected in 16 patients (69.6%). Each of the 5.5, 7, 7.5 and 9 kb deletions existed only in 1 patient. Common deletion (4977bp) and 8 kb deletion were detected in 5 and 3 patients respectively. Multiple deletions were also present in 4 patients. Out of 23 patients included in our study, two cases (8.7%) had Twinkle gene mutation (G1423C) and 5 patients (21.7%) did not show any deletions in mtDNA or the Twinkle gene mutation.

A visual aura locus for migraine on chromosome 9q31

P. Tikka-Kleemola¹, S. Vepsäläinen^{1,2}, V. Arto^{1,2}, M. Kaunisto^{1,3}, V. Anttila^{1,4}, E. Hämäläinen^{1,4}, M. Färkkilä^{1,2}, M. Kallela^{1,2}, M. Wessman^{1,3}, A. Palotie^{1,4};

¹University of Helsinki, Biomedicum Helsinki, Helsinki, Finland, ²Department of Neurology, Helsinki University Central Hospital, Helsinki, Finland, ³Folkhälsan Research Center, Helsinki, Finland, ⁴The Wellcome Trust Sanger Institute, Hinxtion, United Kingdom.

Migraine is the most common cause of chronic episodic severe headache affecting approximately 15 % of the adult population. It has a

well-recognized genetic component based on family and twin studies. However, no genetic variants have been convincingly established for common forms of migraine. In about 30% of all migraine attacks visual, sensory or dysphasic symptoms precede the headache phase manifesting migraine with aura (MA). Here, we present the results of a genome-wide linkage scan on 37 Finnish migraine families having visual aura symptoms. The families were extracted from a large Finnish migraine patient collection ascertained from neurology clinics nationwide during the last 15 years. For this study the families presenting with migraine with typical aura (according to the International Headache Society (IHS) criteria) were selected. Data on IHS defined attack symptoms as well as other clinical features were collected using the validated Finnish Migraine Specific Questionnaire for Family Studies and by a neurologist's examination of index patients. We genotyped 372 individuals using microsatellite markers with an intermarker distance of 10 cM. We detected a locus on 9q31 with significant evidence of linkage (HLOD 4.5 at 104 cM) using two-point parametric linkage analysis. Multipoint parametric and non-parametric analyses support this finding. An additional set of microsatellite markers is currently genotyped to maximize linkage information across the region. In conclusion, our finding indicates a locus for visual aura on 9q31 region previously linked to epilepsy in a Belgian family also suffering from MA.

P06.152

Haplotype analysis for 12 loci in 11 small Portuguese families with autosomal recessive non-syndromic hearing loss

H. Teixeira^{1,2}, T. Matos¹, F. Moreno², G. Fialho¹, H. Caria^{1,3}, I. del Castillo²;

¹Center of Genetics and Molecular Biology, University of Lisbon, Lisbon, Portugal, ²Unidad de Genética Molecular, Hospital Ramón y Cajal, Madrid, Spain, ³Higher College of Health, Polytechnic Institute of Setúbal, Setúbal,, Portugal.

Mutations in DFNB1 were shown to account for ~19% of the cases of congenital deafness in the Portuguese population. The cause of deafness in the remaining cases, including the GJB2/GJB6 monoallelic ones, has to be elucidated. We have thus performed linkage analysis in order to investigate the spectrum of genes/mutations responsible for hearing impairment in the Portuguese population.

This study was conducted in eleven small families with apparent non-syndromic congenital deafness. Haplotype analysis was performed for DFNB1, DFNB4, DFNB7/11, DFNB8/10, DFNB9, DFNB12, DFNB18, DFNB28, DFNB35, DFNB49, DFNB59 and DFNB67, using at least three microsatellite markers for each locus. Sequencing analysis of the related genes was carried out in the case of compatibility with linkage.

In a consanguineous family we found compatibility with linkage to DFNB4 with autozygosity for this region. Sequencing of the SLC26A4 gene revealed a novel mutation, c.1615-2 A>G (IVS14 -2 A>G), in homozygosity in the severely deaf siblings. In a non-consanguineous family, we found compatibility with linkage to DFNB8/10 in heterozygosity. Sequencing of the TMPRSS3 gene revealed a known mutation, c.646C>T (p.Arg216Cys), in compound heterozygosity with a novel mutation that affects the LDLA domain of the protease, c.346G>A (p.Val116Met), in the profoundly deaf siblings. In both families, the genotype is likely to be the cause of deafness.

These are the first DFNB4- and DFNB8/10-related cases of deafness described in Portuguese families, which also provide a first evidence of the genetic heterogeneity of deafness in the Portuguese population.

P06.153

Combined linkage analyses of four isolated populations suggest novel loci for plasma lipid concentrations

A. Isaacs¹, H. Campbell¹, U. Gyllenstein², T. Meitinger³, B. Oostra¹, P. Pramstaller⁴, I. Rudan⁵, A. Wright⁶, Y. Aulchenko¹, C. van Duijn¹;

¹Erasmus University MC, Rotterdam, The Netherlands, ²University of Edinburgh, Edinburgh, United Kingdom, ³University of Uppsala, Uppsala, Sweden, ⁴Technical University Munich, Munich, Germany, ⁵Institute of Genetic Medicine, Eurac Research, Balzano, Italy, ⁶University of Split Medical School, Split, Croatia, ⁷Western General Hospital, Edinburgh, United Kingdom.

Despite considerable progress in elucidating genetic influences underlying circulating lipid levels, large proportions of the variance of these traits remain unexplained. In this study, data from four genetically-isolated populations, located in the Netherlands ($n_{\text{eff}}=1218$), Italy ($n_{\text{eff}}=918$), Sweden ($n_{\text{eff}}=409$), and Croatia ($n_{\text{eff}}=537$) were synthesized in an effort to increase statistical power to detect genomic regions

which may be involved in total cholesterol (TC), low-, and high-density lipoprotein cholesterol (LDL-c and HDL-c) levels. Quantitative multipoint linkage analyses of the four populations were performed individually, utilizing an integrated map, with SOLAR. LOD scores were combined post-hoc, and adjusted thresholds were calculated to account for multiple testing. Diabetics and subjects receiving lipid-lowering therapy were excluded from analysis. Two models were implemented: age- and sex-adjusted; and age-, sex-, BMI-, alcohol consumption-, and smoking-adjusted. Numerous regions surpassed a suggestive linkage threshold corresponding to LOD=1.9 in either the combined sample or in an individual population. For TC, regions centered on 1q21.3 (LOD_{max}=3.21) and 9q31.1 (LOD_{max}=2.54) were determined; the chromosome 9 region was also suggestive for LDL (LOD_{max}=3.22). HDL peaks exceeded the threshold at 2p21 (LOD_{max}=3.77), 10q21.1 (LOD_{max}=2.50), 16q12.2 (LOD_{max}=3.54), and 21q21.1 (LOD_{max}=3.66). The HDL peak on chromosome 2 was also detected for TC/HDL-c ratio (LOD_{max}=2.48), as was a peak located at 1p31.2 (LOD_{max}=3.74). The latter was also identified for LDL-c/HDL-c ratio (LOD_{max}=3.70), in addition to a peak at 22q11.2 (LOD_{max}=3.03). These peaks, many of which are novel, contain numerous promising candidate genes. The EUROSPAN Consortium is currently analysing dense sets of single nucleotide polymorphisms underlying these peaks.

P06.154

Linkage based on a single family--family size requirement

W. Yang, Y. Lau;

University of Hong Kong, Pokfulam,, Hong Kong.

Determination of required family size for linkage studies is not a simple task. With genotyping of high-density single nucleotide polymorphism (SNP) markers replacing that of microsatellite markers in linkage studies, it is possible to accurately determine the genomic regions shared by family members, including remote relatives. This may allow linkage studies to be conducted in a more deterministic fashion. Based on this advancement, we developed a simple method to allow the users to evaluate the inheritance information that can be extracted from their diseased family collection in linkage studies. This includes the total number of linked regions expected to be identified for the family under study, the expected sizes for the linked regions, and the portion of the genome that can be excluded from consideration. We presented a detailed discussion on family size requirement for linkage studies by analyzing some typical family structures, and demonstrated the feasibility of linkage studies on smaller families which are thought not sufficient by classical linkage analysis methods. Simulation results by our program showed that the linked regions containing true mutations are usually larger than regions linked due to random chance. We have made use of this feature in our program to allow evaluation of the linked regions through a Bayesian probability calculation.

P06.155

Genetic diversity and structure of linkage disequilibrium in the MTHFR locus

E. Trifonova, M. Spiridonova, V. Stepanov;

Institute for Medical Genetics, Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation.

Methylenetetrahydrofolate reductase (MTHFR) is a key ferment of folate cycle, which catalyzes for the conversion of 5,10-methylenetetrahydrofolate to 5-methyltetrahydrofolate. The reduction to activities of this enzyme, often conditioned presence of the certain combinations of alleles of MTHFR gene, brings to increase the concentrations of homocystein in blood. In the presented work we explored genetic differentiation and structure of linkage disequilibrium in MTHFR gene in population of the Russians, Tuvinians, north and south Kirghizes, using the set of SNPs: rs17037397, rs4846052, rs1801133, rs1801131 and rs1537516. In the total sample 19 out of 32 possible haplotypes were found (from 10 + 16 per population). The majority of genetic diversity is comprised by 8 main haplotypes, which accounted for 78% of all chromosomes. The population-specific patterns of linkage disequilibrium (LD) at MTHFR locus was revealed. In populations of the Russians, Tuvinians and north Kirghizes 2 LD blocks were found, where as south Kirghizes demonstrates strong linkage of all SNPs, within the single block. The significant genetic differences are discovered between population south Kirghizes and all explored group, as well as between Russians and Tuvinians. Genetic and demographic mechanisms of LD formation in local populations are discussed.

P06.156

Increasing power of variance component linkage analysis of large pedigrees

T. I. Axenovich, I. V. Zorkoltseva, G. R. Svischeva;

Institute of Cytology and Genetics, Novosibirsk, Russian Federation.

Most methods of linkage analysis of quantitative traits are based on the variance component approach. IBD calculation is the most computationally intensive step of this approach. The size of IBD matrix for large pedigrees and especially for those coming from isolated populations is too large for practical calculation. To solve this problem a pedigree is split on smaller non-overlapping fragments and then the fragments are analyzed as independent pedigrees. The split leads to increase the number of IBD matrix elements with zero values. This in turn decreases the linkage power. To diminish this effect we suggested to increase the number of non zero elements of IBD matrix by additional alternative splitting of the pedigree, for example, on overlapping fragments. Using the pedigree with 207 members in 6 generations, we estimated the expected linkage power when IBDs were calculated for a) pairs of genotyped members of each non-overlapping fragments of size no more than 18 bit and b) for (a) plus additional pairs of genotyped relatives from overlapping fragments of size no more than 18 bit. The results demonstrated the effectiveness of our method: the power for variant (b) based on 964 IBDs was 1.2 - 1.7 times greater than for variant (a) based on 844 IBDs. Such once calculated IBD matrix can further be utilized by various programs (for example, SOLAR) for linkage analysis of different traits.

P06.157

A genome-wide association analysis of HDL-cholesterol in the population-based KORA study sheds new light on intergenic regions

I. M. Heid^{1,2}, E. Boes³, M. Mueller^{1,2}, B. Kollerits³, C. Lamina¹, S. Coassin³, C. Gieger^{1,2}, A. Doering¹, N. Klopp¹, R. Frikke-Schmidt⁴, A. Tybjaerg-Hansen⁴, A. Brandstätter³, T. Meitinger¹, H. Wichmann^{1,2}, F. Kronenberg³;¹Helmholtz Zentrum München, Neuherberg, Germany, ²Ludwig-Maximilians-University of Munich, Munich, Germany, ³Innsbruck Medical University, Innsbruck, Austria, ⁴Copenhagen University Hospital, Copenhagen, Denmark.

Objective: High-density lipoprotein cholesterol (HDL) is a strong risk factor for atherosclerosis and assumed to be under considerable genetic control. We aimed to identify gene regions influencing HDL levels by a genome-wide association (GWA) analysis in the population-based KORA Study.

Methods: In KORA S3/F3 (n=1,643), we analyzed the 377,865 quality-checked single nucleotide polymorphisms (SNPs) of the 500K Affymetrix SNP array, complemented by the publicly available GWA results from the Diabetes Genetics Initiative (DGI, n=2,631) and by replication studies in KORA S4 (n=4,037) and the Copenhagen City Heart Study (n=9,205).

Results: Among the 13 SNPs selected from the KORA S3/F3 500K p-value list, three SNPs showed consistent associations in subsequent replications: two from so far unreported regions 50 kb downstream of LIPG or upstream of CETP and one from already reported regions of the LPL. The SNP in CETP and several SNPs downstream of LIPG were independent from already reported SNPs and might be of functional relevance. The other 10 as well as further 13 SNPs selected from the combined GWA p-value list of KORA S3/F3 and DGI failed consistent replication.

Conclusions: Our GWA study identified two new HDL-relevant regions, which generally motivates to extend the focus of future genetic association studies on long-range effects of intergenic regions. Furthermore, our study reinforced CETP and LPL as strong HDL genes and thereby underscores the power of our study and of the GWA approach in general to pinpoint strong effects from common polymorphisms.

P06.158

Genetic variants in the USF1 gene are not associated with MetS, T2DM, and related parameters in Caucasians (KORA study)

N. Klopp¹, C. Holzappel¹, H. Gallert¹, C. Huth¹, C. Gieger¹, C. Meisinger¹, K.Strassburger², G. Gianfranceschi², H. Wichmann¹, C. Herder², W. Rathmann², T. Illig¹;¹Helmholtz Zentrum München, Munich-Neuherberg, Germany, ²German Diabe-

tes Center, Leibniz Institute at Heinrich-Heine-University, Düsseldorf, Germany. Upstream stimulatory factor 1 (USF1) regulates numerous genes of glucose and lipid metabolism and genetic variants in the USF1 gene show association with familial combined hyperlipidemia, which shows phenotypic overlap with the metabolic syndrome (MetS) and type 2 diabetes mellitus (T2DM). The aim of our study was to approve the hypothesis that polymorphisms in the USF1 gene are associated with MetS and related metabolic traits. We genotyped eight single nucleotide polymorphisms in the USF1 gene in 1,653 individuals of the population-based German Caucasian KORA study in the age range between 55 and 74 years. Because of high correlation only six polymorphisms were statistically analyzed. The association with T2DM and the MetS was analyzed by logistic regression in 1,462 subjects and the quantitative parameters were analyzed in 1,231 fasting non diabetic subjects by linear regression respectively by Kruskal-Wallis test. None of the analyzed genetic variants (rs2774279, rs10908821, rs1556259, rs2516839, rs3737787, rs2774276) show significant association with T2DM and MetS. The results for the metabolic traits like triglycerides, total cholesterol, HDL cholesterol, LDL cholesterol, percent body fat, waist to hip ratio, ureic acid, fasting glucose, 2 hour plasma glucose, fasting insulin, blood pressure give also no evidence for any association with USF1. In our large population based study no association between single genetic variants in the USF1 gene and T2DM, MetS and related metabolic parameters was found. We conclude that the single genetic variants in USF1 have no major effect on lipid and glucose parameters in German Caucasians.

P06.159

Genome-wide linkage analysis for identifying quantitative trait loci involved in the regulation of lipoprotein a (Lp(a)) levels

S. Lopez¹, A. Buil^{1,2}, J. Ordoñez^{3,4}, J. C. Souto¹, L. Almasy⁵, M. Lathrop⁶, J. Blangero⁶, F. Blanco-Vaca^{3,7}, J. Fontcuberta¹, J. M. Soria^{1,2};¹Haemostasis and Thrombosis Unit, Department of Hematology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ²Bioinformatic of Complex Diseases Unit. Research Institute of Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ³Department of Biochemistry, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ⁴Department of Biochemistry and Molecular Biology, Universitat Autònoma de Barcelona, Barcelona, Spain, ⁵Department of Population Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, United States, ⁶Centre National du Genotypage, Paris, France, ⁷CIBER de Diabetes y Enfermedades Metabólicas Asociadas, Barcelona, Spain.

Lipoprotein Lp(a) levels are highly heritable and are associated with cardiovascular risk. We performed a genome-wide linkage analysis to delineate the genomic regions that influence the concentration of Lp(a) in families from the Genetic Analysis of Idiopathic Thrombophilia (GAIT) Project. Lp(a) levels were measured in 387 individuals belonging to 21 extended Spanish families. A total of 485 DNA microsatellite markers were genotyped to provide a 7.1 cM genetic map. A variance component linkage method was used to evaluate linkage and to detect quantitative trait loci (QTLs). The main QTL that showed strong evidence of linkage with Lp(a) levels was located at the structural gene for apo(a) on Chromosome 6 (LOD score=13.8). Interestingly, another QTL influencing Lp(a) concentration was located on Chromosome 2 with a LOD score of 2.01. This region contains several candidate genes. One of them is the *tissue factor pathway inhibitor (TFPI)*, which has antithrombotic action and also has the ability to bind lipoproteins. However, quantitative trait association analyses performed with 12 SNPs in *TFPI* gene revealed no association with Lp(a) levels. Our study confirms previous results on the genetic basis of Lp(a) levels. In addition, we report a new QTL on Chromosome 2 involved in the quantitative variation of Lp(a). These data should serve as the basis for further detection of candidate genes and to elucidate the relationship between the concentration of Lp(a) and cardiovascular risk.

P06.160

Identification of a novel autosomal recessive locus on chromosome 5q31-34 for the long QT syndrome

Z. N. Al-Hassnan, S. Majid, M. Al-Fayyadh, N. Dzimir, Y. Mallawi, W. Al-Manea, M. Al-Owain, B. Meyer;

King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia.

It is estimated that a significant percentage of sudden deaths are due to the long QT syndrome (LQTS) which is an inherited arrhythmogenic disorder that is characterized by locus heterogeneity. Mutations in

several genes that code for ion channels have been implicated in the LQTS which exists in two main forms: (i) Romano Ward syndrome inherited as autosomal dominant, and (ii) Jervell and Lange-Nielsen syndrome, an autosomal recessive disorder which is associated with sensorineural deafness.

Here we present result of genetic linkage analysis on a family with a history of sudden death in three children at the age of 7 to 8 years. Screening the other four living children and their consanguineous parents revealed that two sons were affected with prolonged QT intervals with unremarkable hearing assessment. Whole genome scan using Allegro software identified a locus on chromosome 5q31-34 with a maximum positive LOD score of 2.05. This locus has not been described in association with the LQTS. Further analysis of the region with sequencing of potential candidate genes is in progress.

In this work, we report on the identification of a novel locus for the LQTS. In the absence of hearing loss, the autosomal recessive pattern of inheritance in our family suggests a new form of the LQTS. Furthermore, identifying the causative gene on this locus may provide insight into the genetic susceptibility to unexplained sudden death in general.

P06.161

LRP1, a candidate gene for risk modulation of premature cardiovascular disease in heterozygous familial hypercholesterolemia

R. Aledo¹, V. Llorente-Cortés¹, R. Alonso^{2,3}, P. Mata^{2,3}, L. Badimon^{1,4};

¹Cardiovascular Research Institute, Barcelona, Spain, ²Fundación Jiménez Díaz, Madrid, Spain, ³Fundación Hipercolesterolemia Familiar, Madrid, Spain, ⁴CIBEROBN-Instituto Salud Carlos III, Barcelona, Spain.

Heterozygous familial hypercholesterolemia (hFH) is characterized by severely elevated LDL-cholesterol levels and premature atherosclerosis and cardiovascular disease (PCVD). Genetic alterations of the LDL-receptor gene are the main cause of this disease. However, there is a substantial variation in the onset and severity of the disease. This variability might be due to atherogenic risk factors of environmental, metabolic and genetic origin modulating the phenotype of hFH disease. LDL-receptor-related receptor (*LRP1*) is a multiligand binding receptor that acts as a pivotal lipoprotein receptor for the atherothrombotic transformation of the vascular wall. The aim of this study was to analyse the association of *LRP1* polymorphisms with premature cardiovascular disease in 339 hFH-patients (262 PCVD and 77 non-PCVD) from the Spanish FH Register. The polymorphisms c.1-25 C>G, rs715948, rs1799986, rs1800127, rs7968719, rs1800176, rs1800194, rs1800181, rs1140648, rs1800164 distributed along the whole gene were used in the study. The polymorphism rs1799986 showed a significant association with PCVD in the codominant model for the heterozygous genotype CT (nominal $P = 0.0126$, OR 2.07. CI₉₅ 1.14-3.74). The functional effect of rs1799986, that apparently is a synonymous mutation (Asp100Asp), was analyzed by the web interface <http://pupasuite.bioinfo.cipf.es>. This polymorphism completely abolishes an Exonic Splicing Enhancer sequence. This may result in splicing aberrations as exon skipping and therefore in a deficient transcription of the gene. Although further studies are needed to confirm the rs1799986 association with atherosclerosis and cardiovascular risk and to clarify its physiological role, our results suggest that this polymorphism is a biological plausible risk factor for PCVD.

P06.162

No association between polymorphic loci of the G72 gene and major depressive disorder.

A. Gareeva, T. Noskova, E. Khusnutdinova;

Institute of Biochemistry and Genetics of Ufa Scientific center of Russian academy of Sciences, Ufa, Russian Federation.

Major depressive disorder (MDD) is a common and highly heterogeneous psychiatric disorder encompassing a spectrum of symptoms involving deficits to a range of cognitive, psychomotor and emotional processes. The flavoprotein D-amino acid oxidase (DAO) degrades the neurotransmitter D-Ser, a potent activator of N-methyl-D-aspartate-type glutamate receptors. A body of evidence suggests that DAO, together with its activator, G72 protein, may play a key role in the pathophysiology of MDD. The present study tested the hypothesis that the M23 and M15 polymorphic loci of the G72 gene are associated with major depressive disorder (MDD). We studied M23 and M15 polymorphic loci of the G72 gene in 163 MDD patients and in 268 normal controls

from Bashkortostan region (belonged to Russian and Tatars ethnic groups). No significant differences were demonstrated for genotype or allele frequency of the M23 and of M15 polymorphic loci of G72 gene comparing the MDD and control group. The patient and the control samples were not divided according ethnicity, because genotype and allele frequencies were coincide in patient and control sample. Haplotype analysis was conducted to assess the association between the two markers within the G72 gene. The results showed that these two markers are in no linkage disequilibrium (LD): D' (patient sample) = 0.056, D' (control sample) = 0.064. Our findings suggest that M23 and M15 polymorphic loci of the G72 gene do not play a major role in the susceptibility to MDD. However, further studies with a larger sample are required to confirm the obtained results.

P06.163

Search for genetic mechanisms involved in malaria infection in Amazon

R. G. M. Ferreira¹, L. M. Garrido¹, C. E. M. Kawamata¹, L. M. A. Camargo², H. Krieger¹;

¹Departamento de Parasitologia, Instituto de Ciências Biomédicas, Universidade de São Paulo, Brazil, São Paulo, Brazil, ²Universidade São Lucas, Porto Velho, Brazil.

The biochemical pathways involved in the pathogenesis of the parasite infection that causes malaria and the human host mechanisms of defense against it are still not entirely known. Epidemiologic studies, as well genetic studies, suggest the existence of genetic components related to the host innate resistance or susceptibility to malaria (Hill A.V., 2006). Based on results obtained by our group in a genome-wide scan in 182 individuals from Portuquelo (8°37'S, 63°49'W), Rondonia state, Brazil (Ferreira R.G.M. *et al.*, 2007). The following STRs markers in the short arm of chromosome 4 spanning from 0 to 57cM where selected to be genotyped in a distinct population, Monte Negro (10°15'S, 63°18'W), at the same Brazilian state.

The sample, 452 individuals from nuclear families, was genotyped using 7 STRs markers (D4S412 - 4.74cM, D4S2983 - 17.5cM, D4S403 - 25cM, D4S419 - 30cM, D4S3022 - 36cM, D4S391 - 43.6cM, D4S405 - 57cM) along short arm of chromosome 4, with a mean distance of 8.74cM from each other. The software SimWalk2 (Sobel E. *et al.*, 2002) was used to check mendelian segregation of the alleles in the families.

The reported number of malarial episodes, corrected by age and sex, was used as the quantitative trait phenotype. This phenotype showed expected association with Fy- individuals as well as familial aggregation in conformity with genetic mechanisms, indicating its epidemiological importance. Linkage analysis were conducted using the software Solar 2 (Almasy L. *et al.*, 1998).

No evidence of linkage was found both in multi-point and two-point analysis. (FAPESP, CNPq)

P06.164

Matrix Metalloproteinase-3 gene polymorphism and dilatative pathology of ascending thoracic aorta

G. Sinkunaite, V. Lesauskaite, R. Benetis, A. Smalinskiene, S. Simonytė, G.

Jariene, V. Tatarunas, J. Petkeviciene, J. Klumbiene;

Institute of Cardiology, Kaunas University of Medicine, Kaunas, Lithuania.

The aim of the study was to identify whether the mutation in the promoter region of MMP3 gene might be a determinant of dilatative pathology of ascending thoracic aorta (DP ATA).

Material and methods. We studied 76 (55 males, 21 females) patients with DP ATA, the age ranged from 31 to 81 years (median, 64 years) and a random sample of the population ((244 males and 366 females) aged 25-64 yrs., all from Lithuania. Analysis was done on DNA using real-time polymerase chain reaction to genotype polymorphism 5A/6A at a position -1171 of the *MMP3* gene promoter.

Results. The prevalence of MMP-3 genotypes was similar between group of DP ATA and random sample of population. The frequency of 5A allele did not differ between both groups and was 0.506 and 0.514, respectively. Male patients carrying 5A/5A genotype were significantly younger compared with those with the 6A/6A genotype.

In conclusion, the frequency of *MMP-3* promoter 5A/6A genotypes did not differ between the group of patients with DP ATA and the random sample of population, but the males with DP ATA and 5A/5A genotype required aortic reconstruction surgery at the younger age than the

males carrying 6A/6A genotype in the *MMP-3* promoter region.

P06.165

Matrix metalloproteinase-9 polymorphism in relation to cardiovascular disease complications in patients of type 2 diabetes mellitus

E. Kurvinen^{1,2}, K. Nueganen³, M. Viigimaa⁴, A. Veske³, K. Aasvee¹;

¹National Institute for Health Development, Tallinn, Estonia, ²Tallinn Children's Hospital, Tallinn, Estonia, ³Tallinn Technical University, Tallinn, Estonia, ⁴North Estonia Regional Hospital, Tallinn, Estonia.

The process of atherosclerosis is accelerated in patients of type 2 Diabetes Mellitus (T2DM). The traditional risk factors alone cannot explain the excess incidence of cardiovascular complications in T2DM patients. The matrix metalloproteinase 9 (MMP-9) gene promoter genotype was considered to be related to coronary artery disease. Our study aimed to evaluate possible role of C-1562T MMP-9 polymorphism in developing of cardiovascular complications among T2DM patients. We have studied 111 subjects with C/C (group 1) and 50 subjects with T/T (in 1 patient) or C/T genotype (group 2). Fasting serum glucose and lipid metabolism parameters, inflammatory markers and anthropometric data were measured. MMP-9 genotype was detected by the PCR method. Cardiovascular complications were proven angiographically. Results. A cardiovascular complication was detected in 45% among C/C homozygotes and 48% among patients of group 2 (C/T+T/T). Waist/hip ratio and diastolic blood pressure were significantly higher in T allele carriers ($p < 0.05$). In multiple regression analysis independent determinants of diastolic blood pressure were MMP-9 genotype, waist/hip ratio and triglycerides level.

Conclusion. Among diabetic patients carrying MMP-9 T allele were revealed some unfavourable changes in anthropometric, lipid and blood pressure data, which can play a certain role in genesis of cardiovascular complications.

P06.166

Analysis of assembly of A1903G of gene polymorphism of chymase of CMA1/B with maximal oxygen consumption in human subject

E. V. Lekontsev, O. V. Gumerova, V. Y. Gorbunova;

Bashkir State Pedagogical University from after named M.Akmulla, Ufa, Russian Federation.

Introduction: the chymase gene of CMA1/B locates on 14 chromosomes (14q11.2) and the chymase is the main enzyme, controlling the angiotensin II generation from angiotensin I in tissues of cardiovascular system. The analysis of assembly of A1903G of gene polymorphism of chymase of CMA1/B with people physical characters has been carried out.

Methods: maximal oxygen consumption (MOC) of the 100 high-skilled sportsman's in the age 17-25 year had been investigated using Guminokogo method. The group of comparison consisted of 100 healthy individuals of appropriate age, which are not interested in sport (control group). The analysis of genetic polymorphism realized by the polymerase chain reaction (PCR).

Results: the genotypes 1)*A/*A, 2)*A/*G, 3)*G/*G chymase gene of CMA1/B are the most frequent 1)26.25%, 2)60%, 3)13.75% in the group of sportsman's; 1) 50%, 2)50%, 3)0% in control group with low means of MOC. We revealed that the reliable frequency the allele *G rise till mean (43.75% against 25% in control group was found; $P=0.506$; $OR=1.751$, 95%CI 1.102-5.0) and the allele *A low till mean (56.25% against 75% in control group; $P=0.0506$; $OR=0.751$, 95%CI 0.20-0.907). Also revealed the genotype *A/*A low till mean 26.25% against 50.0% in control group; $P=0.0886$; $OR=0.525$, 95%CI 0.129-0.977).

Is known, that the presence in allele genotype of CMA*G leads to the decrease of education of active pressor peptide - angiotensin II. Conclusions: the genotype association of CMA*G/*G of chymase gene with high level of MOC was determined, that provides of full value supply of heart tissue by the oxygen on exertions.

P06.167

Is Mannose Binding Lectin Codon 54 Polymorphism Associated With Predisposition to Acute Poststreptococcal Glomerulonephritis in Childhood?

A. Aykut¹, F. Ozkinay¹, M. Bak², B. Durmaz¹, D. Trak², H. Onay³, C. Ozkinay³;

¹Department of Pediatrics, Subdivision of Genetics and Teratology, Ege University, Faculty of Medicine, Izmir, Turkey, ²Department of Pediatrics, Behcet Uz Children's Hospital, Izmir, Turkey, ³Department of Medical Genetics, Ege University, Faculty of Medicine, Izmir, Turkey.

Acute Poststreptococcal Glomerulonephritis (PSAGN) is the most common form of glomerulonephritis, a disorder marked by inflammation of the kidneys' glomeruli, following a streptococcal infection. However the mechanism of renal injury in PSAGN is still not clear. On the other hand Mannose binding lectin (MBL) is a calcium dependent lectin that has an important role in innate immunity. MBL deficiency increases the overall susceptibility of an individual to infectious disease. The aim of this study is to determine the presence of any association between MBL gene variants and PSAGN in the child population. Codon 54 (allele B) polymorphism in the exon 1 of the MBL gene was investigated by PCR-RFLP method in 110 children diagnosed as PSAGN and 100 age-matched healthy controls. No significant differences in the frequencies of the mutant B allele were found between the patient group (5.5%) and the control group (1%). AB genotype was found to be 20% and 26% in the patient group and the healthy control group respectively, where the difference was statistically not significant. AA genotype was found in 74.5% of the children with PSAGN and 73% of the healthy control group. In our study, we could not find any significant association between MBL genotypes and PSAGN. We conclude that it may be helpful to test the association between MBL genotypes and other infectious diseases in a large series of patients in order to resolve the role of MBL protein in susceptibility to or protection against infections with different pathogens in certain age groups

Medullary Cystic Kidney Disease 1 - The quest for finding the gene

G. Papagregoriou¹, A. Soloukides¹, K. Voskarides¹, C. Charalambous¹, A. Pierides², F. Hildebrandt³, C. Stavrou⁴, C. Deltas¹;

¹Department Of Biological Sciences, University Of Cyprus, Nicosia, Cyprus, ²Hippokraton Private Hospital, Nicosia, Cyprus, ³Department of Pediatrics and Communicable Diseases, University Of Michigan, Ann Arbor, MI, United States, ⁴Royal Artemis Medical Centre, Pafos, Cyprus.

Medullary Cystic Kidney Disease (MCKD) is an autosomal dominant disorder manifesting with interstitial fibrosis, tubular basement membrane thickening and tubular atrophy, leading to CRF or progressing to ESRF at ages between 30-70 years. Renal cysts at the corticomedullary junction are a frequent finding. In certain regions of Pafos, Cyprus, MCKD1 patients constitute nearly 40% of total ESRF cases. The gene responsible for the disease, MCKD1, has been mapped by our group on 1q21 (Christodoulou et al, 1998, Hum Mol Genet 7:905-911), between markers D1S498 and D1S2125. Paucity of progress in cloning the gene, prompted us to re-evaluate and expand linkage analysis data encompassing patients from nine families linked to MCKD1. All patients were examined using global criteria in an attempt to identify an intermediate phenotype. Polymorphic markers were examined throughout the MCKD1 region and haplotypes helped to re-establish the critical region, between markers D1S305-D1S336mw28, encompassing 2.1 Mb. Genes considered as good candidates, NP12, PIAS3, IL6R, APOA1BP, CA14, NCu-GI, FDPS, HCN3, AQP10, SHC1, PMVK, SCAMP3, LOC284620 and MUC1, were re-sequenced, with negative results. Additionally, a microarray expression study using renal fibroblasts from an affected kidney was designed in order to depict pan-oramic gene expression, also with no considerable results. A Comparative Genome Hybridization array experiment was performed searching for allelic copy number variations nested in the critical MCKD1 region. No significant difference was detected between normal and affected samples. From the clinical perspective, this work revealed a putative relationship between carriers of affected haplotype and hyperuricaemia, as an early clinical finding.

P06.169

Absence of causative coding variants in the MEIS1 gene in 245 French-Canadian Restless Legs Syndrome patients

L. Xiong¹, M. Dubé¹, A. Levchenko¹, J. St-Onge¹, S. Girard¹, C. Gaspar¹, G. Tureck¹, J. Montplaisir¹, G. A. Rouleau¹;

¹University of Montreal, Montreal, QC, Canada, ²McGill University, Montreal, QC, Canada.

Introduction: Restless legs syndrome (RLS) is a common sensorimotor disorder with a substantial genetic contribution. Recently, a genome-wide association study reported significant association between common variants within the MEIS1 gene and the RLS phenotype. The odds ratio of the risk allele ranges from 1.8 to 3.0. The MEIS1 gene encodes a homeobox protein involved in limb development, establishment of the intrasegmental spinal motor neuron identity and connectivity, and patterning of sensory organs in the embryonic peripheral nervous system, as well as hematopoiesis.

Patients and methods: We systematically sequenced 245 clinically well-defined RLS patients for the entire coding and UTR regions of the MEIS1 gene. All samples were Caucasians with 95% of French-Canadian (FC) origin; and 77% were severe or very severe cases with mean age of 53±12 yrs and disease onset 30±16 yrs. 77% of patients had positive family history and 83% were also positive for periodic leg movements during sleep. In total, 13 exons/17 fragments (NM_002398.2, 3180 bps) were sequenced. All sequence variants detected in patients were genotyped in 285 FC controls.

Results: In total, 19 variants were detected, five intronic and 14 exonic, including 13 variants within the 3'UTR region and one synonymous SNP (rs13005707) in exon 7. Eight rare variants and eleven common variants showed no association with the disease phenotype.

Conclusion: No causative coding variants were found in the MEIS1 gene in 245 RLS patients. Further deep-sequencing of the non-coding region and studies of the expression and function of the MEIS1 gene are underway.

P06.170

Effect of polymorphisms in the dopaminergic system genes on the mental fatigue

M. A. Kulikova, M. A. Timofeeva, N. V. Maluchenko;

Moscow State University, Moscow, Russian Federation.

Mental fatigue (MF) represents a failure to initiate and sustain tasks that require self-motivation and internal cues in the absence of demonstrable cognitive failure or motor weakness. So development of the mental fatigue is the significant problem for people who work with big amount of data and constantly need focused attention.

Molecular mechanisms of MF origin still are not clear. It is known that basal ganglia play a key role in the development of MF (Chaudhuri et al., 2000). Dopamine is one of the most prevalent neurotransmitters in the basal ganglia. Therefore we suppose that alterations in the functioning of dopamine system provided by genes variations may influence the development of the MF. We tested the hypothesis that allelic variation of the DRD2 and DAT genes located mostly in the striatum could be associated with differences in the onset of MF.

In current investigation 160 volunteers (78 males and 82 females) participated. Subjects were genotyped for TaqI A RFLP of the DRD2 gene and 40-bp VNTR polymorphism of the DAT gene. Psychophysiological indexes were measured before and after mental load consisted in the monotonous passing of personality questionnaires during three hours.

Case-control analyses suggested a strong association between the A1+10/10 genotype and increased mental fatigue ($P < 0.05$). In conclusion, mental fatigue seems to be related to allelic variations within the DRD2 and DAT genes.

P06.171

Effect of genes from the serotonin system on the mental fatigue

M. Timofeeva¹, M. Kulikova², N. Maluchenko²;

¹Russian Research Institute of Sport and Physical Education, Moscow, Russian Federation, ²Moscow State University, Moscow, Russian Federation.

Fatigue is an important factor affecting sporting and mental performances. It is complicated process which includes peripheral and central components. Central fatigue occurs in central nervous system as a result of mental as well as physical activity.

There are evidences that serotonin is implicated in central fatigue de-

velopment. Serotonin turnover in the brain increases in response to physical exercise. Decreased motivation, tiredness, loss of motor coordination - markers of central fatigue, are associated with the rise of brain serotonin concentration. But the role of serotonin in the development of mental fatigue is unclear.

In the current study we investigate associations of serotonin system genes polymorphism with the mental fatigue. In the study students of Moscow State University took part (N=160, male=78, female=82). Volunteers were exposed to intensive mental workload (logical tasks and monotonous persistent completion of psychological tests) during 3 hours. Before and after workload the psychophysiological state was estimated with the help of "NS-Psychotest" (Neurosoft, Russia). Additionally volunteers completed self-ratings of mental fatigue and of functional state.

It was detected that carries of both ss-genotype of the 5HTTLPR and CC-genotype of the 5-HT2A polymorphism (T102C) reported higher level of mental fatigue after performing fatigue task compared with carries of ll(5HTTLPR) genotype and of TT(T102C) genotype. ss-genotype of the 5-HTTLPR as well as CC-genotype of the 5-HT2A are associated with reduced expression of both genes and therefore could cause increasing concentrations of extracellular serotonin in the brain. These findings suggest a role of serotonin transmission efficiency in mental fatigue.

Joint analysis of individual-level data from 17 studies on the association of the IL6 promoter polymorphism -174G>C with glucose levels, interleukin-6 levels, and body-mass index

C. Huth^{1,2}, T. Illig¹, C. Herder³, C. Gieger^{1,2}, H. Grallert¹, Y. H. Hamid⁴, O. Pedersen⁴, T. Hansen⁴, V. Lyssenko⁵, L. Groop⁵, H. Ireland⁶, J. W. Stephens⁷, I. Wernstedt Asterholm⁸, J. Jansson⁸, H. M. Stringham⁹, M. Boehnke⁹, J. Tuomilehto^{10,11}, J. Fernandez-Real^{12,13}, A. Lopez-Bermejo^{12,13}, L. Gallart¹⁴, J. Vendrell¹⁴, S. E. Humphries⁵, F. Kronenberg¹⁵, H. E. Wichmann¹², I. M. Heid¹²;

¹Institute of Epidemiology, Helmholtz Zentrum München, Neuherberg, Germany, ²Institute of Biometry and Epidemiology, University of Munich, Munich, Germany, ³German Diabetes Center, Leibniz Institute at Heinrich Heine University Düsseldorf, Düsseldorf, Germany, ⁴Steno Diabetes Center, Copenhagen, Denmark, ⁵Department of Clinical Sciences, University Hospital Malmö, Malmö, Sweden, ⁶Centre for Cardiovascular Genetics, Royal Free and University College Medical School, London, United Kingdom, ⁷Medical School, University of Wales, Swansea, United Kingdom, ⁸Institute of Neuroscience and Physiology, Sahlgrenska Academy at Gothenburg University, Gothenburg, Sweden, ⁹Department of Biostatistics, University of Michigan, Ann Arbor, MI, United States, ¹⁰Diabetes Unit, National Public Health Institute, Helsinki, Finland, ¹¹Department of Public Health, University of Helsinki, Helsinki, Finland, ¹²Section of Diabetes, Endocrinology and Nutrition, Girona, Spain, ¹³CIBER "Fisiopatología de la Obesidad y Nutrición" CB/06/03/010, Girona, Spain, ¹⁴Research Unit, University Hospital Joan XXIII, Tarragona, Spain, ¹⁵Division of Genetic Epidemiology, Innsbruck Medical University, Innsbruck, Austria.

Background: Several studies have investigated associations between the -174G>C polymorphism (rs1800795) of the IL6 gene and phenotypes related to type 2 diabetes mellitus (T2DM), but presented inconsistent results. This joint analysis aimed to clarify whether IL6 -174G>C was associated with the quantitative phenotypes circulating glucose, body-mass-index (BMI), and circulating interleukin-6 (IL-6).

Methods: Individual participants' data from all published and unpublished studies of the IL6-T2DM consortium on Caucasian subjects with available BMI were collected. As study-specific estimates did not show heterogeneity ($P > 0.1$), they were combined by using the inverse-variance fixed-effect model.

Results: The main analysis included 9440, 7398, 24,117, or 5659 non-diabetic and manifest T2DM subjects for fasting glucose, 2-h glucose, BMI or circulating IL-6, respectively. The IL6 -174 CC- and GC-genotypes were significantly associated with -0.091mmol/L ($P=0.014$) lower fasting glucose. There was no evidence for association between IL6 -174G>C and BMI or IL-6 levels. In an additional analysis of 641 subjects known to develop T2DM later on, the IL6 -174 CC-genotype was associated with higher baseline IL-6 levels (+0.75pg/mL, $P=0.004$), which was consistent with higher IL-6 levels in the 966 manifest T2DM subjects (+0.50pg/mL, $P=0.044$).

Conclusions: Our data on the widely debated IL6 -174G>C polymorphism suggest an association with quantitative glucose, and exploratory analysis indicated modulated IL-6 levels in pre-diabetic subjects,

being in-line with this SNP's previously reported T2DM association and a role of circulating IL-6 as intermediate phenotype. This large joint analysis underscores that a consortium-based approach is well-suited to investigate small genetic effects.

P06.173

Apolipoprotein A5 gene APOA5*2 haplotype variant confers risk for the development of metabolic syndrome

P. Kisfalvi¹, M. Mohász², A. Maász¹, F. Hadarits³, L. Markó², I. Késő², T. Oroszlán⁴, Z. Bagosi⁴, Z. Bujtor⁴, J. Rinfel⁵, B. Gasztonyi⁴, I. Wittmann², B. Melegh¹;
¹Department of Medical Genetics and Child Development, University of Pécs, Pécs, Hungary, ²2nd Department of Medicine and Nephrological Center, University of Pécs, Pécs, Hungary, ³Central Laboratory, Markusovszky County Hospital, Szombathely, Hungary, ⁴2nd Department of Medicine, Zala County Hospital, Zalaegerszeg, Hungary, ⁵3rd Department of Medicine and Family Medicine Institute, University of Pécs, Pécs, Hungary.

The metabolic syndrome may affect 18-30 per cent of the adult population in the industrialized countries and is considered a veritable epidemic. Metabolic syndrome is a clustering of abdominal obesity, increased triglycerides, low levels of high density lipoprotein cholesterol, high blood pressure, and elevated fasting glucose levels and consists of multiple risk factors that are increasing the cardiovascular mortality. The etiology is complex, determined by the interplay of both genetic and environmental factors. Naturally occurring variants of the apolipoprotein A5 gene have been associated with increased triglycerides and have been found to confer risk for cardiovascular diseases. In our study four haplotype-tagging polymorphisms, the T-1131C, IVS3+G476A, T1259C, and C56G alleles, and the haplotype profiles were studied in 343 patients with MS and 284 controls. Minor alleles of all apoA5 variants, except the C56G variant, were associated with increased triglyceride levels both in the MS patients and in the controls. The serum total cholesterol levels did not show allele-dependent differences. The prevalence of the apoA5*2 haplotype, defined by the simultaneous presence of -1131C, IVS3+473A and 1259C variants, was 13.4% in MS patients and 4.91% in the controls ($p < 0.001$). Multiple logistic regression analysis revealed that this haplotype confers risk for the development of MS (OR=2.913; 95% CI: 1.564-5.426; $p < 0.001$). To our surprise, the apoA5*5 was significantly less frequent in the MS patients compared with the controls (0.87 vs 5.26%, $p < 0,05$), and this haplotype was found to confer strong protection against the development of MS (OR=0.158; 95% CI: 0.045-0.553; $p = 0.004$).

P06.174

Polymorphisms of methyl-group pathway genes in spontaneous abortions

M. S. Nazarenko, V. P. Puzryev, I. N. Lebedev, E. N. Tolmacheva, A. A. Kashevarova, E. A. Sazhenova, N. N. Sukhanova;
 State Research Institute of Medical Genetics, Tomsk, Russian Federation.

It's believed that altered methyl-group pathway provides a potential mechanism which influence the DNA methylation of specific genomic regions. Thereafter aberrant methylation can lead to the induction of genomic instability in a manner that have developmental consequences including embryo death. The purpose of current work was to investigate the effect of fetal functional polymorphisms of methyl-group pathway genes (C667T and A1298C *MTHFR*, A2756G *MTR*, G66A *MTRR* and C46359T *DNMT3B*) on spontaneous abortions. First-trimester spontaneous abortions with normal karyotype ($n=151$), with mosaic chromosomal constitution ($n=34$) and induced abortions ($n=33$) were analyzed for chosen polymorphisms by PCR-RFLP. Nothing differences between alleles and genotypes frequencies in studied groups were found, except *DNMT3B*. Carriers of 46359T allele predominated in the group of induced abortions (64%) in compare with spontaneous abortions (47%; $P=0.01$). The 46359TT genotype was more prevalent in the group of induced abortions than spontaneous abortions (42% vs. 17%, respectively; $P=0.002$). Consequently, further studies are needed to clarify the influence of embryo genotype for polymorphisms C46359T *DNMT3B* in the process of human spontaneous abortion.

P06.175

Genetic analysis of autosomal recessive primary microcephaly in Pakistani kindreds

M. S. Hussain^{1,2}, S. M. Baig¹, M. Farooq¹, I. A. Inayat¹, E. Kirs², M. Aslam¹, M. Wajid¹, M. R. Tolia², J. A. Qureshi¹, P. Nürnberg²;

¹Human Molecular Genetics Laboratory (HMG), National Institute for Biotechnology and Genetic Engineering (NIBGE), Faisalabad, Pakistan, ²Cologne Center for Genomics (CCG), Institute of Genetics, University of Cologne, Cologne, Germany.

Autosomal recessive primary microcephaly (MCPH) is a rare genetic disorder in which the affected individuals have head circumference >3 SDs below the age and sex-related mean. The reduced head circumference is due to small but architecturally normal cerebral cortex. This disorder is genetically heterogeneous with six loci and four genes (Microcephalin, CDK5RAP2, ASPM and CENPJ) have been identified. Its incidence is ranging from 1/30,000 to 1/2,000,000.

Eleven families of autosomal recessive primary microcephaly were ascertained from various areas of Pakistan. By PCR (Polymerase Chain Reaction) based genotyping linkage was performed using highly polymorphic fluorescently labeled microsatellite markers. Homozygosity mapping revealed linkage of seven families to MCPH5 locus (ASPM gene), one to MCPH2 locus, one to MCPH4 locus and one with MCPH6 locus (CENPJ) and one was excluded to all known MCPH loci. MCPH5 linked families were subjected to screen the ASPM (Abnormal Spindle-like Microcephaly Associated) gene with direct DNA sequencing. Four previously reported (p.Y3163X, p.R1019X, p.Y3353X, p.W1326X) and two novel mutations (p.L333fs, p.Q2880X) were identified in ASPM gene. One known mutation (p.T6fsX3) was also identified in CENPJ (Centromere-associated Protein J) gene. All these mutations are protein truncating so it is more likely that they are governing the same phenomenon of nonsense mediated mRNA decay. The ultimate objective of our study is to identify the novel locus in a family which is excluded to all known MCPH loci and to identify the genes responsible for autosomal recessive primary microcephaly in MCPH2 and MCPH4 linked families.

P06.176

Genetic Variation in miRNA Genomic Regions: Association with Eating Disorders

M. Muinos-Gimeno¹, J. M. Mercader^{1,2}, M. Montfort¹, M. Bayes¹, F. Fernandez-Aranda², X. Estivill^{1,3}, Y. Espinosa-Parilla¹;

¹Genes and Disease Program, CeGen and CIBERESP, Center for Genomic Regulation, Barcelona, Spain, ²CIBEROBN and Psychiatric Service, Ciutat Sanitaria Bellvitge, L'Hospitalet, Spain, ³Pompeu Fabra University, Barcelona, Spain.

MicroRNAs (miRNAs) are posttranscriptional regulators involved in the regulation of at least a third of mammalian genes. Association studies using single nucleotide polymorphisms (SNPs) in miRNA genomic regions might help to evaluate the contribution of functional miRNA allele variants to complex disease susceptibility. We constructed a panel of 768 SNPs covering 164 miRNA regions and spanning 2 Mb of genomic DNA including 326 known human miRNAs precursor sequences (miRBase, 7.1) and at least 5 kb upstream and downstream of the miRNA regions. For an optimal selection of informative SNPs we used tagSNPs and included 18 SNPs located inside premiRNA sequences. Genotyping of 340 unrelated Spanish controls was performed using a custom Golden Gate assay (Illumina). Nine out of the 18 SNPs located in premiRNAs were monomorphic, which is suggestive of selective constraint on miRNA sequences. A high correlation ($R^2=0.86$) was shown between allele frequencies in the Spanish and HapMap CEU sample confirming the applicability of our SNP panel to study the Spanish population. Further, we performed association analysis in a sample of 294 patients with different types of eating disorders and 340 controls. A nominal association ($p < 0.005$) was found for at least two SNPs per miRNA in the case of two miRNAs and 2 clusters containing 2 and 3 miRNAs each. When stratifying for bulimia and anorexia phenotypes, association for another 3 and one miRNAs was respectively shown. These results indicate a possible role for miRNAs in the aetiology of eating disorders. Supported by Spanish Government and Generalitat de Catalunya.

P06.177**Sequence analysis of circadian clock modulators miR-132 and miR-219 and their targets RFX4 and PHLPP in Mood Disorder Patients**

E. Saus¹, V. Soria², F. Vivarelli¹, J. M. Crespo^{2,3}, J. M. Menchón^{2,3}, M. Urretavizcaya^{2,3}, X. Estivill^{1,4}, M. Gratacòs¹;

¹CIBERESP (CIBER en Epidemiología y Salud Pública), Genes and Disease Program and CeGen Barcelona Genotyping Node, Center for Genomic Regulation, Barcelona, Catalonia, Spain, ²Mood Disorders Clinical and Research Unit, CIBER-SAM, Psychiatry Department, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, Catalonia, Spain, ³Department of Clinical Sciences, Bellvitge Campus, Barcelona University, Barcelona, Catalonia, Spain, ⁴Experimental and Health Sciences Department, Pompeu Fabra University, Barcelona, Catalonia, Spain.

It has been widely supported that circadian rhythms are involved in the pathophysiology of mood disorders (MD). Two brain-specific miRNAs (microRNAs) have been recently reported as modulators of endogenous circadian clock located in the suprachiasmatic nucleus in mice. The authors have functionally characterized miR-132 and miR-219 within the context of circadian clock and gave experimental evidences of genes Rfx4 and Phlpp as respective targets. We first explored the conservation between species for both miRNAs and once the existence of hsa-miR-132 and hsa-miR-219 was corroborated in humans, we used different prediction programs to check the experimentally supported target sites RFX4 and PHLPP in humans. Specifically, miRanda predicted hsa-miR-132 to target RFX4 and TargetScan predicted PHLPP as a target site for hsa-miR-219, consistent with previous work in mice. Once both miRNAs with their respective target sites were confirmed in humans, we questioned whether these two miRNAs and their target genes RFX4 and PHLPP are altered in mood disorder patients. Thus, we re-sequenced both miRNAs and their respective target sites at RFX4 and PHLPP genes in a sample consisting of 365 unrelated patients (218 Unipolar Major Depressive Disorder and 147 Bipolar Disorder) diagnosed according to DSM-IV criteria. All patients completed the Spanish versions of the Seasonal Pattern Assessment Questionnaire and the Horne-Östberg Morningness-Eveningness Questionnaire. This is the first time that the circadian clock regulation by miRNAs is explored in mood disorder, representing a first step to elucidate the underlying mechanism of these proteins and the role of these miRNAs in mood disorders.

P06.178**Allelic frequencies and heterozygosities of microsatellite markers covering the whole genome in the Korean**

J. Lee, M. Park, K. Kim, H. Lee, K. Kim, J. Jung, B. Oh, H. Kim;

Center for Genome Science, National Institute of Health, Seoul, Republic of Korea.

Microsatellite markers are an essential tool for genetic linkage analysis because of their high polymorphism content. Four hundred commercially available markers covering the entire genome were genotyped from 578 sib individuals from 249 Korean families. Allelic frequencies and heterozygosities were determined for each marker loci and compared between Korean, Taiwanese, Japanese and Caucasian populations. In the three Asian populations, 10-13% of the markers had less than 0.6 heterozygosity, whereas in the Caucasian population, only 0.5% of the markers had less than 0.6 heterozygosity. Mean identical by descent (IBD) values were calculated for 578 sib individuals. Analysis of IBD values greater than 0.5 suggested that markers with low heterozygosity can also provide positive linkages, at least for the IBD sharing method of model-free linkage analysis. The data presented in this study will be a useful reference for genome-wide screens of Koreans and comparative studies with other ethnic populations.

P06.179**Association study of migraine and 19 candidate genes involved in serotonergic neurotransmission in a Spanish population**

R. Corominas¹, M. J. Sobrido^{2,3}, E. Cuenca-León¹, P. Blanco^{4,5}, B. Narberhaus⁵, M. Del Toro¹, R. Leira⁶, J. López⁶, M. Ribasés¹, A. Macaya¹, B. Cormand^{7,8};

¹Hospital Universitari Vall d'Hebron, Barcelona, Spain, ²Fundación Pública Galera de Medicina Xenómica, Santiago de Compostela, Spain, ³CIBER Enfermedades Raras, Instituto de Salud Carlos III, Barcelona, Spain, ⁴Grupo de Medicina Xenómica, Universidad de Santiago de Compostela, Santiago de

Compostela, Spain, ⁵Hospital General de Manresa, Manresa, Spain, ⁶Servicio de Neurología, Hospital Clínico de Santiago, Santiago de Compostela, Spain, ⁷Departament de Genètica, Facultat de Biologia, Universitat de Barcelona, Barcelona, Spain.

Migraine is a common neurological disorder with a complex inheritance pattern. Although the pathophysiology of the disease is not well understood, several studies suggest that serotonin-related genes may participate in its pathogenesis. The involvement of some of these genes has been studied in different migraine populations with conflicting results thus far.

In the present study we aimed to evaluate the possible role of 19 genes involved in serotonergic neurotransmission in the susceptibility to migraine in a Spanish population using a case-control approach based on SNPs. A total sample of 528 unrelated patients were recruited and diagnosed following the IInd International Criteria of Headache Disorders from the IHS (308 patients had migraine without aura and 220 had migraine with aura) and compared to 528 sex-matched controls in which migraine was ruled out. All individuals were Spanish of Caucoid origin from Catalonia and Galicia. SNP selection was based on genetic coverage parameters and genotyping was performed using SNPlex technology. Chi-square tests were used for the comparison of allele and genotype frequencies between the patient and control groups for each single SNP. Preliminary data of nominal associations suggest a contribution of *HTR1E*, *HTR2B*, *HTR3B*, *MAOA* and *DDC* in the genetic predisposition to migraine.

P06.180**Genetic diagnosis of Ataxia Telangiectasia and role of Mitochondria on it**

M. Houshmand;

NIGEB, Tehran, Islamic Republic of Iran.

Ataxia telangiectasia (AT) is an autosomal recessive disorder in 1/40,000 to 1/100,000 in reported populations. There is a 25% possibility for having an affected child when parents are carrier for the ATM gene mutation. There is no cure available for this disease and prenatal testing is strongly recommended for prevention of this disease. Although the preferred method is the direct mutation analysis of the ATM gene, the large size of the ATM gene with 63 exons and the large number of possible mutations in patients considerably limit efficiency of mutation analysis as a diagnostic choice. In this study, four molecular markers: D11S2179, D11S1787, D11S535, D11S1343 are genotyped in 19 unrelated families from different regions of Iran. All carriers and affected patients were diagnosed accurately. This method is effectively useful in prenatal diagnosis of AT.

We also investigated mt-DNA deletions and haplogroups in AT patients. In this study, 24 Iranian patients suffering from AT and 100 normal controls were examined. mt-DNA was extracted from whole blood and examined by 6 primers for existence of mitochondrial deletions. We also amplified and sequenced the mtDNA HVS-I by standard sequencing techniques. mtDNA deletions were observed in 54.1% (13/24) of patients (8.9 kb deletion in all samples, 5.0 kb in one and 7.5 kb in two patients), representing mtDNA damage which may be due to oxidative stress in mitochondria. Our results showed that there is no association between mtDNA haplogroups and AT. This data may indicate involvement of mitochondrial damage in the pathogenesis of AT.

P06.181**Role of mitochondria in Friedreich Ataxia**

M. Houshmand;

NIGEB, Tehran, Islamic Republic of Iran.

Friedreich's Ataxia (FA) is the commonest genetic cause of ataxia and is associated with the expansion of a GAA repeat in intron 1 of the frataxin gene. Mitochondrial DNA (mtDNA) could be considered a candidate modifier factor for FA disease, since mitochondrial oxidative stress is thought to be involved in the pathogenesis of this disease. The expansion (GAA) repeat in the first intron causes decreased frataxin expression by interfering with transcription. Activity of mitochondrial respiratory chain complex I (measured as NADH ferricyanide reductase) and intracellular ATP measurement was performed on lymphocyte of FA patients (n=12) and control subjects (n=25). Common deletion were identified and confirmed by southern blotting in FA patients. Homozygous GAA expansion was found in 21 (84%) of all cases. In four cases (16%), no expansion was observed, ruling out the diagnosis

of Friedreich's ataxia. In cases with GAA expansions, ataxia, scoliosis and pes cavus, cardiac abnormalities and some neurological findings occurred more frequently than in our patients without GAA expansion. mtDNA deletions were present in 76% of our patients representing mtDNA damage, which may be due to iron accumulation in mitochondria. Our findings showed that complex I activities and intracellular ATP were significantly reduced ($P=0.001$) in patients compared with control. 8.6 kb deletion in mtDNA was detected in all of patients by multiplex PCR but Southern blot analysis confirmed the presence of deletion in 9 of 12 patients.

The developmental changes in mitochondrial DNA content per cell in human liver and muscle tissue during gestation

M. Pejznochova, M. Magner, M. Tesarova, H. Hansikova, J. Zeman;
Faculty of Medicine, Prague, Czech Republic.

The process of oxidative phosphorylation system (OXPHOS) maturation is still not fully understood during the development of the fetus. Since all mammalian cells except erythrocytes depend on mitochondrial ATP production, knowledge of the OXPHOS maturation is an essential query. Our previous study demonstrated significant changes of mitochondrial DNA (mtDNA) content in cord blood leukocytes during the gestation. To further understand the role of mtDNA content in human prenatal development, we analyzed mtDNA amount in human fetal liver and muscle tissue during the gestation.

DNA was isolated from 26 liver and 26 muscle tissue samples obtained at autopsy from miscarriages between 13th and 28th week of gestation. The mtDNA amount was analyzed by the real-time PCR method using SybrGreen I (Chromo4, Bio-Rad).

The significant positive correlations were found between the gestational age and the relative mtDNA amount in fetal liver tissue ($r = 0,56$; $p < 0,01$) and mtDNA amount in fetal muscle tissue ($r = 0,61$; $p < 0,01$), respectively.

In both fetal liver and muscle tissue, mtDNA content per cell was increasing with onward fetal development. These results are in accordance with the few of studies but there was never analysed as numerous set of tissue samples as in our study. Presently we analyze a relation among changes of the mtDNA content during prenatal development and the transcription activation of some mtDNA maintenance factors (NRF1, TFAM) in the same set of tissue samples.

P06.183

Duplication analysis of the DMD gene by MLPA technique

J. Juan, M. Rodríguez, L. González-Quereda, L. Sedano, E. del Río, E. Tiz-zano, M. Baiget, P. Gallano;
Hospital Sant Pau, Barcelona, Spain.

Duchenne and Becker muscular dystrophies (DMD/BMD) are the most common form of dystrophinopathies, with a reported incidence of 1:3500 and 1:18000 birth males, respectively. About 65% of DMD/BMD cases are attributable to large deletions of the DMD gene, whereas the remaining cases are caused by duplications or point mutations of the gene. The exact frequency of these two last types of mutations is not known. The detection of duplications in Duchenne (DMD)/Becker muscular dystrophy (BMD) has long been overlooked. Recent techniques such as multiplex ligation-dependent probe amplification (MLPA) have simplified the detection of duplications.

We report here 20 duplications recently detected in BMD/DMD unrelated patients using MLPA technique. Although the reading frame rule could be applied in most patients, it was not applied in 2 DMD patients. Special care was taken with one patient presenting non contiguous rearrangements: **c.[2623_2950dup; 11047_11055del]**, a duplication of exons 21 and 22, and a deletion of exon 79. The majority of the duplications clustered towards 5' end of the gene.

The availability of new quantitative methods including MLPA has aroused interest in duplication detection analysis in DMD gene. The MLPA technique enables us to test all the 79 exons, allowing the detection of a significant number of new duplications. We report the duplications in patients in whom a previous molecular screening did not show any deletion.

P06.184

A novel MLPA technique for copy number analysis on small amounts of DNA

K. M. Sorensen¹, P. S. Andersen¹, L. A. Larsen², M. Schwartz³, J. Schouten⁴, A. Nygren⁴;

¹Statens Serum Institut, Kbh. S, Denmark, ²Wilhelm Johannsen Centre of Functional Genome Research, Kbh. N, Denmark, ³Department of Clinical Genetics, Rigshospitalet, Kbh. N, Denmark, ⁴MRC Holland, Amsterdam, The Netherlands. Background: The MLPA technique was introduced in 2002 as a new sensitive technique for relative quantification of up to 40 different nucleic acid sequences in a single, extremely easy to perform, reaction. Today the technique is routinely used for copy number analysis in various syndromes and diseases.

Aim: The aim is to exploit the potential of MLPA in areas where DNA material is limited. The DNA concentration required in standard MLPA analysis is not attainable from dried blood spot samples (DBS) often used in neonatal screening programs. By redesigning the MLPA probes we attempt to perform MLPA analysis on small amounts of DNA.

Patients and methods: 7 patients with Congenital Adrenal Hyperplasia (CAH) were used in this study. DNA was extracted from both whole blood and DBS, and subjected to MLPA analysis using SALSA P050B probemix (normal and modified probes). Results were analysed using GeneMarker™ (Softgenetics) and Excel spreadsheet analysis.

Results: We found a 99.6% concordance of the results obtained with DNA extracted from whole blood compared with DNA from dried blood spot samples.

Conclusion: We demonstrate that MLPA reactions with modified probes are functional and reliable at very low DNA concentrations. This broadens the diagnostic perspectives of biobanks consisting of DBS allowing for CNV analysis in general and particularly testing for CAH.

P06.185

Is SNPs in MSX1 gene playing a role in the development of cleft palate (CP) or cleft lip/palate (CLP)?

B. Lace¹, I. Vasiljeva², I. Dundure¹, B. Barkane³, I. Akota³, A. Krumina¹;

¹Dept. of Med.Biology and Genetics, Riga, Latvia, ²Biomedical study and research centre, Riga, Latvia, ³RSU, Institute of Stomatology, Riga, Latvia.

MSX1 gene role in the development of cleft palate and cleft lip/palate and oligodontia has been confirmed in several studies. *MSX1* (member of muscle segment homeobox gene family) gene expression is related to transcription repression during embryogenesis and craniofacial development.

It was confirmed, that mutations in *MSX1* gene approximately in 2% can cause nonsyndromic CL/CLP. Results were replicated in studies involving different populations.

Objective of our study was to evaluate role of mutations and also SNPs in *MSX1* gene in Latvian nonsyndromic CP and CLP patients.

Materials and methods. DNA from 101 persons with CP or CLP was extracted from venous blood (CP- 21, CL/CLP-80). Promoter region, exons, introns boundaries and 3' UTR region were sequenced.

Results. One mutation 457G>C in exon 2 and 16 SNPs in *MSX1* gene was identified. Thirteen of them were described earlier and were commonly met in Caucasian populations, three of them were not observed in previous studies.

Interestingly two SNPs, who were localized in intron 1 451+(41-51)del and 3'UTR 3969 A>G showed higher frequencies in nonsyndromic CLP patients (0.41;0.38 respectively) than in CP patients (0.17;0.14). Conclusions. Considerable difference observed between SNPs in patients with CP and CLP, who had localised in the non-coding regions, raise suggestions about their possible role in the development of nonsyndromic CLP.

P06.186

Association of C677T and A1298C polymorphisms in the Methylenetetrahydrofolate reductase (MTHFR) gene with cervical dysplasia in Yucatan, Mexico

L. J. Gonzalez-Herrera¹, P. Rodriguez-Morales¹, V. Fernández-Gonzalez¹, I. Rosado-Lopez², T. Canto de Cetina¹;

¹Universidad Autonoma de Yucatan, Merida, Mexico, ²Clinica de displasias del Hospital O'Horán, Merida, Yucatan, Mexico.

The influence of MTHFR activity on DNA methylation, synthesis and repair, presents MTHFR as a candidate cancer-predisposing gene.

Polymorphisms C677T and A1298C in MTHFR gene have been associated with a varying risk of cervical dysplasia. We evaluated the association of C677T and A1298C polymorphisms at the MTHFR locus with cervical intraepithelial neoplasia (CIN) or cervical cancer (CC) in Yucatan, Mexico, where CC is the first most common cancer. A case-control study was performed. Cases were 84 DNA samples of women with CIN or CC (47 CIN I, 14 CIN II, 7 CIN III, 9 invasive cervix cancer and 7 cervical cancer) and controls were 127 DNA samples of women who were negative to PAP. Polymorphisms were determined by PCR-RFLPs. Allele and genotype frequencies were compared between cases and controls in EpiInfo software (OR, IC 95%). Genotype frequencies in cases and controls were according to Hardy-Weinberg expectations ($p > 0.33$) for both polymorphisms. For C677T-MTHFR polymorphism, allele and genotype frequencies were not significantly different between cases and controls ($p > 0.05$), whereas for A1298C polymorphism, frequency of allele C was significantly different between cases and controls ($P = 0.0325$), suggesting an association of 1298C allele with a reduced risk to CIN or CC (OR 0.51, IC 0.25-0.98). Stratification according to phenotype showed that heterozygous genotype AC and allele C were associated only with CIN I, $p = 0.023$ and $p = 0.0180$, respectively. Our results suggest that polymorphism A1298C in MTHFR gene is associated to CIN I as a protective factor to develop more severe dysplasias in Yucatan population.

P06.187

MTHFR gene polymorphisms and neural tube defects - the incidence in Slovak population.

J. Behunova¹, L. Klimcakova², D. Potocekova³, L. Podracka³;

¹I. Department of Pediatrics, Safarik University Children Hospital, Kosice, Slovakia, ²Department of Medical Biology, Safarik University School of Medicine, Kosice, Slovakia, ³Department of Informatics, Safarik University School of Medicine, Kosice, Slovakia.

Neural tube defects (NTD) belong to the most debilitating birth anomalies. The geographical & historical differences in NTD incidence vary tremendously - from 8/1000 till 0,21/1000. Discovery of folic acid's preventive effect influenced the research of NTD genetic background focusing to the genes whose products take part in the folate metabolism. One of the most important enzymes involved is MTHFR - methylenetetrahydrofolate reductase whose common termostable variant C677T in homozygote state reduces MTHFR activity to 30-40% of norm. Lowered activity might play a crucial role in early embryonic development. That is why this polymorphism has been investigated in various NTD populations and in some of them the mutant variant has been proven to be a risk factor for failure of neural tube closure.

In Slovakia with average natality about 50 000 liveborn per year, there are annually 10-20 children born with NTD (0,28/1000) - mostly with meningomyelocele. When including stillborn and selective abortions, the number of NTD pregnancies is even higher (0,35-0,52/1000). To evaluate genetic risk of folate metabolism variations in our population, we investigated MTHFR gene polymorphisms C677T and A1298C in 91 Slovak children with NTD. The obtained results of genetic analyses are being compared with those from 300 newborns from Slovak population. Currently we got the results of C677T polymorphism analysis, which, however, did not show any significant difference in the prevalence of TT genotype or T allele between the patients and controls (OR = 1,22 [95% CI 0,5-2,9]; OR = 1,16 [CI 0,8-1,7] respectively).

Turku, Turku, Finland, ¹¹Department of Clinical Neuroscience, Karolinska Institutet at Karolinska University Hospital-Huddinge, Stockholm, Sweden, ¹²Department of Neurology, Ullevål University Hospital, Oslo, Norway, ¹³Institute of Immunology, Rikshospitalet University Hospital, Oslo, Norway, ¹⁴Department of Neurology, Faculty Division Ullevål University Hospital, University of Oslo, Oslo, Norway, ¹⁵Department of Neurology, Center for Neurologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, United States, ¹⁶Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

MS is a chronic inflammatory disease of the CNS with complex inheritance. The etiology of MS is poorly understood. Large case-control association studies primarily aim to identify common variants contributing to pathogenesis of common traits. To tackle rare alleles contributing to the molecular background of MS, alternative strategies are needed. One approach is to use special populations with a founder effect and isolation, where one could hypothesize allelic enrichment. Such a unique high-risk region for MS is the Southern Ostrobothnia in Finland, where both the prevalence and familial occurrence are exceptionally high. We have performed a high-resolution genome-wide SNP study using the Illumina HumanHap300 panel to monitor, which alleles are shared by 72 familial MS cases from this high-risk isolate. Genealogical studies showed that majority of these patients are distantly related. Genotype data of 68 IBS-matched Finns was used as controls. We first focused on the 45Mb region on 5p, for which we have shown linkage in Finnish MS-families. The haplotype analysis over this region revealed association with one haplotype, and the finding was validated in a larger study set from the high-risk region (OR 2.73, $p = 3.2 \times 10^{-6}$). The identified risk-haplotype flanks two genes, C7 (complement component) and FLJ40243 (predicted protein). Suggestive association with C7-FLJ40243 alleles and MS was also seen in more heterogeneous populations. Interestingly, plasma C7 protein levels and total complement activity were observed to correlate with the risk-haplotype identified. Sequencing of the 31kb C7 region did not reveal an obvious causative variant. Sequencing of FLJ40243 is in progress.

Genetic polymorphisms of IL12B and VDR in association with multiple sclerosis in russians

S. Babenko¹, J. Orlova², V. Alifirova², V. Pusyrev^{1,2};

¹Institute of Medical Genetics, Tomsk, Russian Federation, ²Siberian State Medical University, Tomsk, Russian Federation.

We investigated genotypes and haplotypes frequencies for VDR and IL12B polymorphisms in case-control studies of MS in 92 Russian inhabitants of Tomsk region. Our results show significant differences of alleles and genotypes frequencies in the distribution of the polymorphism 1188A>C IL12B between MS patients and controls ($p < 0.01$ - for frequencies of alleles). The CC genotype frequency was three times higher in patients as compared to the controls (6.7% and 2.1%, respectively, $p < 0.01$). The allele C in MS patients was associated with shorter duration of the first remission ($p = 0.04$) which was 1.80 ± 0.28 in those with the C allele and 3.05 ± 0.56 in other patients. An association of VDR T/t polymorphism with diseases were observed ($p < 0.05$). This marker was also associated with amount of eosinophils in MS patients ($p < 0.05$). On examination of VDR haplotype, including a B/b, F/f and T/t polymorphism, we reveal the difference between distribution in case and control ($p = 0.03$). We demonstrate that the haplotype Bft significantly higher observed at MS patients and btT at healthy person ($p < 0.05$). Received data allow suggests that the allele 1188 C of gene IL12B and Bft haplotype of VDR gene could increase susceptibility to MS and have influence on clinical manifestation of diseases in Russians.

P06.190

Association of IL2RA/CD25 polymorphisms with susceptibility to multiple sclerosis

M. Fuencisla, M. Fedetz, D. Ndagire, A. Alcina;

Instituto de Parasitología y Biomedicina López Neyra, Armilla/Granada, Spain. Multiple sclerosis (MS) is a prototypic idiopathic neurodegenerative disease of the central nervous system (CNS) whose primary mechanism of injury is by inflammatory/autoimmune demyelination and, to variable degree, axonal damage. As a complex disease both environmental and genetic factors contribute to its pathogenesis. As part of an ongoing search for genes associated with MS we have tested the candidate gene IL2RA, which encodes the interleukin-2 receptor (IL2R)

alpha subunit of the high-affinity IL2R complex. Four polymorphisms located in this gene that could be implicated in functional modifications of IL2RA activity were genotyped by PCR/RFLP in a case-control study. We found an association of the *IL2RA4T* allele, located at the 3' untranslated region (3'-UTR) of the gene, with increased susceptibility to MS (OR= 1.24, 95% C.I. = 1.01-1.53, P = 0.04). The International Multiple Sclerosis Genetics Consortium has also found an association between MS and alleles of the IL2RA by a Genomewide Study. Association of polymorphisms at the IL2RA in other diseases of autoimmune origin such as type I diabetes (T1D) and Graves' disease has also been reported. Functional studies will be required to uncover the causal SNPs and to determine what effects they have on the IL2RA protein and its role in MS.

P06.191

Association study of rs6897932 SNP in IL7R α Gene with Multiple Sclerosis in Iranian population

M. Heidari¹, M. Behmanesh¹, M. Sahraiyar²;

¹Department of Genetics, School of Basic Sciences, Tarbiat Modares University, Tehran, Islamic Republic of Iran, ²Department of Neurology, School of Medical Science, Tehran University, Tehran, Islamic Republic of Iran.

Multiple Sclerosis is an autoimmune, demyelinating disease with a strong genetic component, affecting 1/1000 people; mostly young adults; in western countries and about 35,000 in Iran. Previous genetic risk studies have failed to identify consistently linked genes outside of HLA on chromosome 6p. In recent studies allelic association of a polymorphism in the gene encoding Interleukin 7 receptor α chain (*IL7R α*) reported as a significant risk factor in M.S. *IL7R α* gene located on 5p13, spans 8 exons and encodes IL7R α protein on B and T lymphocytes. Variable expression of IL7R α splicing isoforms controls amount of IL7 absorption. From 14 SNPs detected in *IL7R α* gene, rs6897932 in exon 6 and rs987107 in intron 6 seems to change the ratio of soluble and transmembrane isoforms of receptor. In this study we investigate the association of rs6897932 SNP by designed a Multiplex PCR in M.S patients and normal controls.

P06.192

Investigation of relationship between NDUFS1 gene and Multiple Sclerosis

Z. Baratieh Najafabadi^{1,2}, M. H. Sanati², M. Houshmand³, M. Rezaei-Tavirani¹;

¹Cellular & Molecular Biology Department, Khatam University, Tehran, Islamic Republic of Iran, ²National Institute for Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran, ³Genetic section, Special Medical Center, Tehran, Islamic Republic of Iran.

Multiple sclerosis (MS) is the most common inflammatory demyelination disease of the central nervous system. Preferential maternal transmission in familial cases and the occasional association of MS and LHON, suggests on involvement of mitochondrion (mtDNA, electron transport chain enzymes) in the MS etiology. Besides, in recent study, researchers found a relationship between biochemical defect in complex I enzyme activity and pathogenesis of MS.

Complex I is the largest complex of mitochondrial respiratory chain that contains 43 subunits. Thirty six subunits being encoded by nuclear and 7 subunits being encoded by mitochondrial DNA. As mutations in *NDUFS1* gene were reported previously in patients afflicted by complex I deficiency and also biochemical defect in complex I enzyme was found in Iranian MS patients, we encouraged to study relationship between *NDUFS1* gene and MS disease in Iranian MS patients. This gene is a nuclear gene encoding catalytic subunit of complex I enzyme. So we analyzed four exons of *NDUFS1* gene (8, 9, 15 & 19) that some mutations are identified in patients with complex I deficiency. We amplified these exons by PCR and screened them for finding any variations by SSCP method. Suspicious samples for mutation were sequenced. Finally, in our samples, we could not find any variation in these regions of *NDUFS1* gene. To identify the relation between *NDUFS1* gene and complex I with MS disease, further analyzes should be done on other exons of this gene and also other genes of complex I subunits.

P06.193

The role of the Protein Kinase C Alpha (*PRKCA*) gene in the predisposition to multiple sclerosis in the Italian population

C. Dall'Osso¹, G. Rizzo¹, D. Gemmat², P. Zamboni³, M. D. Benedetti⁴, A. Salviati⁵, P. Invernizzi⁶, S. Bonissoni⁶, L. Bergamaschi⁶, S. Duga¹, M. L. Tenchini¹, R. Asselta¹;

¹Department of Biology and Genetics for Medical Sciences, University of Milan, Italy, Milan, Italy, ²Center Hemostasis & Thrombosis, University of Ferrara, Ferrara, Italy, ³Vascular Diseases Center, University of Ferrara, Ferrara, Italy, ⁴Department of Neurological and Vision Sciences, Section of Clinical Neurology, University of Verona, Verona, Italy, ⁵Department of Neurology, Ospedale Maggiore, Novara, Italy, ⁶Department of Medical Sciences and IRCAD, Eastern Piedmont University, Novara, Italy.

Multiple sclerosis (MS) is a chronic neurological disorder characterized by multicentric inflammation, demyelination, and axonal damage.

Besides the well-known HLA region, only 2 other loci (5p, 17q) have been so far linked and associated in at least 2 populations. The 17q region showed the most significant association with the Protein Kinase C Alpha (*PRKCA*) gene in Finns; this association was replicated in Canadian and UK populations, in which specific "risk haplotypes" were identified. Moreover, *PRKCA* transcript levels were shown to be higher in CD4- mononuclear cells of MS patients carrying the risk haplotypes, suggesting a contribution of *PRKCA* regulatory mechanisms in the pathogenesis of MS.

In this study, we analyzed the role of *PRKCA* in the predisposition to MS in a cohort of 294 Italian cases and in an equal number of age- and sex-matched controls. An association analysis was performed genotyping 3 STR and 12 SNP markers covering the whole gene. A weak association (P=0.032) with the STR located in the *PRKCA* promoter was found. This region was further analysed by sequencing the first 424 bp of the promoter and the entire exon 1 of the gene in all MS cases and controls, but no genetic variants specific for MS cases were identified. Moreover, we identified a novel microRNA (hsa-mir-634) located in *PRKCA* intron 15, whose expression levels do not correlate with those of *PRKCA*. The potential role of hsa-mir-634 in the pathogenesis of MS is under investigation.

P06.194

Genome wide linkage scan for loci of musical aptitude in Finnish families: Evidence for a major locus at 4q22

I. Järvelä¹, K. Pulli¹, K. Karma², R. Norio³, P. Sistonen⁴, H. H. H. Göring⁵;

¹University of Helsinki, Helsinki, Finland, ²Sibelius Academy, Helsinki, Finland, ³The Family Welfare Federation, Helsinki, Finland, ⁴The Finnish Red Cross, Helsinki, Finland, ⁵Southwestern Foundation for Genetic Research, San Antonio, TX, United States.

Background: Music perception and performance are comprehensive human cognitive functions and thus provide an excellent model system for studying human behaviour and brain function. However, the molecules involved in mediating music perception and performance are so far uncharacterized.

Objective and methods: We have applied molecular and statistical genetic approaches to unravel the biological background of music perception. We recruited 15 Finnish multigenerational families (with a total of 234 family members) via a nationwide search and defined the phenotype of all family members using three tests used in defining musical aptitude: a test for auditory structuring ability (Karma Music test; KMT) commonly used in Finland, and the Seashore pitch and time discrimination subtests (SP and ST respectively) used internationally. We calculated heritabilities and performed a genome wide variance components-based linkage scan using genotype data for 1000 microsatellite markers.

Results: The heritability estimates were 42% for KMT, 57% for SP, 21% for ST and 48% for the combined **music test scores**. Significant evidence of linkage was obtained on chromosome 4q22 (LOD 3.33) and suggestive evidence of linkage at 8q13-21 (LOD 2.29) with the combined **music test scores** using variance component (VC) linkage analyses. The major contribution for the 4q22 locus was obtained with KMT (LOD 2.91). Interestingly, a positive LOD score of 1.69 was shown at 18q, a region previously linked to dyslexia (DYX6), using combined **music test scores**. Conclusion: Our results show that there is a genetic contribution to musical aptitude that is likely to be regulated by several predisposing genes/variants.

P06.195

Blind assessment of High Resolution DNA Melting Analysis as a tool for mutation screening

S. Dwyer, N. M. Williams, N. Norton, M. J. Owen, M. C. O'Donovan; Cardiff University, Cardiff, United Kingdom.

High resolution DNA melting analysis can be used to identify DNA variants in PCR amplicons. Using a LightScanner™ (Idaho Technologies) we have developed a single analysis protocol that allows the efficient screening of all PCR amplicons by high resolution DNA melting analysis to detect unknown DNA variants. In a blind assessment of our protocol we screened 14 different amplicons in 14 individuals and identified 23/23 sequence variants, distinguishing 100% of those where an individual was heterozygous for at least one site but only 57% of those individuals who were homozygous for a variant. In a direct comparison, analysis using the Wave® DHPLC system distinguished 96% of the heterozygous sequence changes and only 14% of the amplicons that differed by a homozygous sequence change. Our data suggests that high resolution DNA melting analysis using the LightScanner™ can be a highly sensitive mutation detection, which because of its low cost and high speed could potentially allow more comprehensive re-sequencing analysis of candidate genes.

P06.196

Inter-laboratory diagnostic validation of Conformation Sensitive Capillary Electrophoresis.

C. J. Mattocks¹, G. Watkins², T. Janssens², G. Matthijs², E. Bosgoed³, K. van der Donk³, H. Scheffer³, B. Pot⁴, J. Theelen⁵, T. Aspholm⁶, N. C. P. Cross¹; ¹National Genetics Reference Laboratory (Wessex), Salisbury, United Kingdom, ²Center for Human Genetics (EuroGentest), Leuven, Belgium, ³Dept. Human Genetics, Radboud University, Nijmegen, The Netherlands, ⁴Applied Maths, Gent, Belgium, ⁵Applied Biosystems, Europe, The Netherlands, ⁶Applied Biosystems, Europe, Norway.

Much of the work in diagnostic laboratories involves scanning for unknown mutations in particular regions of interest. Whilst this work can be done by sequencing, it is often faster and more economic to use an indirect pre-screen to identify fragments containing variations. Such methods need stringent validation to ensure diagnostic accuracy. Conformation Sensitive Capillary Electrophoresis (CSCE) is a rapid and sensitive method for indirect mutation scanning based on the principle that homoduplex and heteroduplex DNA have different mobilities when subjected to electrophoresis. We have performed a two phase diagnostic validation of this method across three laboratories. Phase I was used to define the performance characteristics of CSCE over a range of critical parameters including the nature of the mutation, fragment length and base composition, as well as a range of electrophoresis variables. Phase II comprised a blinded and randomised investigation of >400 different BRCA1 and BRCA2 variations to determine the diagnostic accuracy of both CSCE itself and a Bionumerics software plug-in used for the automated interpretation of heteroduplex patterns. We will report the findings of these studies and discuss their general applicability to diagnostic mutation scanning using CSCE.

University Hospital, Oslo, Norway, ¹⁴The Broad Institute of Harvard and MIT, Cambridge Center, Cambridge, MA, United States, ¹⁵Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

Multiple sclerosis (MS) is a complex disease manifesting as a chronic inflammation in the central nervous system. It is also commonly classified as an autoimmune disease (AID) and typical of many AIDs shows strong linkage and association to the HLA locus. In addition to HLA, AIDs are likely to share also other genetic risk factors. Recently, SNPs in the 3' region of the MYO9B gene have been reported to associate with celiac disease, inflammatory bowel disease, rheumatoid arthritis and systemic lupus erythematosus. The myosin IXB protein is an unconventional myosin with a Rho-GTPase activity. It is involved in actin cytoskeleton remodeling and is thereby a potential regulator of tight junctions and epithelial and endothelial permeability. High expression in leukocytes also suggests an immunological function. We tested the association of MYO9B variants with MS in four Northern European populations. Family-based association analyses (TDT, Gamete competition) using 18 SNPs covering MYO9B in 730 Finnish MS families showed no evidence for association. In order to increase the power to detect variants with smaller effect size we further genotyped 11 SNPs, 2 of which have previously shown association to other autoimmune diseases, in a set of 2511 MS patients and 2801 population controls from Finland, Denmark, Norway and Sweden. However, no association was observed in the case-control analysis, nor when stratifying for the previously identified genetic MS risk factors at HLA and PRKCA loci. Our results thereby do not support a major role for MYO9B variants in multiple sclerosis.

P06.198

Functional analysis of missense mutations in the Myocyte Enhancer Factor 2A (MEF2A) gene do not support their causal role in the pathogenesis of myocardial infarction

I. Guella¹, V. Rimoldi¹, P. A. Merlini², R. Asselta¹, E. M. Paraboschi¹, M. Franco-lini³, F. Peyvandif⁴, D. Ardissino⁵, P. M. Mannucci⁶, S. Duga¹; ¹Dept. of Biology and Genetics for Medical Sciences, University of Milan, Milan, Italy, ²Niguarda Ca' Granda Hospital, Milan, Italy, ³Dept. of Medical Pharmacology, University of Milan, Institute of Neuroscience - CNR - Cell. Mol. Pharmacology Section, Milan, Italy, ⁴A. Bianchi Bonomi, Hemophilia and Thrombosis Center, University of Milan and Dept. of Medicine and Medical Specialties, IRCCS Maggiore Hospital, Mangiagalli and Regina Elena Foundation, Milan, Italy, ⁵Maggiore Hospital, University of Parma, Parma, Italy.

Coronary artery disease (CAD) and its most severe complication myocardial infarction (MI), are the leading causes of death in Western countries. Mutations in the MEF2A gene, a member of the myocyte enhancer factor-2 (MEF2) family of MADS-box transcription factors, have been reported in patients with CAD/MI. In particular, a 21-bp deletion and 3 missense mutations were demonstrated to affect MEF2A activity either by reducing its transcriptional activity or by impairing its nuclear translocation. However, the association of MEF2A with CAD/MI was not confirmed by other studies.

In this work, we analyzed the role of MEF2A in the pathogenesis of MI in a large cohort (1785 males, 223 females) of Italian patients with premature MI (<45 y) and in an equal number of age- and sex-matched controls.

Firstly, the 21-bp-del was searched in the whole study cohort: it was found in 5 cases and was absent in controls (P=0.027). Mutational screening of exon 8 (containing all known mutations) was performed in all 4016 individuals by DNA sequencing: 5 novel and 2 previously reported missense mutations were found. All identified mutations, either new or previously reported, were then functionally characterized by *in-vitro* expression in HeLa cells. Functional studies evidenced neither alterations in the transactivating properties (all mutants) nor defects in the nuclear localization (21-bp-del). An association analysis performed on 3 STRs at the MEF2A locus showed no significant association with premature MI. These data do not confirm the role of genetic variations in the MEF2A gene in the pathogenesis of MI.

Identification of a novel locus for shortsightedness (myopia) on chromosome 2q37 in three multigenerational Australian families

M. Schache^{1,2}, C. Y. Chen^{1,2}, K. K. Pertile^{1,2}, P. Garoufalis^{1,2}, M. Dirani^{1,2}, A. J. Richardson^{1,2}, P. N. Baird^{1,3};

¹Centre for Eye Research Australia, East Melbourne, Australia, ²Vision Co-

operative Research Centre, Sydney, Australia, ³Vision Cooperative Research Centre, Sydney, Australia.

Myopia (short sightedness) is a complex trait influenced by both genetic and environmental factors. To date, fifteen myopia susceptibility loci (MYP1-15) have been identified but no definitive gene pinpointed. This study reports the identification of a novel locus for myopia located on chromosome 2q37 adjacent to, but not overlapping, MYP12. Three large multigenerational families with autosomal dominant myopia were recruited into this study. These families consist of 49 participants (35 affected) each of which has undergone a comprehensive ophthalmic examination. Individuals with other eye diseases that may affect vision such as glaucoma and keratoconus have been excluded. A genome-wide scan was performed using 400 microsatellite markers spaced an average of 10 cM apart. Using MERLIN, a multipoint parametric LOD score of 2.37 was calculated on chromosome 2q37. This LOD score increased to 3.43 with nonparametric analysis. The 1 LOD support interval initially suggested that this region may overlap with a known myopia susceptibility locus, MYP12. However, further fine mapping and haplotype analysis narrowed down the critical region to a 0.8cM region that no longer overlaps MYP12. Hence, a novel locus for myopia was identified on chromosome 2q37 between markers D2S1397 and D2S2968. Sequencing of all known and hypothetical genes in the region is underway in order to identify DNA sequence variants associated with myopia.

Rapid Analysis of Myotonic Dystrophy 1 using Quantitative Fluorescent and Long PCR

M. Skrzypczak, S. Schinkel, A. Gross, U. G. Froster;

Institute of Human Genetics, University of Leipzig, Leipzig, Germany.

Diagnostics of myotonic dystrophy 1 (DM1) are based on the identification and determination of CTG repeat expansion in the DMPK-gene. This is usually done by Southern blot analysis - a time consuming and very laborious technique requiring high molecular weight DNA. Our study aimed at developing a highly sensitive, rapid and economical molecular analysis characterizing the CTG repeat region of DMPK-gene based on a two step PCR protocol. Therefore we analyzed 105 patients with the clinical diagnosis of myotonic dystrophy 1 derived from the DNA bank of the Institute of Human Genetics, University of Leipzig (Germany) who had already been tested by Southern blot analysis. 60 patients had one normal and one mutated allele of up to 2700 CTG repeats. 12 probands were homozygous for normal CTG repeat length. In the remainder (33 patients) two different normal alleles of up to 37 CTG repeats were present. Firstly, for the detection of alleles of up to 100 repeats quantitative fluorescent (QF) amplification with primers flanking the repeat region and 2 reference genes for standardization were used. With these methods it was possible to identify both homozygous and heterozygous DM1 alleles. Secondly, long PCR was just performed if a single wild type allele was detected by giving a QF-PCR-signal only half as intense. The results of using QF and long PCR indicate high accuracy in comparison to Southern blot analysis. We conclude that our new rapid analysis is reliable for genetic testing of DM1 patients.

P06.201

A case of nail patella syndrome with severe renal involvement in two sisters

J. Reiterová¹, J. Štekrová², M. Urbanová², M. Merta¹;

¹Department of Nephrology, Prague, Czech Republic, ²Institute of Biology and Medical Genetics, Prague, Czech Republic.

Nail-patella syndrome (NPS) is characterized by developmental defects of dorsal limb structures, nephropathy, normal tension glaucoma and sensorineural hearing impairment. NPS is a rare disorder with autosomal dominant mode of inheritance and is caused by heterozygous mutations in the transcription factor LMX1B. Proteinuria was described in 21% of individuals with NPS. Nevertheless, renal failure in a rare event.

A 38-year-old woman was admitted to our nephrology unit because of severe nephrotic syndrome. The diagnosis of NPS was established because of fingernail dysplasia, hypoplastic patellae, iliac horns and dislocation of the radial head. She underwent renal biopsy with the finding of proliferative glomerulonephritis at the age of 7 years. Her sister with NPS suffered under severe nephrotic syndrome and renal

insufficiency which lead to renal failure at the age of 13 years. Her father with NPS suffers only under mild proteinuria at the of 70 years. All 8 exons of the LMX1B gene were amplified by polymerase chain reaction with described primers and then sequenced on an automatic fluorescent sequencer.

The missense mutation in exon 4 (c.599 G>A, p.Arg200Gln) of the homeodomain of the LMX1B gene was detected. This mutation was detected in the examined patient with renal failure as well as in her father with mild renal involvement. This missense mutation was already described in more families with NPS but only in individuals without proteinuria. The patient is nowadays dependent on peritoneal dialysis. To conclude, we describe a case of NPS with severe renal involvement.

Serum levels of some IgG and IgM type natural autoantibodies are differently regulated in carriers and non-carriers of HLA-DR16

G. Füst¹, É. Pozsonyi², B. György³, T. Berk⁴, Z. Bánlaki¹, E. Buzás³, K. Rajczy², Z. Prohászka¹, Á. Szilágyi¹;

¹3rd Dept Intern Med, Budapest, Hungary, ²National Blood Transfusion Service, Budapest, Hungary, ³Institute of Genetics, Immunobiology and Cell Biology, Semmelweis University, Budapest, Hungary, ⁴Department of Immunology and Biotechnology, Pécs University, Pécs, Hungary.

Natural autoantibodies (IgM or IgG type autoantibodies (Abs) present in the sera of most healthy individuals) are most important participants of the immune response. Little is known, however, on the genetic regulation of their plasma levels in human beings. Therefore we determined the concentrations of the IgM and IgG type antibodies against certain conserved self antigens (60 kD heat shock proteins (hsp60), citrate synthase (CITS), and chondroitine sulphate (CONS) in the sera of 78 healthy individuals out of a family study with known alleles of several polymorphisms in the class I, class III and class II regions of main histocompatibility complex (MHC, HLA in humans). We found significantly lower serum levels of the IgM type CITS (p=0.029) and COTS (p=0.026) Abs in the carriers than non-carriers of the HLA-DR16 allele. Even stronger differences were found when levels of two Abs were considered. Frequency of the DR16 alleles were significantly higher in subjects with 1 or 2 low (in the lowest quartile) CITS/COTS Abs (p=0.002), CITS-hsp60 Abs (p=0.001) and COTS/hsp60 Abs (p=0.003) as compared to those with normal Ab titers for both antigens. Abs against these antigens exhibited strong positive correlation (p=0.01) By contrast, concentrations of IgG type anti-hsp60 Abs was significantly higher (P=0.008) in the carriers than non-carriers of the HLA-DR16 allele. Similar differences were found when carriers and non-carriers of the HLA-DR16-DQ5 haplotype were considered. These novel observations indicate that not only induced, acquired but natural, inborn immune response as well is regulated by the MHC.

Cytokine (TNF-alpha, TGF-beta1, IL-10, IFN-gamma, IL-6) genotyping in Turkish Children with nephrotic syndrome: A brief report

S. Pehlivan¹, K. Ozdillil², T. Sever¹, Y. Duvarci³, M. Buyukcelik⁴, F. Savran-Oguz³, S. Oguzkan Balci¹, M. Carin³, A. Balat⁴;

¹University of Gaziantep, Faculty of Medicine, Department of Medical Biology, Gaziantep, Turkey, ²Halic University, Institute of Health Science, Istanbul, Turkey, ³Istanbul University, Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey, ⁴University of Gaziantep, Faculty of Medicine, Department of Pediatric Nephrology, Gaziantep, Turkey.

Considering the recognized influence of cytokines in nephrotic syndrome (NS) development, the aim of this study was to investigate whether this disease may be associated with polymorphisms of the IL-6, IL-10, IFN-gamma, TGF-beta1 and TNF-alpha genes.

Forty-six children with NS, and 46 age- and sex-matched healthy controls were tested for 8 polymorphisms in 5 different genes. DNA was extracted from whole blood by standard salting out method. Cytokine genotyping was performed by polymerase chain reaction sequence-specific primer methods. The polymorphisms analyzed in the present study were IL-6 (-174 G/C), IL-10 (-1082 A/G, -819 T/C, -592 C/A), IFN-gamma (+874 A/T), TGF-beta1 (+10 T/C; +25 C/G) and TNF-alpha (-308 G/A).

The distribution of genotypes and allele frequencies were compared with the groups. No statistically significant differences were observed in allele distribution comparing NS and healthy groups ($P>0,05$). The haplotypes of IL-10 and TGF-beta1 were compared in terms of their expressions and it was shown that the GCC GCC haplotypes of IL-10 had significantly decreased in the NS whereas there were no statistically significant differences in the haplotypes of TGF-beta1. The observed genotype counts were not deviated significantly from those expected according to the Hardy Weinberg Equilibrium ($P>0,05$) except for IL-10 -1082 A/G polymorphism ($P=0,048$).

We conclude that GCC GCC haplotypes of IL-10 gene polymorphisms (-1082 A/G, -819 T/C, -592 C/A) have been associated with NS in Turkish children. However, further studies with larger samples are needed to address the exact role of IL-10 in childhood NS.

P06.204

The C677T/A1298C Genotypes of MTHFR gene and Neural Tube Defects In Kazakhs

Z. S. Makhmutova, G. S. Svyatova;

The Scientific center of obstetric, gynecology and perinatology, Almaty, Kazakhstan.

This study determined the frequencies of *MTHFR* genotypes for 30 NTD cases, 84 their mothers and 150 unrelated healthy Kazakh adults for controls. The frequencies of combined C677T/A1298C genotypes among NTD cases were: CCaa - 6,7%, CCac - 6,7%, CCcc - 6,7%, CTaa - 10%, CTac - 46,7%, CTcc - 10%, TTaa - 10%, TTac - 3,3%. The frequencies of *MTHFR* genotypes among controls were: CCaa - 27,3%, CCac - 22%, CCcc - 7,3%, CTaa - 29,3%, CTac - 12%, CTcc - 0,7%, TTaa - 1,3%. Thus, the frequencies of CTac, CTcc, TTaa, TTac genotypes were higher than the frequencies of this genotypes in a controls ($p<0,05$). The frequencies of *MTHFR* genotypes among the mothers of cases were: CCaa - 20,2%, CCac - 20,2%, CCcc - 8,3%, CTaa - 17,9%, CTac - 19%, CTcc - 6%, TTaa - 7,1%, TTac - 1,2%. The frequencies of this genotypes among controls were: CCaa - 28%, CCac - 21%, CCcc - 6%, CTaa - 30%, CTac - 13%, CTcc - 1%, TTaa - 1%. Mothers of Kazakh NTD cases were homozygous for the C677T mutations at a higher rate than their respective controls ($p<0,05$). In summary, our study provides evidence that maternal C677T *MTHFR* homozygosity and CTac, CTcc, TTaa, TTac genotypes at the fetuses are a risk factor for NTD in Kazakh. The frequencies of TTaa and TTac genotypes were higher at the cases of high-level defects. The frequencies of CTac and CTcc genotypes were higher at the low level defects of spine.

P06.205

An association study of 45 folate related genes in spina bifida: involvement of Cubilin (CUBN) and tRNA aspartic acid methyltransferase 1 (TRDMT1)

B. Franke¹, S. H. H. M. Vermeulen², R. P. M. Steegers-Theunissen³, M. J. Coenen¹, M. M. V. A. Schijvenaars¹, H. Scheffer¹, M. den Heijer², H. J. Blom⁴; ¹Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, ²Department of Endocrinology, Department of Epidemiology, Biostatistics and HTA, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, ³Division of Obstetrics and Prenatal Medicine, Department of Obstetrics and Gynecology, Erasmus University Medical Center, Rotterdam, The Netherlands, ⁴Metabolic Unit, Department of Clinical Chemistry, VU University Medical Center, Amsterdam, The Netherlands.

Spina bifida belongs to the neural tube defects, which are congenital malformations of the central nervous system with a prevalence of 0.5 to 12 per 1000 births around the world. In this study we aimed at identifying genes related to folate and its metabolic pathways that are involved in the aetiology of spina bifida. We selected 50 folate metabolism related genes and genotyped polymorphisms in those. Eighty-seven polymorphisms in 45 genes passed quality controls. Associations of those polymorphisms with spina bifida were investigated in a sample of 180 patients and 190 controls. The relation between polymorphisms that were associated with spina bifida risk and serum and red cell folate, vitamin B₁₂, and homocysteine levels was evaluated in the controls. A polymorphism in *CUBN* was significantly associated with spina bifida after correction for multiple testing and was related to increased vitamin B₁₂ ($P=0.039$) and red cell folate ($P=0.001$). The *CUBN* gene encodes the intrinsic factor-cobalamin receptor (or Cubilin), a peripheral membrane protein which acts as a receptor for

intrinsic factor-vitamin B₁₂ complexes. Vitamin B₁₂ is an important co-factor in the folate metabolism and low B₁₂ status in mothers has been linked to neural tube defects in the offspring. Other interesting findings include nominal significant associations with polymorphisms in *TRDMT1*, *ALDH1L1*, *SARDH*, and *SLCA19A1* (*RFC1*). Our study points out interesting new candidate genes and functional pathways for further study, and confirms earlier findings. Neither of the genes *CUBN*, *TRDMT1*, *ALDH1L1* or *SARDH* have been investigated for association with spina bifida, before.

P06.206

Investigation of the putative functional effect of the 19bp Deletion polymorphism within Intron 1 of the Dihydrofolate Reductase (DHFR) gene

A. Magee, K. O'Brien, A. G. Parle-McDermott;

Dublin City University, Dublin, Ireland.

DHFR is an important folate metabolising enzyme that catalyses the conversion of dihydrofolate to tetrahydrofolate. Folate genes are considered candidates for association with neural tube defects (NTDs) such as spina bifida due to the preventative effect of periconceptional maternal supplementation with folic acid. Investigation of an intronic 19bp deletion polymorphism within the *DHFR* gene found a significant protective effect in mothers of NTD cases when present in one (Relative Risk 0.59 (95%CI: 0.39-0.89), $p=0.01$) or two copies (Relative Risk 0.52 (95%CI: 0.32-0.86), $p=0.01$). Analysis of mRNA levels revealed a small increase in expression (~1.5 fold) associated with the 19bp intronic deletion polymorphism, but this was not significant (Parle-McDermott *et al.*, Am J Med Genet 143(11): 1174-1180 (2007)). We sought to further investigate the potential impact of the *DHFR* 19bp intronic deletion polymorphism on gene expression by employing a recombinant dual luciferase system in HEK293 cells. The results of these experiments showed that the 19bp deletion showed a modest increase in reporter gene expression in agreement with the mRNA data. It is proposed that the sequence of the 19bp deletion harbours an Sp2 binding site that acts as a repressor of transcription. Mobility shift assays are being employed to directly test whether this polymorphism results in loss of an Sp2 binding site.

P06.207

Mutations of MFSD8 is a common cause of variant late-infantile neuronal ceroid lipofuscinosis

M. Kousi^{1,2,3}, E. Siintola^{1,2,3}, L. Dvoráková⁴, H. Vlasková⁴, M. Topcu⁵, D. Yuksef⁶, B. Minassian⁷, M. Elleder⁴, S. E. Mole⁸, A. E. Lehesjoki^{1,2};

¹Folkhälsan Institute of Genetics, Helsinki, Finland, ²Neuroscience Center, University of Helsinki, Helsinki, Finland, ³Department of Medical Genetics, University of Helsinki, Helsinki, Finland, ⁴Institute of Inherited Metabolic Disorders, Charles University, Prague, Czech Republic, ⁵Department of Pediatrics, Hacettepe University Faculty of Medicine, Section of Child Neurology, Ankara, Turkey, ⁶Dr. Sami Ulus Children's Hospital, Ankara, Turkey, ⁷Genetics and Genome Biology, Hospital for Sick Children, Toronto, ON, Canada, ⁸MRC Laboratory for Molecular Cell Biology, University College London, London, United Kingdom.

The neuronal ceroid lipofuscinoses (NCLs), characterized by the accumulation of autofluorescent storage material mainly in neurons, are the most common neurodegenerative disorders of childhood. Six genes (*PPT1/CLN1*, *TPP1/CLN2*, *CLN5*, *CLN6*, *MFSD8/CLN7*, and *CLN8*) underlying late-infantile onset NCL forms (LINCLs) have been identified so far. We analyzed the recently reported *MFSD8* gene for mutations in 79 patients, most of which had a clinical diagnosis of variant LINCL (vLINCL). Eight novel *MFSD8* mutations, including three missense, one nonsense, two splice-site, one deletion and one deletion/insertion mutation were identified in patients of various ethnic origins. Among them, a significant group of Roma Gypsy patients originating from the Czech Republic were shown to bear a mutation in *MFSD8*, possibly due to a founder effect. In one patient with a deletion/insertion mutation resulting in an in-frame amino acid substitution, the disease onset was later and the disease course less aggressive than in vLINCL. Our findings raise the total number of *MFSD8* mutations to 14, with the identified mutations evenly spaced within the gene and with the majority of families having private mutations. Our study confirms that *MFSD8* defects are not restricted to the Turkish population, as initially anticipated, but are a relatively common cause of vLINCL in different populations. *MFSD8* should be considered a diagnostic alternative in

vLINCL but also in NCL patients with later onset and a more protracted disease course.

P06.208

Linkage analysis in 238 ADHD-families identifies genome-wide significant signals on chromosomes 2q21.1 and 13q12.11 for neuropsychological measures

N. N. J. Rommelse¹, A. Arias-Vásquez², M. E. Altink², C. J. M. Buschgens³, E. Fliers³, S. V. Faraone⁴, J. K. Buitelaar³, J. A. Sergeant¹, J. Oosterlaan¹, B. Franke⁵;

¹Department of Clinical Neuropsychology, VU University, Amsterdam, The Netherlands, ²Departments of Psychiatry, Human Genetics and Epidemiology & Biostatistics, Radboud University Medical Center, Nijmegen, The Netherlands, ³Departments of Psychiatry, Radboud University Medical Center, Nijmegen, The Netherlands, ⁴Departments of Psychiatry and Neuroscience & Physiology, SUNY Upstate Medical University, New York, NY, United States, ⁵Departments of Psychiatry and Human Genetics, Radboud University Medical Center, Nijmegen, The Netherlands.

ADHD linkage studies have not revealed consistent findings, suggesting alternative approaches to find genes involved in this disease. Endophenotypes, defined as heritable, continuously distributed traits that increase the risk for ADHD, may be more suitable for linkage analysis: Endophenotypes seem less genetically complex than clinical disease phenotypes. Moreover, they are often quantitative traits rather than dichotomous entities (like DSM diagnostic categories), hence the more powerful Quantitative Trait Loci (QTL) linkage analysis may be applied. Genome-wide linkage analysis was performed in the Dutch subsample of the International Multi-centre ADHD Genetics (IMAGE) study encompassing 238 DSM-IV combined type ADHD probands and their 112 affected and 195 non-affected siblings. Ten neuropsychological measures (cognitive and motor measures) previously shown to be candidate ADHD endophenotypes were used as quantitative traits. In addition, an overall component score of neuropsychological functioning was used, on which all ten individual measures related. A total number of 5,407 autosomal SNPs were used to run a multipoint regression-based linkage analysis. Two genome-wide significant linkage peaks were found, one for Motor Timing on chromosome 2q21.1 (LOD score: 3.944) and one for Digit Span on 13q12.11 (LOD score: 3.959). Eleven suggestive linkage peaks were found (LOD scores ≥ 2) on chromosomes 2p, 2q, 3p, 4q, 8q, 9p, 12p, 12q, 14q, 17q. The suggestive linkage signal of the component score at 2q14.3 (LOD score: 2.878) overlapped with the region linking to Motor Timing. In conclusion, our results suggest that neuropsychological candidate ADHD-endophenotypes may aid in the discovery of novel ADHD genes through linkage analysis

P06.209

NFATC4 gene polymorphism and aerobic performance in athletes

D. V. Popov¹, I. I. Ahmetov², J. V. Shikhova², S. S. Missina¹, O. L. Vinogradova¹, V. A. Rogozkin²;

¹SRC Institute for Biomedical Problems of the Russian Acad. Sci., Moscow, Russian Federation, ²St Petersburg Research Institute of Physical Culture, St Petersburg, Russian Federation.

Nuclear factor of activated T cells C4 gene (NFATC4) encodes transcription factor which regulates cardiac and skeletal muscle metabolism. The aim of the study was to investigate allelic distribution of NFATC4 gene Gly160Ala polymorphism in endurance-oriented athletes (n=549) and controls (n=1057), and to find interrelation between genotypes and physiological parameters in rowers (n=90). Genotyping was performed by restriction fragment length polymorphism analysis. Physiological parameters were evaluated by PM 3 Rower Ergometer and MetaMax 3B Gas Analyzer. The frequency of NFATC4 Gly allele was significantly higher in athletes than in controls (51.5% vs. 43.7%; $p < 0.0001$), and increased with the growth of skills (sub-elite athletes: 36.7%-48.5%; highly elite athletes: 60.6%-62.5%). Furthermore, NFATC4 Gly allele was associated with high values of aerobic performance (when VO₂max and AT in % of VO₂max were measured). Thus, NFATC4 gene Gly160Ala polymorphism is associated with aerobic performance of athletes and plays an important role in sports selection.

P06.210

Pilot study on NIHL in a population of Portuguese noise-exposed workers

N. Correia¹, A. Turkman², M. Antunes², V. Andreozzi², H. Caria^{1,3}, G. Fialho¹;

¹Center of Genetics and Molecular Biology, University of Lisbon, Lisbon, Portugal, ²Department of Statistics and Operational Research, Faculty of Science, Lisbon, Portugal, ³College of Health Care, Polytechnic Institute of Setúbal, Setúbal, Portugal.

Noise-induced hearing loss (NIHL) is one of the most important occupational diseases and, after presbycusis, the second most common form of sensorineural hearing loss. NIHL is a complex disorder, caused by an interaction between environmental and genetic factors. In contrast to the considerable amount of knowledge on environmental factors, almost nothing is currently known about the genetic basis of NIHL.

In humans, a few studies have been performed aiming at identifying an association between variants of relevant genes expressed in the inner ear and NIHL. Significant differences were recently detected between noise susceptible and noise resistant subjects for some variants of genes CDH23 and KCNE1.

In the pilot study here reported, we have analyzed a population of Portuguese noise-exposed workers. KCNE1 and CDH23 genes had been selected for genotyping of some SNPs, preferentially in coding regions, in order to be able to detect significant differences between noise susceptible and noise resistant individuals.

When individually analysed, significant statistic differences were found in three SNPs of exon 50 of CDH23 gene: rs4747193 (intronic SNP); rs4747194 and rs4747195 (nonsynonymous SNPs). However, it was not possible to identify a clear genetic association, when performing bivariate or multivariate analysis.

The lack of strong association between the variants considered in this study and NIHL can indicate that none of these polymorphisms has influence in the susceptibility to NIHL in the Portuguese population, or that their effect could not be detected in our sample due to its small dimension.

P06.211

Lack of important association between ND gene mutations and the risk of progression Norrie disease

G. Modabber^{1,2}, F. Hafez Khiabani², R. Kharkhane², M. Riazi Estefhan², M. Nili Ahmadabadim², M. Hoshmand¹;

¹National Institute of Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran, ²Faraby Hospital, Tehran, Islamic Republic of Iran.

Background: Retinopathy of prematurity (ROP) is a retinal vascular disease which occurs in premature neonates with low birth weight and may lead to retinal detachment and blindness. Mutations in the Norrie disease (ND) gene have been reported as a risk factor of progression to advance stages in cases of ROP. We wanted to determine if any mutation in ND gene may play a role in progression of ROP to advance stages in Iranian infants.

Methods: Fifty Iranian premature neonates with ROP stage 3 and or worse have enrolled in the study. After polymerase chain reaction (PCR) with three primer pairs and direct sequencing and all three exons and their flanking areas and all known ND gene mutation regions were evaluated for any mutation.

Results: A C15078A heterozygote mutation was found in the second intron of 90% of the cases but it has no effect on the structure or the production rate of the norrin protein, the product of ND gene. No other mutations causing changes in norrin protein were found.

Conclusions: Our findings from this case series suggest lack of important association between ND gene mutations and the risk of progression of the disease to advanced stages in patients with ROP.

P06.212

The interaction between gene polymorphisms and carbohydrate intake on metabolic profile in Russian athletes

A. A. Topanova, I. I. Ahmetov, R. R. Dondukovskaya, N. D. Golberg;

St Petersburg Research Institute of Physical Culture, St Petersburg, Russian Federation.

Genetic and nutritional factors interact together and modulate the plasma carbohydrate and lipid profile. The objective was to study whether carbohydrate intake modulates the association between NFATC4, PG-C1A, PPARA, PPARG, PPARC, TFAM, UCP2 and UCP3 gene varia-

tions and metabolic profile in Russian athletes. The study involved 33 male Russian sub-elite endurance-oriented athletes (road cyclists), who were randomly assigned to consume carbohydrates/minerals (CARB, n=17; 6% 200 ml drink "Olympia" (Estonia)) or placebo (CON, n=16; 200 ml pure water) for 20 d at 20th min from the end of evening training. Plasma concentrations of total cholesterol, glucose and resting lactate (La) were evaluated in the morning before and at the end of experiment. NFATC4 Ala160Gly, PGC1A Gly482Ser, PPARA G/C, PPARG Pro12Ala, PPARG +294T/C, TFAM Thr12Ser, UCP2 Ala55Val, UCP3 -55C/T gene polymorphisms were determined by PCR-RLFP. At base-line PPARA C allele carriers exhibited the highest values of La (P=0.008); NFATC4 Ala (P=0.04) and TFAM Ser (P=0.024) alleles were associated with higher glucose concentrations. At the end of experiment PGC1A Ser (r=0.54, P=0.03), PPARG Pro (r=0.58, P=0.019) alleles were positively correlated with high values of La in CARB- and CON-groups, respectively, whilst PPARG C allele (r=0.47, P=0.055) was associated with higher total cholesterol levels in CARB-group. Furthermore, PPARG Pro allele carriers of CARB-group showed the greatest decrease in total cholesterol. Thus, polymorphisms of PGC1A, PPARG and PPARG genes (involved in carbohydrate and lipid metabolism) may interact with carbohydrate intake to modulate metabolic profile of endurance-oriented athletes.

P06.213

Cannabinoid type-1 receptor gene polymorphisms are associated with central obesity in a Southern Brazilian population

J. P. Jaeger¹, V. S. Mattevi², S. M. Callegari-Jacques¹, M. H. Hutz¹;

¹Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, ²Fundação Faculdade Federal de Ciências Médicas de Porto Alegre, Porto Alegre, Brazil.

The CB1 cannabinoid receptor and its endogenous ligands, the endocannabinoids, are involved in energy balance control, stimulating appetite and increasing body weight in wasting syndromes. Different studies have investigated the relationship between polymorphisms of the cannabinoid receptor 1 (CNR1) gene and obesity with conflicting results. In the present study, we investigated the 1359G/A (rs1049353), 3813A/G (rs12720071) and 4895A/G (rs806368) polymorphisms in the CNR1 gene in a Brazilian population of European descent. To verify the association between these variants and obesity-related traits in this population, 756 individuals were genotyped by PCR-RFLP methods. The 4895G allele was associated with waist to hip ratio (WHR) (P=0.014; P=0.042 after Bonferroni correction). An additive effect with the GAA haplotype was associated with WHR (P=0.028), although this statistical significance disappeared after Bonferroni correction (P=0.084). No significant association was observed between the genotypes of the 1359G/A and 3813A/G polymorphisms and any of the quantitative variables investigated. Our findings suggest that CNR1 gene polymorphism is associated with central obesity in this Brazilian population of European ancestry.

P06.214

Association between haptoglobin phenotype and serotonin transporter gene polymorphism (5HTTVNTR) in the obesity inflammatory process

P. Levy¹, C. Marinho¹, J. Ferreira¹, A. Esteves¹, D. Figueiredo¹, M. Laires², P. Teixeira², J. Themudo Barata², L. Sardinha², M. Bicho¹;

¹Genetic Laboratory, Medical School, Lisbon, Portugal, ²School of Sport and Exercise Sciences, Lisbon, Portugal.

Introduction: Obesity is a chronic disease associated with an increase of oxygen reactive species. BMI is related with immunologic changes resulting in a decrease of antigen tolerance and in a predominance of Th2 immunologic system profile. Haptoglobin is an acute phase protein. It has three genotypes 1.1, 2.1 and 2.2 that differ in their affinity to complex haemoglobin and that are involved in the modulation of immunological response. Genotype 1.1 is associated with a predominant Th2 response. Serotonin participates in Th1/Th2 balance as it regulates cytokines release. Their intra and extracellular concentrations are regulated by its transporter whose efficacy depends on its genetic polymorphisms.

Objective: Haptoglobin and 5HTTVNTR polymorphisms as risk factors for obesity.

Methods: 289 women were studied, 248 with overweight or obesity (BMI=30,19±3,74 Kg/m²; 47,31±12,63 years old) and 41 controls

(56,29±11,67 years old). 5HTTVNTR was amplified by PCR and haptoglobin phenotype by PAGE.

Results: Women carrying allele 1 of Hp showed a higher risk for obesity (OR=2,270; IC 95% [1,011-5,098]; p<0,05) and the same was verified for allele 12 of 5HTTVNTR (OR=2,148; IC 95% [1,071-4,311]; p<0,05). The risk increases when these two alleles are associated (OR=3,659; IC 95% [1,426-9,390]; p<0,01).

Conclusion: An association between allele 1 of haptoglobin and allele 12 of 5HTTVNTR increases the predisposition for obesity. The fact that obese individuals show a higher risk for allergic diseases has been associated with a predominant Th2 response. It is in concordance with our results as both polymorphisms seem to change Th1/Th2 balance for a predominant humeral immunity.

P06.215

Association study of genetic polymorphisms in immunoresponse genes (IL1b, IL1RN, TNFA, LTA, IL8, IL10) in occupational chronic bronchitis

L. Akhmadishina¹, G. Korytina¹, O. Tselousova¹, K. Danilko², T. Victorova^{1,2};

¹Institute of Biochemistry and Genetics, Ufa, Russian Federation, ²Bashkir State Medical University, Ufa, Russian Federation.

The purpose of this study was to investigate the possible roles of the cytokines genes in the development of occupational chronic bronchitis. Polymorphisms in the genes encoding *IL1b*, *IL1RN*, *TNFA*, *LTA*, *IL8*, *IL10* were investigated in patients with occupational chronic bronchitis (N=122) and healthy workers (N=166) from Bashkortostan Republic. Tests for Hardy-Weinberg equilibrium among controls were conducted using observed genotype frequencies and a χ^2 -test with one degree of freedom. We also used chi-square tests to examine the association between genetic polymorphisms and individual susceptibility to occupational exposure. A value of p<0.05 was considered as statistically significant. The frequencies of the *TNFA* (-308G/A) and *LTA* (252A/G), *IL1B* (3953C/T) and *IL1RN* gene haplotypes were computed using the expectation-maximization algorithm with the EH software program. Odds ratios and 95% confidence intervals were calculated to estimate the individual risk of occupational chronic bronchitis.

No difference was found between patients and healthy controls in the distribution of genotypes and frequencies of alleles of the *TNFA* (-308 G/A), *LTA* (252A/G), *IL1B* (3953C/T), *IL1RN* (VNTR), *IL10* (-327C/A), *IL8* -251A/T gene polymorphisms. However, it was shown that the *IL1B*, *IL1RN* genes haplotypes frequency distribution patterns significantly differed between workers with occupational chronic bronchitis and healthy workers ($\chi^2=9.31$, df=5, p=0.03). The *IL1B* 3953T/*IL1RN**2 haplotype was associated with higher risk of occupational chronic bronchitis (4.67% vs. 1.30%, in healthy workers; $\chi^2=4.29$, p=0.04; OR=3.73, 95%CI 1.06-14.29).

Our results indicate that the *IL1B* and *IL1RN* genes polymorphisms may play a role in pathogenesis of occupational chronic bronchitis.

P06.216

Common genetic polymorphisms in the human organic cation transporters 1, 2 and 3 and the pharmacokinetics of biguanide class drug metformin

M. V. Tzvetkov, S. Vormfelde, T. Schmidt, D. Sehr, I. Meineke, J. Brockmüller; University Medicine, Goettingen, Germany.

Organic cation transporter subtypes 1, 2 and 3 (OCT1, OCT2 and OCT3) mediate the cellular uptake of N,N-dimethylimidodicarbonyl diamide (metformin) used as antidiabetic drug. Earlier, lost-of-function polymorphisms in the OCT1 gene were associated with reduced metformin efficacy in mice and humans.

We analyzed the effect of common genetic variants in the three genes on metformin pharmacokinetics in 103 healthy male Caucasians. Thirty functional or haplotype-tagging SNPs and one potential copy number variation were genotyped. Polymorphism-dependent and tissue-specific variation in gene expression was assessed by quantitative RT-PCR.

The reduction in the OCT1 activity due to one of the amino acid substitutions, R61C, G401S, 420del, or G465R, was associated with a higher renal clearance of metformin (means of 30.62, 33.14 and 37.14 l/h for carrier of two, one or none active OCT1 alleles respectively, P=0.04). In addition, a haplotype in the promoter region of the OCT1 gene was associated with an increased renal clearance (30.96, 33.65 and 40.56 l/h for two, one or non haplotype carrier respectively, P=0.03) and with

decreased gene expression in lymphoblastoid cell lines. No association was observed for the polymorphisms in the OCT2 and OCT3 genes. Additionally, previously suggested effect of the "silence" A411A polymorphism on the OCT3 splicing could not be validated in exon-trapping experiments.

In conclusion, genetic variants in humanOCT1 but not in OCT2 and OCT3 genes were associated with alternation in the metabolism of metformin. The best explanation of our data is that OCT1 is involved to some extent in tubular reabsorption of metformin.

P06.217 Interferon regulatory factor 6 (IRF6) variation contributes to oral clefts in South America

I. M. Orioli¹, R. F. Fonseca¹, A. R. Vieira², E. E. Castilla^{3,4};

¹ECLAMC at Genetics Department, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil, ²Departments of Oral Biology and Center for Craniofacial and Dental Genetics, School of Dental Medicine, University of Pittsburgh, Pittsburgh, PA, United States, ³ECLAMC at Instituto Oswaldo Cruz, Rio de Janeiro, Brazil, ⁴ECLAMC at CEMIC (Center for Medical Education and Clinical Research), Buenos Aires, Argentina.

Interferon regulatory factor 6 (IRF6) has been associated with non-syndromic (NS) oral-facial clefts (OFC). ECLAMC (Latin American Collaborative Study of Congenital Malformations) population that was included in the original IRF6 association study [Zucchero et al., 2004] did not show association. Six SNPs within and in the boundaries of the IRF6 gene were genotyped to test for association with OFC in 304 trios of affected newborn patients and their parents. The ECLAMC samples were from Argentina, Bolivia, Brazil, Chile, Ecuador, Colombia, and Venezuela; there were 168 cases of isolated cleft lip with or without cleft palate (CL/P), 47 isolated cases with cleft palate only (CPO), and 73 cases with OFC and other defects. The most significant results were for SNPs rs 17015215 (VAL274I) in all OFC ($p=0.0002$), and isolated CL/P ($p=0.0004$), and rs 2013162 in isolated CPO ($p=0.0009$). Suggestive results were also found for SNPs rs 861019 in all OFC ($p=0.05$), CL/P (0.05), and CPO ($p=0.02$), and rs 17015215 (VAL274I) ($p=0.048$), and rs 2073487 ($p=0.048$) in CPO. No association was found in the OFC group associated with other defects. Our results demonstrate that variation in IRF6 is a significant genetic contributor to OFC in South American populations.

P06.218 Allelic variants of IL1R1 and IL1RL2 genes associate with severe hand osteoarthritis

A. Näkki^{1,2}, S. Kouhia¹, J. Saarela¹, A. Harilainen³, K. Tallroth³, T. Videman⁴, M. C. Battié⁴, J. Kaprio⁵, L. Peltonen^{1,5}, U. M. Kujala⁶;

¹National Public Health Institute, Helsinki, Finland, ²University of Helsinki, Helsinki, Finland, ³ORTON Orthopedic Hospital, Helsinki, Finland, ⁴University of Alberta, Edmonton, AB, Canada, ⁵Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom, ⁶University of Jyväskylä, Jyväskylä, Finland.

Objective. In search for genes predisposing to osteoarthritis (OA), several genome wide scans have provided evidence for linkage on 2q. In this study we targeted a 470 kb region on 2q11.2 presenting the locus with most evidence for linkage to severe hand OA in our previous genome wide scan families.

Methods. We genotyped 32 single nucleotide polymorphisms (SNPs) in this 470 kb region comprising 6 genes belonging to the interleukin 1 superfamily. We monitored for association with individual SNPs and SNP haplotypes among severe bilateral hand OA cases ($n=107$) and also end-stage bilateral primary knee OA cases ($n=113$) and controls ($n=436$).

Results. In a single SNP analysis with hand OA material, we found a significant association to a 174 kb region, covered by a single haplotype block, comprising genes *IL1R1* and *IL1RL2* (p -value=0.001). Haplotype analysis provided further evidence for the *IL1R1* gene.

Conclusion. This study demonstrates a consistent association between hand OA and gene *IL1R1*. But since the associated SNPs are part of a wide LD block, we cannot unequivocally confirm which of the two genes explains the observed association. *IL1R1* and *IL1RL2* represent highly relevant candidate genes since they encode proteins that are known modulators of inflammatory processes associated with joint destruction.

P06.219 Association of polymorphisms and haplotypes in the 5' region of COL1A1 gene with BMD and osteoporotic fractures in Russian women from Volga-Ural region

L. Selezneva¹, R. Khusainova¹, E. Fazlyeva², R. Nurliyaganov³, E. Khusnutdinova¹;

¹Institute of Biochemistry and Genetics, Ufa, Russian Federation, ²City Clinical Hospital no. 5, Ufa, Russian Federation, ³City Clinical Hospital no. 21, Ufa, Russian Federation.

The collagen type I alpha 1 (*COL1A1*) gene is a strong candidate for susceptibility of osteoporosis. We analyzed the possible association of the *COL1A1* genotypes and haplotypes, defined by -1997G/T, -1663indelT and *Spl* polymorphisms in 340 Russian postmenopausal women. Patients with chronic diseases and conditions which may potentially affect bone mass were excluded. The -1997G/T, -1663indelT and *Spl* polymorphisms were in strong linkage disequilibrium ($D' = 0.66-0.95$). The distribution of three common haplotypes in our population was as follow: -1997*G/-1663*insT/*S - 62.2%, -1997*T/-1663*insT/*S - 19.9%, -1997*G/-1663*delT/*s - 14.9%. The *Spl* and -1663indelT polymorphisms were associated with BMD: homozygote carries of the *Spl**S allele had increased BMD ($p=0.035$ for FN-BMD; $p=0.015$ for LS-BMD) and homozygotes for the -1663*insT allele had higher values of BMD ($p=0.017$ for FN-BMD; $p=0.009$ for LS-BMD). There was a significant association between the -1997*G/-1663*delT/*s haplotype and FN-BMD ($p=0.01$) with reduced BMD values in homozygote carriers of the haplotype -1997*G/-1663*delT/*s ($p=0.023$ from carries of no copies of the haplotype by Tukey's post-test). We found an association of the -1663*I*D genotype (OR=1.7; 95%CI 1.06-2.71; $p=0.024$) and the -1663*delT allele (OR=1.6; 95%CI 1.09-2.4; $p=0.015$) with osteoporotic fractures. The association of the -1997*G/-1663*delT/*s haplotype with fractures was nominally significant ($p=0.04$), but these did not reach the threshold for significance when multiple testing was considered. There was no significant association of the -1997G/T polymorphism with BMD or fractures in our population. Our results suggest that the *COL1A1* gene is a susceptibility locus for osteoporosis in postmenopausal Russian women from Volga-Ural region.

P06.220 Epidemiological and genetic studies of otosclerosis with a new locus OTSC8 in tunisian population

I. Bel Hadj Ali¹, M. Thys², N. Beltaief³, E. Mnif³, G. Besbes³, G. Van Camp², S. Ben Arab¹;

¹Faculté de Médecine de Tunis, Tunis, Tunisia, ²Center of Medical Genetics, Antwerp, Belgium, ³Hôpital La Rabta, Tunis, Tunisia.

Otosclerosis is a very common hearing impairment among Caucasians with a prevalence of about 0.3-0.4% among white adults. In Tunisia, clinical otosclerosis has a prevalence of 0.4 to 0.8. Our aim is to perform an epidemiological, genetic and linkage analyses of otosclerosis in northern Tunisia.

Segregation analysis were performed and showed that the pattern of the disease is due to a rare dominant major gene with a high polygenic component.

Our study showed that in north-eastern areas of Tunisia, the sex ratio in probands with clinical otosclerosis being twice as often in women than in men. This probably suggests that an endocrine mechanism and/or biochemical factor are involved in disease aetiology. However, in north-western areas, there was no significant difference between the rates of otosclerosis between sexes.

Geographical distribution of affected subjects according to the ethnic origin of their parents showed that the areas with the highest concentration of affected individuals were urban or seaside areas. The frequency of otosclerosis was lower in rural areas and/or areas far from the seaside.

Genetic study was undertaken in some genealogies segregating autosomal dominant otosclerosis and linkage analysis showed that three families are linked to the known loci responsible of otosclerosis (OTSC1, OTSC2, and OTSC3). For the fourth family, the genome wide linkage analysis was performed and revealed a new otosclerosis locus named OTSC8.

The presence of a genetic factor associated with hormonal, biochemical or environmental factors, probably lead to variable expression of the otosclerosis according to age and sex.

P06.221**High throughput mutation screening in patients with isolated respiratory chain complex I deficiency**

M. Taverna¹, F. Madignier¹, B. Rolinski², R. Horvath², P. Freisinger², T. Meitinger^{1,3}, H. Prokisch^{1,3};

¹Helmholtz Zentrum München, Neuherberg, Munich, Germany, ²Metabolic Disease Centre Academic Hospital München-Schwabing, Munich, Germany, ³Institute of Human Genetics, Technical University of Munich, Munich, Germany.

Almost 50 causal variants in nuclear genes associated with OXPHOS disorders are known. Despite this success, in the majority of cases the molecular defects remain unknown. Most mitochondrial disorders are associated with three main categories of biochemical defects: respiratory chain complex I (RCC I), complex IV (RCC IV) and combined RCC I+RCC IV deficiencies. The number of genes potentially harbouring pathogenic mutations is very high. This situation calls for a technological improvement for carrying out the diagnosis of this group of disorders.

We deployed high-throughput protocols for genetic screening using high resolution melting point analysis (Idaho-Light-Scan). So far 96 samples have been analyzed in parallel followed by direct sequencing of those PCR products that display divergent melting curves. We have screened 50 genes (250 amplicons) coding for the subunits and assembly factors of RCC I. Causative mutations have been identified in 16% of patients. A single variant was identified in 30% of additional samples and in 54% of samples no mutations have been found yet.

P06.222**Association of p53 polymorphism with recurrent pregnancy loss**

N. Ghasemi, R. Dehghani Firouzabadi, M. Ayazi, H. Fazli, N. Tabibnejad; Research and Clinical Centre for Infertility, Yazd, Islamic Republic of Iran.

The p53 tumour suppressor gene is a well-known factor regulating apoptosis in a wide variety of cells and tissues. Alterations in the p53 gene are among the most common genetic changes in human cancers. In addition, recent data provide evidence that p53 plays a critical role in mediating pregnancy by regulating steroid hormone activation. Several polymorphisms of the p53 tumour suppressor gene have been associated with recurrent pregnancy loss. We evaluated the hypothesis that polymorphisms in the p53 tumour suppressor gene in women may be associated with occurrence of repeated miscarriages.

The prevalence of a common polymorphism of the p53 tumour suppressor gene (Arg and Pro variants at codon 72) in 50 women with recurrent pregnancy loss compared with 50 normal women with at least two alive children as control group. For each patient, two p53 tumour suppressor alleles (Arg and Pro) were identified by using PCR-RFLP technique and genotypes were defined as Arg/Arg, Pro/Pro, or Arg/Pro. Statistical analysis was done by SPSS software and the p-values under 0.05 were considered to be statistically significant.

The homozygous Pro/Pro genotypes were found more often (27.5%) among women with recurrent abortion versus other group (21.9%). It is concluded that P53 codon 72 polymorphism may serve as a susceptibility factor affecting the chances of recurrent pregnancy loss.

P06.223**DNA polymorphisms in proinflammatory cytokines IL1B and IL6 are not associated to pain in Spanish patients**

P. Álvarez Feraud^{1,2}, C. Murie³, J. del Pino⁴, J. Santos^{1,3}, P. Armero^{1,2}, R. González-Sarmiento^{1,2};

¹Unidad de Medicina Molecular-Departamento de Medicina, Salamanca, Spain,

²Cátedra extraordinaria del dolor-Fundación Grunenthal. Universidad de Salamanca, Salamanca, Spain, ³Unidad del dolor. Servicio de anestesia. Hospital Universitario de Salamanca, Salamanca, Spain, ⁴Servicio de Reumatología. Hospital Universitario de Salamanca, Salamanca, Spain.

The characterization of genes responsible for multifactorial diseases with genetic substrate such as pain, can be done through linkage analysis or association studies. Association studies can be performed with candidate genes.

In the case of pain, in addition to genes encoding proteins involved in neurotransmission, genes coding for inflammatory proteins can also play an important role. We have analysed allelic variants of genes encoding IL1B and IL6 proinflammatory proteins in order to determine whether variants of these genes may be associated with increased susceptibility to pain. We have studied 404 cases: 250 with neuropathic pain and 154 with inflammatory pain, in all of them the diagnosis

was accompanied by a study of levels of pain using EVA.

Our results show no relationship between allelic variants of studied genes, neuropathic pain, inflammatory pain, or with the levels of pain according to EVA. Therefore we conclude that pain is not associated with variants IL1B and IL6 genes

P06.224**Alpha-synuclein gene duplication analysis in familial Italian Parkinson patients**

F. Sironi^{1,2}, P. Primignani³, M. Zini¹, L. Trotta^{1,4}, T. Brambilla¹, S. Tunesi^{1,5}, A. Antonini¹, D. A. Coviello³, G. Pezzoli¹, S. Goldwurm¹;

¹Parkinson Institute, Istituti Clinici di Pefezionamento, Milano, Italy, ²Medical Genetics Laboratory, Foundation IRCCS "Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena" Genetics Laboratory, Milan, Italy, ³Medical Genetics Laboratory, Foundation IRCCS "Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena" Genetics Laboratory, Milan, Italy, ⁴Medical Genetics Laboratory, Foundation IRCCS "Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena" Genetics Laboratory, Milan, Italy, ⁵Institute of Medical Statistics and Biometry, University of Milan, Milan, Italy.

Alfa-synuclein gene (*SNCA*) duplication or triplication was found in autosomal dominant Parkinson disease (PD). Our aim was to analyse *SNCA* multiplication in an Italian series of familial PD.

We examined *SNCA* multiplication in an Italian series of 134 unrelated Italian PD patients with at least one first degree relative affected. Our sample population derived from the "Human genetic bank of patients affected by Parkinson disease and parkinsonisms" (<http://parkinson.it/dnabank.html>). We investigated the presence of *SNCA* multiplication using the MLPA approach (Kit "SALSA P51"). The kit also allows the detection of exon rearrangements in the *PKRN*, *PINK1*, *DJ1* genes and of two point mutations: p.G2019S (*LRRK2* gene) and p.A30P (*SNCA* gene). Each result was confirmed in two independent experiments. Up to now we performed MLPA assay on the first 58 familial PD patients.

This preliminary screening has identified 1 *SNCA* duplication positive patient, 1 heterozygous deleted allele in the *PINK1* gene (exon 6), 1 in the *PARK2* gene (exon 3-4) and 3 mutated alleles in the *LRRK2* gene (p.G2019S in exon 41).

The patient carrier of the *SNCA* duplication is a woman of 45 years of age affected by a classical PD. She developed depression and bradikinesia as first symptoms at 41 years. She responded to L-Dopa therapy and does not have cognitive decline. The mother developed PD at 45 years of age and died at 60 with dementia.

Our data indicate that *SNCA* duplication is present also in Italian population: approximately 1.5% (1/58) of familial PD patient.

P06.225**Parkin mutation analysis in patients with sporadic early-onset Parkinson's Disease**

G. Provenzano¹, F. Annesi¹, M. T. Pellecchia², F. E. Rocca¹, E. De Marco¹, D. Civitelli¹, P. Tarantino¹, P. Barone², L. Morgante³, M. Zappia⁴, G. Annesi¹;

¹Institute of Neurological Sciences, National Research Council, Mangone (CS), Italy, ²Department of Neurological Sciences, University Federico II, Napoli, Italy,

³Department of Neuroscience, Psychiatry and Anesthesiology, University of Messina, Messina, Italy, ⁴Clinica Neurologica I, Department of Neuroscience, University of Catania, Catania, Italy.

Mutations in the *parkin* gene (*PARK2*) are responsible for about 50% of familial autosomal recessive early onset (≤ 45 years) Parkinson's Disease (EOPD) and 10 to 20 % of sporadic EOPD. Recently, a novel *parkin* mutation, consisting of a deletion of the promoter and exon 1 of *parkin*, was described in a family with autosomal recessive EOPD and in an isolated case with EOPD. The aim of this study is to perform mutational analysis of the coding regions of the *parkin* gene in sporadic EOPD and subsequently to investigate whether rearrangements within both the shared promoter region and the *parkin* gene are present in the patients with only one or no mutations. A total of 53 index cases with sporadic EOPD and an age at onset ≤ 45 years from Southern Italy were screened for *parkin* mutation. DNA was extracted from peripheral blood using standard protocols and each exon of *parkin* was amplified and sequenced. Absolute quantification was performed by real time PCR 7900 HT-SDS. Among 53 patients screened for *parkin* mutations, 8 carried single heterozygous mutations, 4 had simple homozygous mutations, 1 was a compound heterozygous and 40 had no mutations. Gene dosage experiment failed to reveal an exonic rearrangement of

the *parkin* gene in patients with single heterozygous mutations. Our results show a substantial number of sporadic EOPD patients carrying single heterozygous mutations, suggesting that a second mutation could be localized in the promoter. In our study the gene dosage of core *parkin* promoter is still in progress.

P06.226

A functional G-463A polymorphism in the myeloperoxidase gene promoter and Parkinson's disease

F. E. Rocca^{1,2}, P. Tarantino¹, E. V. De Marco¹, D. Civitelli¹, I. C. Cirò Candiano¹, S. Carrideo¹, F. Annesi¹, G. Provenzano¹, V. Greco¹, G. Squillace¹, V. Scornaienchi¹, G. Nicoletti^{1,2}, G. Annesi¹;

¹Institute of Neurological Sciences, Mangone (Cosenza), Italy, ²Institute of Neurology, University Magna Graecia, Catanzaro, Italy.

Epidemiological studies suggest that inflammation increases the risk of developing Parkinson's disease (PD) and experimental models of PD show that inflammatory oxidants modulate neuronal death. Myeloperoxidase (MPO) is an antimicrobial enzyme involved in the inflammatory process that produces reactive oxygen species. It is demonstrated that the levels of catalytically active myeloperoxidase are elevated in diseased brains and a functional G-463A polymorphism in the promoter of the MPO gene is associated with the risk of developing neurodegenerative disorders. There is biologic evidence implicating MPO in PD neurodegeneration process, but no data are currently available on the possible role of MPO polymorphism in the development of PD. Our study is the first to examine the association between MPO genotype and PD risk. We investigated the G-463A polymorphism in 233 PD cases and 100 controls. All patients were screened for this SNP by combination of PCR and RFLP analysis. We did not find significant differences in allele or genotype distribution between PD cases and controls ($p=1$). Genetic findings show that the less common A allele decreases myeloperoxidase expression, apparently by destroying a binding site for the transcription factor. The reactive oxygen species play an important role in PD and individual susceptibility to PD may be modulated by the G-463A SNP. This work will be completed by increasing the number of the controls analysed to provide a more powered study. Our preliminary data suggest that G-463A MPO polymorphism is not a risk factor for PD nevertheless further studies in other populations are needed to confirm these results.

P06.227

Characterization and replication of a novel locus for late-onset Parkinson's disease detected in a genome-wide association study in an isolated population

Z. Bochanovits^{1,2}, P. Rizzu^{1,2}, K. Rak^{1,2}, L. Pardo-Cortes^{1,2}, P. Heutink^{1,2};

¹VU Medical Center, Amsterdam, The Netherlands, ²Center for Neurogenomics and Cognitive Research, Amsterdam, The Netherlands.

Genetically isolated populations have two major advantages above general populations when conducting genome-wide association studies: 1- more extended LD allows for using less markers and 2- less genetic heterogeneity, hence a higher relative risk of individual susceptibility alleles. We have performed a genome-wide association study in a young genetic isolate in Turkey for late onset Parkinson's disease (LOPD). This isolate exhibits increased prevalence of the disease suggesting that susceptibility alleles of relatively high risk are segregating in this homogeneous population. We used the Affymetrix 10K SNPChip to genotype 31 LOPD disease patients and 27 unrelated controls. Strong LD ($r^2>0.8$) was commonly found up to approximately 150kb, hence the 10K SNPChip is sufficient to cover the entire genome in this isolate. Single SNP associations were carried out followed by a permutation test to determine the genome wide significance threshold. One SNP, rs1492592, was found to be significantly associated with LOPD ($p=4\times 10^{-6}$). Finemapping a 1.1 Mb region surrounding the initial SNP has confirmed the association. Within 1.5 Mb of the locus, several interesting candidate genes are located, most notably GRIN3A and PPP3R2. A known limitation of using genetic isolates is that the loci detected in one population might not be of relevance in other isolates or the general population. Therefore we screened two additional genetic isolates and the general Dutch population for association with tagging SNPs covering six candidate genes. We replicated our locus by showing that multiple tagging SNPs are significantly associated with LOPD in the additional populations.

P06.228

ParkScreen: a Linkage Marker Panel for Parkinson's Disease

A. De Grandi¹, C. Béu Volpato¹, E. Bedin¹, C. Pattaro¹, F. Marroni¹, I. Pichler¹, A. Hicks¹, G. Casar², P. P. Pramstaller^{1,3,4};

¹European Academy, Institute of Genetic Medicine, Bolzano, Italy, ²Department of Neuroscience, Vita-Salute University and San Raffaele Scientific Institute, Milan, Italy, ³Department of Neurology, General Regional Hospital, Bolzano, Italy, ⁴Department of Neurology, University of Lübeck, Lübeck, Germany.

PURPOSE: Parkinson's disease (PD) is a complex disease with both genetic and environmental susceptibility factors. We set out to develop a rapid inexpensive tool to aid in the characterization of known or novel loci that may contribute to PD in families. **METHODS:** We developed a genetic marker screening panel, ParkScreen, optimized for simultaneous marker amplification, to test families for linkage to known PD loci using only a few affected individuals. We also used ParkScreen for screening patients within genetically isolated homogenous populations. It was applied to three groups of apparently sporadic PD patients originating from different Italian Alpine valleys. **RESULTS:** Panel functionality was proven by detection of linkage to *PARK2* in a family with known *Parkin* mutations. Linkage to several known PD loci in the examined pedigrees was excluded, and suggestive linkage to *PARK8*, *PARK3*, and *PARK11* was found. For one family, linkage was excluded for all known loci, thus marking it as a candidate for further studies. **CONCLUSION:** ParkScreen is a useful, rapid, and inexpensive tool for assessing the involvement of known loci in familial PD. It allows the selection of families suitable for clinical follow-up and genotyping in order to identify specific mutations or novel genes.

P06.229

A genetic variant in PC-1 gene is associated with susceptibility to type 2 diabetes among Japanese population

P. Keshavarzi¹, H. Inoue²;

¹Gilan university of medical science, Rasht, Islamic Republic of Iran, ²The university of Tokushima, Tokushima, Japan.

Previous studies have demonstrated the K121Q polymorphisms in the plasma cell membrane glycoprotein-1 (PC-1, recently known as ENPP1) gene influences insulin resistance, obesity and risk of type 2 diabetes. However conflict association results are reported in different population. We previously found no evidence for association of K121Q polymorphisms with risk of type 2 diabetes in a Japanese population. This study for first time was carried out in samples of Japanese to explore the key role of other previously reported polymorphisms and haplotypes containing K121Q variant with risk of type 2 diabetes. To accomplish this, we genotyped the rs997509, rs1799774 (IVS20delT-11) and rs7754561 (A/G_1044TGA) polymorphisms for association analysis in 911 type 2 diabetic patients (459 female/452 male) and 876 control subjects (430 female/446 male) using TaqMan assay. According to single locus association test, in IVS20delT-11, we identified a significant association of delT allele with type 2 diabetes in Japanese (adjusted odds ratio, 1.50; 95% confidence interval, 1.15-1.99); $p=0.0002$). In a haplotype association analysis, we failed to find any significant association between Q-delT-G haplotype and type 2 diabetes ($p>0.05$). A subanalysis of subjects depending their body mass index (BMI) status revealed no significant impact of the 3 polymorphisms and Q-delT-G haplotype on BMI. In conclusion our study indicated the potential role of an intronic polymorphism IVS20delT-11 with type 2 diabetes in Japanese.

P06.230

Searching for molecular markers of polycystic ovary syndrome

K. Wertheim¹, A. Sobczynska-Tomaszewska¹, J. Maciejewski², P. Kubik², U. Szutkowska², J. Bal³;

¹Institute of Mother and Child, Department of Medical Genetics, Warsaw, Poland, ²Institute of Mother and Child, Clinic of Obstetrics and Gynaecology, Warsaw, Poland, ³Department of Genetics and Biotechnology, Warsaw University, Warsaw, Poland.

Polycystic ovary syndrome (PCOS) affects about 10% of women in reproductive age. PCOS is recognized in the presence of at least two of the following symptoms: oligomenorrhea, hiperandrogenism, polycystic ovaries morphology. Disease results in infertility and increased risk of diabetes type 2, cardiovascular disease, endometrial cancer. Etiology of the syndrome remains unknown, although interaction of genetic and environmental factors is mostly discussed. Several meta-

bolic genes are probably involved in PCOS pathogenesis.

The aim of our study was to investigate whether there is a correlation between variants of genes: *IRS-1*, *IGF-2*, *SHBG*, *INS* and symptoms of PCOS in Polish patients.

Up-to-date 64 PCOS patients (diagnosed on the basis of criteria mentioned above) and 37 health controls were enrolled to our study.

We focused on four polymorphisms G972R (*IRS-1*), Apal-rs680A/G (*IGF-2*), TAAAn (*SHBG*) and VNTR class/III (*INS*) tagged by -23HphI-rs689 A/T.

Our results indicate that:

- prevalence of 972R variant is higher in PCOS group
- allele A of Apal is less frequent in the patient group compared with controls. On the contrary genotype A/A is more prevalent in patients group.
- VNTR class/III distribution in both groups is nearly the same, whereas class III alleles homozygotes are more frequent among PCOS patients
- TAAAn - any association with neither PCOS nor its severity was found.

Our preliminary studies indicate, in consistent with literature, that variants of genes (*IRS-1*, *IGF-2*, *INS*) can be among the factors involved in PCOS pathogenesis. Nevertheless further analysis on larger cohort is performed.

Linking Genetic Susceptibility with clinical findings: a case study in periodontitis

V. **Moustakis**^{1,2}, G. Potamias¹, M. Laine³, B. Loos³, L. Koumakis¹;

¹Institute of Computer Science, FORTH, Heraklion, Greece, ²Dept. of Production Engineering and Management, Technical University of Crete, Chania, Greece, ³Dept. of Oral Microbiology and Dept. of Periodontology, Academic Centre for Dentistry Amsterdam (ACTA), Amsterdam, The Netherlands.

Diagnosis and hypothesis formation in clinical decision making (CDM) involves the integration of patient history, clinical and laboratory findings. Patient history incorporates genotypic information and carries genetic susceptibility towards disease manifestation. We present a hybrid multi-stage computational model which, in the first stage assesses a genetic susceptibility index (GSI) towards disease, in the second stage links GSI with phenotypic (clinical and laboratory) parameters and in the third stage generates comprehensible knowledge patterns that tie together genotypic and phenotypic information sources. The model integrates two inductive machine learning methods, namely: association rule mining (ARM) and decision tree learning (DTL) with behavioral communication theory. ARM is used to support formation of genotypic patterns which, are taken through a behavioral communication theory model to establish GSI both at the genotype and phenotype levels. DTL is included at the third stage to validate learned knowledge.

The model is demonstrated by means of a case study on periodontitis. Data are drawn from the warehouse of ACTA and incorporate genotypic and phenotypic data. Genotypic data include single nucleotide polymorphisms (SNP) and origin and clinical data include microbial values, life style habits, and age. The application of the model on the abovementioned data validates the proposed approach.

Presentation is cast in topic "Genetic analysis, linkage, and association" and documents a generic procedure, which can be used in any endeavor aimed at genotype - phenotypic data and knowledge integration.

Work reported was partially supported via the INFOBIOMED NoE, and to be also used in the GEN2PHEN European project.

The GATC project: identification of novel genetic markers of cisplatin induced hearing-loss in children

H. **Katzov-Eckert**^{1,2}, C. J. D. Ross^{1,2}, H. Visscher^{1,2}, C. Hildebrand³, M. Dube⁴, R. S. Rassekh³, P. Rogers³, M. S. Phillips⁴, B. C. Carleton^{2,3}, M. R. Hayden^{1,2};

¹Centre for Molecular Medicine and Therapeutics, Vancouver, BC, Canada,

²University of British Columbia, Vancouver, BC, Canada, ³Children's and Women's Health Centre of B.C., Vancouver, BC, Canada, ⁴University of Montreal, Montreal, QC, Canada.

Adverse drug reactions (ADRs) are potentially life-threatening responses to medications. Children are at greater risk for ADRs, because >75% of approved drugs used in children are untested in pedi-

atric populations. Adverse drug reactions in pediatric oncology regimens are especially severe and account for 22% of all pediatric oncology hospital admissions. Cisplatin is one of the most effective anti-cancer agents for the treatment of solid tumors. However, a major dose-limiting toxicity of cisplatin is severe, permanent hearing loss. In previous studies the risk of developing cisplatin ototoxicity was increased with younger age and higher cumulative dose, but the contribution of genetic risk factors remains undetermined. We aimed to evaluate genetic markers predictive of hearing loss in children treated with cisplatin. DNA samples and detailed clinical information from cisplatin induced hearing-loss cases (n = 60) and drug-matched controls (n = 44) were collected through the GATC nation-wide ADR surveillance network. DNA samples were genotyped for a panel of 3072 single nucleotide polymorphisms (SNPs) in 220 genes. A significant genetic association with increased hearing loss risk was found for patients carrying variants in a key drug metabolizing enzyme (P-value=0.0001; OR=infinity). In addition, variants in known drug transporters were also associated with cisplatin ototoxicity (P<0.002; OR=3). Our results confirm findings that cisplatin-hearing loss is associated with a genetic susceptibility. The identification of genetic variants contributing to cisplatin ototoxicity is essential in the development of diagnostic markers to reduce the incidence of hearing loss, and make cisplatin treatment safer for children.

P06.233

The ability to become an elite endurance athlete depends on the carriage of high number of endurance-related alleles

I. I. **Ahmetov**, A. M. Hakimullina, J. V. Shikhova, I. A. Mozhayskaya, V. A. Rogozkin;

St Petersburg Research Institute of Physical Culture, St Petersburg, Russian Federation.

The objective was to evaluate the total contribution of CNB, NFATC4, PGC1A, PGC1B, TFAM, VEGF, UCP2, UCP3 gene alleles in defining predisposition to sports. The study involved 1580 Russian athletes and 1057 controls. CNB (calcineurin B) 5I/5D, NFATC4 (nuclear factor of activated T-cells, calcineurin-dependent 4) Ala160Gly, PGC1A (PPARGgamma coactivator-1-alpha) Gly482Ser, PGC1B (PPARGgamma coactivator-1-beta) Ala203Pro, TFAM (transcription factor A, mitochondrial) Thr12Ser, VEGF (vascular endothelial growth factor) G-634C, UCP2 (uncoupling protein 2) Ala55Val, UCP3 (uncoupling protein 3) -55C/T gene polymorphisms were determined by PCR-RLFP. We found that the frequency of endurance-related alleles (CNB I, NFATC4 Gly, PGC1A Gly, PGC1B Pro, TFAM Thr, VEGF C, UCP2 Val, UCP3 T) were significantly higher in Russian elite endurance-oriented athletes (n=351) compared to controls, both separately and cumulatively (45.6% vs. 37.4%, p<0.0001). Furthermore, 66.7% of highly elite endurance-oriented athletes (Olympic and World championship winners; n=12) were carriers of 8 to 12 endurance-related alleles (the others were carriers of 7 alleles), while there were only 18.1% of such persons in the control group (p<0.0001). Thus, the success in sports can be attributed to the carriage of high number of alleles associated with certain physical qualities.

P06.234

Screening of the PKD1 gene in Czech patients with autosomal dominant polycystic kidney disease

J. **Stekrová**¹, J. Reiterová², S. Svobodová¹, V. Kebrdlová¹, P. Lněnička¹, M. Merta², J. Zidovská¹, M. Kohoutová¹;

¹Institute of Biology and Medical Genetics of the 1st Faculty of Medicine and General Teaching Hospital, Charles University, Prague, Czech Republic, ²Department of Nephrology of the 1st Faculty of Medicine and General Teaching Hospital, Charles University, Prague, Czech Republic.

Autosomal dominant polycystic kidney disease (ADPKD) is the most common hereditary renal disease. The disease is caused by mutations of PKD1 (affecting roughly 85 % of ADPKD patients) and PKD2 (affecting roughly 14 % of ADPKD patients) genes, though in several ADPKD families the PKD1 and/or PKD2 linkage was not found. Mutation analysis of the PKD1 gene is complicated by the presence of highly homologous genomic duplications of the first two thirds of the gene.

The direct detection of mutations in the non-duplicated region of the PKD1 gene was performed in 78 nonrelated ADPKD patients. The direct detection of mutations in the whole PKD1 gene was performed in next 12 nonrelated ADPKD patients.

The duplicated region of the PKD1 gene was amplified by long range polymerase chain reaction (PCR) followed by nested PCR. Mutation screening was performed using denaturing gradient gel electrophoresis (DGGE), heteroduplex analysis (HA) and high-resolution melting (HRM). Suspected samples were then sequenced.

In the PKD1 gene we detected 30 germline mutations among 90 unrelated individuals; 24 mutations unique for Czech population. We identified 11 nonsense mutations, 13 missense mutations, 3 frameshifting mutations, 2 deletion in-frame and 1 mutation in splice site. In the PKD1 gene we detected great numbers of different polymorphisms or unclassified variants.

Establishment of localisation and type of mutations and their genotype - phenotype correlation in ADPKD families will improve DNA diagnosis and could help to assess the clinical prognosis of ADPKD patients.

The association of metabotropic glutamate receptor subtype 8 (mGluR8) polymorphism with executive attention

J. V. Schegolkova, V. A. Shleptsova, A. G. Tonevitsky;
Moscow State University, Moscow, Russian Federation.

The glutamatergic signaling pathway represents candidate susceptibility system involved in mechanism of forming attention and working capacity. One of attractive candidate for study of molecular physiology of attention is metabotropic glutamate receptor subtype 8 (mGluR8). Expression of mGluR8 was observed in the olfactory system, the neocortex, the limbic cortex including the hippocampus and the amygdala. Electron microscopically, mGluR8 was largely observed on the axon terminals. Especially in several regions of the hippocampus it was found in the active zone of both asymmetrical and symmetrical synapses where mGluR8 may regulate glutamate release as an autoreceptor or GABA release heterosynaptically.

Influence of mGluR8 polymorphism located 29 bp after the termination codon (2756C/T) on executive attention was conducted on volunteers. 108 students of Moscow State University (mean age 20±2, girls = 61, boys = 47) were tested by Schulte tables. We found significant association of mGluR8 polymorphism with executive attention only in males. Carriers of T allele (TT,CT) implemented the test faster than CC group (p=0,02).

Q192R and L55M polymorphism of PON1 in patients with coronary heart disease (CHD) of different age and sex.

G. D. Pardo Perales¹, M. A. Bogdanova², A. N. Voitovich³, O. S. Romashkina², O. A. Bercovich³, S. I. Yagashkina⁴, O. N. Semenova⁴, V. A. Isakov², O. A. Berkovich⁵, H. B. Kirillova¹, V. I. Larionova²;

¹St. Petersburg State Chemical Pharmaceutical Academy, Saint-Petersburg, Russian Federation, ²St. Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation, ³St. Petersburg Electrotechnical University, Russia, Saint-Petersburg, Russian Federation, ⁴Research Center for people who lived in blockaded Leningrad, Saint-Petersburg, Russian Federation, ⁵St. Petersburg State Medical University, Saint-Petersburg, Russian Federation.

Paraoxonase-1, a high-density lipoprotein-associated enzyme, is believed to protect low-density lipoproteins from oxidation and thus decrease the risk of CHD. The aim of this study was to investigate if paraoxonase-1 gene (*PON1*) Q192R and L55M polymorphisms influence the risk of CHD. 597 patients (438 men and 159 women) were included in our study: 227 men who survived myocardial infarction (MI) under the age of 45 (group I), 96 men with MI after 60 years (group II) and 115 healthy men (group III); 75 angiographically diagnosed CHD women (group IV) and 84 women without CHD (group V). All patients originated from Saint-Petersburg, Russia. Genotypes were determined by PCR-RFLP, paraoxonase activities were measured spectrophotometrically and standard enzymatic methods were used to determine levels of total cholesterol, triglycerides and HDL cholesterol on a spectrum analyzer. Statistical significance of differences between groups was assessed with χ^2 -test. We found that in group IV the frequency of 55M allele of *PON1* was a statistically higher comparing to group V (p=0,029). In group I amount of QR patients were significantly higher comparing to group IV (p=0,003). In group II amount of QQ patients were significantly lower comparing to group IV (p=0,009). There were no any differences in allele or genotype frequencies distributions be-

tween the groups of CHD men. Our results suggest that both Q192R and L55M *PON1* polymorphisms play the role in risk of CHD. Furthermore, *PON1* polymorphisms act in various ways in patients of different age and sex.

P06.237

The associations between PON1 55MM genotype and coronary artery disease and between the low HDL/LDL ratio values and the large arteries diseases

E. Strauss¹, K. Waliszewski², W. Supinski³, J. Gluszek², W. Majewski², M. Swierczek¹, M. Juszcak¹, A. L. Pawlak¹;

¹Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland,

²Medical University, Poznan, Poland, ³Regional Hospital, Gorzow Wlk, Poland.

The differences in the vascular diseases risk factor profiles, depending on the localization of the arterial diseases were analyzed in the series of 428 patients with coronary artery disease (CAD), 210 patients with aortoiliac occlusive disease (AIOD) and 255 cases of abdominal aortic aneurysm (AAA) - total 893 of vascular disease patients, as well as in 262 persons without symptoms of vascular disease. The SNPs of the genes related to the homocysteine metabolism: MTHFR 677 C>T, PON1-108C>T, L55M; as well as the lipoprotein profiles were analyzed in search for the functional differences predisposing either to the CAD or to the diseases of the large arteries. The SNPs were determined by PCR-RLFP methods.

In CAD group frequency of PON1 55MM genotypes (16,6%) was about 1,7-fold higher as compared to this either in AIOD+AAA group (10,8%, p<0,01) or in control group (9,9%; p<0,01), indicating the increased risk of CAD in persons with this genotype. In CAD group also the marginally higher frequencies of MTHFR 677TT and PON1 -108TT homozygotes were noted. On the other hand, the higher susceptibility to the large arteries diseases AIOD+AAA was found to be associated with the low values of HDL/LDL ratio (p<0,001), the highly heritable parameter which may be related to the lower activity of paraoxonase 1. In summary, the PON1 55MM genotype and the low HDL/LDL ratio appear to be the vascular disease type specific risk factors for the CAD and the large arteries diseases (AIOD+AAA), respectively.

P06.238

PPARG and PPARGC1A gene variants are associated with height in athletes

I. A. Mozhayskaya, I. I. Ahmetov, V. A. Rogozkin;

St Petersburg Research Institute of Physical Culture, St Petersburg, Russian Federation.

PPARGamma nuclear receptor positively promotes adipogenesis and negatively regulates osteoblast differentiation, indicating that PPARGamma is a negative regulator of bone mass. The Ala12 variant of PPARG gene Pro12Ala polymorphism is associated with lower transcriptional activity, increased body mass index and height in humans. PPARGC1A has been identified as a transcriptional coactivator of PPARGamma. Carriers of the Ser482 allele have been reported to have lower levels of PPARGC1A by comparison with Gly482 allele homozygotes. Therefore, one could expect that the Gly482Ser polymorphism might affect height too. The aim of the study was to investigate an association of PPARG Pro12Ala and PPARG1CA Gly482Ser polymorphisms with height in Russian male rowers and speed skaters. The study involved 99 rowers (height - 191.1 (5.4) cm, weight - 86 (9.7) kg; aged 20-27) and 64 speed skaters (height - 179.6 (6) cm, weight - 74.9 (8.8) kg; aged 20-25). Rowers were divided into three groups: the highest group (195-204 cm), the middle group (189-194 cm) and the lowest group (182-188 cm). Gene polymorphisms were determined by PCR-RLFP. We found that the presence of the PPARG 12Ala allele was significantly associated with higher body height (Ala/Ala+Pro/Ala- 182.7 (4.9) cm vs. Pro/Pro - 178.7 (6.1) cm; P=0.023) in speed skaters. The frequency of the PPARG1CA 482Ser allele was significantly higher in the highest group of rowers (33.3%), than in the middle (22.5%) and the lowest (18.8%) groups (P=0.032). In conclusion, functional polymorphisms in PPARG and PPARG1CA genes may influence the growth of the skeleton in male athletes.

P06.239**Susceptibility to preeclampsia in relation to ethnicity: multiple genes case-control study**

G. S. Demin¹, T. E. Ivashchenko¹, I. Bouba², E. V. Mozgovaia¹, V. S. Baranov¹, I. A. Georgiou²;

¹Ott's Institute of Obstetrics & Gynecology, St.-Petersburg, Russian Federation, ²University of Ioannina, Ioannina, Greece.

Pathogenesis of preeclampsia suggests endothelial dysfunction during pregnancy. Considering that endothelial gene polymorphism may affect relevant protein production the aim of the study was to investigate whether genetic variability in endothelial dysfunction-related proteins contributes to individual and ethnic preeclampsia susceptibility differences.

317 women from Greece and Russia with normal pregnancy or uncomplicated preeclampsia participated in the case-control study. Polymorphisms of the TNF-alpha (-308G>A and -238G>A), NOS1 (AAT)n, NOS2 (CCTTT)n, NOS3 (894G>T and 4a/4b), PAI-1 (4G/5G) and ACE (I/D) genes were determined by a PCR-based RFLP method.

Considering genetic heterogeneity between populations we carried out the comparison of allelic frequencies between controls from Russia and Greece and between patients from these countries. Analyzing results revealed that the frequencies of variants of NOS2, NOS3 and TNF-alpha genes differed between controls and patients according to ethnic origin. Our results show that it is incorrect to join samples from different countries if significant differences in allelic frequencies have been revealed.

According to the analysis of the polymorphisms independently and the development of preeclampsia, an association NOS3 4a/4b genotype (OR=2.18, 95%CI:1.07-4.45) was observed for Russian population. Severe preeclampsia was associated with TNF-alpha -308A allele (OR=5.07, 95%CI:1.10-23.48) in Greek population. When we investigated an interaction among these polymorphisms on the development of the preeclampsia, it was revealed that several combined genotypes were significant risk factors different in various populations.

The study of two populations has shown that preeclampsia is associated with misbalance in endothelial gene system, but genetic markers of disease vary in different countries.

P06.240**The X-linked DIAPH2 gene is a risk-factor for Premature Ovarian Failure (POF) and accounts for female preponderance among POF patients offspring**

S. Bione^{1,2}, T. Corre², F. Rizzolio², S. Sansanelli², S. Carrabino^{1,2}, M. Testa², R. Ricotti¹, D. Toniolo²;

¹IGM-CNR, Pavia, Italy, ²DIBIT-San Raffaele Scientific Institute, Milan, Italy.

Premature Ovarian Failure (POF) is a complex disorder, resulting in primary or secondary amenorrhea before the age of 45 and affecting 1% of women. Environmental factors have been shown to play a role in POF, but a strong genetic component is demonstrated by the prevalence of familial cases. The X chromosome was shown to be affected by structural rearrangements in several cases. Mendelian genes mutated in the disease are rare and the premutated allele at the FMR1 locus was shown to be a risk factor predisposing for the disease. These observations lead to the hypothesis of POF being a complex disorder caused by the additional effect of several risk factors.

The X-linked DIAPH2 gene was identified as interrupted by the breakpoint of a POF associated balanced translocation but its role in the pathogenesis of the disorder remains unclear as no causative mutations were found in a large number of cariotypically normal patients. An association study was performed in a large cohort of POF patients and controls revealed the presence of a risk-haplotype significantly associated to the disorder. Moreover the analysis of the offspring sex-ratio in the POF cohort demonstrated a strong female preponderance mainly attributable to the risk-haplotype identified. Taken together these results demonstrated that the POF condition is preferentially due to additional risk-factors and thus with a multifactorial pattern of inheritance. The DIAPH2 gene is one of the susceptibility genes involved and its role in the process of oogenesis and ovulation will be further investigated.

P06.241**Correlation of genotype/phenotype in primary Congenital Glaucoma patients from different ethnic groups of the Israeli population**

D. Bercovich^{1,2}, C. Shochat¹, S. Korem¹, O. Geyer³;

¹, Migal - Galilee Bio-Technology Center, Kiryat-Shmona, Israel, ²Tel Hai Academic College, Tel Hai, Israel, ³Department of Ophthalmology, Carmel Medical Center, Haifa, Israel.

Mutations in the CYP1B1 gene are responsible for more than 50% of primary congenital glaucoma (PCG) and mutations in the MYOC gene have also been associated with this disease. The OPTN gene is known to be associated with primary open-angle glaucoma and low-tension glaucoma. We noticed a different clinical presentation of PCG in our patients according to ethnicity. Our goal was to find a correlation between genotype and phenotype in people with PCG according to their ethnic origin. We screened the CYP1B1 gene in 86-individuals from 22-families of Israeli Moslem Arabs, Druze family and Ashkenazi and non-Ashkenazi Jewish, using the DHPLC apparatus. The screening revealed the cause for PCG in 11 of these 22-families. The mutations, includes a homozygous missense mutation R469W in exon-3 of the CYP1B1 gene in 4 different Druze and one Moslem families. Two Druze and two Moslem Arabs and one non-Ashkenazi families with the typical severe type of PCG were found to be compound heterozygous for two different DNA alterations. Screening the MYOC gene revealed in one of the non-Ashkenazi patient a heterozygous missense mutation and the patient was compound to another mutation in the CYP1B1 gene. No mutations were found in the OPTN gene in the families with no mutations in the CYP1B1 or MYOC. Establishing the genotype-phenotype correlations of PCG in our various ethnic backgrounds may add valuable knowledge for predicting the prognosis of the disease, for guiding therapeutic decision making and for genetic counseling of carriers of this cause of blindness in children.

P06.242**Gene screening for primary lateral sclerosis on chromosome 4pter-4p16.1 in a French-Canadian family**

V. V. Belzil¹, P. N. Valdmans^{1,2}, J. St-Onge¹, N. Dupre^{1,3}, G. A. Rouleau¹;

¹Universite de Montreal, Hopital Notre-Dame-CHUM, Montreal, QC, Canada,

²Department of Human Genetics, McGill University, Montreal, QC, Canada,

³Department of Neurological Sciences, CHAUQ Enfant-Jesus, Quebec, QC, Canada.

Primary lateral sclerosis (PLS) is a degenerative disease of upper motor neurons, characterized by a progressive spasticity resulting from the degeneration of cortical motor neurons which affects mainly the descending pathway of the corticospinal system. The lower extremities are first affected, followed by a spasticity of the trunk, of upper extremities and of bulbar muscles. A 550-marker whole genome scan was performed on a French-Canadian family with 12 individuals affected with PLS. This led to the identification of a locus on chromosome 4 between the telomere and marker D4S2928 (4pter-4p16.1). This is the first locus described for PLS. A maximum LOD score of 3.01 has been found for marker D4S2936. This region spans 10.2 megabase pairs and encompasses about 130 genes; 29 of those genes are clearly expressed in the brain. Five genes have already been screened without the detection of a coding mutation. We are currently screening the remaining genes in the candidate region. The identification of a gene responsible for PLS would help better understand motor neuron biology and pathology.

P06.243**Haplotype associations of the MHC with psoriasis vulgaris in Russian patients**

E. Galimova¹, V. Akhmetova¹, L. Gazizova², Z. Sultanova², E. Shushenacheva³, M. Kizlasova³, E. Khusnutdinova¹;

¹Institute of Biochemistry and Genetics, Ufa Scientific Center of Russian Academy of Sciences, Ufa, Russian Federation, ²Dermato-Venereology Hospital, Ufa, Russian Federation, ³Dermato-Venereology Hospital, Abakan, Russian Federation.

Psoriasis is a common inflammatory skin disease with a strong genetic component. Although eight psoriasis susceptibility loci (PSORS1-9) have been identified by genome-wide screening, linkage and association analysis have defined that MHC is the major genetic determinant related to psoriasis susceptibility. Haplotype associations of the MHC

with psoriasis vulgaris (PV) have been demonstrated in different racial or ethnic populations. To identify special haplotypes in Russian population that may contribute to the genetic susceptibility to PV, we investigated the distribution of the associated haplotypes in Russian cohort. 407 patients with PV and 418 controls were genotyped for *HLA-Cw6*, *HCR-C325T*, *HCR-A1911G* and *CDSN-C1243T* SNPs. The results showed: *HLA-Cw6* and *HCR-C325T*, *HLA-Cw6* and *HCR-A1911G* were in strong linkage disequilibrium (LD) ($D' = 0.67$, $r^2 = 0.4$ in all subjects and $D' = 0.66$, $r^2 = 0.37$ in patients; $D' = 0.87$, $r^2 = 0.13$ in all subjects and $D' = 0.88$, $r^2 = 0.16$ in patients, respectively), whereas LD was weaker between *HCR-C325T* and *CDSN-C1243T*; *HCR-A1911G* and *CDSN-C1243T* ($D' = 0.28$, $r^2 = 0.024$ in all subjects and $D' = 0.13$, $r^2 = 0.007$ in patients and $D' = 0.17$, $r^2 = 0.019$ in all subjects and $D' = 0.10$, $r^2 = 0.006$ in patients, respectively), suggesting a relative recombination hot-spot between *HCR* and *CDSN*. $Cw6/HCR-325^*T/HCR-1911^*G/CDSN-1243^*C$ ($\beta = 1.5$, $P < 0.000001$), $Cw6/HCR-325^*T/HCR-1911^*G/CDSN-1243^*T$ ($\beta = 2.6$, $P < 0.00005$) were identified as risk haplotypes for Russian population. In summary, our study of the Russian population suggest that a major psoriasis susceptibility gene resides in a region between *HLA-C* and *HCR* gene. Thus, the study of different populations will allow us to reduce the boundaries of the minimal PSORS1 region.

P06.244

Late cornified envelope (LCE) 3C and 3B genes deletion as a susceptibility factor for psoriasis

E. Riveira Muñoz¹, R. de Cid¹, J. Robarge², W. Liao³, P. L. J. M. Zeeuwen⁴, E. Dannhauser⁵, C. Helms⁶, G. Escaramís¹, E. Ballana¹, G. Martín⁶, E. E. Eichler⁷, C. Lázaro⁸, R. Pujol⁸, L. Armengol¹, J. Armour⁹, P. Kwok³, J. Schalkwijk⁴, A. Bowcock², X. Estivill¹;

¹Center for Genomic Regulation (CRG), Barcelona, Spain, ²Washington University School of Medicine, Saint Louis, MO, United States, ³University of California, San Francisco, CA, United States, ⁴Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, ⁵Institute of Genetics and School of Biology Queen's Medical Centre, Nottingham, United Kingdom, ⁶Hospital del Mar-IMAS, Barcelona, Spain, ⁷University of Washington, Seattle, WA, United States, ⁸Catalan Institute of Cancer, L'Hospitalet de Llobregat, Spain.

Psoriasis is a common inflammatory skin disease with a prevalence of 2 to 3% in Caucasian population, characterized by abnormal keratinocyte differentiation and recruitment of inflammatory cells in the epidermis. Although it is generally accepted that environmental and genetic factors contribute to its etiology, the genetic susceptibility alleles of psoriasis remain poorly understood. By using comparative genomic hybridization (CGH) analysis we have identified a copy number variant (CNV) spanning 32 kb of chromosome 1q21 and mapping to the psoriasis susceptibility locus PSORS4. This CNV comprises two genes of the epidermal differentiation complex, LCE3C and LCE3B, both members of the late cornified envelope gene cluster. The absence of LCE3C and LCE3B is significantly associated ($p = 0.0004$) with risk of psoriasis (OR = 3.0) in Spanish samples. The association was analysed in samples from The Netherlands and the US (combined allelic association of the three samples $p < 10E-10$). The CNV-deleted allele is tagged by telomeric SNPs that showed epistatic effects with the HLA locus. Since LCE3C expression was also shown to be induced in psoriasis lesions of patients that do not have the LCE3C/LCE3B deletion, it can be postulated that on deletion chromosomes, other genes in the cluster could be expressed in a similar pattern. Preliminary analyses also suggest that the LCE3C/LCE3B CNV loss may have a positional effect on neighboring genes. Thus, loss of LCE3C/LCE3B or altered expression of LCE genes in genetically susceptible individuals harboring the deletion might lead to abnormal skin barrier formation and psoriasis susceptibility.

Genomic gains and age at onset of psychosis

M. Fatjó-Vilas¹, M. J. Muñoz², S. Campanera³, S. Miret⁴, M. E. Navarro², M. Martín², M. Aguilera¹, **L. Fañanás¹**;

¹Unitat d'Antropologia, Dep. de Biologia Animal, Facultat de Biologia. Universitat de Barcelona, Barcelona, Spain, ²Àrea d'Adolescents. Benito Menni, Complex Assistencial en Salut Mental, Sant Boi de Llobregat, Spain, ³Centre de Salut Mental de Lleida, Servei de Psiquiatria i Drogodependències. Hospital

Santa Maria, Lleida, Spain.

Background: The recently discovered copy number variation of DNA segments is suggested to play a role in the development of complex disorders such as schizophrenia (Redon 2006, McCarroll & Altshuler 2007). This abundant genomic variability (submicroscopic deletions and duplications) directly links disease phenotypes to gene dosage alteration. Although early onset forms of some neuropsychiatric disorders have been associated to genetic abnormalities, molecular mechanisms of early psychosis remain unclear. The aim of the present study was to study the relationship between copy number genomic variability and early onset psychosis.

Methods: We performed a comparative genomic hybridization (CGH) analysis in 20

Caucasian male patients with a first episode of schizophrenia-spectrum disorder characterised for: age at onset (age of first symptoms range: 13-30 years; assessed with the Symptom Onset in Schizophrenia Inventory, Perkins 2000), neurocognitive profile (WISC/WAIS) and premorbid adjustment (Premorbid Adjustment Scale, Cannon-Spoor 1982). Pooled DNA of 20 Caucasian healthy males, without psychiatric history in their first and second degree relatives, was used as reference in hybridizations. Array CGH analyses were performed using Agilent Human Genome Microarray 244K (genome-wide coverage).

Results: Genomic gains in chromosome 17q have been associated to early psychosis (childhood and adolescent onset) (Benjamini-Hochberg (adjusted) $p < 0.01$).

Conclusions: Genomic variability in 17q chromosomal region seems to be underlying a significant proportion of illness early expression.

Is psychosis correlated with differential HSP90 expression?

L. Kapur¹, N. Pojskic¹, J. Ramic¹, J. Krehic², N. Pojskic³, D. Stefatic⁴, L. Oruc⁵;

¹Institute for Genetic Engineering and Biotechnology, Sarajevo, Bosnia and Herzegovina, ²Institute of Pharmacology, KCUS, Sarajevo, Bosnia and Herzegovina, ³Psychiatric Clinic, KCUS, Sarajevo, Bosnia and Herzegovina, ⁴International University of Sarajevo, Sarajevo, Bosnia and Herzegovina, ⁵Psychiatric Clinic KCUS, Sarajevo, Bosnia and Herzegovina.

Endoplasmic reticulum (ER) has a clear role in stress response signaling mechanism. Clear association of heat shock protein with schizophrenia was presented by Kim et al (2001) indicating significantly higher levels of HSP90 variant among schizophrenia patients. Recently, the involvement of HSP90 variability in development of major psychotic disorders was renounced by studying of differential expression of this gene preferentially associated with its rs17034977 polymorphism in bipolar disorder patients (Kakiuchi et al. 2007).

In this study, pathophysiological role of endoplasmic reticulum (ER) stress response signaling has been questioned for different subsets of patients with psychotic symptoms within schizophrenia, bipolar disorder and posttraumatic stress disorder. Association of specific HSP90B1 variant with psychosis was investigated.

Gender-biased prevalence of the risk allele of the PTPN22 gene in patients with type 1 diabetes and Addison's disease

M. Fichna¹, M. Zurawek², D. Januszkiewicz-Lewandowska², M. Gryczyńska¹, P. Fichna¹, J. Sowiński¹, J. Nowak²;

¹Poznań University of Medical Sciences, Poznań, Poland, ²Institute of Human Genetics, Polish Academy of Sciences, Poznań, Poland.

The *PTPN22* gene, encoding protein tyrosine phosphatase, a negative regulator in the T-cell activation and development, has been associated with susceptibility to several autoimmune diseases. The aim of this study was to investigate the association of *PTPN22*

G(-1123)C and C1858T polymorphisms with type 1 diabetes (T1D) and autoimmune Addison's disease (AAD) in the Polish population. A case-control study was performed with 215 T1D patients, 87 AAD individuals and 236 healthy controls. The *PTPN22* G(-1123)C and C1858T SNP were genotyped using PCR-restriction fragment assay (SacI and RsaI respectively). The CC genotype of G(-1123)C polymorphism was increased in AAD ($p = 0.030$) and (-1123)C was more prevalent in affected than in healthy males ($p = 0.003$). No significant difference was

found between T1D patients and controls. The 1858T allele presented an association with both T1D (OR=1.73, 95%CI 1.19-2.51, $p=0.0035$) and AAD (OR=1.84, 95%CI 1.15-2.94, $p=0.0099$). 1858T was associated with both diseases in males ($p=0.022$ and $p=0.008$, respectively). No statistical difference in females was found. Stratification according to the presence of concomitant autoimmune disorders revealed an association of 1858T with both clinical forms of T1D and polyendocrine cases of AAD. G(-1123)C and C1858T were in linkage disequilibrium ($D'=1.000$; $r^2=0.5396$ for AAD, and $D'=0.9818$; $r^2=0.6104$ in T1D). No significant association between the *PTPN22* haplotypes and ADD was found. The haplotype including both mutant alleles was significantly more frequent in T1D than in controls ($p=0.0033$). The results confirm the association of *PTPN22* C1858T polymorphism with T1D and AAD in Polish male population, while the G(-1123)C impact is less explicit.

P06.248

Mutation analysis of the PVRL1 gene in Caucasians with non-syndromic cleft lip/palate

M. A. Sözen^{1,2}, R. A. Spritz²;

¹Afyon Kocatepe University School of Medicine, Afyonkarahisar, Turkey, ²University of Colorado Denver Anschutz Medical Campus, Aurora, CO, United States.

Non-syndromic cleft lip with or without cleft palate (CL/P, MIM 119530) is perhaps one of the most common major birth defects. It has been shown that homozygosity for a nonsense mutation of PVRL1, W185X, result in an autosomal recessive CL/P syndrome (CLPED1), whereas heterozygosity for the same mutation is associated with sporadic, non-syndromic CL/P in Venezuela. The aim of the study was to investigate further involvement of the PVRL1 gene in non-syndromic cleft lip and/or palate in North American and Australian Caucasian populations. Therefore, a mutation analysis of PVRL1 gene covering all isoforms were carried out in 216 North American and Australian Caucasian patients and 223 population-matched controls using Single Stranded both populations studied. Particularly two variants were more frequent in Caucasian nsCL/P patients than in Caucasian controls. One, an in-frame insertion at Glu442, was more frequent in Caucasian nsCL/P patients than in Caucasian controls though not significant and another, S447L (PVRL1 beta isoform specific one), was found to be significantly more frequent in non-syndromic CL/P in North American Caucasian patients versus controls ($p=.032$), despite its failure to replicate in Australian population. These results suggest that PVRL1 may play a minor role in susceptibility to the occurrence of nsCL/P in Caucasian populations. It also suggests that the beta (HlgR) isoform might have a particular importance for craniofacial development based on this marginal association, and suggesting a possible genetic heterogeneity in the development of non-syndromic CL/P among the populations studied.

P06.249

Detecting associations in the presence of extreme allelic heterogeneity: Application to the rare variant common disease hypothesis

B. Li, S. M. Leal;

Baylor College of Medicine, Houston, TX, United States.

Association studies are frequently utilized to map variants which are susceptibility loci for common diseases. Critical assumptions of this approach are that the disease is due to a common functional variant which is in strong linkage disequilibrium with genotyped SNP(s) and there is minimal allelic heterogeneity. If the rare variant common disease hypothesis holds, current association based methods will be underpowered due to allelic heterogeneity, low allele frequencies and poor correlation (r^2) with tagSNPs. For common diseases where the underlying etiology is believed to involve extreme allelic heterogeneity, large scale candidate gene sequencing is currently underway to discover multiple causal rare variants. However, which methods are optimal for analyzing this type of data to detect associations is unknown. In this study, we analytically demonstrate that collapsing genotypes and rare variants across multiple loci is more powerful than multi-marker test (Hotelling's T^2) and single marker test (Fisher exact test). Although bioinformatics tools are used to classify variants, variants can be misclassified and erroneously included or excluded from the analysis based upon predicted functionality. Collapsing methods are robust against misclassification of rare variants, but misclassification of common variants can lead to a substantial loss of power. For

the situation where it is suspected that both common and rare variants are involved in disease etiology a powerful and robust novel method was developed which combines collapsing and multilocus tests. It is also demonstrated empirically that for both collapsing and combined methods type I error is well controlled.

P06.250

New mutation in the IGF-I receptor (IGF1R) gene associated with intrauterine growth retardation

E. Barrio¹, M. CALVO¹, J. Labarta², M. Miramar¹, F. Lorente¹, A. Rodríguez¹, E. Mayayo², A. Ferrández Longás²;

¹Molecular Genetics, HMI Miguel Servet, University of Zaragoza, ZARAGOZA, Spain, ²Unit of Pediatric Endocrinology, HMI Miguel Servet, University of Zaragoza, ZARAGOZA, Spain.

PATIENTS: We have studied 55 Spanish patients with short stature (<P3) associated with IUGR. We have also quantified plasma GH, IGF1 and IGFBP-3. The patients had normal or low levels of GH and high or normal levels of IGF1 and IGFBP-3. We have also studied 126 control samples.

MATERIAL AND METHODS: Genomic DNA was isolated from peripheral blood lymphocytes and amplified by PCR using primers that flank the coding regions of the 21 exons of the IGF1R gene.

Direct sequencing of the double stranded PCR fragments was performed (Abi Prism 310 Genetic Analyzer, Applied Biosystems).

RESULTS: In one patient with IUGR and short stature, we have found a mutation, in exon 7 in heterozygosis: Y487F. This mutation leads to a change in the aminoacid sequence. We have studied the IGF1R gene in this family and we have found this mutation present in the mother and the grand-mother also affected of short stature. This mutation was not found in the father, the aunt and the grand-mother aunt. We have not found this mutation in any of the 126 control samples studied.

DISCUSSION: The IGF1R gene is a tyrosine-kinase transmembrane receptor. The mutation Y487F changes a Tyrosine by a Phenylalanine, two aminoacid with a different polarity but with similar structure. This mutation in exon 7 should affect the extracellular domain, α subunit. This region is responsive of the binding IGF1. This nucleotide change is not a SNP as it was not present in the controls

P06.251

Reelin gene variation in working memory performance

J. Wedenoja¹, A. Tuulio-Henriksson^{2,3}, J. Suvisaar², T. Paunio^{1,4}, A. Loukola¹, J. Ekelund^{1,4}, T. Varilo¹, T. Partonen², J. Lönngqvist^{2,4}, L. Peltonen^{1,5};

¹Institute for Molecular Medicine Finland FIMM, National Public Health Institute, Helsinki, Finland, ²Department of Mental Health and Alcohol Research, National Public Health Institute, Helsinki, Finland, ³Department of Psychology, University of Helsinki, Helsinki, Finland, ⁴Department of Psychiatry, Helsinki University Central Hospital, Helsinki, Finland, ⁵Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

Lack of convincing results in gene identification for psychiatric disorders has increased interest towards quantitative traits and endophenotypes, which provide more power for the data analysis and are potentially more closely related to underlying biology.

In our previous study, we replicated schizophrenia linkage on chromosome 7q21-32 in 352 Finnish families. A regional Reelin (RELN) gene on 7q22, encoding for Reelin glycoprotein involved in neuronal migration during the brain development, and contributing to synapse remodelling, crucial for cognitive abilities, showed strong association with with an intragenic microsatellite marker (STR) and multiple cognitive traits in a subsample of 186 families with 618 neuropsychologically tested individuals.

Here, we utilized neuropsychological test data from 292 Finnish schizophrenia families with 923 tested individuals and 376 independent Finnish controls, and genotyped 96 RELN intragenic and flanking SNPs, two intragenic STRs, and one STR in RELN promoter. In the family sample, multiple SNPs associated with visual attention, visual working memory, learning, and executive functioning ($p=0.006$ to 0.0001). Furthermore, we obtained strengthened evidence for association between the previous STR and especially verbal and visual working memory ($p=0.007$ to 0.00002). Also multiple SNPs associated with positive symptoms of schizophrenia ($p=0.005$). Interestingly, also in the control sample multiple SNPs associated with visual attention, visual working memory, information processing speed, and general abilities ($p=0.004$

to 0.00008). The strongest signals emerged from the haploblock harboring the trait-associated STR.

These data provide further evidence for involvement of RELN gene variations in cognitive functions.

P06.252

The risk of respiratory distress syndrome in neonates from Bashkortostan, Russia and gene polymorphisms of cytochrome P450 (CYP1A1, CYP1A2) and glutathione-S-transferase M1 (GSTM1)

L. Khamidullina¹, K. Danilko², R. Fayzullina², T. Victorova¹;

¹Institute of Biochemistry and Genetics, Ufa, Russian Federation, ²Bashkortostan State Medical University, Ufa, Russian Federation.

We have investigated association between polymorphisms of cytochrome P450 genes (CYP1A1 (A2455G, T3801C), CYP1A2 (A-163C, T-2467delT)), glutathione-S-transferase M1 (deletion GSTM1) and risk of developing respiratory distress syndrome (RDS) in neonates from Bashkortostan.

After birth molecular oxygen and free radicals influence on the neonates lung. They are potentially harmful to cellular components. Antioxidants provide protection against oxidative damage to proteins, lipids and DNA.

We used whole peripheral blood of 144 patients with RDS and umbilical cord blood of 217 healthy term neonates for the isolation of genomic DNA. It was used PCR amplification. We used chi-square tests to detect the association between genes polymorphisms and RDS babies. It was shown that the CYP1A1 (T3801C) gene genotypes frequency distribution patterns not significantly differ between patients with RDS and healthy neonates ($\chi^2=1.92$, $df=2$, $P=0.382$). In male infants the CYP1A1 TC genotype was associated with higher risk of RDS (38.1% in patients vs. 20.5% in healthy babies; $\chi^2=6.8$, $P=0.009$; OR=2.39, 95%CI 1.23-4.68). While, the CYP1A1 TT genotype had a protective effect (60.7% vs. 78.7%; $\chi^2=7.0$ $P=0.009$; OR=0.41, 95%CI 0.22-0.81).

But at the same time we found no differences in the genotypes frequency distributions of the CYP1A1(A2455G), CYP1A2 genes within the patients and healthy groups.

We also didn't find any association of GSTM1 gene with RDS.

Our results showed that the polymorphisms in CYP1A1 may play a significant role in the development of RDS in male neonates.

P06.253

Genetic diagnosis of autosomal dominant and recessive Retinitis Pigmentosa using SNP high-throughput genotyping

E. Pomares^{1,2}, G. Marfany^{1,3}, R. González-Duarte^{1,2};

¹Dept. de Genètica. Universitat de Barcelona, Barcelona, Spain, ²CIBERER. Instituto de Salud Carlos III, Barcelona, Spain, ³IBUB. Universitat de Barcelona, Barcelona, Spain.

Retinitis Pigmentosa (RP), the major cause for blindness in the adults, is an extremely heterogeneous monogenic disorder which shows all mendelian types of inheritance. Up to now, more than 30 RP genes have been described, 17 of which are involved in autosomal dominant (adRP) and 20 in autosomal recessive (arRP) forms. However, many cases remain unassigned. Proper genetic diagnosis of the patients and potential carriers requires screening of all the candidates, but the high number of genes, with no major mutation sites, makes conventional mutation analysis time-consuming and costly for a small/medium sized laboratory. In addition, before undertaking the search for new RP genes, the already known candidates have to be ruled out. Taking into account these data and the fact that there is increasing evidence assigning the same candidate genes as responsible for distinct retinal dystrophies, we have designed an innovative time-cost effective strategy for cosegregation analysis of 39 RP and LCA genes by SNP genotyping on isolated families. This high-throughput strategy allows to discard the genes that do not cosegregate with the disease and highlights the remaining candidates. Subsequent mutational screening has allowed us to identify the causative mutations for several families. This type of analysis is very powerful in the arRP forms, particularly when the family is consanguineous. For adRP families, the analysis of several affected siblings is usually informative enough to discard most of the candidates. This approach can also be successfully applied to diseases with high genetic heterogeneity.

P06.254

Genomewide Linkage validation of the RP25 locus and Molecular Evaluation of Forty three Candidate Genes

J. Pieras^{1,2}, M. Abd El-Aziz², I. Barragan^{1,2}, C. O'Driscoll³, S. Borrego^{1,2}, L. Abu Safieh³, M. El-Ashry³, N. Carter⁴, C. Ponting⁵, S. Bhattacharya³, G. Antiñolo^{1,2};

¹Unidad de gestión Clínica de Genética, Reproducción y Medicina Fetal, Hospitales Universitarios Virgen del Rocío, Sevilla, Spain, ²Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), ISCIII, Seville, Spain, ³Department of Molecular Genetics, Institute of Ophthalmology, London, United Kingdom, ⁴The Wellcome Trust Sanger Institute, Wellcome Trust Genome Campus, Hinxton, Cambridge, United Kingdom, ⁵The Medical Research Council Functional Genetics Unit, Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, United Kingdom.

RP25locus (Chr.6:56.02-89.78Mb) was identified as the genetic cause in 14% of autosomal recessive Retinitis Pigmentosa (RP) in Spain. Linkage analysis has also reported the presence of this locus in Pakistani and Chinese families.

Our objective was: to confirm the initial findings of linkage to RP25locus by genomewide linkage analysis; mutation screening of genes from the RP25 region in 6 Spanish families with autosomal recessive RP (arRP) linked to this locus; analysis of new arRP families by microsatellite markers spanning the chromosome 6p12.1q15.

The data obtained using the 10KGeneChip-Mapping array have confirmed the original evidence of linkage to only the RP25locus in the three families with no linkage to any other region in the genome. Targeted linkage analysis of 18 newly ascertained arRP families led to the identification of five additional Spanish families also linked to RP25locus.

Bioinformatics analysis of the RP25 region indicated in excess of 111 genes with many showing retinal expression. 43 candidate genes were selected on the basis of their function, tissue expression pattern and/or the genetic data.

The direct sequence analysis from these genes (38,7%) led to the identification of 244 Single Nucleotide Polymorphisms, of which 76 were novel.

In conclusion, the fact that none of the observed variants were pathogenic exclude the screened genes as disease causing in these families. However, we could not rule out these genes as good candidates for other retinal degenerations mapping to the same chromosomal region.

These results support and validate the high prevalence of RP25 in the Spanish population.

P06.255

Retinoblastoma and microdeletion syndrome: identification of PCDH8 as a candidate for developmental delay

C. Dehainault¹, D. Michaux¹, L. Castera¹, I. Aerts¹, L. Desjardins¹, D. Stoppa-Lyonnet^{1,2}, M. Gauthier-Villars¹, C. Houdayer^{1,3};

¹Institut Curie, Paris, France, ²INSERM U830 Université Paris Descartes, Paris, France, ³UMR INSERM 745 Université Paris Descartes, Paris, France.

Retinoblastoma (RB), the most common pediatric intraocular neoplasm, results from inactivation of both alleles of the RB1 gene, located in 13q14.2. Whole germline RB1 gene deletions represent 6% of RB1 mutational spectrum. When the deletion involves the RB1 flanking regions it also causes a variable degree of mental retardation and several dysmorphic abnormalities.

In order to refine the role of chromosomal regions adjacent to RB1 in mental retardation and developmental delay, we decided to map the breakpoints in seven RB patients harbouring a whole gene deletion. Five of these patients presented no associated clinical abnormality, one presented a mild developmental delay with epileptic seizures, and one presented developmental delay with facial dysmorphism.

To precisely map the deletion breakpoints we designed a 385 000 oligo-custom array (Nimblegen) focusing on RB1 and its flanking regions (34-74Mb). We also used MP/LC, a multiplex semi quantitative PCR assay running on a DHPLC platform to further narrow the breakpoint regions. Then PCRs spanning the breakpoints were performed and sequenced which allowed the deletion breakpoints to be defined at the nucleotide level.

We compared the deleted intervals between RB-only patients and RB patients with developmental delay and define a 3Mb critical interval that includes a good candidate, protocadherin 8 (PCDH8). PCDH8 is thought to function in signalling pathways and cell adhesion in a cen-

tral nervous system-specific manner.

Further studies are now needed to refine the critical interval and to check putative involvement of PCDH8 in developmental delay.

P06.256

A functional heme oxygenase-1 promoter polymorphism confers susceptibility to rheumatoid arthritis

B. Rueda¹, J. Oliver¹, G. Robledo¹, M. Lopez-Nevo², A. Balsa³, D. Pascual-Salcedo⁴, M. Gonzalez-Gay⁵, M. Gonzalez-Escribano⁶, J. Martin¹;

¹Consejo superior de investigaciones científicas (CSIC), Armilla - Granada, Spain, ²Division of Immunology, Hospital Virgen de las Nieves, Granada, Spain,

³Division of Rheumatology, Hospital La Paz, Madrid, Spain, ⁴Division of Immunology, Hospital La Paz, Madrid, Spain, ⁵Division of Rheumatology, Hospital Xeral-Calde, Lugo, Spain, ⁶Division of Immunology, Hospital Virgen del Rocío, Sevilla, Spain.

Objective: To investigate the role of heme oxygenase-1 (HO-1) gene as a novel functional candidate gene for rheumatoid arthritis (RA).

Methods: We carried out a case-control study including 736 RA patients and 846 healthy controls of Spanish Caucasian origin. Two putative functional HO-1 promoter polymorphisms, a (GT)_n microsatellite and a -413 T/A single nucleotide polymorphism (SNP), were selected as genetic markers and genotyped using PCR-based methods. In addition, the intracellular expression of HO-1 was determined in healthy individuals with different (GT)_n genotypes.

Results: The distribution of HO-1 (GT)_n alleles (Short [S] ≤ 25 GT repeats and long [L] > 25 GT repeats) revealed a significant protective effect of S (GT)_n alleles (P = 0.019; OR 0.8, [95 % CI 0.7-0.9]) and SS (GT)_n genotype (P = 0.002; OR 0.4, [95 % CI 0.6-0.9]). In contrast, the -413 HO-1 promoter SNP did not yield any statistically significant deviation between RA patients and controls considering either allelic or genotypic frequencies. The haplotype analysis showed a strong protective effect of the S-A haplotype (P = 7E-07, P_c = 0.000003; OR 0.4 [95 % CI: 0.3-0.6]), whereas the L-A haplotype showed the opposite tendency (P = 0.008, P_c = 0.03 OR 1.2 [95 % CI 1.1-1.4]). In addition, we demonstrate that individuals carrying the SS (GT)_n genotype show a significantly higher percentage of HO-1 expression than LL homozygous individuals (P=0.0003).

Conclusion: In this study we identified the HO-1 (GT)_n microsatellite as a new genetic marker involved in RA genetics in our population.

P06.257

STAT4 gene and the risk of Rheumatoid Arthritis in the Tunisian population

M. Ben Hamad¹, H. Mbarek², S. Marzouk³, Z. Bahloul³, F. Fakhfakh¹, F. Cornelis², H. Ayadi¹, E. Petit-Teixeira², A. Maalej¹;

¹Laboratoire de Génétique Moléculaire Humaine, Sfax, Tunisia, ²Genotol-EA3886 Laboratoire de Recherche Européen pour la polyarthrite Rhumatoïde, Evry, France, ³Service de Médecine Interne CHU Hédi Chaker, Sfax, Tunisia.

The STAT4 (Signal transducer and activator of transcription 4) gene encodes a protein that plays an important role in the regulation and activation of certain cells of the immune system. In order to search an association of STAT4 rs7574865 T allele in the genetic predisposition to RA, we have studied 140 Tunisian patients affected with RA and 200 healthy controls. DNAs genotyping was carried out with a Taq-Man 5' allelic discrimination assay on an ABI 7500 real time PCR machine (assay: C_29882391_10) and data were analyzed by χ^2 -test. Genotype relative risk and Odds Ratio with 95% confidence interval. Our results showed that the T allele and the T/T genotype were more frequent in RA patients compared to controls ($p=0.008$; $p=0.003$, respectively) (OR = 0.6; CI = [0.41-0.88]). We next examined patients RA subgroups according to clinical and immunological data for association with STAT4. A significant association of both T allele and T/T genotype were found in patients presented erosion ($p=0.003$ and $p=0.006$). A genotypic association was observed according to the presence of nodules ($p=0.007$). Moreover, an allelic association were found when patients were stratified according to the presence of rheumatoid factor antibody (RF) ($p=0.015$) as well as the presence of another autoimmune disease ($p=0.021$). However, no significant differences in allele and genotype frequencies of rs7574865 were detected with anti-cyclic peptides antibodies (ACPA) positive RA patients ($p=0.1$ and $p=0.13$ respectively). These results support the involvement of STAT4 gene in the genetic susceptibility to RA in the Tunisian population.

Specific neuromuscular diseases in the Roma population living in Hungary

V. Karcagi¹, A. Herczegfalvi², J. S. Müller³, A. Abicht⁴, M. C. Walter⁵, R. Horvath², H. Lochmüller³, L. Kalaydjieva⁴;

¹National Institute of Environmental Health, Dept. of Molecular Genetics and Diagnostics, Budapest, Hungary, ²Bethesda Children's Hospital, Dept. of Neurology, Budapest, Hungary, ³Ludwig-Maximilians-University Munich, Friedrich-Bauer-Institute and Dept. of Neurology, Munich, Germany, ⁴Western Australian Institute for Medical Research and Centre for Medical Research, the University of Western Australia, Perth, Australia.

Interest in the unique genetic background of the Gypsy population led to the discovery of novel disorders in Bulgaria such as Hereditary Motor and Sensory Neuropathy type Loom (HMSNL) and type Russe (HMSNR) and the Congenital Cataracts Facial Dimorphism (CCFDN) syndrome. Studies across Europe characterized unique founder mutations in disorders such as Limb-Girdle Muscular Dystrophy 2C (LGM-D2C), Congenital Myasthenia Syndrome (CMS) and Spinal Muscular Atrophy (SMA).

Our group has recently investigated affected Hungarian Gypsy families. Large experience was obtained with CMS, as 43 Gypsy families with 65 affected and 90 unaffected family members were analyzed. In 63 patients the 1267delG founder mutation has been detected in homozygous form in the CHRNE gene, whilst two independent patients showed compound heterozygosity of the frame shifting founder mutation and a missense mutation. Out of the other specific neuromuscular diseases three families showed HSMNL with homozygous R148X mutation in the NDGR1 gene and another family was linked to 10q22, the candidate region of HSMNR. Two patients were genetically diagnosed as having CCFDN with homozygous mutation IVS6+389C→T in the CTPD1 gene. Four patients were found to be affected by LGMD2C where the gamma-sarcoglycan gene carried the C283Y founder mutation in homozygous form.

In Hungary, 8% of the population is represented by Romas. Therefore, the exact knowledge of the frequent disorders, with the nature and prevalence of the founder mutations and the carrier frequency is required. Precise genetic diagnosis, carrier testing and genetic counseling programs should be offered for this population at risk.

P06.259

Integration of omic data in identification of sarcoidosis candidate genes

A. Maver¹, I. Medica¹, B. Salobir², M. Tercelj², M. Sabovic², B. Peterlin¹;

¹Clinical Institute of Medical Genetics, Department of Gynecology and Obstetrics, UMC Ljubljana, Ljubljana, Slovenia, ²Department of Pulmonary Diseases and Allergy, UMC Ljubljana, Ljubljana, Slovenia.

Integration of genomic and transcriptomic information together with linkage analysis data allows for the identification of the genetic background of complex multifactorial diseases. This approach was performed in our search for possible candidate genes for sarcoidosis, combined with literature-based discovery knowledge.

A comprehensive search of Pubmed database for available transcriptomic, proteomic and genomic scan data for sarcoidosis has been performed. Additional information on possible candidate genes has been obtained by using BITOLA software, itself enabling advanced literature-based discovery searches of the Pubmed database. After careful inspection of discovered candidate genes, the most plausible candidates were selected for further analyses. Additionally, after identification of informative polymorphisms, the association of the candidate genes with the disease was investigated. In our previous studies we found a statistically significant association of PPARG and PPARGC1A polymorphisms with sarcoidosis.

By using omic approach we have identified new genes as potential gene candidates for sarcoidosis: Glutathione S-transferase Pi (GSTP1), Endothelin-1 (EDN1), 25-(OH)-Vitamin D₃-1 α -hydroxylase (CYP27B1), Osteopontin (SPP1).

In our study on 105 sarcoidosis patients and 100 controls, the preliminary results did not show evidence of significant association of allelic variants of single polymorphism in GSTP1, EDN1, SPP1, CYP27B1 gene with susceptibility to sarcoidosis. Further studies on larger sample of patients and multiple polymorphism/gene molecular analyses are currently in progress.

P06.260**Clinical and genetic analysis of a four-generation family with autosomal dominant cerebellar ataxia**

F. Annesi¹, D. Italiano², G. Provenzano¹, A. Laganà², P. Tarantino¹, F. Pisanò², E. V. De Marco¹, G. Annesi¹, A. Quattrone^{1,3}

Autosomal dominant cerebellar ataxias (SCAs) are a heterogeneous group of neurodegenerative disorders characterized by imbalance, dysarthria, progressive gait and limb ataxia which are variably associated with other neurological signs. There are many distinct loci associated to Mendelian forms of SCA, but only 15 genes have been identified (SCA 1-8, 10, 12-14, 17, 27 and DRPLA). Molecular genetic studies have shown that SCAs are caused by abnormal repeat expansions and that the age at onset is inversely correlated with repeat length. In the present study we conducted a genetic analysis of a SCA family from southern Italy, that included 15 affected members over four generations. The mean age at onset was 34 years with a strong evidence of anticipation across generations. We performed a mutational analysis searching for the most common SCA mutations and a linkage analysis for known genetic loci. The LOD score values were calculated using the LINKAGE program package, assuming an autosomal dominant inheritance and a disease frequency of 1 to 100,000. Penetrance in each subject was assigned to five liability classes determined from the age at onset. Pathological repeat expansions in the SCA 1, 2, 3, 6, 7, 8, 12, 17 and DRPLA genes were excluded. In addition, there was no evidence of linkage to SCA5 and SCA14 loci. We are now performing linkage analysis of remaining SCA known loci. The lack of any association will lead a full genome wide scan in order to identify the disease-related locus.

P06.261**Association analysis of 42 SNPs in the TSNAX and DISC1 genes in schizophrenia and bipolar affective disorder in the Polish population**

P. M. Czerski¹, A. Karpushova², S. Herms², P. Kapelski³, M. Wilkość⁴, B. Gdlewski⁵, M. Tomaszewska⁴, A. Leszczyńska-Rodziewicz³, J. Hauser⁶, J. Landowski⁶, A. Borkowska⁴, M. Rietsche⁶, M. M. Nöthen², S. Cichon²

¹Poznan University of Medical Sciences, Laboratory of Psychiatric Genetics, Poznan, Poland, ²University of Bonn, Department of Genomics, Life & Brain Centre, Bonn, Germany, ³Poznan University of Medical Sciences, Department of Psychiatry, Poznan, Poland, ⁴Clinical Neuropsychology Unit, Nicolaus Copernicus University Torun, Collegium Medicum, Bydgoszcz, Poland, ⁵Medical University of Gdansk, Department of Psychiatry, Gdansk, Poland, ⁶Central Institute of Mental Health, Division of Genetic Epidemiology in Psychiatry, Mannheim, Germany.

Linkage between schizophrenia and chromosome 1q42.2 markers has been reported independently in different populations worldwide. This region contains the gene TSNAX and Disrupted in Schizophrenia 1 (DISC1) which had been found to be disrupted by a balanced translocation and to co-segregate with schizophrenia in a large Scottish pedigree. Association studies investigating DISC1 single nucleotide polymorphisms (SNPs) in a number of samples were promising but not yet compelling.

In the present study, we aimed at investigating the possible contribution of TSNAX and DISC1 variants on the pathogenesis of SCH and bipolar affective disorder.

We investigated 42 SNPs, on the basis of previous association findings, using MALDI-TOF mass spectrometry-based SNP genotyping (Sequenom's iPLEX technology). The study sample comprised 501 DSM-IV diagnosed patients with schizophrenia, 418 DSM-IV diagnosed patients with bipolar affective disorder and 530 controls - all from the Polish population.

For single marker analysis DISC1 rs1615409 was associated with schizophrenia at the allelic ($p=0.001$) and genotypic ($p=0.002$) level. TSNAX rs1411776 showed an association with bipolar disorder and schizophrenia at the allelic ($p=0.015$, and $p=0.053$ respectively), and genotypic level ($p=0.038$ for bipolar disorder).

Our results provide evidence for the contribution of rs1615409 to schizophrenia susceptibility (particularly in females - $p=0.0004$), and modest evidence for an involvement of rs1411776 in the predisposition

to both studied diseases. However, only one SNP association survived correction for multiple testing - for rs1615409 in schizophrenia. More detailed analyses, including haplotype and subgrouping according to age at onset and family loading are currently underway and will be presented.

P06.262**A common haplotype of DRD3 affected by recent positive selection is associated with protection from schizophrenia**

J. Costas¹, N. Carrera¹, E. Domínguez², E. Vilella³, L. Martorell³, J. Valero³, A. Gutiérrez-Zotes³, A. Labad⁶, Á. Carracedo^{1,4}

¹Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain, ²BIOFARMA, Departament de Farmacologia, University of Santiago de Compostela, Santiago de Compostela, Spain, ³Psychiatric Hospital Institut Pere Mata. Faculty of Medicine, University Rovira i Virgili, Reus, Spain, ⁴Genomic Medicine Group, Institute of Legal Medicine, University of Santiago de Compostela, and CIBERER, Santiago de Compostela, Spain.

Recently, two independent reports identified association between haplotypes of the dopamine receptor (DRD3) gene and schizophrenia using different sets of tagSNPs. One of the reports suggests the existence of a common protective haplotype. A case-control association study was conducted in 273 schizophrenic patients and 512 controls from NE Spain. The characterization of the linkage disequilibrium patterns between tagSNPs of the previous reports was determined to allow for pooled analysis, comprising a total of 794 cases and 1078 controls. Searching for natural selection was done with tests based on extended linkage disequilibrium around specific haplotypes. The pooled analysis gives a strong statistical support for the existence of the protective haplotype (Mantel-Haenszel chi-square P value = 0.00227). This haplotype is linked to another haplotype at the locus, characterized by the Ser variant at the non-synonymous SNP rs6280, who increased its frequency recently by natural selection. Therefore, we can conclude that there is a DRD3 schizophrenia protective haplotype that has reached intermediate frequency due to the action of selection on a linked functional polymorphism. This finding reveals that natural selection may play a role in the existence of common alleles of susceptibility to schizophrenia, suggesting a new approach to find susceptibility loci.

P06.263**Recent adaptive selection at MAOB and ancestral susceptibility to schizophrenia**

N. Carrera¹, J. Sanjuán², M. Moltó³, Á. Carracedo^{1,4}, J. Costas¹

¹Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain, ²Psychiatric Unit, Faculty of Medicine, Clinical Hospital, University of Valencia, Valencia, Spain, ³Department of Genetics, Faculty of Biology, University of Valencia, Valencia, Spain, ⁴Genomic Medicine Group, Institute of Legal Medicine, University of Santiago de Compostela, and CIBERER, Santiago de Compostela, Spain.

The ancestral susceptibility hypothesis has been proposed to explain the existence of common susceptibility alleles. Some ancestral alleles, reflecting ancient adaptations, may be poorly adapted to the more contemporary environmental conditions giving rise to an increased risk to suffer some common disorders. In order to test this hypothesis in schizophrenia, we focus on monoamine oxidase B (MAOB). This gene is involved in deamination of several monoamines, including both xenobiotic amines present in several foods, as well as neurotransmitters such as dopamine. In addition, preliminary analysis based on phase I HapMap data suggested that recent natural selection have acted on this locus. We further explored the existence of this recent positive selection using a test based on extension of linkage disequilibrium (LD) to large distance at the specific selected haplotype taking data from HapMap phase II, and searched for association of the ancestral haplotypes to schizophrenia in a sample of 532 schizophrenic patients and 597 controls from Spain. Our analysis suggests the existence of a haplotype of MAOB subject to recent selection. In agreement with the ancestral susceptibility hypothesis, the ancestral haplotypes were significantly over-represented in patients ($P = 0.047$). These haplotypes confer an increased risk to schizophrenia, restricted to males ($P = 0.024$, $OR = 1.41$, 95% CI 1.01-1.90). Thus, pending on replication studies, MAOB seems to fit the ancestral susceptibility model, opening a new strategy to search for common schizophrenia susceptibility genes by focusing in those functional candidate genes subject to recent positive selection.

P06.264**Support for the involvement of NRG1 in schizophrenia in Iranian population: Evidence from a case: control association study**

S. A. M. Shariati¹, M. Behmanesh¹, H. Galehdar², A. Fathian², A. Foroughmand²;

¹Department of Genetics, School of Basic Sciences, Tarbiat Modares University, Tehran, Islamic Republic of Iran, ²Department Of Genetics, School of Basic Sciences, Chamran University, Ahwaz, Islamic Republic of Iran.

It has been accepted widely that schizophrenia is a multifactorial disorder and evidence in support of the involvement of genetic factor in pathology of schizophrenia is compelling. As a result of extensive study, a list of genes has emerged as candidate genes for schizophrenia. Research into genetics of schizophrenia has found Neuregulin1 (NRG1) among the most promising candidate genes for schizophrenia. For the first time in 2002, Steafansson et al suggested NRG1 as a candidate susceptibility gene for schizophrenia in a linkage study carried out in an Icelandic population. Since then, the association of NRG1 with schizophrenia was further confirmed by several studies in different population. However, analyzing allele and haplotype frequencies of NRG1 in distinct populations have yielded varying results and also different alleles or haplotypes have been associated with schizophrenia. Meanwhile, some studies have failed to replicate the association. In this work we attempted to study the association of two NRG1 polymorphisms with schizophrenia in Iranian population. SNP8NRG241930 and SNP8NRG221533 were studied in 100 cases of schizophrenia matched with 100 healthy individuals. For the first time in Iranian population, we showed a positive association between NRG1 and Schizophrenia. Our statistical analyses indicate that there are significant differences in allelic and genotypic frequencies between two studied groups.

P06.265**Autosomal recessive form is the predominant pattern in Iranian patients with Severe Combined Immune Deficiency Disease**

S. Safaei;

Immunology, Asthma and Allergy Research Institute, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Severe Combined Immune Deficiency is a X-linked and Autosomal Recessive disorder. World investigations showed nearly 48% X-linked inheritance which caused by mutations of the IL-2RG. This form of SCID is characteristically T-/NK-/B+. Also many genes involved in Autosomal Recessive pattern. The aim of this study was to determine the inherited pattern of SCID affected families in Iranian patients.

Methods: Genomic DNA of 5 male unrelated patients with T-B+ clinical symptoms of SCID was purified from peripheral blood. The sequencing of IL2RG was performed to find out if they harbour any mutation in these exons or not.

Result: We analyzed the IL-2RG (The X-linked mode of inheritance) of the patient for mutations by direct genomic sequencing, but found it to be normal, suggesting an autosomal mode of inheritance of SCID.

Discussion: About 48% of SCID patient were reported to have IL2RG deficiency in the word but our result shows that autosomal recessive pattern is the predominant in Iranian SCID patients even the number of patients is not enough to say strongly that. Because of consanguinity marriage it is also very hard to say that the patient who lost boy because of SCID had cause from IL2RG gene. Because of complexity of SCID we suggest that for those family who lost boy first linkage with Chromosome X and then if it is negative for that linkage with other causative genes. This is pilot study and much more investigation need to clarify that which gene is more frequently causative in Iranian Patient.

P06.266**Association of a GABA(B) gene haplotype and Temporal Lobe Epilepsy**

I. Manna¹, A. Gambardella^{1,2}, P. Forabosco³, A. Labate^{1,2}, E. Colosimo², R. Ambrosio², E. Le Piane⁴, U. Aguglia⁴, G. Di Palma¹, A. Quattrone^{1,2};

¹Institute of Neurological Sciences, National Research Council, PIANO LAGO DI MANGONE, Cosenza, Italy, ²Institute of Neurology, University Magna Graecia, Catanzaro, Italy, ³Department of Medical and Molecular Genetics, King's College London School of Medicine at Guy's, London, United Kingdom, ⁴Regional Epilepsy Centre, Hospital of Reggio Calabria, Reggio Calabria, Italy.

There is experimental evidence that dysfunctions of the GABA(B) receptor I gene (GABBR1) are implicated in the pathogenesis of temporal

lobe epilepsy (TLE). Using a candidate gene approach, we recently illustrated that the G1465A polymorphism in the GABBR1 is a strong risk factor for non-lesional TLE. Afterwards, other studies observed no evidence of association. To better investigate this association, we set out to examine whether common variations in GABBR1 predisposes to the development of non-lesional TLE. We performed a genetic association analysis of GABBR1 sequence variants by evaluating three SNPs and an (AC)_n repeat in a sample of 236 patients with non-lesional TLE and 380 age and geographic origin matched healthy controls. The program UNPHASED was used to compare genotype, allele and haplotype frequencies between cases and controls, including age and gender as covariates in the model.

We found that each variation conferred an increased risk of disease development. In addition, the four-SNP haplotypes were associated with the disease.

Our data show that genetic variability in GABBR1 is highly associated with susceptibility to non-lesional TLE, further corroborating our earlier observations. Further studies in different TLE patient-control cohorts are needed.

P06.267**Interleukin-23 receptor (IL23R) gene polymorphisms in patients with Sjögren syndrome**

E. Sáfrány¹, V. Csöngéi¹, L. Járómi¹, L. Magyari¹, A. Maász¹, C. Sipeky¹, M. Zeher², B. Melegh¹;

¹Department of Medical Genetics and Child Development, University of Pécs, Pécs, Hungary, ²Medical and Health Science Center, Institute for Internal Medicine, 3rd Department of Medicine, University of Debrecen, Debrecen, Hungary.

Sjögren syndrome (SS) is an autoimmune disease that mainly affects the exocrine glands. It is clinically characterized by keratoconjunctivitis sicca and xerostomia. Duerr et al. (Science, 2006; 314:1461-1463) found an association between Crohn's disease and the interleukin-23 receptor gene using genome-wide association; amongst the reported SNPs the 3'-UTR C2370A (rs10889677) conferred risk for Crohn's disease, the Arg381Gln (rs11209026) showed the strongest protective effect and the Pro310Leu (rs7530511) had no association with the disease. Since the IL23 pathway is known to associate also with other autoimmune diseases, we theorized that these SNPs might also have significance in the development of SS. We performed genotyping using DNA samples collected from 156 patients with SS and 182 unrelated, healthy controls. The genotypes were analysed using PCR/RFLP-methods. We found no significant difference between the allele frequencies of the two groups, as for rs10889677 the distribution of genotypes were CC 45.5%, CA 43.6%, AA 10.9% in patients with SS, while we observed CC 45.6%, CA 48.4%, AA 6.04% in the control group (not significant). For rs11209026 the genotypes were GG 87.8%, GA 12.2% and GG 86.3%, GA 13.7% in the examined groups. Similar results were obtained for rs7530511 also: CC 73.7%, CT 22.4%, TT 3.85% and CC 72.5%, CT 25.3%, TT 2.20% in the groups of patients and controls, respectively. Our results suggest that these SNPs do not play a role in the development of Sjögren syndrome.

P06.268**The STK11-PRKAA2-CRTC2 genes are play a major role in the genetic susceptibility to type 2 diabetes**

P. Keshavarz¹, H. Inoue², M. Itakura²;

¹Gilan University of Medical Science, Rasht, Islamic Republic of Iran, ²The university of Tokushima, Tokushima, Japan.

The activation of hepatic LKB1-AMPK-TORC2 signaling pathway, which is the probable target for the antidiabetic drug metformin, have a key role for development of type 2 diabetes (T2D). We hypothesized that genetic polymorphisms of the STK11, PRKAA2 (encoding AMPK α_2 subunit) and CRTC2 (encoding TORC2) could influence the susceptibility to T2D. We screened STK11 and CRTC2 by direct sequencing and genotyped in 1787 Japanese subjects. Additionally, the previously described association between the PRKAA2 haplotype and T2D was tested for replication. According to single locus association test, an intronic SNP in the STK11 (rs741765; OR 1.33, 95% CI 1.05-1.67, p = 0.017, under a recessive model), and a non-synonymous SNP in the CRTC2 (6909C > T: Arg379Cys; OR 3.01, 95% CI 1.18-7.66, p = 0.016, under a dominant model) showed a nominal significant association with T2D. In PRKAA2, two non coding SNPs, rs1418442 and rs932447 were associated moderately with T2D (OR 0.62, 95%

CI 0.40-0.96, $p = 0.030$, under a recessive model). Haplotype analysis showed that only in *STK11*, one haplotype containing the minor T allele of rs741765 was slightly associated with T2D ($P=0.04$). The association of *PRKAA2* haplotype reported previously in Japanese was not replicated in our samples. Among the three genes investigated herein, gene-gene (SNP-SNP) interaction studies provided evidence for an interaction between *STK11* and *CRTC2* influencing susceptibility to type 2 diabetes. In conclusion, this study has found a weak evidence that *STK11*, *PRKAA2*, or *CRTC2* polymorphisms contribute to the susceptibility to T2D in Japanese.

P06.269

Extremely High Carrier Frequency of SMA in Iranian Population

M. Hasanizad^{1,2}, M. Azad³, B. Shoja Saffar¹, A. Aghajani Refah¹, K. Kahrizi¹, H. Najmabadi^{1,3};

¹Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, ²Islamic Azad University, Tehran Medical Unit, Tehran, Islamic Republic of Iran, ³Kariminejad-Najmabadi Pathology and Genetics Center, 14665/154, Tehran, Islamic Republic of Iran.

Spinal muscular atrophy (SMA) is one of the most common autosomal recessive diseases, affecting approximately one in 6000 to 10000 live births and with a carrier frequency of approximately one in 40 to 60. About 94% of individuals with clinically typical SMA lack both copies of SMN1 exon 7.

Carrier frequency studies of SMA have been reported to be variable in different population and no population-based studies has been done in Iran, however our observations indicate that the incidence of SMA is much higher in Iranian population partly because of high rate of consanguineous marriages. The copy number of SMN1 gene was determined in 400 normal individuals by quantitative real-time PCR with SYBR Green I dye. The comparative threshold cycle (Ct) of each sample was calculated and albumin was used as a reference gene. The homozygous SMN1 deletion $\Delta\Delta$ Ct ratio of patient was 0.00 and the hemizygous SMN1 deletion $\Delta\Delta$ Ct ratio of obligate carriers ranged from 0.29 to 0.55. The $\Delta\Delta$ Ct ratio of 92 persons among 400 normal individuals was within the carrier range, 0.31-0.57.

Our data indicated that the carrier frequency of SMA in Iranian population is higher (1 out of 5) than other countries.

P06.270

Determination of the SMN1 and SMN2 copy number based on real-time PCR in Hungarian SMA families

M. Nagymihaly¹, A. Herczegfalvi², L. Tima³, V. Karcagi¹;

¹National Institute of Environmental Health, Dept. of Molecular Genetics and Diagnostics, Budapest, Hungary, ²Bethesda Children's Hospital, Dept. of Neurology, Budapest, Hungary, ³National Institute of Child Health, Genetic Counseling, Budapest, Hungary.

Spinal muscular atrophy (SMA) is characterized by progressive muscle weakness caused by degeneration of the spinal anterior horn cells. Patients with SMA have been classified into three types on the basis of clinical severity. The survival motor neuron gene is present in two copies, SMN1 and SMN2, which differ by only five nucleotides. Only SMN1 gene provides fully functional protein due to exon 7 skipping in SMN2. On the other hand, the SMA phenotype can be modified by the presence of several copies of SMN2.

SMA is a common and fatal disorder, therefore the carrier detection is essential for prevention and proper genetic counseling. Therefore, estimation of the SMN1 and SMN2 copy number in patients by real-time PCR has been recently introduced in Hungary. This technique is used also for the detection of possible compound heterozygotes.

Until now, SMN1 copies were determined in 25 affected patients and their 132 family members and twenty controls. Seven patients were identified as being compound heterozygotes and thus, the diagnosis of SMA was assumed. The intragenic point mutations will be identified later on by sequencing. Additionally, 151 SMA patients with undefined genetic diagnosis still have to be tested for the SMN1 copy number. For urgent family planning, 24 relatives of the known carrier parents were tested and 8 were confirmed as carriers of the common SMN1 mutation. Additionally, SMN2 copy number were estimated in 64 patients and in 33 family members and a good correlation was found between copy number and severity of the disease.

P06.271

Highly significant association between Contactin Associated Protein-like 2 (CNTNAP2) and non-word repetition in a language impaired sample

D. F. Newbury, L. Winchester, L. Addis, S. L. I. Consortium (SLIC), A. P. Monaco;

Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom.

Specific Language Impairment (SLI) is defined as a substantial delay in the development of language despite normal development in other areas and in the absence of accompanying neurological conditions like autism. Despite the diagnostic division between autism and SLI, the two disorders share many clinical features and researchers have proposed that they may share risk factors and involve mutual neurodevelopmental pathways. The lack of any clear genetic candidates has precluded the validation of this hypothesis at the molecular level. However, converging evidence from genetic research has recently implicated members of the neurexin gene family in autism. In the present study we therefore investigated a neurexin gene, Contactin Associated Protein-like 2 (*CNTNAP2*), within families affected by SLI. We typed 37 SNPs within 184 families ascertained by the SLI Consortium (SLIC). Quantitative TDT (QTDT) was used to assess marker-trait association for three language-related measures. Expressive and receptive language abilities were assessed with the Clinical Evaluation of Language Fundamentals (CELF-R) and a test of non-word repetition (NWR) was used to measure phonological short-term memory. We found a highly significant level of association (max $P=0.00005$) between NWR and a cluster of 9 SNPs within the *CNTNAP2* gene. A suggestive level of association was also observed in this region to both CELF measures (max $P=0.003$). These results were supported by subsequent haplotype and regression analyses. Our findings support the existence of shared genetic risk factors between SLI and autism, a conclusion which yields important consequences for the conceptualisation, diagnosis and treatment of these disorders.

P06.272

An investigation of dyslexia risk loci in families with Specific Language Impairment, (SLI), implicates KIAA0319 as a shared genetic factor

L. Addis, D. F. Newbury, L. Winchester, S. L. I. Consortium (SLIC), A. P. Monaco;

Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom.

Specific Language Impairment, (SLI), is defined as a considerable developmental delay in the acquisition and/or use of language in the absence of other diagnostic features such as hearing loss and autism. There is substantial co-morbidity of SLI with developmental dyslexia, in which children are described as having unexpected difficulties in learning to read, write and spell. This has led researchers to investigate the possibility of shared risk factors for the two disorders. Several genomic regions have shown consistent association to dyslexia on chromosomes 2, 6 and 15. We typed 16 SNPs identified within these regions in 175 language-impaired families, ascertained by the SLI Consortium (SLIC). Quantitative TDT (QTDT) was used to assess marker-trait association using both orthogonal (within family) and total (within- and between- family) association to three reading-related measures. These measures, taken from the Wechsler Objective Reading Dimensions (WORD), assess basic reading, spelling, and reading comprehension. Single SNP orthogonal analysis identified association of these measures to SNPs within *MRPL19/C2ORF3* on chromosome 2, and *DCDC2* on chromosome 6. Total association was found to the same SNP in *MRPL19/C2ORF3*, and also to a SNP within *KIAA0319* on chromosome 6. We used the SNP data to reconstruct haplotypes that had previously been reported to be associated with dyslexia. In this analysis, association was replicated only in the *KIAA0319* gene and with all reading-related measures. This investigation therefore indicates that the loci identified by studies of dyslexia, and in particular *KIAA0319*, may also contribute to reading ability in language impaired populations.

P06.273

Intronic sequence changes may have unpredictable effects on splicing

F. Joncourt, S. Gallati;

Human Genetics, Department of Pediatrics, University Hospital, Berne, Switzerland.

Mutation scanning often identifies yet undescribed sequence changes in genomic DNA, which are not easily classified as either pathogenic or neutral solely by sequence inspection. Increasing knowledge about the splicing process has revealed its great complexity: In addition to the well known splice-site consensus sequences in recent years a multitude of regulatory elements have been identified both within introns as well as within exons. In order to assess / confirm their pathogenic nature, we have analysed the effect on splicing of several yet functionally uncharacterized intronic sequence changes in different genes by analysing their respective RNA's. Lymphocytes from patients were immortalized, RNA was extracted and reverse transcribed. The cDNA was then amplified by PCR and analysed by PAGE or agarose gel electrophoresis. Bands with altered electrophoretic mobility were isolated, purified and sequenced. Two mutations located within the conserved donor and acceptor splice sites respectively (NF1: c.3496+1G>A and SPG4: c.1688-2A>G) were shown to lead to exon skipping as expected. c.357+2T>A identified in a patient's DMD-gene, however, resulted in the inclusion of 31 bases of intronic sequence into the mRNA leading to a frameshift, while exon skipping would have left the reading frame intact. This latter case further illustrates that the effect of an unknown mutation on the splicing process can not easily be predicted. The results emphasize the need for functional characterization of newly described sequence changes.

P06.274

SPRY1 molecular analysis in subjects with ureteral duplicity

L. Artifoni¹, E. Benetti², S. Negrisol¹, S. Centi¹, G. Caridi³, G. Ghiggeri³, L. Murer^{1,2};

¹Laboratory of Nephrology, Department of Paediatrics, University of Padua, Padua, Italy, ²Paediatric Nephrology, Dialysis and Transplantation Unit, Department of Paediatrics, University of Padua, Padua, Italy, ³Laboratory of Physiopathology of Uremia, Gaslini Institute, Genoa, Genoa, Italy.

Studies on murine models demonstrated that Sprouty1 protein, encoded by Spry1 gene, modulates Gdnf/Ret signal, which activates a crucial gene network in urinary tract development. Spry1-knockout mice develop supernumerary ureteric buds, that result in multiple ureters and kidneys. In the literature, there only one report about mutational analyses of human SPRY1 gene, the homologue of murine Spry1, even if the gene is known to be expressed in fetal renal tissue.

We carried out mutational analysis of SPRY1 gene in patients with ureteral duplicity: 23 isolated and 4 familial cases. On each DNA sample, the coding region and 5'UTR were analysed by SSCP and all PCR products were then directly sequenced (ABI PRISM 3100 Applied Biosystem). DNA from 6 subjects without kidney and urinary tract anomalies was used as control group.

We detected 5 polymorphisms (SNPs), previously reported in databases, and 1 nucleotide substitution, which has never been reported. The frequency of this substitution was estimated in 127 umbilical cord blood DNA samples and was 0.094. In order to understand SPRY1 role in renal development, mutational analysis will be extended to a population of subjects with different malformative nephrouropathies and association studies with the detected polymorphisms will be performed.

P06.275

Transcriptomic analysis of statin treated rat skeletal muscle cells

M. J. Ko, H. S. Choi, H. S. Jeong, J. I. Ahn, S. Y. Kim, H. J. Chung;

National Institute of Toxicological Research of Korea, Seoul, Republic of Korea. Statins are competitive hydroxy-3-methyl glutaryl coenzyme A(HMG-CoA) reductase inhibitors that inhibit the synthesis of cholesterol from mevalonic acid. Statins are the drugs most frequently used to reduce plasma cholesterol levels and decrease cardiovascular events. However, the side effects associated with the use of statins have been highlighted by the withdrawal of cerivastatin from the market in 2001, but little is currently known about the effect of statins on the RNA expression profile of skeletal muscle cells and mechanism of myopathy.

To address this issue, we used rat L6 myoblast cells, which can differentiate into myocytes, in this study. We treated cells with cerivastatin which had developed potent myopathy or pravastatin relatively less toxic than cerivastatin, and measured cell viability using MTT assay. MTT assay showed significant concentration-dependent decrease of cell viability by treatment of statins and revealed cerivastatin is much more toxic than pravastatin. It seems that DNA microarrays could be very helpful not only to predict drug-induced toxicity, but also to better understand the mechanism of actions of drug. Using DNA microarrays, we discovered 522 genes that are specifically responsible to cerivastatin-induced muscle cell toxicity and these genes correctly classified as muscle toxicity group. Moreover fifteen genes that are the potential candidates as myopathy biomarkers were selected. Among them, seven genes are the sensitive genes that were showed response even at the low toxic dose, and eight genes are responded in dose-dependent manner.

Genetic association study of Kalirin and Ropporin with ischemic stroke

T. Krug¹, H. Manso^{1,2}, L. Gouveia³, B. V. Fonseca¹, I. Albergaria², G. Gaspar², M. Correia⁴, M. Viana-Baptista⁵, R. M. Simões⁶, A. N. Pinto⁶, R. Taipa⁴, C. Ferreira⁷, J. R. Fontes⁷, M. R. Silva⁸, J. P. Gabriel⁸, I. Matos⁹, G. Lopes⁴, J. M. Ferro³, A. M. Vicente^{1,2}, S. A. Oliveira¹;

¹Instituto Gulbenkian de Ciencia, Oeiras, Portugal, ²Instituto Nacional de Saude Dr. Ricardo Jorge, Lisboa, Portugal, ³Hospital de Santa Maria, Lisboa, Portugal, ⁴Hospital Geral de Santo Antonio, Porto, Portugal, ⁵Hospital Garcia de Orta, Almada, Portugal, ⁶Hospital Fernando Fonseca, Amadora, Portugal, ⁷Hospital Sao Marcos, Braga, Portugal, ⁸Hospital de Sao Pedro, Vila Real, Portugal, ⁹Hospital Distrital de Mirandela, Mirandela, Portugal.

Introduction: Cerebrovascular and cardiovascular diseases such as stroke and coronary artery disease (CAD) are the leading causes of death and disability worldwide. They are complex disorders resulting from the interplay of genetics and environment, and may share several susceptibility genes. Recently, an association-mapping study in the chromosome 3 linkage peak for CAD found that the rs9289231 SNP in the Kalirin gene (*KALRN*) was associated with CAD in multiple datasets. *KALRN* is involved, among others, in the inhibition of inducible nitric oxide synthase, in guanine exchange factor activity, and in the Rho GTPase-signaling pathway. The goal of the present study was to determine whether SNPs or haplotypes in the *KALRN* gene region, which includes the Ropporin gene (*ROPN1*), predispose to ischemic stroke (IS) in a cohort of Portuguese patients and controls.

Methods & Materials: We genotyped 27 tagging SNPs in the *KALRN-ROPN1* chromosomal region, on 565 IS patients and 518 unrelated controls, and performed single-marker association tests.

Results: Intronic SNP rs11712619 in *KALRN* was associated with IS risk in unadjusted (allelic and genotypic $p=0.003$) and adjusted (log-additive model $p=0.027$, adjusted for age-at-examination, hypertension, diabetes, ever smoking/drinking) tests. A block of six SNPs (from rs2280422 to rs12637456), located mostly in the *ROPN1-KALRN* intergenic region, had a modest ($0.02 < p < 0.05$) allelic and genotypic association with IS risk when unadjusted for co-variables. The rs9289231 SNP was not associated with IS in any test performed.

Conclusions: This study suggests that variants in the *ROPN1-KALRN* region may constitute risk factors for stroke in the Portuguese population.

P06.277

Polymorphisms in PDE4D gene region are associated with ischemic stroke recovery

H. Manso^{1,2}, T. Krug¹, T. Magalhães^{1,2}, B. V. Fonseca¹, J. Sobral^{1,2}, I. Albergaria², G. Gaspar², J. M. Ferro³, S. A. Oliveira¹, A. M. Vicente^{1,2}, t. Portuguese Stroke GENetics (PORTSGEN) Group⁴;

¹Instituto Gulbenkian de Ciência, Oeiras, Portugal, ²Instituto Nacional de Saúde Dr. Ricardo Jorge, Lisboa, Portugal, ³Hospital de Sta. Maria, Lisboa, Portugal, ⁴Portugal, Portugal, Portugal.

Stroke is a major cause of permanent disability in developed countries. It is therefore of major importance to understand how to reduce brain damage and how to improve patient's recovery. Evidence from animal studies and an association between family history of stroke and stroke outcome suggests the existence of genetic factors influencing stroke recovery. The PDE4D gene, a regulator of cAMP degradation,

is a possible candidate because cAMP levels in immunocompetent cells influence the release of inflammatory mediators and relevant cytokines, which are important mediators of stroke recovery. Forty five SNPs covering genetic variation in the 5' region of the PDE4D gene, including SNPs previously associated with stroke risk in the Icelandic population, were genotyped in 430 ischemic stroke patients and tested for association with functional recovery. Stroke recovery was assessed 3 months after a stroke episode, using the modified Rankin Scale (mRS). Patients were classified in two groups: good (mRS \leq 1) or poor recovery (2 \leq mRS \leq 6). Binary logistic regression analysis was carried out to adjust for clinical severity parameters and risk factors with a significant impact on stroke recovery. Seven SNPs were associated with mRS (0.00098 $<$ P $<$ 0.048) after adjusting for significant co-variables - history of hypertension, aphasia, paresis, consciousness disturbance and medical complications during hospitalization. Five haplotypes, including at least one of the associated individual SNPs, were also associated with stroke outcome (0.0056 $<$ P $<$ 0.0367). These results suggest that PDE4D gene variants may contribute to individual variability in ischemic stroke recovery, possibly by playing a role in the neuroinflammatory processes that occur after stroke.

Association analysis of 677C>T polymorphic marker of MTHFR gene and suicide

Z. Khalilova¹, D. Gaysina², A. Kazantseva¹, E. Khusnutdinova¹;

¹Russian Academy of Sciences, Ufa, Russian Federation, ²Institute of Psychiatry, King's College London, London, United Kingdom.

Suicide is almost always a complication of a psychiatric illness, the most common of which is a mood disorder that generally accounts for 60% of cases. It has been reported that a functional single gene polymorphisms 677C>T (rs1801133) of methylenetetrahydrofolate reductase gene (MTHFR) is involved in pathogenesis of depression, and also of schizophrenia and bipolar disorder. The aim of our study was to conduct the association analysis of 677C>T polymorphism of MTHFR gene and suicidal behavior in 310 patients (134- Russians, 107- Tatars) and 434 health volunteers (169- Russians, 248- Tatars) from Bashkortostan (Russia) using PCR-RFLP technique. The distribution of genotype frequencies was in accordance with Hardy-Weinberg equilibrium. No significant differences in either allele or genotype frequencies of MTHFR 677C>T polymorphism were found between suicidal and control groups in Russian population. However in Tatar population MTHFR**T* allele (X² = 16.48; p $<$ 0.001; df = 1; OR = 2.13; 95%CI 1.47-3.08) and MTHFR**C*/*T* genotype (X² = 21.14; p $<$ 0.001; df = 1; OR = 2.95; 95%CI 1.85-4.737) were shown to be significantly associated with suicidal behavior. Moreover, MTHFR**C* allele (X² = 16.48; p $<$ 0.001; df = 1; OR = 0.47; 95%CI 0.33-0.68) and MTHFR**C*/*C* genotype (X² = 21.95; p $<$ 0.001; df = 1; OR = 0.33; 95%CI 0.21-0.53) are reported to be protective markers of suicidal behavior in Tatar population. Our study reports the involvement of MTHFR gene in predisposition to suicidal behavior; and it is shown that the effect is influenced by ethnicity.

¹CSIC, Armilla (Granada), Spain, ²Uppsala University, Uppsala, Sweden, ³Hospital Virgen de las Nieves, Granada, Spain, ⁴Hospital Xeral-Calde, Lugo, Spain, ⁵Hospital Clínico San Cecilio, Granada, Spain, ⁶Hospital Carlos-Haya, Malaga, Spain, ⁷Hospital Virgen del Rocío, Sevilla, Spain, ⁸Immunology Department, Hospital Virgen de las Nieves, Granada, Spain, ⁹Karolinska Institutet/Karolinska University Hospital, Solna, Sweden, ¹⁰Lund University Hospital, Lund, Sweden, ¹¹Lund University Hospital Section MIG, Lund, Sweden, ¹²Immunology Department, Hospital Virgen del Rocío, Sevilla, Spain, ¹³Medical School Hannover, Hannover, Germany.

The aim of this study was to determine the potential role of the CD24 A57V gene polymorphism with SLE. Our study includes three Caucasian cohorts: cohort 1 from Spain (696 SLE patients and 539 controls),

cohort 2 from Germany (257 SLE patients and 317 controls) and cohort 3 from Sweden (310 SLE patients and 247 controls). The CD24 A57V polymorphism was genotyped using a PCR system with pre-developed TaqMan allelic discrimination assay. In the Spanish cohort we found a statistically significant difference in the distribution of the CD24V allele between SLE patients and controls (P $<$ 0.0001, OR= 3.6, 95%CI 2.13-6.16). In addition, the CD24V/V genotype was increased in SLE patients (P $<$ 0.00001, OR= 3.7, 95%CI 2.16-6.34) compared with controls. Additionally, we sought to replicate this association with SLE in a Swedish and a German SLE population. A similar trend was found in the German set, where the CD24V/V genotype and the CD24V allele were more frequent in SLE patients than in controls, although this difference did not reach statistical significance. No differences were observed in the Swedish set. A meta-analysis of the Spanish and German cohorts demonstrated that the CD24V allele has a risk effect in SLE patients (Pooled OR= 1.25, 95%CI 1.08-1.46, P= 0.003). In addition, homozygosity for the CD24V risk allele significantly increased the effect (Pooled OR= 2.19, 95%CI 1.50-3.22, P= 0.00007). Our data suggest that the CD24A57V polymorphism plays a role in the susceptibility to SLE in a Spanish population.

P06.280

Genetic polymorphism of Eta-1/Osteopontin is associated with systemic lupus erythematosus in Korea

H. Kim¹, J. Song²;

¹laboratory medicine, Seoul, Republic of Korea, ²Internal medicine, Seoul, Republic of Korea.

Background: The aim of this study is to investigate the association with this SNP at position nucleotide 9250 (C->T) in OPN gene and susceptibility to SLE patients firstly. Also, we try to compare the allele frequency of Korean with them of USA and Japanese.

Materials and Methods: A total of 40 Systemic lupus erythematosus (SLE) patients and 104 healthy controls were studied. SNP located at position 9250 in the Osteopontin (OPN) gene were genotyped using the restriction fragment length polymorphism (RFLP). The wild-type sequence contains a C while the polymorphism variant is a T (C->T), which results in the appearance of an Alu I restriction site.

Results: The gene frequencies of C/C, C/T, and T/T at position 9250 on the Eta-1/osteopontin gene in SLE patients were 37.5%, 12.5%, and 50.0%, respectively, compared with 6.7%, 27.9%, and 65.8% in controls (p $<$ 0.05). The allele frequencies of C and T at this position in such SLE patients were 43.75 and 56.25, whereas those in controls were 20.7 and 79.3 (p $<$ 0.05), respectively. The allele frequencies found in the present study were compared with those coding SNP described in the USA database; 60 and 39 (USA) vs 20.7 and 79.3 (Korea) (p $<$ 0.05).

Conclusions: Those findings suggest Eta-1/osteopontin genetic polymorphism and allele frequencies were significantly association with SLE patients. Also we observed the difference of allele frequencies in our controls and in USA controls, these differences may be caused by a difference in incidence of SLE patients between the two countries.

P06.281

Analysis of the genetic variability in the TFF gene cluster

F. Marín^{1,2}, N. García^{1,2}, X. Muñoz^{1,2}, B. Hurtado¹, C. A. González², G. Capellà¹, N. Sala^{1,2};

¹Translational Research Laboratory, Institut Català d'Oncologia (ICO-IDIBELL), Hospitalet de Llobregat, Spain, ²Unit of Nutrition, Environment and Cancer, Cancer Epidemiology Program, Institut Català d'Oncologia (ICO-IDIBELL), Hospitalet de Llobregat, Spain.

The genes encoding the trefoil factor peptides (*TFF1*, *TFF2* and *TFF3*) are clustered in a 55 kb region on 21q22.3. TFFs are a small protein family secreted onto the mucous epithelia that play an important role in gastrointestinal mucosal maintenance. Genetic variation in these genes could influence inflammation progression to gastric cancer. To study association between polymorphisms in the *TFF* genes and gastric carcinogenesis, the purpose of this study was to characterize variability in the *TFF* cluster.

We selected *TFF* polymorphisms from public databases and used RFLP and SSCP/HD analysis to validate them in a control sample group. SSCP/HD was also used to scan the *TFF* genes for novel variants. Validated polymorphisms were genotyped in a larger population by real-time PCR and, one of them, by the recently developed *High*

Resolution Melting technology in the LightCycler 480. We performed linkage disequilibrium (LD) and haplotype analysis using the Haploview and SNPstats programs.

Six of the nine polymorphisms initially selected from the public databases were validated in our population. SSCP/HD analysis allowed for the identification of 9 novel SNPs (3 in *TFF1*, 4 in *TFF2* and 2 in *TFF3*), 7 of which could be functional, and a novel insertion polymorphism c.*66_67InsCTT, in the 3'UTR region of *TFF2*. Preliminary LD analysis indicates that each *TFF* gene is located in independent LD blocks and that high LD exists between SNPs in *TFF2*. Genotyping of these polymorphisms in case-control studies of gastric cancer is at present underway.

P06.282

Investigation of genetic component of susceptibility to atopic bronchial asthma and tuberculosis: xenobiotic-metabolising enzymes.

E. Bragina¹, M. Freidin¹, A. Rudko¹, O. Kolokolova², L. Ogorodova², A. Strelis², V. Pusyrev¹;

¹Institute of Medical Genetics of Tomsk Scientific Center of Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation, ²Siberian State Medical University, Tomsk, Russian Federation.

The relationships of polymorphic variants of the genes encoding xenobiotic-metabolising enzymes (*CYP2C19*, *CYP2E1*, *GSTT1*, *GSTM1*, *GSTP1*) with atopic bronchial asthma and lung tuberculosis, were studied in people of Tomsk region. An association of a deletion polymorphism of the *GSTM1* gene and a 7632T>A exchange of the *CYP2E1* gene with bronchial asthma were revealed ($p=0.008$ and $p=0.049$, respectively). Prevalence of a "null" genotype of the *GSTT1* gene was significantly different in groups of patients with various severity of bronchial asthma ($p=0.045$). It was shown that 313G/G genotype of the *GSTP1* gene is a factor of resistance to tuberculosis (OR=0.43; 95%CI: 0.20-0.91; $p=0.026$). 681G>A polymorphism of the *CYP2C19* gene was associated with scope of a pulmonary tissue damage ($p=0.040$) and with amount of erythrocytes in tuberculosis patients ($p=0.027$). 313A>G polymorphism of the *GSTP1* gene was associated with variability of alanine aminotransferase levels ($p=0.021$). The combination of the *GSTM1* +/- and *GSTP1* 313G/G, played a protective role for the both studied diseases (OR=0.10; $p=0.018$ for the asthma; OR=0.37; $p=0.045$ for the tuberculosis). This suggests that the genotypes and their combinations of *CYP2C19*, *GSTT1*, *GSTM1* and *GSTP1* genes have influence on predisposition and clinical polymorphisms of atopic asthma and lung tuberculosis.

Sex-specific genetic determinants in plasma levels of fibrinogen

M. Sabater-Lleal¹, A. Buif¹, J. Souto¹, L. Almasy², J. Blanger³, J. Fontcuberta¹, J. Soria^{1,2};

¹Haemostasis and Thrombosis Unit, Department of Hematology, Barcelona, Spain, ²Bioinformatic of Complex Diseases Unit. Research Institute of Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, ³Department of Population Genetics. Southwest Foundation for Biomedical Research, San Antonio, TX, United States.

A major challenge of biomedical research is the identification of risk factors for complex diseases. One well-established risk factor for cardiovascular disease is the plasma fibrinogen levels. These levels are influenced largely by genetic factors. But the exact nature of these genetic factors is unknown.

Our aim was to localize QTL responsible for the plasma levels of fibrinogen. We present the results of a Genome Wide Scan for fibrinogen levels that includes a gender-specific analysis in 21 Spanish families from the GAIT (*Genetic Analysis of Idiopathic Thrombophilia*) Project. We used 500 DNA microsatellites scattered throughout the genome. Our results revealed a highly significant LOD score (3.52, nominal $p=0.00003$) on Chromosome 17 that was only detected in females, indicating that a QTL on this chromosome was responsible for fibrinogen levels only in women.

A bioinformatic study in the region of Chromosome 17 revealed the presence of some hormone-related genes (steroid hormone receptors) that affect fibrinogen levels and that could explain this gender-specific finding.

To our knowledge, this is the first report of a gender-specific QTL related to cardiovascular disease. It demonstrates that a gender-specific

genetic analysis can increase our ability to detect phenotypes that are affected by sex. We hope that our results will help to understand the regulation of fibrinogen plasma levels that determine the susceptibility of cardiovascular disease. Our results may provide a template for future genetic studies of quantitative traits affecting complex diseases.

P06.284

Genetic variants of the TBX15 gene associated with thyroid cancer susceptibility

M. Akdi¹, P. Galofré², R. Marcos¹, A. Velázquez¹;

¹Universitat Autònoma de Barcelona and CIBERESP, Cerdanyola, Spain, ²Hospital Josep Trueta, Girona, Spain.

Association studies to identify susceptibility genetic factors for thyroid cancer have been appeared recently. Our initial case-control association studies had shown that the rs2145418 and the rs4658973 markers that map 377 kb apart on the 1p12 region have an independent association with thyroid cancer susceptibility. Next we have expanded these initial studies by genotype and haplotype analysis in the region containing the two markers. Here we present the results related to the rs2145418 region. Thus, the MassArray technique was used to genotype 136 control individuals and 201 thyroid patients. First we have confirmed our previous results, by genotyping the rs2145418 SNP along with two SNPs surrounding this marker. Only the rs2145418 polymorphism showed association with thyroid cancer. Consequently, our hypothesis that rs2145418 could reside in a regulatory sequence of casual genes mapping near or at certain distance of this marker can not discarded. In addition, we have studied nine SNPs that cover the TBX15 gene sequence, this gene maps 550 kb downstream of rs2145418. Four of these SNPs lying on the 5'-UTR region have shown significant association with thyroid cancer ($p<0.05$). Furthermore, the association of each SNP alone is less significant than that of a variant haplotype (TACT) of the four 5'-UTR markers (OR, 2.18; 95% CI, 1.23-3.88; $P=0.0085$). The TBX15 gene is involved in developmental processes; thus, based in our results, we can conclude that the TBX15 gene may be involved in thyroid cancer risk.

P06.285

Polymorphisms of TLR2, TLR4 and CD14 genes and risk of meningococcal and pneumococcal infections in children

J. J. Telleria^{1,2}, D. Varillas^{1,2}, J. Casado³, M. Alonso^{1,2}, I. Fernández-Carvajal^{1,4}, A. Blanco-Quirós^{1,2};

¹Facultad de Medicina. Universidad de Valladolid, Valladolid, Spain, ²Instituto de Biología y Genética Molecular (UVA/CSIC), Valladolid, Spain, ³Hospital del Niño Jesús, Madrid, Spain, ⁴Instituto de Biología y Genética Molecular (UVA/CSIC), Valladolid, Austria.

The Toll-like receptors (TLRs) and CD14 are factors of the innate immune defences to microbial infections and seem to play an important role in signalling of molecules of pathogens and of endogen proteins related to immune activation and influence the susceptibility to and the evolution of several diseases as can be sepsis, asthma and atherosclerosis.

In the present study, we have genotyped the polymorphisms p.R677W and p.R753Q within TLR2 gene, p.D299G of TLR4 gene and c.-159C>T of CD14 gene in 157 blood samples from children admitted in the Critical Care Unit of the Hospital Niño Jesús (Madrid) with meningococcal (Gram-negative) ($n=55$) or pneumococcal (Gram-positive) ($n=102$) infections. Sixty six controls were genotyped in order to compare the genotypic frequencies.

Genotypic frequencies of TLR2 polymorphisms were clearly different in both groups of patients, when compared to control population, especially for the p.R753Q polymorphism, being more frequent the p.753Q allele ($p=0.0004$ in meningococcal infections, and $p=0.0005$ in pneumococcal infections).

Conversely, TLR4 polymorphism did not show different genotypic distribution when compared to control population. Finally, the study of the polymorphism of the CD14 showed different distribution when compared to controls, with a $p=0.0113$ in meningococcal infections and $p=0.0353$ in pneumococcal infections.

No differences were found among both groups of studied patients.

These results confirm the key role of the innate immunity system in predisposition to severe infections. For both studied bacteria, the main risk factor is the p.753Q allele followed by the CD14 promoter polymorphism. TLR4 polymorphism did not influence the risk of suffering infections.

P06.286**Novel assay for TLR4 single nucleotide polymorphisms testing in patients with acute coronary syndrome**

S. A. Wisniewski, M. Popiel, A. Olasinska-Wisniewska, K. Kordel, S. Grajek, R. Wachowiak;

University of Medical Sciences, Poznan, Poland.

Our aim was to investigate occurrence of: A896G(Asp299Gly), C1196T(Thr399Ile) and other single nucleotide polymorphisms (SNP) of toll-like receptor TLR4 in patients with ACS and healthy controls. TLR4 is activated in the innate immunity response to lipopolysaccharide LPS. TLR4-dependent reaction is involved in the pathogenesis of atherosclerosis i.e. acute coronary syndrome (ACS). SNP A896G and SNP C1196T of TLR4 are postulated to occur more often in patients with ACS.

Blood samples were collected from 50 patients with ACS within 24 hours from admission to ICCU and from 100 healthy controls. Genomic DNA was extracted and TLR4 genetic variations A896G and C1196T have been analyzed by genotyping with LightTyper system. Unknown SNP's of TLR4 were investigated with MSSCP.

Frequency of A896G(Asp299Gly) and C1196T(Thr399Ile) allele were in ACS patients and controls: G - 0,03 and 0,01, resp., A - 0,97 and 0,99, resp.; C - 0,955 and 0,95, resp. and T - 0,045 and 0,05, resp. Very rare homozygous G/G variant of A896G was found in one patient with ACS. New cost-effective genotyping technique has been developed - allele specific PCR reaction was performed with primer length modification with poli(T), which allows analysis of multiplex PCR reaction.

Frequency of A896G and C1196T allele did not differ significantly among patients with ACS and controls. However, relatively small number of patients requires caution in extrapolating results to population study. The second part of our study will be quantified assessment of TLR4 expression: in controls, in patients during ACS and then in stable period of CAD.

P06.287**Relation of TPH1 gene polymorphic variants to personality traits associated with psychiatric disorders**

A. Kazantseva¹, D. Gaysina^{1,2}, E. Khushnutdinova¹;

¹Institute of Biochemistry and Genetics, Ufa Scientific Centre of Russian Academy of Sciences, Ufa, Russian Federation, ²MRC SGDP Centre, Institute of Psychiatry, King's College, London, United Kingdom.

Individual differences in personality are influenced by both environmental and genetic factors. Enormous studies indicated association between *TPH1* A218C polymorphism and personality disorders (characterized by impulsivity, anxiety and low extraversion). It is likely that genetically mediated variability of the *TPH1* gene functioning can contribute to individual differences in personality traits.

We aimed to define genotype effect of *TPH1* A218C polymorphism and to check possible *TPH1**gender and *TPH1**ethnicity interaction effect on personality traits (assessed with the EPI and TCI questionnaires). We recruited 602 healthy individuals (men-206, women-396) of Caucasian origin (Russians-214, Tatars-388) from Russia (mean age±SD, 19.85±2.43 years).

Association between C-allele and higher Extraversion ($p=0.001$; $F=11.127$), and lower Harm Avoidance ($p=0.027$; $F=4.922$) was observed, that was also reported in women and Tatars. Gender and ethnicity specific differences on personality were detected, with women and Tatars scoring higher on Harm Avoidance, Tatars scoring lower on Extraversion. MANOVA (carried out with gender and ethnicity as second factors) revealed the influence of *TPH1**ethnicity interaction on Extraversion ($p=0.032$; $F=4.634$) observed due to the differences in this trait between Tatars with C-allele and A/A-genotype ($p=0.000$; $F=15.779$); Tatars with A/A-genotype and Russians with C-allele ($p=0.000$; $F=19.770$); Tatars and Russians with A/A-genotype ($p=0.007$; $F=7.820$). The same pattern of *TPH1**ethnicity interaction influence on Extraversion was demonstrated in women ($p=0.043$; $F=4.139$).

Current findings suggest that the variance in Extraversion and Harm Avoidance could be explained by *TPH1**ethnicity interaction, although the single *TPH1* genotype and ethnicity effect occurs.

This work was supported by RSCI grant 06-06-00163à and «Russian Science Support Foundation» (to A.Kazantseva, D.Gaysina).

P06.288**TUB gene polymorphisms are associated with anthropometry and eating behavior in middle-aged women**

J. V. van Vliet-Ostapchouk¹, C. Onland-Morel², R. Shiri-Sverdlov³, P. van Gorp³, P. Peeters², C. Wijmenga^{1,2}, M. Hofer^{1,3}, Y. van der Schouw²;

¹University Medical Center Groningen, Groningen, The Netherlands, ²University Medical Center Utrecht, Utrecht, The Netherlands, ³Maastricht University, Maastricht, The Netherlands.

The *TUB* gene, encoding an evolutionary conserved protein, is highly expressed in the hypothalamus and might act as a transcription factor. Mutations in *TUB* cause late-onset obesity, insulin-resistance and neurosensory deficits in mice. An association of common variants in the *TUB* gene with body weight in humans has been reported. The aim was to investigate the relationship of single nucleotide polymorphisms (SNPs) of the *TUB* gene (rs2272382, rs2272383 and rs1528133) with both anthropometry and macronutrient intake in general population.

The association of SNPs in *TUB* with body composition and macronutrient intake from a validated food frequency questionnaire was studied in a population-based study of 1680 middle-aged Dutch women.

The minor allele C of the rs1528133 was significantly associated with increased weight (+1.88 kg, $P = 0.022$) and BMI (+0.56 units, $P = 0.05$). Both AG and AA genotypes for the rs2272382 were associated with an increased energy intake from carbohydrates (0.69%, $P = 0.04$ and 1.68%, $P = 0.003$, respectively), mainly because of a higher intake of mono- and disaccharides. Both these SNPs were also associated with a higher glycemic load (GL) in the diet. The GL was higher among those with AG and AA genotypes for the variant rs2272382 than among the wild types (+1.49 and +3.89 units, respectively). Carriers of the minor allele C of rs1528133 were associated with an increased GL of 1.85 units compared with non-carriers.

Our results suggest that the effect of *TUB* on body composition might be due to the increased intake of carbohydrates.

P06.289**Influence of several polymorphisms in the risk of anti-tuberculosis drug-induced hepatotoxicity in Caucasian population**

D. Valverde¹, V. Leiro², A. Fernández-Villar², L. Constenla³, R. Vázquez², L. Anibarro⁴, L. Piñeiro²;

¹University of Vigo, Spain, Vigo, Spain, ²Pulmonary Department, Hospital Xeral-Ciés, Complejo Hospitalario de Vigo (CHUVI), Vigo, Spain, ³Unidad de Apoyo a la Investigación Biomédica, Complejo Hospitalario Universitario de Vigo (CHUVI), Vigo, Spain, ⁴Internal Medicine Department, Hospital Provincial, Complejo Hospitalario de Pontevedra (CHOP), Vigo, Spain.

Homozygous deletion *GSTM1* (glutathione S-transferase M1) polymorphism, slow *NAT2* (*N*-acetyltransferase 2) acetylator genotypes and *c1/c1* *CYP2E1* genotype increase the risk of antituberculosis drug-induced hepatotoxicity in Asian population. There are no studies about these polymorphisms and the risk of antituberculosis drug-induced hepatotoxicity in Caucasians.

Case-control prospective study of tuberculosis patients treated with isoniazid, pyrazinamid and rifampin. Cases were patients with antituberculosis drug-induced hepatotoxicity and controls patients without this complication. After DNA extraction from periferic blood, *GSTM1* and *T1* null polymorphisms were performed by PCR and *NAT2* slow polymorphisms and *CYP2E1* *c1* and *c2* polymorphisms by PCR and RFLP.

We included 38 cases and 60 controls without differences in age, sex, BMI and basal transaminases values. The homozygous deletion at *GSTM1* locus was present in 34.3% cases and 41.7% controls ($P = 0.47$) and at the *GSTT1* locus in 48.6% cases and 26.7% controls ($P = 0.03$). Slow *NAT2* acetylator genotypes were present in 65.8% cases and 61% controls ($P = 0.67$). The 6*/7* genotype was only present in cases ($P = 0.02$). *CYP2E1* *c1/c1* genotype was present in 86.8% cases and 87.3% controls and *c1/c2* genotype in 13.2% cases and 12.7% controls ($P = 0.95$). The *CYP2E1* *c2/c2* was not found in any patient. We did not find any relation between *NAT2* slow genotypes and *CYP2E1* *c1/c1* genotype and the risk of antituberculosis drug-induced hepatotoxicity.

P06.290**DNA diagnostics in tuberous sclerosis - development of reliable and economical test**

R. Vrteř¹, H. Filipová¹, R. Vodicka¹, G. Voutsinas², D. Konvalinka³, A. Santava¹, J. Santavy¹;

¹University Hospital and Palacky University Olomouc, Olomouc, Czech Republic, ²NCSR "DEMOKRITOS", Institut of Biology, Athens, Greece, ³CGB laboratory, Ostrava, Czech Republic.

Tuberous sclerosis (TSC) is inherited autosomal dominant disorder with incidence of up to 1/5.800 births. Almost 80% of cases are new mutations. Extreme clinical variability complicates diagnostics and genetic counselling. Accurate diagnosis is essential in order to detect and treat a life threatening neurological, renal and cardiac lesions and for prenatal diagnosis purposes. Mutations in TSC1 and TSC2 tumor-suppressor genes were shown to be responsible for development of TSC. The TSC2 gene on 16p13.3 spans over 41 exons, coding for tuberin and the TSC1 gene on 9q34 has 21 exons coding for hamartin. No „hot-spot“ with more frequent mutation occurrence was found. Presented study is a project of bilateral Czech-Greek cooperation in research and development, ME 923. The aim is to establish a comprehensive genetic test for the analysis of TSC mutations in Greek and Czech patients. Greek team is introducing direct sequencing of TSC1 and TSC2 coding sequences what is recent trend, though quite expensive. Czech team is performing preliminary screening for mutations by DGGE and LOH test and MLPA for larger rearrangements. Especially the utilization of LOH test simplifies and accelerates TSC diagnostics in some cases. Czech and Greek sample files are exchanged and examined in the other laboratory. The reliability of DGGE was tested on positive samples from partners' lab. Sensitivity of DGGE was proved on artificial mosaics, revealing 10% mutant lineages. The knowledge acquired from the research collaboration should contribute significantly to the development of valid diagnostic methods at a minimum cost.

P06.291**Polymorphism of TNFA gene promoter region and chronic inflammatory disorders**

T. Ivashchenko, J. Nasyhova, J. Ostankova, N. Semenov, V. Baranov; Ott's institute of Obstetrics and Gynecology, St.Petersburg, Russian Federation.

Tumor necrosis factor alpha (TNFA) is a potent immunomodulator and proinflammatory cytokine that has been implicated in the pathogenesis of chronic inflammatory disorders. Several polymorphisms located in the promoter region of the TNFA gene have recently been reported to be associated with production of TNFA. We have studied the genetic polymorphisms -238G/A and -308G/A of the TNFA gene by PCR-RFLP analysis in 100 patients with Crohn's disease, in 71 ulcerative colitis patients, in 103 asthmatic patients and in relevant population group (n=117). It is known that these diseases are characterized by the development of chronic inflammation.

The analysis of genotypes and alleles distribution for polymorphisms -238G/A in patient groups and in population has not revealed significant differences.

For Crohn's disease the -308A allele of the TNFA gene was detected in 27% of patients but only in 6.8% of population (p<0.0001). Similar results were obtain for patients with ulcerative colitis and with asthma (19%, p=0.015 and 32%, p<0.0001, respectively). The distribution of genotypes for -308 G/A polymorphism was also different in studied groups compared to population. The frequency of combined genotype -238A/G + -308 G/G of the TNFA gene which is associated with the lowest level of gene expression considerably decreased in patients with chronic inflammatory disorders.

Thus, the polymorphism in promoter region (-308 G/A) which is associated with increased expression of the TNFA gene might be considered as an inherited risk factor contributing to development of multifactorial inflammatory diseases.

P06.292**Gene copy number analysis of complement genes in type 1 diabetes**

A. Castellanos-Rubio, I. Santin, L. Castaño, J. Bilbao;

Research Unit in Endocrinology and Diabetes, Barakaldo, Spain.

The major contributor to type 1 diabetes (T1D) is located in the MHC complex, and HLA DR3 and DR4 confer maximum risk. Other genes also associated with T1D include INS, CTLA4, PTPN22 and innate im-

mune response genes. Differential activation of the complement genes could alter the innate response and contribute to T1D development. These quantitative changes could be caused by copy number variations, a recently described polymorphism type that has been associated with autoimmune diseases.

Our aim was to determine whether gene copy number variants of complement genes C2 and C4B are associated with T1D.

We analyzed 60 T1D patients and 60 nondiabetic control individuals. C2 and C4B copy number quantitation was performed by real-time PCR using specific Taqman assays. Experiments were performed in duplicate using 20ng of genomic DNA. Raw data were normalized using the endogenous RNaseP gene and expressed relative to a reference sample, using the $-2\Delta\Delta Ct$ method. Comparisons between the two groups were performed using a Student's T test.

T1D patients presented a significantly (p<0.01) increased abundance in C2 (mean relative values±SD=1.17±0.58 in T1D vs. 0.94±0.31 in controls) and a decrease in C4B (0.47±0.43 vs. 0.91±0.45, respectively).

We conclude that these differences in gene copy number of complement genes could affect the risk to develop T1D, and these polymorphisms seem to be associated with genetic susceptibility to T1D. However, we have to take into account that these associations could be due to linkage disequilibrium with the HLA class alleles and not to a primary effect.

P06.293**Polymorphisms in NOS1(C/T), NOS3 (VNTR4a/b, 894G/T), IL4RA (I50V) genes are associated with microvascular complications in patients with type 1 diabetes**

N. V. Tarasenko¹, E. I. Kondratieva², V. P. Puzyrev¹;

¹State Research Institute of Medical Genetics, Tomsk, Russian Federation,

²Siberian State Medical University, Tomsk, Russian Federation.

Type 1 diabetes (T1D) is a multifactorial autoimmune disease. T1D patients face the risk of late diabetic microvascular complications: retinopathy (DR), nephropathy (DN) and polyneuropathy (DP). Genetic polymorphisms genes for NO-synthases and cytokines could be risk factors of vascular damages in diabetes. The aim of this study was analysis of association of candidate genes polymorphisms with diabetic microvascular complications (DR, DN, DP) in groups of T1D patients with DR (n=41), DN (n=60), DP (n=39), combination of DR, DN and DP (n=36) and their families (n=110). The following polymorphisms were studied: NOS1(C/T), NOS3 (-691C/T, VNTR4a/b, 774C/T, 894G/T), IL1B (+3953 A1/A2), IL1RN (VNTR), IL4 (G/C 3'-UTR), IL4RA (I50V). Using Transmission/Disequilibrium Test (TDT), we found following associations: IL4RA allele I and DR (TDT=4.22, p=0.0498); NOS3 allele B (VNTR4a/b), allele G (894G/T) and IL4RA allele I with DN (TDT=4.50, p=0.0340; TDT=4.32, p=0.0376; TDT=4.97, p=0.0259; respectively); NOS1 allele C, NOS3 allele B (VNTR4a/b) and IL4RA allele I with DP (TDT=4.69, p=0.0303; TDT=4.50, p=0.0339; TDT=3.84, p=0.0500; respectively); IL4RA allele I with combination of DR, DN and DP (TDT=4.27, p=0.0389). Thus, NOS-genes and cytokines genes are the risk factors for T1D and its microvascular complications. Further studies should be conducted to address the molecular basis for such effect.

P06.294**Presence of additional T1DM risk determinants on HLA-DR3 conserved extended haplotypes (CEH)**

I. Santin¹, A. Castellanos-Rubio¹, A. M. Aransay², J. L. Vicario³, J. Noble⁴, L. Castaño¹, J. R. Bilbao¹;

¹Research Unit in Endocrinology and Diabetes, Barakaldo, Spain, ²Functional Genomics Laboratory - CIC Biogune, Derio, Spain, ³Histocompatibility Unit - Transfusion Centre of Madrid, Madrid, Spain, ⁴Children's Hospital Oakland Research Institute, Oakland, CA, United States.

Type 1 diabetes mellitus (T1D) is a complex autoimmune disease in which insulin-producing pancreatic β cells are destroyed by an aberrant immune response. The major T1DM susceptibility locus is located in the HLA region on chromosome 6p21, and DR3-DQ2 and DR4-DQ8 are the most predisposing haplotypes. Among Caucasians of Southern European origin, DR3/3-conferred predisposition is comparable to DR3/4 risk, probably due to the relative abundance of the extraordinarily homogeneous B18-DR3 CEH in this population, and support the presence of additional determinants within this CEH, that are absent

from other less T1D-predisposing DR3 chromosomes (like B8-DR3 CEH).

To test this hypothesis, we genotyped a panel of 2,360 SNPs in the MHC region, spanning 4.9 Mb (MHC Panel Set - *Illumina Inc, San Diego, CA*) in 21 T1D patients and 39 non-diabetic individuals who were homozygous for HLA-DR3 and carried only one copy of the complete B18-DR3 CEH (HLA-A*30-B*18-DR3-DQ2). Genotype and allele frequency calculations and association analyses were performed using *PLINK v.1.0* (<http://pngu.mgh.harvard.edu/purcell/plink/>).

After stringent correction for multiple testing (Bonferroni) six independent SNPs remained associated (uncorrected p-value: $1.03 \cdot 10^{-5}$ and $2.73 \cdot 10^{-7}$).

Our results add further evidence for the presence of additional susceptibility determinants in the MHC. Since the associated markers might just be *proxies* of the etiological variants in B18-DR3 haplotypes, we are genotyping these SNPs in HLA-unmatched cases and controls. Further in-depth analysis of these associated regions might be necessary to identify the etiological variants.

P06.295

Family-based analysis of tumour necrosis factor and lymphotoxin alpha tag polymorphisms and type 1 diabetes in the population of South Croatia

V. Boraska¹, E. Zeggin², C. J. Groves³, N. W. Rayner², V. Škrabić⁴, M. Diakite², K. A. Rockett², D. Kwiatkowski², M. McCarthy², T. Zemunik¹;

¹School of Medicine, Split, Croatia, ²Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, ³Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, United Kingdom, ⁴Clinical Hospital Split, Split, Croatia.

Type 1 diabetes is an autoimmune disease characterized by destruction of pancreatic β cells. It is influenced by environmental and genetic factors. TNF and LTA are cytokines with a wide range of inflammatory and immunomodulatory activities possibly related with type 1 diabetes. The aim of the present study was to evaluate the association of 11 *TNFI/LTA* tag polymorphisms in 160 type 1 diabetes trio families from South Croatia. Investigated tag polymorphisms were designed to capture the majority (62%) of common variation in *TNFI/LTA* gene region, based on the HapMap database. We observed overtransmission of alleles from parents to affected child at four variants: rs909253, allele C, $p=1.2 \cdot 10^{-4}$; rs1041981, allele A, $p=1.1 \cdot 10^{-4}$; rs1800629 (G-308A), allele A, $p=1.2 \cdot 10^{-4}$ and rs361525 (G-238A), allele G, $p=8.2 \cdot 10^{-3}$. We also identified overtransmission of the rs1800629(G-308A)-rs361525(G-238A) G-A haplotype, $p=2.384 \cdot 10^{-5}$. The present study found an association of *TNFI/LTA* gene region with type 1 diabetes. A careful assessment of *TNFI/LTA* variants adjusted for linkage disequilibrium with *HLA* loci is needed to further clarify the role of these genes in type 1 diabetes susceptibility.

P06.296

Polymorphisms of the NOS2, TNFB and TNFR1 genes are associated with Type 1 Diabetes Mellitus in Tatars and Russians from Bashkortostan

Z. R. Balkhiyarova¹, D. S. Avzaletdinova², T. V. Morugova², O. E. Mustafina¹;

¹Institute of Biochemistry and Genetics, Ufa Research Center, Russian Academy of Sciences, Ufa, Russian Federation, ²Bashkir State Medical University, Ufa, Russian Federation.

Apoptosis may play a role in two different aspects of autoimmune disease - generation of autoreactive cells and tissue destruction. Type one diabetes mellitus (T1DM) is a typical autoimmune disease. The aim of the present study was to investigate the association between apoptosis genes (*NOS2*, *TNFB* and *TNFR1*) polymorphisms with T1DM in Tatar and Russian ethnic groups (Bashkortostan, Russia).

We studied 254 T1DM patients and 544 controls. DNA was isolated by phenol-chloroform extraction from 8 ml venous blood and used as template in PCR-RFLP. Two-tailed test of Fisher was used for statistical analysis.

We have found that *NOS2**G/*G genotype was associated with decreased risk and *G/*A genotype was associated with increased risk of T1DM in Tatar males (OR=0.50, P=0.02, CI: 0.28-0.88 and OR=2.18, P=0.011, CI: 1.22-3.87, respectively).

Carriers of *TNFB* *A/*A genotype had lower risk of T1DM in Tatars (OR=0.56, CI=0.36-0.87). At the same time, *TNFB* *G/*G is associated with higher risk of T1DM (OR=2.52, CI=1.33-4.79) in Russian ethnic

group.

We have shown that *TNFR1**G/*G genotype was less frequent among patients with T1DM ($15.5 \pm 2.2\%$ vs. $26.1 \pm 2.8\%$, P=0.020). We may conclude that *TNFR1**G/*G genotype is associated with decreased risk of T1DM in Tatars (OR=0.52, CI: 0.30-0.90 and OR=0.73, CI: 0.54-0.99).

Region wide association study on chromosome 10q25.1-26.3 and its contribution to type 2 diabetes susceptibility in Japanese

P. Keshavarz¹, H. Inoue², M. Itakura³;

¹Guilan University of Medical Science, Rasht, Islamic Republic of Iran, ²The University of Tokushima, Tokushima, Japan, ³The university of Tokushima, Tokushima, Japan.

Several linkage studies indicated that human chromosome 10q is one of a candidate susceptibility locus for type 2 diabetes (T2D). But there is no information about certain variant(s) or gene(s) have strong effects on the disease within the region. In order to identify T2D disease susceptibility genes in Japanese, verified SNPs from the databases with a minor allele frequency larger than 0.15 were applied to 10 intervals across a 25 Mb region on chromosome 10q25.1-26.3. Using the 993 SNPs for genotyping a two-stage case-control analysis was applied to Japanese subjects consisted of 888 T2D patients and 898 control subjects. Haplotype and linkage disequilibrium (LD) were assessed based on SNP genotypes of all study subjects. To search for new SNPs in the detected significant gene, screening of exons and 3'UTR are performed in 32 randomly selected T2D patients. We detected 10 SNPs (six intronic and four 3'UTR) in *DOCK1* (detector of cytokinesis 1) gene were showed replicated association in the two set of independent DNA samples. These nominal significant SNPs were located in two different Linkage disequilibrium (LD) block containing exons 7-23 and exons 51-52 respectively. When the two data were combined, the most significant association was observed with SNP 827 in 3' UTR of *DOCK1* gene ($p=0.0005$). Real time quantitative revealed that the expression of *DOCK1* was rather ubiquitous with relatively abundant expression in the pancreas, kidney and brain in T2D patients. Our region-wide association analysis suggests the strong impact of *DOCK1* gene with risk of T2D in Japanese.

P06.298

Study of mtDNA polymorphism in type 2 diabetes patients

S. V. Buikin¹, M. V. Golubenko¹, K. V. Puzyrev², O. A. Makeeva¹, I. V. Tsimbaluk³, O. A. Koshelskaja², V. P. Puzyrev¹;

¹Research Institute of Medical Genetics, Tomsk, Russian Federation, ²Research Institute of Cardiology, Tomsk, Russian Federation, ³Siberian State Medical University, Tomsk, Russian Federation.

Diabetes is among frequent endocrine diseases. Endocrine system is one of energy-dependent systems in human organism. Phylogenetic mtDNA haplogroups possess different common polymorphisms and can mark effects of these variants on predisposition to common diseases. Samples of 119 type 2 diabetes patients (78 women, 41 men) and 134 healthy people were studied (all living in Tomsk region). Mean age in the groups was 52 ± 5.5 and 47.6 ± 10.2 years, respectively. Ultrasound examination, 24-hours monitoring of blood pressure and fasting glucose measure were performed. Comparison of frequencies of some of Europeans haplogroups (H, U, T, J) has uncovered lower frequency of haplogroup T in type 2 diabetes patients as compared to control group (OR=0.14; $0.02 < OR < 0.66$; $p=0.007$). In the group of type 2 diabetes patients this haplogroup was detected only in two cases, whereas in control it corresponds to known frequencies for European population (11.6%). Our previous study which was conducted on patients with arterial hypertension has shown higher prevalence of haplogroup T in group of patients with left ventricular hypertrophy against patients without this complication. These alternative effects of mitochondrial haplogroup T may reflect different adaptive advantages for an individual carrying the haplogroup, in respect to different conditions. The findings suggest that particular mtDNA haplogroup (i.e. set of haplogroup-specific polymorphisms in mtDNA) may have some impact on energy metabolism and may be predisposing or protective factor for some diseases and their complications. The work was supported by Russian Foundation for Basic research (RFBR) grants 07-04-01526, 06-04-08326.

P06.299

Further evidence for association of the RGS2 gene with antipsychotic-induced parkinsonism: Protective role of a functional polymorphism in the 3' untranslated region

E. Ben-Asher¹, L. Greenbaum², R. C. Smith^{3,4}, A. Rigbi⁵, R. Strous⁵, O. Teltsch², K. Kanyas², M. Korne², D. Lancet¹, B. Lerer²;

¹The Weizmann Institute of Science, Rehovot, Israel, ²Hadassah-Hebrew University Medical Center, Jerusalem, Israel, ³New York University Medical School, New York, NY, United States, ⁴Manhattan Psychiatric Center, New York, NY, United States, ⁵Beer Yaakov Mental Health Center, Beer Yaakov, Israel.

In our previous study using a candidate gene approach we have shown that the RGS2 gene (regulator of G protein signaling 2) is associated with susceptibility to extrapyramidal symptoms (EPS) induced by antipsychotic drugs (Pharmacogenet Genomics. 2007 Jul; 17(7):519-28). Thus supporting our hypothesis that since regulators of G protein signaling (RGS) play a pivotal role in dopaminergic transmission, genetically based, functional variation could influence therapeutic response to antipsychotic drugs.

To further investigate our previous report we performed a replication study. EPS were rated in U.S. patients with schizophrenia (African-American and Caucasian) treated for at least a month with typical antipsychotic drugs risperidone, olanzapine, or clozapine. Six single nucleotide polymorphisms (SNPs) within or flanking RGS2 were genotyped. Odds ratios and confidence intervals calculations indicate association of SNP rs4606 with antipsychotic-induced parkinsonism (AIP) in the overall sample and in the African-American sub-sample with the minor allele having a protective effect. Sequence analysis of the RGS2 gene further indicated that this SNP is biologically meaningful and could have clinical utility.

P06.300

UCP3 gene polymorphism and cardiac growth in response to 1 year of endurance training

S. B. Goriyeva¹, I. I. Ahmetov^{1,2}, O. L. Vinogradova¹;

¹SRC Institute for Biomedical Problems of the Russian Acad. Sci, Moscow, Russian Federation, ²St Petersburg Research Institute of Physical Culture, St Petersburg, Russian Federation.

Reduced fatty acid utilization and increased oxidative stress both can contribute to the development of cardiac hypertrophy. Left ventricular hypertrophy in endurance-oriented athletes is generally understood to be a limiting factor for improving maximal oxygen uptake (VO₂max). Cardiac uncoupling protein 3 (UCP3) can serve to protect the heart against lipid-induced oxidative stress, and stimulate fatty acid transport and oxidation. A variant in the UCP3 gene associated with higher mRNA levels has been identified (UCP3 -55C/T). This variant has been associated with reduced risk of type 2 diabetes and obesity. Recently we have shown that -55T allele was overrepresented in highly elite rowers and was associated with high values of VO₂max. If UCP3 is important for muscle and heart metabolism and can protect against development of LVH, then one might anticipate -55T variant of UCP3 gene to be associated with insignificant cardiac growth (rational adaptation) in response to endurance training. We have tested this hypothesis in the study of elite Russian rowers (n=19, males). UCP3 -55C/T polymorphism was determined by PCR-RLFP. Echocardiography was performed for two times with one year interval. We found that subjects of CC genotype exhibited the greatest cardiac growth (when interventricular septal wall thickness was measured; CC: 3 (1.4) mm, CT: 1 (0) mm, TT: -1 mm; P=0.019), whereas the individuals of TT genotype exhibited the reduction in septal wall thickness. In conclusion, we demonstrate that variation in the UCP3 gene influences cardiac growth in response to endurance training in rowers.

P06.301

Powerful new methods for whole genome copy number association studies

C. G. Lambert¹, G. F. Rudy¹, I. H. Lake¹, J. G. Grover¹, D. M. Hawkins²;

¹Golden Helix, Inc., Bozeman, MT, United States, ²School of Statistics, University of Minnesota, Minneapolis, MN, United States.

The latest genotyping arrays provide over a million markers across the genome to interrogate copy number variation (CNV), making it possible to perform whole genome copy number association studies. However, the various statistical and computational challenges involved with the analysis of copy number data on such a large scale have pre-

vented such association studies from being completed. Instead, whole genome copy number studies have been limited to paired sample analysis or visual inspection on small numbers of samples. Arguably, due to small sample sizes and the susceptibility of visual inspection to human error, such approaches offer only cursory insights and lack in their effectiveness to uncover CNV associations.

To address these issues, we developed a series of novel methods embodied in a new tool called CNAM. CNAM is capable of efficiently and accurately preprocessing whole genome copy number data for thousands of samples, finding large to single probe CNVs, and performing a range of statistical tests to identify CNV associations.

Discussed methods include accurately extracting log ratio signals, quantile normalization without gender bias to properly normalize against reference populations, optimal univariate and multivariate segmenting based on dynamic programming (Hawkins Segmentation) to determine regions of variation, enhanced Eigenstrat-based principal component analysis to detect and correct for population stratification and batch effects, and association testing using various copy number measures as covariates.

We demonstrate the utility of these methods by presenting preliminary results on public whole-genome data using thousands of case-control samples.

P06.302

First case of maternal UPD7 and recessive congenital myotonia

C. Bulli¹, C. Pecconi¹, P. Battistella², M. Bordignon³, L. Salviati³, F. Sangiulio¹, G. Novelli¹;

¹Department of Biopathology, Tor Vergata University, Rome, Italy, ²Department of Pediatrics, Padua University, Padua, Italy, ³Department of Clinical Genetics, University of Padova, Padua, Italy.

Autosomal congenital myotonia dominant (Thomsen) and recessive (Becker) are rare non dystrophic disorders due to allelic mutations of the muscle chloride channel gene, CLCN1, located on chromosome 7q35. Both diseases are characterised by muscle stiffness and myotonia, which is based on an electrical instability of the muscle fiber membrane, but they differ clinically by age at onset.

We report on the clinical and molecular data of the first case of a Becker patient carrying two identical mutations because of a maternal UPD of the entire chromosome 7.

The proband is 14-year-old male with involuntarily prolonged contraction of muscles, hypertrophy calves, normal CPK and EMG with dynamic myotonia. Moreover he was reported as having severe growth retardation and a facial anomalies compatible with the diagnosis of Silver-Russell syndrome. Proband's DNA analyses showed homozygosity for a novel mutation leading to a G355R substitution (GGG→AGG). The mutation segregated only from the mother, while the father was not carrier for G355R. Non paternity was excluded using a panel of 15 highly polymorphic markers and one marker for amelogenin. Only markers located on chromosome 7 showed some segregation anomalies from the father. For this reason, a fluorescent microsatellite analysis was performed using 9 polymorphic markers spanning the entire chromosome 7 region. PCR products were analysed by automated sequencer. All the markers showed homozygosity in proband's DNA. Our results clearly allowed us to affirm the presence of a maternal isodisomy of the entire chromosome 7 (matUPD7) in the affected proband.

P06.303

A genome wide association study reveals SLC2A9 as a major gene for uric acid levels with pronounced gender-specific effects

C. Gieger^{1,2}, A. Döring¹, D. Mehta³, H. Gohlke¹, H. Prokisch^{3,4}, S. Coassin⁵, G. Fischer¹, K. Henke⁶, N. Klopp^{1,2}, F. Kronenberg⁵, B. Paulweber⁷, A. Pfeufer^{3,4}, D. Rosskopf⁸, H. Völzke⁹, T. Illig¹, T. Meitinger^{3,4}, H. E. Wichmann^{1,2}, C. Meisinger^{1,9};

¹Institute of Epidemiology, Helmholtz Zentrum München, Neuherberg/Munich, Germany, ²Institute of Medical Informatics, Biometry and Epidemiology, Ludwig-Maximilians-Universität, Munich, Germany, ³Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg/Munich, Germany, ⁴Institute of Human Genetics, Klinikum rechts der Isar, Technical University Munich, Munich, Germany, ⁵Division of Genetic Epidemiology, Department of Medical Genetics, Molecular and Clinical Pharmacology, Innsbruck Medical University, Innsbruck, Austria, ⁶Department Pharmacology, Ernst-Moritz-Andt University, Greifswald,

Germany, ⁷First Department of Internal Medicine, St. Johann Spital, Paracelsus Private Medical University, Salzburg, Austria, ⁸Institute for Community Medicine, Ernst-Moritz-Arndt University, Greifswald, Germany, ⁹Central Hospital of Augsburg, MONICA/KORA Myocardial Infarction Registry, Augsburg, Germany. Serum uric acid (UA) levels are correlated with gout and clinical entities such as cardiovascular disease and diabetes. In a genome-wide association study (KORA F3-500K, n=1644), we identified a QTL associated with UA level located on chromosome 4 including 40 SNPs with P-values below the genome-wide significance level. The most significant SNPs mapped within intron 4 and 6 of *SLC2A9* (effects -0.18 to -0.36 mg/dL per copy of the minor allele). These findings were replicated in three independent samples from Germany (KORA S4 and SHIP) and Austria (SAPHIR) with P-values ranging from 1.2×10^{-8} to 1.0×10^{-32} . The *SLC2A9* genotypes in addition showed significant association with self-reported gout. The proportion of the variance of serum UA levels explained by genotypes was about 1.2% in men and 6% in women. Analysis of whole blood RNA expression profiles from a KORA F3-500K subgroup (n=117) revealed a significant association between the *SLC2A9* isoform 2 and urate levels. *SLC2A9* encodes a transporter protein that belongs to class II of the facilitative glucose transporter family. A potential substrate of GLUT9 is fructose, as GLUT9 has the highest similarity with the fructose transporters GLUT5 and GLUT11. Our expression studies allow discrimination between two annotated isoforms of this gene. The significant association with the shorter protein GLUT9 Δ N argues for a prominent role of the *SLC2A9* isoform 2 in the regulation of urate concentrations. The association with the isoform 2 suggests an involvement of the protein in urate excretion.

P06.304

Association of polymorphisms Ala62Thr in ZNF365 gene and Taq I and Fok I in VDR gene with metabolic alterations in adults with urolithiasis from Yucatan, Mexico

M. M. Medina-Escobedo¹, L. González-Herrera², S. Villanueva-Jorge¹, E. Gala-Trujano¹, M. Salazar-Canul¹, G. Martín-Soberanis³;

¹Hospital General "O'Horán" S.S.Y., Mérida, Mexico, ²CIR "Dr. Hideyo-Noguchi", Universidad Autónoma de Yucatán, Mérida, Mexico, ³Hospital General No. 12 "Lic. Benito Juárez", IMSS, Yucatán, México, Mérida, Mexico.

Urolithiasis (UL) is an endemic health problem in Yucatan, Mexico. Hypocitraturia, hypercalciuria and hyperuricosuria are frequent metabolic alterations in UL. Polymorphisms Ala62Thr in ZNF365 gene and Taq I and Fok I in VDR gene have been associated to UL. Polymorphisms might affect the metabolic pathways involved in UL, so we analyzed the association of these polymorphisms with metabolic alterations in adults with UL from Yucatan, Mexico. 169 patients, 59 males (34.9%) and 110 females (65.1%) were analyzed. UL was confirmed by RX and ultrasonography. 24 hours urine excretion of Na, K, Ca, P, Mg, uric acid, oxalates and citrates were determined. Polymorphisms were determined in DNA samples by PCR-RFLPs. Genotypic and allelic frequencies of each polymorphism were compared between patients with metabolic alterations and patients with normal metabolism. Metabolic alterations found were hypercalciuria 16.6%, hyperuricosuria 13.6%, hyperphosphaturia 7.7%, hypomagnesuria 1.2%, hyperoxaluria 24.9% and hypocitraturia 61.5%. Genetic frequencies obtained for VDR were: Taq I (tt 1.2%, tT 30.8%, TT 68.0%), Fok I (ff 20.7%, fF 53.5%, FF 26.0%) and for ZNF365 (AA 8.9%, AG 29.0%, GG 62.1%). Polymorphisms in the VDR gene were not associated with metabolic alterations ($p > 0.05$), whereas allele G of ZNF365 gene was associated with hypocitraturia ($p = 0.044$). Mean concentrations of K, Mg and citrate in urine excretion were significantly lower ($p < 0.05$) in subjects with GG genotype compared to wildtype. Polymorphism Ala62Thr in ZNF365 gene was associated with hypocitraturia, whereas GG mutated genotype was associated with a lower urine excretion of K, Mg, and citrate in the studied population.

P06.305

Genetics and Clinical Aspects of Usher and Pendred Syndromes in Iranian Population

K. Kahrizi¹, G. Asaadi¹, N. Sadeghpour¹, N. Bazazzadegan¹, M. Mohseni¹, M. Jaber², S. Sakethkoo¹, N. Meyer³, N. Hilgert⁴, W. J. Kimberling⁵, G. Van Camp⁴, R. J. H. Smith³, H. Najmabadi¹;

¹Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, ²Retinitis Pigmentosa Institute, Tehran, Islamic Republic of Iran, ³Molecular Otolaryngology Research Laboratories, De-

partment of Otolaryngology Head and Neck Surgery, University of Iowa, Iowa, IA, United States, ⁴Department of Medical Genetics, University of Antwerp (UA), Antwerp, Belgium, ⁵United States Boys Town National Hospital, Omaha, NE and University of Iowa Medical School, Iowa, IA, United States.

Over 440 genetic syndromes that include hearing loss have been described. Syndromic hearing impairment accounts for 30% of pre-lingual deafness. The two most common types are Usher and Pendred syndromes. Up to now 12 different loci and 9 genes have been identified. Also Pendred is characterized by congenital sensorineural hearing loss, goiter (40-60%) and inner ear abnormalities and impaired vestibular function test. The objective of this study was to identify the prevalence of USH loci in deaf-blind patients and PDS gene mutations in Iranian Population.

Thirty USH families and 80 families with autosomal recessive non-syndromic hearing loss, having two or more affected individuals were subjected to linkage analysis using STR markers. The sequencing for mutation screening was performed for the linked families.

Nine out of thirty USH families were linked to the studied USHI and USH II loci which we identified the mutation in three of these families and mutation screening in the other linked families is on the way. Also we were able to link fourteen autosomal recessive hearing impaired families to DFNB 4 locus and nine of them showed different types of PDS mutations. In conclusion 30% of the families with USH syndrome were linked to one of the known loci, however additional study needed to determine the causative genes involve in the other families. We have also been able to determine Pendred syndrome as the second cause of hearing loss in our population. In addition we have determined four novel mutations in SLC26A4 gene in Iranian patients.

P06.306

Genetic profile of the PCDH15 gene in probands with Usher syndrome type I

T. Jaijo^{1,2}, A. Oshima³, E. Aller^{1,2}, C. Nájera⁴, C. Ayuso^{5,2}, W. J. Kimberling^{6,7}, J. M. Millán^{1,2};

¹Hospital Universitario La Fe, Valencia, Spain, ²Center for Biomedical Research on Rare Diseases (CIBERER). ISCIII., Valencia, Spain, ³Department of Otorhinolaryngology. Center for the Study and Treatment of Usher Syndrome, Boys Town National Research Hospital, Omaha, NE, United States, ⁷7. Department of Ophthalmology, Carver School of Medicine, Iowa City, IA, United States.

INTRODUCTION

Usher syndrome type I (USH1) is the most severe form Usher syndrome. It is characterized by congenital severe-profound sensorineural hearing loss, prepubertal retinitis pigmentosa and vestibular areflexia. The *PCDH15* gene is implicated in this disorder and it encodes for protocadherin-15, a large transmembrane protein belonging to the cadherin superfamily.

OBJECTIVE

The main of this study is to identify the USH1 causative mutations and to evaluate the *PCDH15* implication in this syndrome.

PATIENTS AND METHODS

Fifty-six USH1 patients from Spain and USA, which had previously discarded the most prevalent USH1 gene, *MYO7A*, were studied.

The mutation screening was performed by directly sequencing of all 33 exons and intron-exon boundaries from the *PCDH15* gene.

RESULTS

In this study, seventeen different pathologic variants and forty-five polymorphisms in the *PCDH15* gene have been found in USH1 patients. Mutations identified include twelve missense variants, three premature stop codons and two splice site changes. These variants have been found in seventeen of fifty-six USH1 patients (30.6%). One patient was compound heterozygous and two patients had a homozygous mutation. One unique pathologic variant was detected in the rest of studied patients.

CONCLUSIONS

Out of a total of 112 alleles, 20 of them (17.9%) were considered pathologic in the *PCDH15* gene.

It can be estimated that the *PCDH15* gene is responsible for about 16% of USH1 patients.

Most of studied patients were carriers of only one mutation. Large rearrangements within this gene could explain this fact.

P06.307**Genome-wide screen for aberrant DNA methylation in human uterine leiomyoma by MS-RDA**

S. Izumi¹, L. Cai², M. Abe², A. Kondo¹, Y. Morita³, M. Mizoguchi³, N. Uchida¹, S. Takagi³, T. Ushijima²;

¹Department of Obstetrics and Gynecology, Tokai University School of Medicine, Isehara, Japan, ²Carcinogenesis Division, National Cancer Center Research Institute, Tokyo, Japan, ³Department of Clinical Genetics, Tokai University School of Medicine, Isehara, Japan.

Uterine leiomyoma are very common benign tumors in women of reproductive age. However the molecular mechanisms of cause and development of these tumors are poor understood. This study is attempted to examine whether aberrant DNA methylation occurred in these tumors. Therefore we carried out a genome-wide screen for aberrant DNA methylation, adopting methylation-sensitive-representational difference analysis (MS-RDA) using normal adjacent myometria as tester and myoma tissue driver. As the results, a total of 192 clones were sequenced, 27 DNA fragments derived from CpG islands (CGIs) were isolated, and seven of them were from CGI in the 5' regions of known genes, which include *CHARC1*, *FAM44B*, *FLJ33655*, *HSUP*, *MLLT3*, *SLC16A1*, and *ZNF96*. Then, methylation statuses of those CGIs were analyzed by methylation-specific PCR (MSP) using five primary samples of human uterine leiomyoma. Aberrant DNA methylation did not observed in seven genes in five human uterine leiomyoma eventually. Though, this study failed to identify aberrant DNA methylation occurring in the human uterine leiomyoma by a genome-wide screen, it does not exclude that epigenetic modifications of DNA methylation are involved in the cause and development of uterine leiomyomas. A large population of primary samples and more attempts, such as use cell lines or primary monolayer cultures established from tissue samples, are needed be done to develop this issue

P06.308**Study of the VEGF Polymorphism in HELLP Syndrome patients**

B. Nagy¹, A. Molvarec¹, T. Várkonyi¹, B. Rigó¹, H. Savlíř, P. Hupuczli², J. Rigó Jr¹;

¹Semmelweis University, Budapest, Hungary, ²Kocaeli University, Izmit, Turkey. **Background:** The vascular endothelial growth factor (VEGF) has a critical role in vasculogenesis and vascular permeability in several diseases including preeclampsia. VEGF G+405C, C-2578A and C-460T SNPs are known to be related to VEGF production. We decided to determine the allele and genotype frequencies of VEGF G+405C, C-460T and C-2578A SNPs in healthy pregnant women and HELLP syndrome patients.

Methods: The authors introduced a quantitative real-time PCR method for the determination of the three VEGF SNPs. Blood samples were collected from 71 HELLP syndrome patients and 93 healthy controls.

Results: There were significant differences in the allele and genotype frequencies of VEGF C-460T SNP between the two study groups. The T allele was present in 71.1% in the HELLP group, while in 53.8% in the controls (p=0.0014). The TT genotype occurred significantly more frequently in the HELLP group than in the control group (45.1% vs. 21.5%; p (for genotype frequencies)=0.0011). The TT genotype carriers had an increased risk of HELLP syndrome, which was independent of maternal age and primiparity (adjusted odds ratio (OR)=3.03, 95% confidence interval (CI)=1.51-6.08; p=0.002). Although the VEGF G+405C allele and genotype distributions did not differ significantly between the two groups, the CC genotype carriers were also found to have an increased risk for HELLP syndrome after adjustment for maternal age and primiparity (adjusted OR=3.67, 95% CI=1.05-12.75; p=0.041). The VEGF C-2578A SNP was not associated with HELLP syndrome.

Conclusions: We found that the VEGF -460TT and +405CC genotype carriers have an increased risk of HELLP syndrome.

P06.309**VEGF A2578C polymorphism is associated with muscle fiber type distribution in athletes**

E. V. Lyubaeva¹, I. I. Ahmetov², A. M. Hakimullina², O. L. Vinogradova¹, V. A. Rogozkin²;

¹SRC Institute for Biomedical Problems of the Russian Acad. Sci., Moscow, Russian Federation, ²St Petersburg Research Institute of Physical Culture, St

Petersburg, Russian Federation.

There is strong relationship between muscle fiber type distribution and human physical performance. For example, elite weightlifters and sprinters exhibit large percentages of fast-twitch fibers (FT, also known as type II muscle fibers) compared to controls and endurance athletes. FT fibers have comparatively low capillary density and blood flow capacity and low mitochondria content. Vascular endothelial growth factor (VEGF) is important in the basal maintenance of skeletal muscle capillarization and may influence the determination of muscle fiber type distribution. To investigate the question of the influence of VEGF gene polymorphism on the proportion of fibers types of m. vastus lateralis, we have analyzed the muscle biopsies obtained from 21 elite Russian athletes (all-round speed skaters). The immunoperoxidase technique was employed for immunohistochemical identification of myosin isoforms. VEGF gene A2578C polymorphism was determined by PCR-RLFP. Mean percentages of FT fibers were significantly higher in VEGF CC homozygotes than in VEGF A allele carriers (AA/AC - 38.3 (6.2) %, CC - 47.8 (12.4) %; P=0.03). Then we determined distribution of VEGF alleles in 60 elite and sub-elite weightlifters and in 1,113 controls. We found that the frequency of VEGF 2578C allele was significantly higher in weightlifters than in controls (58.3% vs. 48.0%; P=0.035). In conclusion, VEGF 2578C allele is associated with increased proportion of FT muscle fibers in all-round speed skaters and with elite power athlete status.

P06.310**VEGF ID polymorphism and peripheral neuropathy susceptibility**

M. Stavarachi¹, D. Cimponeriu¹, P. Apostol¹, M. Toma¹, I. Radu¹, A. Craciun², D. Cheta², L. Gavrilă²;

¹University of Bucharest, Institute of Genetics, Bucharest, Romania, ²"N. Paulescu" Institute, Bucharest, Romania.

Vascular endothelial growth factor (VEGF) is a cytokine involved in angiogenesis and in maintaining of neuronal function. The genetic variation in VEGF promoter may be responsible for different neuropathies, including the diabetic one.

The aim of our study was to investigate the relationship between the -2549 I/D VEGF gene promoter polymorphism and diabetic peripheral neuropathy susceptibility.

A case-control study was performed in 60 diabetic patients with peripheral neuropathy and 60 healthy subjects, sex and age matched. After the informed consent was obtained, DNA was extracted from peripheral blood. The VEGF -2549 I/D genotyping were assessed using PCR method.

The distribution of VEGF -2549 ID in both lots respected the Hardy-Weinberg condition. The frequencies of genotypes and alleles in the patients and healthy control groups were compared using the contingency tables. Although the DD genotype and D allele frequencies were higher in diabetic patients than in controls (DD: 33.3% vs 25%, D: 57.5% vs 52.5%) these differences do not reach the statistical power. We also observed that the trend of association increases if only patients with early onset were compared (OR~1,2).

This preliminary study indicates that the VEGF ID polymorphism may be associated with early onset diabetic peripheral neuropathy. A future study with an increased statistical power is necessary to clarify the relationship between this polymorphism and peripheral neuropathy susceptibility.

The research was funded by GAR 183/ 2007.

P06.311**Linkage and association study for VEGF serum level in the isolated population of Campora**

D. Ruggiero¹, R. Sorice¹, C. Bellenguez², T. Nutile¹, G. Fardella¹, M. Aversano¹, C. Bourgair², M. Ciullo¹;

¹Institute of Genetics and Biophysics A. Buzzati-Traverso, CNR, Naples, Italy,

²INSERM U535, Villejuif, France.

Vascular Endothelial Growth Factor (VEGF) is an angiogenic factor having a key role in both physiological and pathological angiogenesis. In order to identify QTLs influencing VEGF serum levels, we performed a genome-wide linkage analysis using a sample of individuals randomly chosen in Campora, an isolated population in South Italy. VEGF serum levels were measured using ELISA method in a sample of 656 individuals. 627 individuals out of the 656 were all related through a 3049-member pedigree and genotyped for 1122 microsatellites on

the genome (average marker spacing of 3.6cM). The heritability for VEGF serum levels was estimated to 0.86 after adjusting for age.

To perform linkage analysis we broke the large genealogy using GREFFA method through a multiple splitting approach recently proposed by Bellenguez and coll.

With the regression-based linkage statistic, we detected a strong linkage on chromosome 6p12.3 (LOD=10.08) at marker D6S459. This linkage signal exactly corresponds to the location of the VEGF gene. Hence, coding and regulatory regions of VEGF gene were sequenced in a sample of 42 individuals. 31 polymorphisms were identified, 22 of which having a MAF>0.05.

The association between these 22 SNPs and VEGF levels was tested using GTAM test, that also corrects for relatedness between individuals through the genealogical information. After correction for the number of independent tests performed, significant association was detected with two SNPs ($p<0.001$) and VEGF serum levels.

Our data indicate that polymorphisms located in the regulatory regions of VEGF gene are significantly associated with VEGF serum levels in Campora population.

P06.312

Genetic polymorphisms in patients with vesico-ureteric reflux

B. Zagradisnik, N. Marčun Varda, K. Bračić, A. Gregorič, N. Kokalj Vokač; University Medical Centre, Maribor, Slovenia.

Primary congenital vesico-ureteric reflux (VUR) is a very common urogenital tract disorder. It has a strong genetic component which is assumed to influence the development of the disease as well as its progress. So far different genes were analyzed and also several polymorphisms were tested for association with VUR with mixed results. This study presents association analysis for several polymorphisms from candidate genes of interest.

Genotyping was done in 170 children diagnosed with primary congenital vesico-ureteric reflux and in 300 healthy controls with no medical record of reflux. Genomic DNA was extracted from whole blood samples using standard methods. Allele specific polymerase chain reaction as well as PCR-RFLP was used for analysis. Detection was performed with agarose gel electrophoresis.

Following polymorphisms were included in the study: M31R, S275T, C335R from the gene IL8RA, G-800A, T-509C, L10P, R25 and T233I from the gene TGFB1, rs2229773 from the gene RARA and D299G from the gene TLR4. Allele frequencies were not significantly different between patients and normal controls.

The results of our study indicate that polymorphisms from genes IL-8RA, TGFB1, RARA or TLR4 are not associated with the development primary congenital vesico-ureteric reflux. Therefore it is unlikely that these particular variations play a role in the development of this disease.

P06.313

Vitamin D receptor gene polymorphisms and vitamin D deficient rickets in Turkey

G. Bora¹, B. Özkan², D. Dayangaç-Erden¹, H. Erdem-Yurter¹, T. Coşkun³;

¹Hacettepe University Faculty of Medicine Department of Medical Biology, Ankara, Turkey, ²Atatürk University Faculty of Medicine Department of Pediatrics, Erzurum, Turkey, ³Hacettepe University Faculty of Medicine Department of Pediatrics, Nutrition and Metabolism Unit, Ankara, Turkey.

In Turkey, considerable number of children suffer from vitamin D deficient rickets, which causes growth retardation, impaired bone formation and fracture risk. To explore the association between vitamin D receptor gene polymorphism and vitamin D deficient rickets, we analyzed VDR gene polymorphisms (FokI, TaqI and ApaI) in 24 Turkish vitamin D deficient rickets patients and 100 healthy controls. We showed that "A" (ApaI) allele is more common in patients (83%, $p=0.002$) but there were no significant differences for FokI ($p=0.693$) and TaqI ($p=0.804$) allele frequencies between patients and controls. We also found that the frequency of Tt and Aa genotypes were significantly decreased in patients. This is the first report that demonstrated VDR gene polymorphisms might be an important factor for genetic susceptibility to vitamin D deficient rickets in Turkish population.

Identification of two new mutations in the VLGR1 and the PDE6B genes segregating in a Tunisian family

M. Hmani^{1,2}, Z. Benzina³, F. Zulficar⁴, H. Dhoub⁵, A. Shahzad⁶, A. Ghorbel⁶, P. Söderkvist⁷, S. Riazuddin⁸, W. Kimberling⁹, H. Ayad⁷;

¹Laboratoire de Génétique Moléculaire Humaine, Sfax, Tunisia, ²Unité Cibles pour le Diagnostic et la Thérapie, Centre de Biotechnologie, Sfax, Tunisia, ³Service d'Ophthalmologie, C.H.U. Habib Bourguiba, Sfax, Tunisia, ⁴Centre of Excellence in Molecular Biology, University of the Punjab, Lahore, Pakistan, ⁵Service d'O.R.L., C.H.U.Habib Bourguiba, Sfax, Tunisia, ⁶Centre of Excellence in Molecular Biology, University of the Punjab, Lahore, Pakistan, ⁷Division of Cell Biology, Department of Clinical and Experimental Medicine, Faculty of Health Sciences, Linköping, Sweden, ⁸Center for Hereditary Communication Disorders, Boys Town National Research Hospital (BTNRH), Omaha, NE, IA, United States.

Autosomal recessive retinitis pigmentosa (ARRP) is a genetically heterogeneous disorder. ARRP could be associated with extraocular manifestations that define specific syndromes such as Usher syndrome characterized by retinal degeneration and congenital hearing loss (HL). The Usher syndrome typeII (USH2) subtype associates RP and mild to moderate HL with preserved vestibular function. At least three genes *USH2A*, the very large G-protein coupled receptor *VLGR1* and *WHRN* are responsible for USH2 syndrome.

Here, we report on the segregation of non-syndromic ARRP and USH2 syndrome in a consanguineous Tunisian family, which was previously used to define USH2B locus. Upon extending this family, the genotyping with additional STR markers excluded linkage to USH2B locus. In addition, ophthalmologic reexamination showed phenotypic heterogeneity. We therefore reanalyzed the extended family with regard to the co-occurrence of two different pathologies i.e non-syndromic ARRP and USH2 syndrome. Surprisingly, linkage analysis disclosed the cosegregation of the USH2 phenotype with D5S428 and D5S618 markers corresponding to the USH2C locus while the ARRP perfectly segregates with *PDE6B* flanking markers D4S3360 and D4S2930. Molecular analysis revealed two new missense mutations p.Y6044C and p.W807R occurring in *VLGR1* and *PDE6B* genes, respectively. Both mutations were absent in 95 genetically unrelated controls. Finally, the combination of molecular findings for *VLGR1* and *PDE6B* genes enable us to explain the phenotypic heterogeneity in particular the severe ocular affection first observed in one USH2 patient. This report presents an illustration of how consanguinity could increase familial clustering of multiple hereditary diseases within the same family.

P06.315

MLPA in Diagnostics of Copy Number Variations in X-linked Mental Retardation

M. Nawara¹, B. Nowakowska¹, A. Kutkowska-Kazmierczak¹, K. Szczaluba¹, K. Chrzanoska², A. Lauda³, J. Bal¹, T. Mazurczak¹;

¹Institute of Mother and Child, Dept. of Medical Genetics, Warsaw, Poland, ²The Children's Memorial Health Institute, Dept. of Medical Genetics, Warsaw, Poland, ³University Medical School, Dept. of Medical Genetics, Bydgoszcz, Poland.

X-linked mental retardation (XLMR) is highly heterogeneous. Because of the low prevalence of mutations in known nonspecific XLMR (MRX) genes the systematic screen is not feasible in a routine practice. It is important to introduce new techniques which enable to screen many loci.

MLPA (multiplex ligation dependent probe amplification) is such a technique and it allows a relative quantification of up to 45 different sequences in one reaction. In our study we used the MLPA kit containing probes for 14 different MRX genes to search for copy number variations in a group of 106 XLMR patients. 68 of them were from potential XLMR (pXL) families with two males in different generations affected, and 38 from families with two or more brothers affected (BP).

We detected three variants: two deletions (IL1RAPL1 and PAK3) and one duplication (IL1RAPL1), all in the pXL patients. The duplication was also present in two affected maternal uncles of the proband. All these rearrangements are being confirmed by other molecular (PCR) or cytogenetic (FISH) techniques. The clinical evaluation of all affected patients from the families is in progress.

The frequency of copy number variations in our studied group was 2.8%, but if we consider only pXL patients it becomes as high as 4.4%. We recommend MLPA as a screening for microduplications and micro-

deletions in a large proportion of known MRX genes. Because of its low cost and sensitivity it is suitable for routine diagnosis of X-linked mental retardation.

P06.316

The chromosome abnormalities, Y-chromosome microdeletions and CFTR gene mutations testing of infertility man from Western Ukraine

M. Tyrkus, N. Huleyuk, O. Bilevych, D. Zastavna, H. Makukh;

State institution "Institute of Hereditary Pathology of Academy of Medical Science of Ukraine", Lviv, Ukraine.

The most widespread genetic factors causing male infertility include different quantitative and structural chromosome abnormalities, Y-chromosome microdeletions and CFTR gene mutations.

DNA and cultivated leukocytes from peripheral blood of 150 males with spermatogenesis failure were analyzed.

Cytogenetic analysis revealed Klinefelter's syndrome - 47, XXY (7 persons), de la Chapelle syndrome - 46, XX (3), disomy of Y-chromosome - 47, XYY (1). Totally quantitative and structural chromosome abnormalities were found in 13 males (9%).

Any changes in the structure of Y-chromosome hadn't been found in males with Klinefelter's syndrome. In patients with 46, XX karyotype whole sequence of AZFa, AZFb and AZFc is absent. Among 3 patients with de la Chapelle syndrome SRY gene had been detected in 2 persons.

We detected various cases of AZF gene subregions deletions: AZFa (1 patient), AZFb (1), AZFb+c (1), AZFc (6). Whole absence of PCR-product of AZFa, AZFb and AZFc and SRY gene was detected in male with azoospermia and normal karyotype that requires next sequencing analyses. Thus, in 7% of examined infertile males with normal karyotype Y-chromosome microdeletions were found. In regard to the group of examined infertile males the percentage of Y-chromosome microdeletions reached approximately 10%.

The molecular-genetic analysis of CFTR gene mutations and IVS8polyT polymorphic locus revealed F508del mutation in 4 persons, 5T polymorphic allele - in 12 males with spermatogenesis failure.

The studies point on high effectiveness of the complex of cyto- and molecular-genetic researches in males with impaired fertility and state their necessity in diagnose.

P06.317

ZNF750 in psoriasis

R. Y. Birnbaum¹, A. M. Bowcock², I. Cohen¹, S. Sivan¹, R. Ofir¹, O. S. Birk¹;

¹National Institute for Biotechnology in the Negev, Beer-Sheva, Israel, ²Department of Genetics, Washington University School of Medicine, Saint Louis, MO, United States.

We have previously shown that a dominant mutation in ZNF750 underlies seborrhea-like dermatosis with psoriasiform elements. To assess the contribution of ZNF750 to the pathogenesis of bone fide psoriasis, we screened 250 psoriasis patients from the U.S. for mutations in the 3 exons of ZNF750, the intron-exon boundaries and 1000bp upstream sequences. While no mutations were found in the coding region, a heterozygous ZNF750 5' UTR variant (+46 C>T) was seen in 3 unrelated psoriasis patients. This change was not found in 300 healthy control samples. Our data suggest that the ZNF750 5' UTR variant (+46 C>T) might be associated with psoriasis

P06.318

β₂-adrenergic receptor (ADRB2) polymorphisms in the childhood asthma

E. A. Isupova, G. A. Novik, V. I. Larionova;

Saint-Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation.

Gene polymorphisms of ADRB2 are candidate gene of genetic predisposition to bronchial asthma (BA) and allergic diseases. From data of literature the genetic variants of cellular receptors possibly influence on efficiency of action of antiasthmatic drugs.

The aims of our study was to investigate genotypes and alleles frequency of two common polymorphisms of ADRB2 gene (Arg16Gly and Gln27Glu) in boys and girls with different severity BA.

Patients and methods: 160 Caucasians children, 129 boys (81%) and 31 girls (19%) with the set diagnosis of bronchial asthma of different severity were included. Mild asthma was diagnosed in 10 children (6%),

75 children (47%) had moderate asthma and 75 children (47%) had severe asthma. Two common ADRB2 polymorphisms 16 (Q→E) and 27 (G→R) were detected by PCR method with the subsequent restriction assay.

Results: we have revealed association between distribution of haplotypes ADRB2 and severity of BA. Patients with the severe asthma had significantly more frequent haplotype EE/GG than patients with moderate asthma (p=0,024) in which more frequent where was haplotype QQ/GR. In group of boys we detected analogical changes (p=0,017), but there were no differences in girls.

P06.319

No significant role of the FXII 46C→T mutation in Spanish and Tunisian cardiovascular patients

G. Athanasiadis¹, E. Esteban¹, M. Gayà-Vidal¹, M. Resano¹, R. Carreras Torres¹, H. Chaaban², P. Moral¹;

¹Unitat d'Antropologia, Dpt. de Biologia Animal, Facultat de Biologia, Universitat de Barcelona, Barcelona, Spain, ²Faculté de Pharmacie de Monastir, Monastir, Tunisia.

Background.- The 46C→T polymorphism in the Coagulation Factor XII gene consists of a cytosine to thymidine transition at the position 46 from the transcription initiation point in exon 1 of the 5'-untranslated region. Previous case-control studies have indicated an association between this polymorphism and variation in plasma levels of FXII. The 46C→T seems to affect the translation efficiency, leading to reduced plasma levels of the protein. It has been inferred that this mutation accounts for 40% of the variance in FXII activity levels in a Spanish Mediterranean population. As other case-control studies in the same region indicate, genotype T/T is an independent risk factor for venous thrombosis, ischemic stroke and acute coronary artery disease (CAD).

Aim.- In this study, we try to confirm the importance of the 46C→T polymorphism in two patient samples from Spain and Tunisia.

Methods.- We have implemented two different approaches: a Transmission Disequilibrium Test (TDT) based on 101 families (N=302) from Spain (Barcelona) with one offspring with CAD; and a classical case-control study based on 76 patients with CAD complicated by myocardial infarction and on 118 healthy individuals from North and Centre-South Tunisia. All subjects were genotyped for the 46C→T polymorphism with Real-Time PCR using a TaqMan® SNP Genotyping Assay (Applied Biosystems) and the appropriate software was implemented for the data analyses.

Results.- No statistically important association was detected in any of the two samples (TDT: p=0.16, statistical power = 99%; case-control study: p=0.65).

Conclusion.- The results suggest that 46C→T is not a risk factor for CAD in any of the two analysed samples. So far as we know, the TDT analysis for this mutation is the first one carried out in a Spanish population and suggests that 46C→T might not be the only functional site that would explain the susceptibility to thrombotic disease.

P06.320

BsmI, Apal and TaqI Polymorphisms of Vitamin D receptor gene in Turkish nephrolithiasis patients

N. Ersoy, K. Incekara, O. Kose, O. Cakir;

Halic University, Department of Molecular Biology and Genetics, Istanbul, Turkey.

Nephrolithiasis is a multi-factorial disease influenced by genetic, hormonal and environmental effects. Calcium oxalate (CaOx) is the most common constituent of kidney stones. Vitamin D receptor (VDR) involves in controlling the effects of 1,25dihydroxyvitaminD₃. The 3'UTR region of the VDR gene includes a cluster of polymorphisms: BsmI, Apal and TaqI. These polymorphisms have been studied in patients with urolithiasis, but yielded inconclusive results. Since the contribution of alleles may appear to be different in different ethnic populations, the relationship of the individual and combined polymorphisms should be studied for each population. In this study, we investigated the association of BsmI, Apal and TaqI polymorphisms in 98 Turkish CaOx stone patients and 70 controls. 52% of the patients reported a family history of stones. The polymorphic sites were amplified with PCR, subjected to restriction enzyme digestion and analyzed on agarose gels. Associations between the disease and genotypes were assessed by calculating odds ratios and 95% confidence intervals. VDR genotype distribution was compared with that of controls using the chi-square

test. VDR genotype frequencies were in Hardy-Weinberg equilibrium. We also carried out haplotype analysis as the polymorphisms are inherited together. In patients, six different haplotypes were defined, with over-representation of BA_T (40.7%). On the other hand, ba_T haplotype was the most frequent in controls. Ba_T haplotype was four times and ba_T haplotype was two times more frequent than in controls. This study also provides evidence that there is a statistically significant association of the b_T VDR haplotype and formation of CaOx kidney stones.

P06.321

Changes in Ca homeostasis lead to electrical and structural remodeling of the heart in the 'human PLN' mouse model

D. A. Arvanitis¹, M. Dong², W. Zhao², V. Papalouka¹, E. G. Kranias¹, H. S. Wang², D. Sanoudou¹;

¹Biomedical Research Foundation of the Academy of Athens, Athens, Greece, ²University of Cincinnati, Cincinnati, OH, United States.

Phospholamban (PLN), the reversible inhibitor of SERCA2, is a key regulator of calcium homeostasis and cardiac function, and it has been directly implicated in the development of dilated cardiomyopathy. Its amino acid sequence is highly conserved across species except for humans, where Asn is replaced by Lys at amino acid position 27. To evaluate the significance of this single nucleotide difference we induced cardiac-specific insertion of the human-PLN in the null background. The "humanized" PLN expressing transgenic (TG) mouse hearts presented increased inhibition of SERCA2, abnormal calcium handling, fibrosis, and hypertrophy. Using whole genome microarrays (Codelink), we identified significant changes in ion transport, muscle contraction, cell cycle and proteolysis, as well as numerous transcription related genes. The observed changes in key sodium, potassium and calcium plasma membrane pumps were confirmed at the protein level and suggested an ongoing electrical remodeling process. In support to these findings, *ex vivo* Langendorff perfusion of intact hearts revealed decreased rates of contraction and relaxation in TG mice. Furthermore, patch clamp analysis of isolated cardiac myocytes unveiled significantly prolonged cardiac myocyte action potential, decreased transient outward current (I_{to}) and increased sodium/calcium exchanger activity. Significant changes were also detected in key cytoskeletal and contractile proteins. In conclusion, "human-PLN" directly affects calcium cycling and contractility, which in turn triggers electrical and structural remodeling. These compensatory mechanisms ultimately enable long term survival of the TG mice.

P06.322

The Human and Canine Dopamine D4 Receptor Genes

E. Szantai¹, K. Héjjas¹, J. Vas², A. Miklós², J. Topá², Z. Rónai¹, M. Sasvári-Székely¹, M. Sasvári-Székely¹;

¹Institute of Medical, Chemical, Molecular Biology and Pathobiology, Semmelweis University, Budapest, Hungary, ²Department of Ethology, Eotvos Lorand University, Budapest, Hungary.

The human dopamine D4 receptor (DRD4) is a candidate gene of great interest in molecular studies of human personality and psychiatric disorders. This gene is unique in having an exceptionally high amount of polymorphic sites both in the coding and in the promoter region. One of the most thoroughly investigated polymorphisms is the 48 base pair variable number of tandem repeats in exon III that has been carefully studied as a possible genetic risk factor for several psychological traits and psychiatric disorders, such as novelty seeking, drug abuse and attention deficit hyperactivity disorder.

Mice or rat possess no analogous repeat sequences, whereas similar tandem repeat polymorphism of the DRD4 gene was identified in dogs and chimpanzees. Therefore, genotyping method was developed for exon III length polymorphism of DRD4 gene in dogs; genotype and allele frequency values were measured in several dog breeds, in wolves and in human DNA samples.

Moreover two other VNTRs were identified and analyzed in dogs in exon I and intron II of the DRD4 gene and were found to be polymorphic.

Our results show that DRD4 gene is also variable in dogs, which means that these animals have the potential to become a natural model for testing relationships between this candidate gene polymorphism and psychiatric disorders (such as hyperactivity).

P06.323

Expression profiles of non-syndromic thoracic aortic aneurysms

C. Patuzzo¹, A. Pasquali¹, M. Iafrancesco², G. Faggiari², I. Dal Pra³, A. Chiarini³, U. Armato³, A. Mazzucco², P. F. Pignatti¹, E. Trabetti¹;

¹Department of Mother and Child and Biology-Genetics, Verona, Italy, ²Division of Cardiac Surgery, Dpt of Biomedical and Surgical Sciences, Verona, Italy, ³Histology and Embryology Unit, Dpt of Biomedical and Surgical Sciences, Verona, Italy.

Thoracic aortic aneurysms occur when the arterial wall is unable to resist the dilating force of arterial pressure. Aortic aneurysms tend to expand without symptoms until aortic rupture or dissection take place. The aim of the study has been to define the molecular circumstances in which non-syndromic aneurysm of thoracic ascending aorta can develop.

Fragments of human ascending thoracic aortas with (35, cases) and without (22, controls) aneurysms have been isolated during surgical intervention (aortic/cardiac transplantation or aortic valve replacement). The three layers of each isolated aortas have been dissected. We now report on media layer results.

Gene transcription and proteomic profiles of the aneurysmal compared to non aneurysmal aortic media layer have been studied. Our preliminary oligonucleotide microarray (22000 genes) results evidenced down regulation of genes such as Decorin (DCN), Thrombospondin 1 (THBS1), Reticulocalbin 2 (RCN2), Reticulon 1 and 4 (RTN1 and 4). Paucity of these transcripts delineate a structural lack of resistance to mechanical stress and an increase of angiogenesis possibly as an attempt to remodeling the vessel. Proteomic analysis indicated a hyper expression of Testican 2 (SPOCK2) and Jagged 1 (JAG1), confirmed by Real Time PCR analysis: mRNAs for these genes are upregulated. The implication of angiogenesis in the aneurysmal aorta is consistent with upregulated Eph transcripts found in microarray analysis. Preliminary results from microRNA microarray (794 miRNA) analysis indicate differential expression between cases and controls of miRNA 15, 16, 21, 128, 487, and 133, and this is consistent with down and up regulated genes found.

Determination of a novel OA1 gene deletion identified by MLPA in a Spanish family.

M. Martínez-García^{1,2}, C. Villaverde^{1,2}, M. López-Martínez^{1,2}, R. Cardero^{1,2}, D. Cantalapiedra^{1,2}, E. Vallespin^{1,2}, R. Riveiro-Álvarez^{1,2}, M. Rodríguez de Alba^{1,2}, M. Trujillo-Tiebas^{1,2}, C. Ayuso^{1,2};

¹Fundación Jiménez Díaz, Madrid, Spain, ²Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), ISCIII, Madrid, Spain.

Nistagmus is the common symptom of a range of diseases involving the macula, including X-linked disorders like ocular albinism type 1. Prevalence of OA type 1 is estimated around 1 in 50,000 live births in Caucasian populations. The OA1 gene, which has been assigned to the Xp22.3 region and spans approximately 40 Kbp of genomic DNA containing nine exons, encodes a melanosomal membrane glycoprotein G consisting of 404 residues belonging to the protein-coupled receptor family.

A purified DNA sample of a female carrier in a Spanish family suffering from ocular albinism was subject to the p054 probe mix of MLPA, showing a decreased peak corresponding to exon 2 of the OA1 gene. In order to determine whether the OA1 gene was altered, we analysed a DNA sample from an affected male (proband's father), and after MLPA, no peak was observed. Therefore, we focused our sequencing analysis on exon 2 because it appears to be particularly prone to deletions. Here, we report a mutation (g.5815delA) identified in 2 affected males and 4 female carriers of this particular family. This mutation which results in a truncated protein 35 codons downstream, generates a new restriction target site for XcmI, that we further confirmed by digestion of DNA from the 6 affected patients. Indirect approach analysis by using OA-CA, a STR located in intron 1, showed co-segregation with the disease in the family.

In conclusion, the prior screening by MLPA is a suitable molecular strategy for diagnosis of patients suffering from X-linked ocular albinism.

P06.325

Further support for the contribution of the NRG1 gene (8p12-p21) to the risk for schizophrenia: Case-control association study in a German population based on the GRAS Data Collection (Goettingen Research Association for Schizophrenia)

S. Papiol¹, M. Begemann², H. Krampe², S. Klaus², F. Bensele³, S. Sperling², S. Stawicki², K.A. Nave¹, H. Ehrenreich²;

¹Neurogenetics Department, ²Division of Clinical Neuroscience and ³Molecular Neurobiology Department, Max Planck Institute of Experimental Medicine, Hermann-Rein-Strasse 3, D-37075 Goettingen, Germany.

Background: Schizophrenia is a severe neuropsychiatric disorder with a worldwide prevalence of around 1% and outstanding heritability estimates (80%; Cardno & Gottesman, 2000). The neuregulin 1 gene (8p12-p21) has been strongly associated with an increased risk to develop schizophrenia by numerous studies in several human populations since the first association reported in an Icelandic population (Stefansson et al., 2002). However this prominent genetic risk factor has not been analyzed in the German population so far.

Methods: Authors analyzed the genetic variability contained in the «Icelandic core-at-risk» haplotype as well as in the intron 1 of the NRG1 gene in a sample of German origin based on the GRAS Data Collection (Goettingen Research Association for Schizophrenia), made up of 883 DSM-IV-diagnosed schizophrenic patients and 880 healthy controls, in the context of a case-control study. SNPs were genotyped through melting curve analysis in a LightCycler@480 system while microsatellite analyses were carried out in a 3730xl DNA Analyzer@. Haplotype analyses were performed using UNPHASED (Dudbridge, 2006) and PHASE (Stephens et al., 2001).

Results: Sliding windows analysis revealed that the frequency of a haplotypic combination defined by markers SNP8NRG241930, 487-2 and D8S1810 (G-12-18) was increased in cases (7.9%) with respect to controls (3.8%), and was significantly associated with an increased risk for the disorder (P-value=7.0x10⁻⁷; OR=2.21 95%CI(1.60-3.08)).

Conclusions: Our results reinforce the interest in the NRG1 gene as a risk factor with a moderate but robust contribution to the risk for schizophrenia.

Acknowledgements: Grant support from the Max-Planck Society and the Deutsche Forschungsgemeinschaft (CMPB). S. Papiol was supported by a postdoctoral fellowship of the Spanish MEC.

Population-based linkage analysis of schizophrenia case-control cohorts identifies a potential susceptibility locus on 19q13

C. Francks¹, P.Muglia¹, D. Rujescu², D. St Clair³;

¹Medical Genetics, GlaxoSmithKline, Via Fleming 4, Verona 37135, Italy., ²Division of Molecular and Clinical Neurobiology, Department of Psychiatry, Ludwig-Maximilians-University, Munich, Germany, ³Department of Mental Health, University of Aberdeen, Aberdeen, UK.

Population-based linkage analysis is a novel method for analysing genomewide SNP genotype data in case-control samples that does not assume a common-disease, common-variant model. The genome is scanned for increased identity-by-descent sharing of extended genomic segments within case-case pairs, relative to case-control or control-control pairs. The method is robust to allelic heterogeneity and is suited to mapping genes which contain multiple, rare susceptibility variants of relatively high penetrance. The method has been proposed by Purcell et al. (Am J Hum Genet 2007) and implemented in the software PLINK.

We analysed genomewide SNP genotype datasets for two schizophrenia case-control cohorts, collected in Aberdeen (461 cases, 459 controls) and Munich (429 cases, 428 controls). This analysis must be performed within homogeneous samples and it was therefore necessary to analyse the cohorts separately. Each cohort was first subjected to several procedures to improve genetic homogeneity, including identity-by-state outlier detection and multidimensional scaling analysis.

Using the complete cohorts there was no significant overlap in signals between the Munich and Aberdeen cohorts. However, when testing only those cases with a positive family history of major psychiatric disease, which would fit better with a model of strongly penetrant susceptibility alleles, we saw a distinct peak on chromosome 19q in both samples (spanning the gene APOE but many others too), that appears in meta-analysis (P=0.000016) to be around the traditional level for calling genomewide significance for linkage.

DNA analysis for blood group ABO determination and RhD DNA typing for prenatal diagnosis

A. V. Kirov, T. Todorov, A. Todorova;
Genetic laboratory Genica, Sofia, Bulgaria.

Blood type group can be determined immunologically or by genetic methods, but genetic methods are more accurate.

We report on a method for ABO and RhD blood type determination, performed by multiplex PCR and PCR-SSP (sequence-specific primers). These analyses provide fast, cheap and easy to perform method for blood type determination. We utilize two PCR reactions for RhD determination - first amplification covers the fragment spanning the intron 3/intron 4 of RhD gene to look for 37bp insert in exon 4. Second PCR is multiplex (3 fragments), it amplifies intron 7 and 3'UTR of RhD locus. Until now we have already done 14 prenatal diagnoses in RhD (-) mothers. The obtained results for the fetuses RhD blood type were: 13 RhD positive and 1 RhD negative.

Determination of ABO blood type includes 4 specific regions analyzed by PCR-SSP. Until now we have tested this method only using control DNA probes to detect the method specificity and sensitivity. The obtained results are promising and the method could be applied routinely for ABO blood group determination. Both methods for DNA blood group/RhD typing will be applied for the purposes of the individual identification and paternity testing, as such analysis is in some cases requested simultaneously with the DNA genotyping of the individuals.

P07.002

The ACE I/D polymorphism in Lithuanian professional athletes

V. Ginevičienė^{1,2}, J. Kasnauskienė¹, V. Kučinskas¹;

¹Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania, ²Lithuanian Olympic Sports Centre, Vilnius, Lithuania.

Human physical performance is under strong influence of genetic factors. I/D polymorphism in the human angiotensin-1-converting enzyme (ACE) gene characterised by the presence (I allele) or absence (D allele) of a 287-base-pair Alu repeat within intron 16 is among most extensively investigated ones with respect to ACE activity and its involvement in various pathophysiological conditions related to endurance. Nevertheless, the results are still conflicting across studies and populations. In the present study, ACE gene I/D polymorphism was investigated in 413 Lithuanian professional athletes representing four functional groups [endurance (N=57); mixed sports (N=44); strength and speed (N=30), and team sports (N=282)], as well as in 120 samples from general population of Lithuanians. Statistically significantly higher D allele frequencies were found in strength and speed group (P=0.02) as well as in endurance group (P=0.06), contrary to the prevailing data from other studies showing association of endurance with I allele. D allele also appeared to be more frequent in the general population of Lithuanians (60,4 %) in comparison to the majority of other European populations (30-50%). Thus, increased D allele prevalence in strength and speed group of athletes from Lithuania can be a reflection of population frequency of this allele. In conclusion, our results imply that the role of ACE gene I/D polymorphism in athletic performance is not straightforward and can be masked by other genetic and non-genetic factors.

P07.003

Association of the ACTN3 gene variant with endurance athlete status

A. M. Druzhevskaya, I. I. Ahmetov, I. V. Astratenkova, V. A. Rogozkin;
St Petersburg Research Institute of Physical Culture, St Petersburg, Russian Federation.

Alpha-actinin-3 (ACTN3) is a myofibrillar protein found in fast-twitch glycolytic muscle fibers. The less common X-allele of the R577X polymorphism in the ACTN3 gene results in a premature stop codon and alpha-actinin-3 protein deficiency in XX homozygotes. A strong association has been reported between the R577X polymorphism and elite athletic performance. The aim of the study was to investigate genotype and allele distribution of ACTN3 gene in endurance-oriented athletes and controls. The study involved 501 athletes (biathletes; rowers; long

distance runners, swimmers and skaters, road cyclists, skiers, triathletes, race walkers) and 1197 controls. Genotyping was performed by restriction fragment length polymorphism analysis. The distribution of ACTN3 genotypes (athletes: RR - 37.1%, RX - 53.1%, XX - 9.8%; controls: RR - 36.8%, RX - 49.0%, XX - 14.2%) was significantly different between athletes and controls ($P=0.038$). While R allele frequency did not differ between athletes (63.7%) and controls (61.3%), the frequency of XX genotype was under-represented in athletes compared to controls (9.8% vs. 14.2%, $P=0.013$). We therefore conclude that XX genotype is unfavorable for endurance performance.

P07.004

Analysis of IGF-1 gene and PGC-1 gene polymorphism in newborn and elderly people from North-west region of Russia

S. V. Potulova¹, O. S. Glotov², V. S. Baranov²;

¹Saint-Petersburg State University, St-Petersburg, Russian Federation, ²Ott Institute of Obstetrics and Gynecology, St-Petersburg, Russian Federation.

Our goal was to investigate whether a polymorphism in the insulin-like growth factor I promoter gene (*IGF-1*, wild-type, 192 base pairs) and in the peroxisome proliferator activated receptor coactivator-1 gene (*PGC-1*, Gly482Ser polymorphism) influence life expectancy. Different distribution of *IGF-1* (CA repeats) gene polymorphism was shown. Increasing of 20/- genotype in elderly people compared with newborn group (26.7% and 44.1%, accordingly, $\chi^2=8.57$, $p=0.0034$) and decreasing of 19/19 genotype (51% and 27.9%, accordingly, $\chi^2=14.815$, $p=0.0001$) were founded. Furthermore, it was shown different distribution of *IGF-1* (CA repeats) gene polymorphism in man and woman. Increasing of 19/20 genotype in newborn man compared with newborn woman (23.2% and 11.3%, accordingly) as well as significant increasing of 19/20 genotype in elderly man compared with elderly woman (44.4% and 21.1%, accordingly, $\chi^2=5.009$, $p=0.025$) was detected. We suggest a possible role of *IGF-1* gene CA- polymorphism in ageing.

The prevalent Gly482Ser polymorphism of the *PGC-1* gene has not been shown to be associated with life expectancy. Increase of Gly/Gly genotype in elderly woman compared with elderly man (51.0% and 27.3%, accordingly, $\chi^2=4.063$, $p=0.0438$) was registered. Analysis of joint contribution of both genes in ageing revealed the significant difference between groups of newborn and elderly people (20%, 41.8%, accordingly, $\chi^2=4.858$, $p=0.0275$). We suggest that both genes (*IGF-1* and *PGC-1*) could be involved in ageing together.

Allele frequency distribution for 3 microsatellite marker in chromosome 12 in Tehran Lipid and Glucose Study

M. S. Daneshpour¹, M. Houshmand², M. Hedayati¹, S. Alfadhli³, F. Azizi¹;

¹Obesity Research Center, Research Institute for Endocrine Sciences, Tehran, Islamic Republic of Iran, ²Department of Medical Genetics, National Institute for Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran,

³Department of Medical Laboratory Sciences, Faculty of Allied Health Sciences, Kuwait, Kuwait.

Objective To study the distribution of allele frequency of 3 microsatellite marker (D12S96, D12S1632 and D12S329) in chromosome 12 on a representative sample of Iranian population

Methods 534 members of 110 families were selected from Tehran Lipid and glucose Study. The DNA samples amplified by multiplex PCR in ABI thermal cycler. Electrophoresis of amplification product performed on an ABI genetic analyzer. After PCR amplification and separation by electrophoresis, raw data was compiled; analyzed and numerical allele designations of the profiles obtained. Deviation from Hardy-Weinberg equilibrium, observed and expected heterozygosity, power of discrimination, and power of exclusion were calculated. Bonferroni's correction performed before each comparative analysis.

Results: Several new alleles (not yet reported in the NIST Short Tandem Repeat DNA Internet Data Base [http://www.cstl.nist.gov/biotech/strbase/]) detected in this study. We found 15 alleles for D12S96, 10 alleles for D12S1632 and finally 10 alleles for D12S329. The most heterozygote and informative allele was D12S1632 with 0.7270 heterozygosity (208-230bp) and 0.7395 PIC number. There was no significant deviation from Hardy-Weinberg equilibrium for all the observed loci.

Conclusion: Comparing Iranian data with those obtained from other populations, the most informative allele in this population is D12S1632.

P07.006

Alpha 1 antitrypsin gene mutation in patients with a suspected alpha 1 antitrypsin protein deficiency

C. Mordillo, Y. Robles, J. Seco, L. Alvarez, A. Ortega, E. Massip, D. Gómez; Balagué Center S.A., Hospitalet de Llobregat, Spain.

Alpha 1 antitrypsin (AAT) deficiency is the most prevalent potentially lethal hereditary disease of Caucasians. Individuals with AAT deficiency have an increased risk of early onset for severe pulmonary emphysema and for liver disease. The most common variants of AAT are classified as M, S, and the most prevalent type of clinically important AAT deficiency, the Z genotype.

MATERIAL AND METHODS: We sequenced the coding region of the AAT gene in 105 patients with a suspected deficiency of AAT protein. We analyzed the sequences by comparing all exons amongst them and also with the reported AAT sequence in the databases to identify all known and novel allelic variants in the gene. Some patients were also tested for plasma levels.

RESULTS: We found eight new genetic variants in the coding sequence of the AAT gene. Two were small deletions and six were SNP's. Some of them changed the amino acidic sequence of the protein and were found in more than one patient. All new genetic variants were found in an heterozygous state.

CONCLUSION: Naturally occurring mutations have been very useful in understanding regulation-functionality of proteins. Using the sequencing method for genotyping, has showed to be a very useful tool for discovering new genetic variants. The knowledge of new genetic variants in the AAT gene, specially when they occur in the coding region of the gene, could contribute to identify new genetic risk factors for suffering the AAT deficiency disease.

P07.007

Phenotyping of alpha-1-antitrypsin in hospitals of three regions of Azerbaijan

A. B. Ismayilova;

Baku State University, Baku, Azerbaijan.

Alpha-1-antitrypsin (α 1AT) is a low molecular protease inhibitor, synthesized by liver cells and suppressing the activity of many serine proteolytic enzymes. In our experiments for revealing subtypes of normal Pi alleles: M1, M2, M3 and diagnosis of mutated alleles - PiZ, PiS we used analytical method of isoelectrofocusing (IEF) in thin layer polyacrylamide ampholine gels (PAAG), pH 4-6. We have done identification of α 1AT phenotypes in quite healthy persons as well as in patients with COPD. Capillary blood (0,2 ml) with anticoagulation agent - heparin was collected in eppendorf tubes. Altogether there were screened 919 persons' blood samples in 3 regions : Siyazan and Khachmas areas are located 110 km northward and Khazakh area 450 km west-northward from Baku city. The frequency of mutated gene PiZ and PiS varied in the limits of 0.0046-0.0114 and 0.0037 and 0.0066 respectively. The lowest frequencies PiZ of the gene were revealed at population of Khazakh, PiS gene at the population of Siyazan. Among the patients with COPD from all centrals region hospitals there were identified the homozygote state for PiZ mutations with phenotypic frequency 0.83% (Khazakh) up to 1.81% (Khachmas) at the average - 1.16%. Only among the patients in Siyazan there was identified compound- i.e. double heterozygote state of PiZ and PiS genes. About the three regions there were revealed 32 mutations of PiZ heterozygote, homozygote - 19 people, mutations of PiS heterozygote - 22, homozygote one and one compound with PiZ/PiS genotype.

P07.008

Leukocyte and Plasma Alpha-Galactosidase Enzyme Activity Levels in Healthy Young Adults: Evidence that Females Have Higher Plasma Levels

J. Oliveira¹, S. Ferreira¹, J. Barceló¹, F. Carvalho¹, J. Månsson²;

¹Faculdade de Medicina, Universidade do Porto, Porto, Portugal, ²Sahlgren's University Hospital, Molndal, Sweden.

Background: Lysosomal α -galactosidase is the enzyme deficient in Fabry disease, an X-linked glycosphingolipid storage disorder affecting both genders. Although in males the leukocyte and plasma α -galactosidase assays are used interchangeably for the diagnosis of Fabry disease, in females the enzyme assays are less reliable and the plasma assay appears to have a much lower sensitivity than the leukocyte assay.

Methods: To investigate possible biologic gender differences in normal α -galactosidase activity, plasma and leukocyte enzyme activities were determined in eight male and nine female healthy unrelated Caucasian young adults. All subjects had been genotyped and carried the standard genomic sequence for the 5' untranslated region of the α -galactosidase gene, a region that may contain single nucleotide polymorphisms affecting the level of gene expression. Differences in gender means were compared by the independent samples t-test.

Results: The mean (\pm SD) α -galactosidase activity levels were 28.7 (\pm 3.7) and 27.5 (\pm 4.7) μ kat/Kg in leukocytes ($p=0.57$) whereas mean plasma activities \pm SD were 2.2 (\pm 0.5) and 2.9 (\pm 0.7) nkat/L ($p=0.03$), respectively for males and females.

Conclusion: There seems to be a gender difference in normal plasma α -galactosidase activity. This finding, if confirmed in a larger sample, may have to be taken into account in the definition of normal laboratory reference ranges and may warrant a reassessment of the sensitivity of the plasma α -galactosidase assay for the identification of females with Fabry disease. We hypothesize that a higher fractional post-translational sialylation of the newly synthesized enzyme in the female Golgi apparatus may contribute to this difference.

P07.009

Familial amyloid polyneuropathy (ATTR V30M): a change in paradigm?

A. Sousa^{1,2}, A. M. Silva³, L. Maia³, T. Coelho³;

¹ICBAS (Instituto Ciências Biomédicas Abel Salazar), U.P., Porto, Portugal,

²BMC (Instituto Biologia Molecular e Celular), U.P., Porto, Portugal, ³Unidade Clínica de Paramiloidose, HGSA (Hospital Geral Santo Antonio), Porto, Portugal.

Andrade first described FAP (1952) as a disease occurring between 25 and 35 yrs. He reported 64 patients, 13 of which had no family history of the disease. Later PE Becker established its AD mode of inheritance and interpreted isolated cases not as a *de novo* mutation but as the expression of incomplete penetrance of the gene in one of the parents. This hypothesis could only be tested after the finding of the mutation in 1985.

Our aims were: 1) to estimate the number of probands with no affected parent at time of diagnosis; 2) to study age at onset of proband and its changes over time. Between 1939 and 2005, 2075 patients (525 families) were diagnosed at HGSA. Families were classified as "new" when the proband reported no similar disease in earlier generations.

Age-at-onset varied from 20-80 yrs (mean 37.1 in women, 32.4 in men). 209 probands (40%) had no affected parent at time of diagnosis. This type of family represented 68% of those diagnosed in last decade (only 27% before 1985). Mean age-at-onset of probands of "new" families was 46.0 yrs (vs. 32.3 yrs for "classical" families) and it has increased over time, being 49.5 yrs in last decade.

Regarding FAP two realities coexist in Portugal: families with several generations of affected (where probands have "classical" onset) and probands with late-onset who report no similar disease in previous generations. The mutation may cross generations without clinical manifestations, then expresses as late-onset and later anticipation occurs.

P07.010

The β_2 -adrenergic receptor gene polymorphism and arterial hypertension in children

S. V. Kuzmina¹, M. A. Bogdanova², O. S. Romashkina², O. A. Mutafyan¹, V. I. Larionova²;

¹St.Petersburg State Medical Academy of Postgraduate Studies, Saint-Petersburg, Russian Federation, ²St.Petersburg State Pediatric Medical Academy, Saint-Petersburg, Russian Federation.

The β_2 -adrenergic receptor (*ADRB2*) is thought to be associated with arterial hypertension (AH) and its altered function can result in increased blood pressure (BP). Q/E27 polymorphism of *ADRB2* gene is considered functionally important.

Though some reports indicate that polymorphism in the *ADRB2* gene is associated with essential hypertension, its role in BP levels remains unclear.

The aim of this study were to investigate distribution of *ADRB2* genotypes and allele frequencies of Q/E27 polymorphism in hypertensive and normotensive children and to compare clinical systolic BP levels between carriers of the different genotypes.

84 children with systolic AH (aged 7-17) and 90 normotensive children

(aged 7-17) were include the study.

Arterial hypertension was defined as systolic/diastolic blood pressure measurements higher than 95 age-gender-height percentile of the adopted reference values.

DNA was extracted from blood samples according to standard protocols. The Q/E27 polymorphism was genotyped by using the PCR restriction fragment length polymorphism analysis.

The distribution of *ADRB2* genotypes and allele frequencies did not differ significantly between patients with AH and control subjects.

Clinical systolic BP in patients with QQ- genotype was 133,65 \pm 11,5 mm Hg, QE-genotype was 133,43 \pm 8,4 mm Hg, EE- genotype was 132,52 \pm 7,5 mm Hg. Clinical systolic BP differences among genotypes were not found.

The allelic and genotypic frequencies of the Q/E27 polymorphism in hypertensive and control subject

Q/E27	Hypertensive (n=84)	Control (n=90)	<i>p</i>
QQ	17 (20,2%)	14 (15,6%)	0,722
QE	46 (54,8%)	52 (57,8%)	
EE	21 (25,0%)	24 (26,7%)	
Q	80 (47,6%)	80 (44,4%)	0,5527
E	88 (52,4%)	100 (55,6%)	

P07.011

IL4 genetic polymorphisms contribution to Madeira population risk of asthma

A. G. Berenguer¹, R. Câmara², A. T. G. Fernandes¹, S. Oliveira², A. Brehm¹;

¹Human Genetics Laboratory, Funchal, Portugal, ²Imunoallergology Unit, Central Hospital of Funchal, Funchal, Portugal.

The allergic disease prevalence is influenced by both environmental exposure and the population's genetic predisposition to the disease. Five different polymorphisms of previously associated genes to some of asthma's phenotypic characteristics namely IL4RP2 and IL4-590 (C/T) at 5q31-32; *ADRB2* 16A/G at 5q31-32; *ADAM33* S1 (G/A) and *ADAM33* V4 (C/G) at 20p13 were studied in 28 asthmatic children with positive skin prick test to house dust mite from affected sib-pair families composed by two children and their biological parents. Allele frequencies from asthmatic patients were then compared to a sample from Madeira general population. Both genotypic and allelic frequencies as well as comparisons between both groups were accessed by ARLEQUIN 3.1.

We have found significant differences regarding both IL4RP2 and IL4-590 (C/T) polymorphisms between the two groups ($p<0,05$). No significant differences were detected for the remaining polymorphisms.

There seems to be an association between asthma development and both RP2 and -590 (C/T) polymorphisms within IL4 gene for Madeira population. These two loci may be useful genetic markers for detecting atopic asthma disease predisposition in Madeira.

P07.012

Gene-Environment-Interactions: Increased Risk for Atopic Eczema

C. Gräbsch¹, S. Röder¹, O. Herbarth^{1,2}, U. Krämer³, H. Wichmann⁴, J. Heinrich⁴, M. Bauer⁴;

¹Helmholtz Centre for Environmental Research - UFZ, Department for Human Exposure Research and Epidemiology, Leipzig, Germany, ²Universität Leipzig, Medical Faculty, Environmental Medicine & Environmental Hygiene, Leipzig, Germany, ³Institut für Umweltmedizinische Forschung (IUF) an der Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany, ⁴Helmholtz Zentrum München - German Research Center for Environmental Health, Institute of Epidemiology, Neuherberg, Germany.

Within the atopic march, atopic eczema (AE) is one of the first clinical manifestations. Possible interaction of genetic disposition and environmental factors "in utero" or postnatal could influence the susceptibility for AE.

For a reliable prognosis of an individual responsiveness to environmental factors, children of the epidemiological LISA-study (n=881) were genotyped for common polymorphic xenobiotica-metabolizing enzymes involving in biotransformation of industrial pollutants, cigarette smoke and in defence against oxidative stress.

The study revealed, that children with the genotype combination *CYP2D6**1A/*1A, *GSTP1**1A/*1A, *GSTT1**null/*null and *GSTM1**1A/*null or *1A/*1A (n=26) had a higher susceptibility for AE, when ex-

posed to tobacco smoke (mother smoked actively). For the exposure scenario "mother smokes during the first trimester of pregnancy", the OR for AE within the first years of the children's life are statistically significant (at the age of **1 year: OR 6.4** [95%CI: 1.0-41]; **1½ years: OR 9.5** [95%CI: 2.0-43.9]; **2 years: OR 5.5** [95%CI: 1.2-24.6] as well as **6 years: OR 3.5** [95%CI: 0.8-15.5], adjusted to gender, positive family history of atopy, vaccination and infections and refurbishing during pregnancy). Children without tobacco smoke exposure show no association between the genotype combination and a higher risk for AE. Additionally, "smoking after pregnancy" could confirm the previously association, but only by a trend due to the small subgroup. These associations show a putative role of the gene-environment-interactions in the manifestation of AE. However, an identification of a closer time-frame of risk toward the exposure "mother smokes" is not yet possible.

Auditory neuropathy (AN) encompasses a variety of disorders characterized by normal otoacoustic emissions (OAE) and absent or grossly abnormal auditory brainstem responses (ABR) in the affected subjects. AN can result from environmental or genetic causes. It can be part of a systemic neurodegenerative disorder or it can be an isolated clinical entity. The primary lesion in AN can be located in the inner hair cells, in the auditory nerve, or in the synapse in between. In the last few years, several genes have been shown to be involved in AN. We have investigated the prevalence of mutations in the genes encoding otoferlin, pejkakin and TIMM8a (*OTOF*, *DFNB59* and *DDP1*, respectively) in subjects with isolated auditory neuropathy. A cohort of 36 unrelated subjects with isolated auditory neuropathy were screened for mutations in these genes by DNA sequencing of all exons and flanking intronic sequences. In 25 subjects (69%), we found two mutant alleles of *OTOF*, two of the mutations being novel. In one subject (2.8%), we found a novel mutation in the *DDP1* gene. Mutations in this gene are responsible for Mohr-Tranebjaerg syndrome, an X-linked condition associating deafness and muscular dystonia. The affected child did not present with dystonia at the age at which the study was performed. No mutations were found in the *DFNB59* gene. Our results show that mutations in the *OTOF* gene are a major cause of inherited auditory neuropathy and suggest that cohorts of apparently isolated auditory neuropathy may contain additional cases of the rare Mohr-Tranebjaerg syndrome.

Since 1998, a collaborative study has been undertaken between the genetic department of Necker Enfants Malades hospital and 5 psychiatric outpatient care units of Île-de-France region. From 1998 to 2008, 159 patients with autistic spectrum disorders (ASDs) have undergone on-site genetic consultation gathering the following data: family and

personal medical history, detailed psychiatric evaluation, dysmorphological and neurological clinical examination. Blood and/or urine samples were collected for genetic testing each time a specific disorder was suggested after the first consultation, or for systematic screening of common ASD-related disorders. Systematic screening comprised high resolution banding karyotype, with 22q13 and 15q11q13 FISH analyses, *FMR1* gene triplet expansion testing, and metabolic screening (*blood aminoacid and urine organic acid chromatographies, AICAR, urinary creatin and guanidinoacetate, N-glycosylation, lactate, pyruvate, ammonium*). CGH-array analysis was undertaken in 6% of patients thus far. Most of the 159 ASD patients (50 females and 106 males) had associated mental retardation ranging from mild to profound.

21 specific diagnoses were obtained for 30 patients: fragile X (8 patients), 15q11q13 duplication (2 patients), 22qter deletion, 22q11.2 deletion, 1p36 deletion, Williams syndrome, trisomy X, Turner syndrome, interstitial 19q deletion, mosaic ring 15, 8q23q24 duplication, 17p11.2 duplication, 1q31 duplication, 1q21 duplication, *AP1S2* mutation, Prader-Willi, Cornelia de Lange, CHARGE and Rubinstein-Taybi syndromes, creatin transporter deficiency (2 patients), *GAMT* deficiency, phenylketonuria, and histidinaemia. We present a cohort of 159 patients with ASD. 23 specific genetic disorders were found in 32 patients (20,1 %). These results emphasize the importance of on site evaluation of these patients.

Analysis of ACE and AT1R gene polymorphisms in Balkan Endemic Nephropathy

Z. Krcunovic¹, I. Novakovic¹, N. Maksimovic¹, D. Bukvic², S. Simic-Ogrizovic³, L. Djukanovic³, S. Jankovic⁴;

¹Institute of Human Genetics, School of Medicine, Belgrade, Serbia, ²Institute of Endemic Nephropathy, Lazarevac, Serbia, ³Institute of Nephrology and Urology, Belgrade, Serbia, ⁴Institute of Epidemiology, Belgrade, Serbia.

Balkan endemic nephropathy (BEN) is a multifactorial disorder with still unexplained hereditary component. Similarity of BEN and cyclosporine nephropathy suggests possible common ethiopathogenetic mechanisms. Considering the role of renin-angiotensin system in emergence of cyclosporine nephropathy and other types of kidney disease, candidate genes for association studies in BEN were chosen. We performed analysis of I/D polymorphism in gene encoding for angiotensin-converting enzyme (ACE) and A1166C polymorphism in gene encoding for type I receptor for angiotensin II (AT1R). The study was carried out in a group of 50 patients with BEN diagnosis according to criteria of Danilovic, derived from endemic region in Kolubara district. Two control groups consisted of 50 healthy persons (C) and of 45 patients with other nephropathies (NBEN), both matched by age and gender. DNA for gene analysis was extracted from peripheral blood leukocytes. For detection of ACE I/D and AT1R A1166C gene polymorphisms PCR and PCR/RFLPS methods were used, respectively. We found that frequency of ACE DD genotype was 41.66%, 43.14% and 84.61% in BEN, C and NBEN group, respectively. For AT1R A1166C gene polymorphism frequency of CC genotype was 10.41%, 8.69% and 5.72%, respectively. Our results showed no difference in analysed genotypes between BEN and C group. However, we found significantly higher frequency of ACE DD genotype and lower frequency of AT1R 1166 CC genotype in NBEN group. Although these results do not indicate significant role of ACE and AT1R gene polymorphisms in BEN, we will proceed in investigation of other members of renin-angiotensin system.

P07.016

Compound heterozygosity between HbS and b-thalassemia. Implication for the neonatal diagnostic of hemoglobinopathies

S. Pissard^{1,2}, N. Ellachter³, C. Albert¹, C. Godart¹, F. Galacteros⁴, H. Puehringer⁵, C. Oberkanins⁵, H. Wajcman⁶;

¹laboratory of genetics, AP-HP, Hop Henri Mondor, creteil, France, ²INSERM, U841 eq 11, Creteil, France, ³INSERM, U841 eq 11, creteil, France, ⁴UMGGR, AP-HP, Hop Henri mondor, creteil, France, ⁵ViennaLab Diagnostics, Vienna, Austria.

Compound heterozygosity between Hb S and b-thalassemia is a form of sickle cell anemia (SCA) with a clinical severity varying considerably. The clinical phenotype depend upon the type of thalassaemic defect but also on other factors. To clarify the spectrum of b-thal associated with

HbS in the French population, we studied a cohort of about 150 S/bthal patients and we found 20 different thalassaemic traits, 9 of them representing 79% of the patients. Spectrum of mutations vary depending on the patients origin but one interesting finding is that in the group of patients of unidentified origin (n = 31) we found the largest spectrum with 20 different mutations. This finding may be explained by the increasing heterogeneity of the French population and the admixture of thalassaemic traits from various parts of the world with the HbS. In France, newborns belonging to populations at risk are screened for SCA by means of IEF and CE-HPLC of Hb eluted from a dried blood spot. In order to know the proportion of incorrectly diagnosed newborns we extracted DNA from blood spot and genotyped the codon 6. Results obtained with 100 spots diagnosed as "S/S" with Hb study, revealed that 15% of samples displayed one Hb S allele and one normal codon and thus were improperly diagnosed. These data, lead us to develop a fast and simple method which will allow to provide an "one shot" correct diagnosis of SCA and related syndromes in neonates.

P07.017
Genetic heterogeneity of β-thalassaemia in Catalonia: molecular characterization of 74 cases

M. Mañú-Pereira¹, A. Cabo², N. Radó¹, J. Vives-Corrons¹;
¹Hospital Clínic i Provincial, Barcelona, Spain, ²Hospital de Mataró, Barcelona, Spain.

Introduction: A study performed in Catalonia in 1988 showed 8 mutations responsible for the total of β-thalassaemia cases. The objective is to investigate the β-thalassaemia underlying mutations to ensure proper genetic counseling and prenatal diagnosis. We also describe a new β-thalassaemia mutation.

Methods: 74 patients for β-thalassaemia were studied. The 8 most prevalent mutations (>90%) of β-globin in the Mediterranean: CD39(C>T), IVS1:110(G>A), IVS1:6(T>C), IVS1:1(G>A), IVS2:745(C>G), IVS2:1(G>A), -87(C>G), CD6(-A) were screened by ASO. Negative samples were sequenced for β-globin gene.

Results: Distribution of the identified β-gene mutations and data of 1988 are shown in Table 1.

Discussion: Identification of mutation leading to β-thalassaemia by analyzing the most prevalent mutations in the Mediterranean has decreased 15-25%. The 4 mutations most prevalent in our study are common in the West Mediterranean but the last 4 considered prevalent are responsible only for 2.8% of our cases. In comparison with the 1988 study, analysis of the 8 mutations then identified is responsible for 82.6% in the recent study, changing the relative percentage. Molecular heterogeneity has increased: 19 mutations, including Chinese and sub-Saharan variants are now responsible for all cases. Since immigration flows and increased rates of rare and even new variants make genetic diagnosis more difficult, this shows the high importance of identifying β-thalassaemia mutations in order to provide appropriate genetic counseling and prenatal diagnosis

Polymorphism in CaRS A986S gene and serum or urine concentration of bone mineral related parameters in random selected postmenopausal women .

L. Navarro Casado, J. A. Blázquez Cabrera, C. Andrés Fernández, M. Cháfer Rudilla, J. H. Ontañón Rodríguez, M. L. Quintanilla Mata;
 CHUA, Albacete, Spain.

Background. Calcium-sensing receptor (CaSR) is a candidate gene for osteoporosis susceptibility. There are only a limited number of studies available regarding the relationship between the CaSR gene A986S polymorphism and serum or urine concentration of bone mineral related parameters.

Objectives. To evaluate whether CaSR gene A986S polymorphism affects bone mineral related parameters on serum as: calcium (s-ca), phosphorus (s-ph), alkaline phosphatase (s-alp), acide phosphatase (s-acp), or on urine as calcium creatinine ratio (u-ccr).

Subjects and methods. 158 women with natural menopause were randomly selected (mean age 52.7±1.6 yr). They did not have any diseases to affect bone metabolism. Genomic DNA was extracted from peripheral blood leukocytes by the Higuchi method. A fragment of exon 7 of CaSR gene containing the A986S polymorphism was amplified by polymerase chain reaction (PCR). After amplification, all samples were digested with Bsa H1 restriction enzymes, and the fragments were separated by agarose gel electrophoresis. The levels of s-ca, s-ph, s-alp, s-acp or u-ccr were measured by P-module from Roche.

Results. Genotype frequencies of CaSR gene A986S polymorphism was: AA, 121 (76.6%); AS, 34 (21.5%), and SS, 3 (1.9%). We found no association between CaSR polymorphism and s-ca, s-ph, s-alp, s-acp. Women with the AS/SS genotype had higher u-ccr than those with AA genotype, (AS/SS 0.205 ± 0.88; AA, 0.167 ± 0.76 mg/mg; p=0.014).

Conclusions. 1) We found no association between CaSR gene A986S polymorphism and serum concentration of bone mineral related parameters. 2) We found association between CaSR gene A986S and calcium creatinine ratio.

P07.019
BRCA1 and BRCA2 sequence variants in healthy women in Croatia

M. Levačić Cvok, V. Musani, M. Čretnik, P. Ozretić, S. Levanat;
 Rudjer Boskovic Institute, Zagreb, Croatia.

BRCA1 and BRCA2 are the major genes predisposing to breast and ovarian cancer. Mutations in either of these tumor suppressor genes are associated with both sporadic and hereditary forms of breast cancer. In hereditary cancer, a person inherits one mutated copy of either one of these genes. Tumorigenesis occurs when in addition to having a mutated copy individual develops an inactivating mutation of the remaining healthy allele.

Breast cancer is the most common malignant disease of female population, and the second most common malignancy-related cause of death. At least ten percent of cases are attributable to familial inheritance. In Croatia, more than 2200 new cases of breast cancer are diagnosed each year, and about 800 women die of this malignancy.

The screening was performed by high resolution melting approach, which is based on differences in melting curves caused by variations in nucleotide sequence; detected variants were confirmed by direct sequencing.

In total, we analyzed 230 samples for BRCA1 gene and 140 samples

for BRCA2 gene. We found 21 different sequence variants in BRCA1 (2 novel) and 36 variants in BRCA2 gene (7 novel).

We analyzed the distribution and occurrence of sequence variants in BRCA1 and BRCA2 genes on a healthy population of women in Croatia in an attempt to distinguish non-tumorigenic from tumorigenic changes in genomic sequences of BRCA1 and BRCA2 genes. This may contribute to easier distinction of potentially dangerous from harmless changes in patients with family history of breast cancer.

P07.020

DNA-repair genetic polymorphisms and breast cancer risk among Cypriot women

M. Loizidou¹, T. Michael¹, Y. Marcou², M. Danie¹, E. Kakouri², P. Papadopoulou², S. Malas³, K. Kyriacou¹, A. Hadjisavvas¹;

¹The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ²Bank of Cyprus Oncology Centre, Nicosia, Cyprus, ³Limassol General Hospital, Limassol, Cyprus.

Breast cancer is the most common malignancy which affects women worldwide. In an attempt to identify genetic variants which modify breast cancer risk we are conducting a case-control genetic epidemiology study using a cohort of 2286 Cypriot women (1109 breast cancer patients and 1177 age-matched healthy controls). In the present study we genotyped 11 single nucleotide polymorphisms (SNPs) in BRCA2, ERCC2, FANCA, MLH1, MRE11A, MSH2, OGG1, p53, RAD51 and RAD52 genes which are all involved in the DNA repair pathway. The prevalence of the 11 SNPs was compared between cases and controls. Genotype frequencies were compared across groups using the chi square test and the Mantel-Haenzel test for linear trend. The association between breast cancer and each SNP was examined using logistic regression with the SNP genotype tested under models of complete dominance and recessive inheritance. Three SNPs showed significant associations with breast cancer. For the most significant SNPs, the estimated ORs were 0.74 (95%CI 0.59-0.93) and 1.41 (95%CI 1.08-1.83) under a dominant inheritance model, with a combined Ptrend 0.0087 and 0.0076 respectively. These results suggest that a proportion of the SNPs under study are modifying breast cancer risk. Large numbers of samples will be needed to verify our results in other populations. We are currently expanding our analysis to include a greater number of SNPs and to evaluate potential underlying gene-gene or gene-environment interactions, in order to advance our knowledge on the effect of genetic polymorphisms on breast cancer susceptibility in Cypriot women.

P07.021

Variants in the vitamin D receptor gene and breast cancer

E. Barroso¹, L. P. Fernández¹, R. L. Milne¹, G. Pita¹, P. Zamora², J. I. Arias³, J. Benítez¹, G. Ribas¹;

¹CNIO, Madrid, Spain, ²La Paz Hospital, Madrid, Spain, ³Monte Naranco Hospital, Oviedo, Spain.

Breast cancer is the most commonly occurring cancer among women, constituting 23% of all cancers. 5-10% of all breast cancers are caused by germ-line mutations in *BRCA1* and *BRCA2*. Multiple low-risk genes with variants common in the general population are thought to produce a mild susceptibility risk to sporadic breast cancer.

The vitamin D receptor (VDR) gene is a key mediator in the vitamin D pathway, and has been of long interest in breast cancer aetiology, since vitamin D exposure has been reported to reduce breast cancer risk. In the present study we have explored the implication of VDR in sporadic breast cancer, in the Spanish population since previous studies have been done in different populations than South European ones.

A total of 576 healthy controls from the Spanish population and 576 consecutive and non-related sporadic breast cancer cases, collected from different hospitals in Spain, were used in this study. Genotyping studies were carried out over four SNPs within the *VDR* gene, located on exons, in the putative promoter region or in untranslated regions. Genotyping was performed using TaqMan.

We detected associations for two of the selected SNPs: rs10735810 with OR=1.49 (95% C.I. 1.01-2.21; p=0.045), and rs731236 with OR=0.72 (95% C.I. 0.51-1.02; p=0.064). We also studied both haplotype and diplotype using PHASE v2.0, and detected associations with disease that were considered with the genotype results. Additionally, VDR proliferation parameters such as tumor differentiation grade and tumor aggressiveness will be discussed.

P07.022

Mutations in CARD15 and smoking confer susceptibility to Crohn's disease in the Danish population

A. Ernst¹, I. S. Pedersen¹, H. Okkels¹, M. Ostergaard², B. A. Jakobsen¹, N. Thorsgaard³, E. Dagliene¹, V. Anderser², A. M. Drewes¹, H. B. Krarup¹;

¹Aalborg Hospital, Aalborg, Denmark, ²Viborg Hospital, Viborg, Denmark, ³Herning Hospital, Herning, Denmark.

INTRODUCTION: Three mutations in the Caspase Recruitment Domain gene (*CARD15*) predispose to Crohn's disease (CD) in Caucasian populations.

The frequencies of the three most common *CARD15* mutations differ greatly between ethnic groups. Heterogeneity even exists between the European countries.

AIMS & METHODS: The aim of this study was to investigate the mutation frequency in patients with inflammatory bowel disease and healthy controls in Denmark. Genotyping of the three *CARD15* mutations were performed in 388 patients with Crohn's disease, 565 patients with ulcerative colitis and 796 healthy controls using Real-Time PCR. A comparison of allele and genotype frequencies in the three groups was made. A possible additive effect of smoking on *CARD15* mutations was also examined.

RESULTS: *CARD15* mutations were significantly more common in CD patients compared with healthy controls (21% vs. 10%; P<0.001). A gene-dosage effect was observed (OR_{adj.smoking} 22.2; P<0.001 for two *CARD15* mutations vs. OR_{adj.smoking} 1.8; P=0.01 for one *CARD15* mutation). The 1007insC protein truncating mutation was the major contributing mutation. Among the Danish CD patients ileal involvement was more common among patients having *CARD15* mutations (OR_{adj.smoking} 3.6; P<0.001). Smoking was independently associated with CD (OR 1.8; P<0.001), and no additive effect of smoking on *CARD15* genotypes was found.

CONCLUSION: In the Danish population *CARD15* mutations were associated with Crohn's disease. The *CARD15* mutation frequency was in agreement with the lower frequency found in Northern European countries. Smoking was found to be a risk factor for developing CD.

P07.023

Cultural practice of consanguineous marriages in Morocco : prospective study in Rabat city

H. Hami, A. Soulaymani, A. Mokhtari;

Laboratory of Genetic and Biometry, Faculty of Sciences, Kenitra, Morocco.

The practice of consanguineous marriages has been widespread for hundreds of years, and is still very common, especially among various Middle Eastern, Asian and African populations. Their health consequences are primarily linked to the increased risk of congenital malformations and autosomal recessive disease.

The present study set out to determine the frequency of consanguineous marriages, identify and analyze the factors associated (bivariate analysis) with a randomly selected sample of 270 mothers postpartum in maternity of the Souissi Hospital in Rabat city (north-west of Morocco), between November 2004 and June 2005. All information was based on structured face-to-face interviews.

The Results showed that 21% of marriages were consanguineous (95% CI 12-28%), among which 70% were between first cousins. According to these results, several variables are associated with the choice of this type of marriage, namely women's education, their age at first marriage, place of residence, as well as type of childhood residence (rural or urban).

P07.024

Matrimonial choice in the Souss Massa Draa region in Morocco

L. Sbii, D. Benali, H. Hami, A. Mokhtari, A. Soulaymani;

University Ibn Tofail, Faculty of Sciences, Kenitra, Morocco.

The study of geographical endogamy has relevance for indications on the genetic variability of the population, given that related parents have more chances to carry the same alleles, favouring homozygosity in their children.

The objective of this study was to evaluate geographical endogamy in the population of the region of Souss Massa Draa in south Morocco, as an indicator of the degree of genetic isolation of the population.

A prospective study was carried out between October 2005 and April 2007 on 190 randomly picked families of Souss Massa Draa. The choice of the mate was evaluated according to the geographical origin

of the couple and their parents. The intensity of the endogamic behaviour is determined by the endogamy ratio.

The results indicated clearly a tendency of the couples to geographical endogamy. 95% of the couples involved in the study, chose a mate of the same geographical origin, 98% did so in the generation of their parents.

The intergenerational comparison of the measured endogamy ratio shows the same degree of genetic isolation for both generations ($p > 0.05$).

Compared to other results obtained in other regions of Morocco, the Souss Massa Draa region can be qualified as "closed", which reflects the cultural and traditional heritage of this region.

P07.025

The frequency of cholesteryl ester transfer protein Taq1B polymorphism in the Western Anatolia

C. Kilincarslan, S. Pehlivan;

University of Gaziantep, Faculty of Medicine, Department of Medical Biology, Gaziantep, Turkey.

The main aim of our studies is to indicate Taq1B polymorphisms in Cholesteryl Ester Transfer Protein (CETP) gene in healthy Turkish population as statistically and to explore the difference between other populations. We have examined allele frequencies for cholesteryl ester transfer protein (CETP) gene Taq1B polymorphism in our 100 healthy control subjects (74 men and 26 women) residing in Izmir (Turkey), by PCR-RFLP. We found the ratio for B1/B1 carriers as 30.0% , for B1/B2 carriers as 45.0% and for B2/B2 carriers as 25.0%. B1 allele frequency was 52.5% and B2 allele frequency was 47.5%. Depending on this results we observed that percentage of homozygotes for the B1 allele is lower in our samples than other populations (Spain, Greece, Japan, France, Scotland, Finland, USA) but for the B2 allele, it is much more higher than the other populations which have been studied before in other countries. The percentage of heterozygotes in our population is also mostly lower than the other populations except healthy Spanish population.

P07.026

Long-term cytogenetic effects of natural radiation on Gudalore inhabitants in India

K. Sasikala, V. Balachandar, B. LakshmanKumar, R. Sangeetha, K. Suresh; Human Genetics Laboratory, School of Life Sciences, Bharathiar University, COIMBATORE, India.

Some locations in the Indian subcontinent have high levels of natural radiation due to the presence of monazite along with other heavy minerals such as ilmenite, zircon, garnet, etc. Gudalore situated on the Nilgiri Mountain, is the oldest and important ecosystem in peninsular India. Indoor gamma radiation dose rates were measured inside residential buildings in Gudalore using a CaSO₄:Dy thermoluminescent dosimeter for 1 year. The dose rates observed are between 77.9 and 229.3 nGy h⁻¹ and may be attributed to the type of building materials used in the dwellings monitored. The pioneering work on cytogenetics has evolved a long way for detection of various clastogenic insults and biodosimetry can help to verify the result derived from physical dosimeters during latter's improper use.

The focal aim of the present investigation was to identify the chromosomal aberrations in Gudalore area. In order to investigate the possible cytogenetic damage to the residents of contaminated buildings, a G-banding method was carried out on the lymphocytes of 61 radiation-exposed individuals and equal number of controls selected. Experimentals and controls were selected by confirmed by TLD measurement. In the present study volunteers provided blood samples (5 ml) to establish cell cultures at 52 h. For karyotyping, 40 complete metaphase cells from each subject were evaluated.

All the recognizable structural aberrations of chromosomes or chromatid were recorded and statistically analyzed. In 3 experimental cases showed dicentric chromosomes. In addition, the chromosomal regions close to the centromere were found to break more frequently than elsewhere in the genome.

P07.027

ABCC1 polymorphisms contribute to level and decline of lung function in two general population cohorts

M. Siedliński¹, H. M. Boezen¹, J. M. A. Boer², H. A. Smit³, D. S. Postma⁴;

¹Department of Epidemiology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands, ²Centre for Nutrition and Health, National Institute for Public Health and the Environment, Bilthoven, Netherlands, ³Centre for Prevention and Health Services Research, National Institute of Public Health and the Environment, Bilthoven, Netherlands, ⁴Department of Pulmonology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands.

Background: The metabolism of xenobiotics plays an important role in smoking related lung function loss and the development of Chronic Obstructive Pulmonary Disease (COPD). The *ATP-Binding Cassette, Subfamily C, Member 1* (*ABCC1* i.e. *Multidrug Resistance Protein 1*) is a membrane pump excreting a variety of xenobiotics from the cell. We previously showed a lower expression of *ABCC1* in bronchial epithelium of COPD patients than of healthy controls, and even further decrements in more severe COPD stages.

Methods: We tagged *ABCC1* using all 51 prevalent (minor allele frequency > 5%) and non-correlated ($r^2 < 0.8$) single nucleotide polymorphisms (SNPs). Effects of SNPs in relation to the level and longitudinal course of lung function were assessed in two independent, prospective, population-based studies, i.e. the Doetinchem (n=1,152) and Vlagtwedde-Vlaardingen (n=1,390) cohorts.

Results: Two SNPs (rs212093 and rs4148382) in the 3' untranslated region of *ABCC1* were significantly associated with a lower Forced Expiratory Volume in one second (FEV₁) in both cohorts. Four moderately correlated ($0.5 < r^2 < 0.8$) SNPs (rs4148330, rs4781699, rs8045000, and rs7190484) in the *ABCC1* promoter and intron 1 had a significant effect in both cohorts of the same, negative, magnitude, but on different lung function outcomes, i.e. FEV₁ or FEV₁/VC (Vital Capacity) ratio. One SNP in intron 14 (rs35621) was significantly associated with a highly excessive FEV₁ decline in both cohorts.

Conclusions: This is the first study showing a significant relation between *ABCC1* SNPs and lung function level and decline in two independent population-based cohorts. These SNPs are therefore putative candidates for studies to prevent COPD development and pharmacogenetics in established COPD.

P07.028

The relation of common diseases SNPs and life span: no evidence for shared genetic component

O. Y. Byichkova¹, O. A. Makeeva¹, I. V. Tsimbal'uk², K. V. Puzyrev³, V. N. Maksimov⁴, V. P. Puzyrev^{1,2};

¹Research Institute of Medical Genetics, Tomsk, Russian Federation, ²Siberian State Medical University, Tomsk, Russian Federation, ³Research Institute of Cardiology, Tomsk, Russian Federation, ⁴Research Institute of Therapy, Novosibirsk, Russian Federation.

Life span is a multifactorial trait with a strong genetic component. Besides the number of genes has been directly implicated into the processes of ageing and longevity, the genes responsible for common diseases such as cardiovascular (CVD) or immunity disorders are also had to be under intent consideration. The persistence and both elimination from human populations 'predisposing' common genetic variants is forced by a complex interplay of different evolutionary processes; some variants being unfavorable during particular periods of life can offer their owners advantages on the others. Latter should be taken into account e.g. while developing genetic test and interpreting frequently discrepant genetic data on disease association. Testing the hypothesis that CVD predisposing alleles can be related to the life span, we investigate several cohorts: healthy controls of childbearing age (aged from 20 to 45, n=282), nonagenarians (aged 90 and over, n=235) and patients with cardiovascular disease (arterial hypertension with different complications) (n=231) from the same geographic region and ethnicity (East Siberia, Russians) and genotyped for several well-known CVD candidate genes polymorphisms (*G-308A TNF*, *C894T NOS3*, and *A1166C AGTR1*). While all the three SNPs under study affected several important cardiovascular endophenotypes (arterial blood pressure measurements, cardiac parameters, left ventricular hypertrophy development est.) no significant differences had been revealed among nonagenarians and middle aged group. In this study we never found actual proof for the stated hypothesis, though a huge

amount of other genetic variants and the larger samples are needed to be tested before its decline.

P07.029

Natural Background Radiation Dictates Extensive Structural Polymorphism in the Human Y-Chromosome

S. Premi, J. Srivastava, S. Ali;

National Institute of Immunology, Delhi, India.

Ionizing radiations are known to affect the human genome but its impact on human Y chromosome still remains unaddressed. Here we analyze 300 males residing in an area containing the world's highest level of natural background radiation (NBR) and 390 controls from different parts of India. Random microdeletions were observed in 95% of the NBR exposed males with higher frequency in AZFc region but without gr/gr or b2/b4 phenotypes. Scrutiny of the male fertility associated genes showed copy number polymorphism (CNP) and tandem duplication in 84%, and exclusive deletion of *DBY* in 25% of the exposed males. Detailed analysis revealed multiple polymorphic copies of *SRY* and *CDY1* genes in addition to several known and novel mutations of the *SRY* gene. Amongst NBR exposed males with multiples copies of the *DAZ* genes, 75% showed varying FISH signals for *DAZ* genes with unilocus or bilocus duplications whereas 30% showed mosaicism in terms of presence/absence of the signals in 6-8% cells and unexpected number of signals in 9-12% interphase nuclei. Interestingly, all these alterations were exclusively somatic in nature substantiating normal fertility status of NBR exposed males. Though the actual mechanism is not known, we hypothesize that some putative innate protective mechanisms are operative in germline to counteract the effect of NBR. Analysis of additional Y linked loci may uncover the overall impact of NBR on the structural and functional attributes of this chromosome.

P07.030

Genome-wide screen for copy number variation in a Finnish schizophrenia case-control sample identifies a submicroscopic deletion in 22q

O. P. H. Pietiläinen¹, T. Paunio^{1,2}, A. Tuulio-Henriksson^{3,4}, J. Suvisaari³, J. Haukka³, T. Varilo¹, K. Rehnström¹, E. Jakkula¹, A. Loukola¹, J. Wedenoja¹, S. Ripatti¹, M. Jussila¹, J. Del-Favero^{5,6}, J. Lönnqvist^{6,3}, H. Stefansson⁷, L. Peltonen^{1,8};

¹FIMM, Institute for Molecular Medicine Finland and National Public Health Institute, Helsinki, Finland, ²University of Helsinki and Helsinki University Central Hospital, Department of Psychiatry, Helsinki, Finland, ³National Public Health Institute, Department of Mental Health and Alcohol Research, Helsinki, Finland, ⁴University of Helsinki, Department of Psychology, Helsinki, Finland, ⁵Applied Molecular Genomics Group, Department of Molecular Genetics, VIB, Belgium, Helsinki, Finland, ⁶University of Antwerp (UA), Antwerpen, Belgium, ⁷deCODE genetics, Reykjavik, Iceland, ⁸Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom.

Copy number variations (CNV) are likely to comprise considerable source for diversity in human genome and in determining heritable susceptibility to diseases with complex etiology. We utilized Genome-wide SNP-array data from Illumina 318K genotyping platform on a Finnish sample of 200 familial schizophrenia cases and 200 controls with well established genealogy to search for CNVs potentially predisposing to schizophrenia. Half (47%) of the sample originated from an Internal Isolate of Finland with an exceptionally high prevalence of schizophrenia (3% versus 1.2% for the general population). The sample was a part of a large international EU-funded consortium, SGENE, combining 1,454 schizophrenia patients and 1,600 controls of European origin. In the Finnish sample we identified a novel 240-280 kb heterozygous deletion in chromosome 22q11.22 in 13 patients and three controls all originating from the Isolate. We extended our investigations to 17,808 additional European population controls (2,525 from Finland) and 1,254 cases of European origin including the rest of the SGENE project. Among these individuals we found 29 carrying the deletion, 22 of which originated from the Isolate. In a Finnish schizophrenia family sample we found 27/354 affected family members and 51/736 unaffected family members carrying the deletion. One mentally retarded individual was homozygous for the deletion. The deletion overlaps with three genes, *PPM1F*, *TOP3B* and *IGLV2-14*, not previously linked to schizophrenia. Our finding confirms the impact of population bottleneck on the enrichment of large CNV and implies the impact of this 22q

region in the etiopathogenesis of familial schizophrenia.

P07.031

Analysis of normal human variation to identify mechanisms of the monogenic disease, cystinosis

J. E. Curran, M. P. Johnson, M. A. Carless, H. H. H. Goring, J. Charlesworth, K. Freed, T. D. Dyer, S. A. Cole, E. K. Moses, J. Blangero; Southwest Foundation for Biomedical Research, San Antonio, TX, United States.

Mutations in *CTNS* on 17p13 cause cystinosis, a rare autosomal recessive disease characterized by defective transport of cystine out of lysosomes. Using complex genomic approaches we studied the biology of *CTNS* in large unaffected families assuming normal human variation in *CTNS* expression could inform us about this gene's function. Using lymphocyte samples from 1240 individuals, we significantly detected over 20,000 transcripts, including *CTNS*. To identify regulatory variants, we resequenced *CTNS* in 191 founders, identifying over 180 SNPs for genotyping. Analysis of these variants with *CTNS* expression revealed strong evidence for *cis*-regulation (p-values as low as 2.4×10^{-39}). We performed association analysis on the transcriptional profiles to identify genes causally downstream of *CTNS*. Preliminary analyses revealed multiple genes related to the mediation of polyglutamine tracts and the unfolded protein response. To identify *trans*-acting upstream genes influencing *CTNS* expression, we performed both genome-wide linkage and association scans. Genome-wide linkage results identified a region at 9q21 (p = 0.0025). Examination of the genetic correlations of expression levels of genes within this region with *CTNS* expression identified a novel candidate gene, *VPS13A* (vacuolar protein sorting 13A). *VPS13A* and *CTNS* expression levels were inversely genetically correlated (p = 9×10^{-6}), indicating *VPS13A* as a potential inhibitor of *CTNS* expression. Sequence variation in *VPS13A* also influenced *CTNS* expression (p = 0.009). Genome-wide association results identified five additional *trans*-acting regions containing several reasonable positional candidates. These results show the biological value of integrative genomic and transcriptomic approaches for the identification of disease gene function using normal human variation.

CYP2D6 genetic polymorphism in Mexican Nahuas

M. López¹, J. Guerrero², R. Peñaloza³, L. Buentello⁴, F. Salamanca³, M. Alonso⁵;

¹Metropolitan Autonomous University, Mexico City, Mexico, ²National Institute of Neurology and Neurosurgery Manuel Velasco Suárez, Mexico City, Mexico, ³Centro Médico Nacional Siglo XXI, Mexico City, Mexico, ⁴Instituto de Investigaciones Antropológicas, UNAM, Mexico City, Mexico, ⁵National Institute of Neurology and Neurosurgery, Mexico City, Mexico.

CYP2D6 catalyzes the metabolism of 25-33% clinically important drugs and is highly polymorphic. There are at least 50 different alleles of *CYP2D6*, which are correlated to ultrarapid, extensive and poor metabolizer phenotypes. Interethnic differences in allele frequencies of *CYP2D6* have been documented for Europeans, Asians, Africans and Hispanics; however data on Amerindians are scanty and limited to a few populations. Nahuas are individuals that speak Nahuatl and comprise the largest Mexican indigenous population. Nowadays, Nahuas can be found at Mexico D.F. Southern area (central group) and in other states (peripheral group). In this study 315 donors representing 7 different Nahua populations were genotyped for *CYP2D6**3, *CYP2D6**4, and *CYP2D6**10 by PCR-RFLP. Additionally, *CYP2D6**17 was determined in the Coyolillo group as previous data revealed a predominant influence from African origin (Buentello-Malo, 2003). The frequency of *CYP2D6**3, 4, and 10 among 315 Nahuas was 1.6%, 12.2% y 1.9%, respectively; while *CYP2D6**17 frequency was 32% in 36 Coyolillo Nahuas. Allelic frequencies for each group are presented in the table and compared to data from Mexican Mestizos (López, 2005). Our findings show that Nahua groups are heterogeneous and different from Mexican Mestizos. This study will extent the knowledge of the genetic structure of Mexican Nahuas; in particular it could have important implications for the use of drugs that are substrates of *CYP2D6* and have a narrow therapeutic index.

CYP2D6 allele frequencies

Group	N	CYP2D6*3	CYP2D6*4	CYP2D6*10

P07.033**Frequency of CFTR mutations in infertile Italian individuals**

A. Verri, G. Miano, K. Roda, V. Prina, V. Grazioli;

Centro Diagnostico Italiano, Milano, Italy.

In our institute, one of the main Italian private healthcare institutions focused on out-patient and day hospital services, we perform the analysis of 57 mutations and of poly-T polymorphism in intron 8 of the Cystic Fibrosis gene (CFTR) on patients of Medically Assisted Procreation (MAP) Centers.

At the present, more than 1400 different mutations have been registered in the CF Mutation Database (<http://www.genet.sickkids.on.ca/cftr>); few of them show frequencies higher than 1% whereas most of them are "private mutations". Analysis of the Italian population show patterns of genetic differentiation: the "capture rate" of the test in use is quite different for various Italian regions, ranging from 74.7% for Lombardia to a maximum of 88.3% and 88.1% for Basilicata e Sardegna respectively (data inferred by the frequency of CFTR mutations in different Italian regions (1)). We present results about the analysis on 2320 individuals comparing them with those obtained by the authors in other MAP Centers (2): as expected, the frequencies of the analysed CFTR mutations show significant differences.

We do believe that data obtained in infertile individuals could be very useful for evaluation of carriers frequency in general population.

38° Congresso Nazionale della Società Italiana di Biochimica Clinica e Biologia Molecolare Clinica, Torino, 19 - 22 settembre 2006

P07.034**The analysis of polymorphism CYP1A1 and CYP1A2 genes at the population of Russia (Republic Bashkortostan)**

O. Kochetova, L. Karimova, T. Victorova;

Institute of Biochemistry and Genetics, Ufa, Russian Federation.

In three ethnic groups of Republic Bashkortostan: Russian (N=451), Tatars (N=333) and Bashkirs (N=171) was studied distribution of alleles, genotypes and haplotypes polymorphic loci CYP1A1 (A2455G, Ö3801Ñ) and CYP1A2 (-2464T/delT, -163Ñ/Ä). It was shown the similarity of groups Tatars and Russian on haplotypes frequencies CYP1A1 gene ($\chi^2=0.97$, df=3, $\delta=1.00$) è CYP1A2 gene ($\chi^2=1.55$, df=3, $\delta=0.92$). We found significant differences in haplotypes frequencies CYP1A1 gene between the ethnic group Bashkirs and groups Tatars and Russian ($\chi^2=12.33$ df=3, $\delta=0.008$; $\chi^2=9.22$ df=3, $\delta=0.034$, accordingly), that is connected with high frequency of CYP1A1*2B (10.17%) among the Bashkirs.

The MspI locus (T3801C) is in linkage disequilibrium with the A2455G polymorphism in the Bashkir population, the Tatars and Russian (1.61%) populations. The frequency of the CYP1A2*1D haplotypes was highest in the Bashkir population (11.02%) compared to frequencies that were found in the Tatars (2.36%) and Russian (1.61%) populations. Similar distinctions of on haplotypes frequencies CYP1A1 gene an ethnic group the Bashkir with Russian and Tatars ($\chi^2=18.78$, df=3, $\delta=0.0001$ and $\chi^2=14.33$, df=3, $\delta=0.003$, accordingly). The CYP1A1*2A haplotype was meet with High frequency in all ethnic groups. The frequency of CYP1A1*2A haplotype considerably increased in The Bashkir ethnic group (15.79%) that is comparable to frequency of this haplotype in Asian populations (14.9%). The increasing of the CYP1A1*2A haplotype frequency in the Russian ethnic group up to 9.0% in comparison with 5.8% in samples of Europeans also reflects presence Asian components in origin of Russian ethnic group living in

Republic Bashkortostan.

P07.035**A study of the Insertion-Deletion polymorphism of the gene CYP2E1**

E. M. Vasilieva;

Bashkir State Pedagogical University it. M.Akmulla, Ufa, Russian Federation.

INTRODUCTION: We studies gene, encoding ferments of the first phase biotransformation xenobiotics, cytochrome P-450 2E1 (CYP2E1). CYP2E1 coding the ferment N,N-dimethilnitrozoamin-n- dimethylazy is located on the chromosome 10 (q24.3) consist of 9 exons and 8 introns.. In given gene exists polymorphism, given by insertion 96 p.b. in promoter region (the allele: *D - 633 p.b., *I - 729 p.b.). The ferment, coded gene, have charge of removing ethanol and acetone expression level is significantly lower in other organs and tissues, in particular, kidneys, pancreas, brain, lung, nasal and intestinal mucosa.

Materials and methods: We studied 3 groups: individuals living in region with disadvantage ecological condition, group persons concerning with sport, and the general sample. The individuals age made up from 14 up to the ages of 30. The analysis genetic polymorphism is realized by polymerase chain reaction (PCR).

RESULTS: In group of the inhabitants region with disadvantage ecological condition frequency genotype *D/*D vastly increased (96.2%), but in group athlete tends to reduction (58.5%) in contrast with the total sample (69.2%). The frequency genotype *I/*D is lowered in group of the inhabitants region with disadvantage ecological condition (3.8%) and increased beside athlete (41.5%) in contrast with the total sample (30.4%). In sharing the frequencies alleles in group of the inhabitants region significant increasing of the frequency allele exists with disadvantage ecological background *D (98.1%) and reduction allele *I (1.9%) in contrast with the total sample (84.4% and 15.6% accordingly).

P07.036**The effect of the DAOA (G72/G30) gene and developmental risk factors on depression and related temperament traits in Finnish birth cohort**E. S. Nyman¹, P. Soronen¹, J. Miettunen^{2,3}, A. Loukola^{1,4}, M. Joukamaa^{5,6}, P. Mäkr², M. Järvelin^{7,8}, N. Freimer⁹, L. Peltonen^{1,10}, J. Veijola^{2,3}, T. Paunio^{1,11};

¹FIMM, Institute for Molecular Medicine Finland and National Public Health Institute, Helsinki, Finland, ²Department of Psychiatry, University of Oulu and Oulu University Hospital, Oulu, Finland, ³Academy of Finland, Helsinki, Finland, ⁴Finnish Genome Center, University of Helsinki, Helsinki, Finland, ⁵Tampere School of Public health, University of Tampere, Tampere, Finland, ⁶Department of Psychiatry, Tampere University Hospital, Tampere, Finland, ⁷Department of Epidemiology and Public Health, Imperial College, London, United Kingdom, ⁸Institute of Health Sciences, University of Oulu, Oulu, Finland, ⁹Semel Institute for Neuroscience and Human Behavior, University of California, Los Angeles, CA, United States, ¹⁰Wellcome Trust Sanger Institute, Cambridge, United Kingdom, ¹¹Department of Psychiatry, Helsinki University Central Hospital, Helsinki, Finland.

D-Amino acid oxidase activator (DAOA or G72/G30) encodes for a protein with a possible role in glutamate signaling, and it has been implied in the development of schizophrenia and bipolar disorder. It has been suggested to increase susceptibility to episodes of mood disturbances across diagnostic boundaries. We investigated the role of DAOA in depression in a population-based Northern Finland Birth Cohort 1966 (n=12058). We ascertained a sample based on developmental risk factors (high risk n=285, low risk n=926) with a clinically postulated connection to depression susceptibility, including difficulties during the perinatal or early childhood periods or related to the psychosocial environment, to dissect genetic effects increasing liability to depression from environmental effects. Depressive symptoms were quantified according to the Symptom Checklist (SCL) and dichotomous depression was classified as self-reported depressive disorder diagnosed by a clinician. We also wanted to examine Cloninger's Temperament and Character Inventory (TCI) temperament traits because of previous affirmative reports, especially on Harm avoidance to depressive disorder. We genotyped evenly spaced haplotype tagging SNPs at the DAOA locus, and performed linear regression and case/control association testing against the selected traits. In preliminary analyses we detected an association of DAOA with depression in low risk females and with depressive symptoms in low risk males. We

also found suggestive association of DAOA with the Harm Avoidance subcomponent 2 (HA2), Fear of Uncertainty, in high risk males and females. Our findings support the role of DAOA in depression and in a related temperament trait, HA2.

P07.037

DFNB1 mutations outside the GJB2 coding region in UK hearing loss referrals: testing and prevalence

C. Bosomworth¹, L. A. Mavrogiannis¹, J. Prothero², D. J. Cockburn¹, J. S. Rowland¹, A. F. Brady², H. M. Kingston³, C. P. Bennett¹, R. S. Charlton¹;

¹Regional Genetics Service, Leeds, United Kingdom, ²Regional Genetics Service, Kennedy-Galton Centre, London, United Kingdom, ³Regional Genetics Service, Manchester, United Kingdom.

GJB2, a component of the recessive *DFNB1* locus at 13q, encodes connexin 26 and is the major gene in non-syndromic sensorineural deafness. Pathogenic *DFNB1* mutations that map outside of the *GJB2* coding region exist, but routine clinical testing often focuses on the single coding exon of *GJB2*. This bias presents as a high proportion of unresolved subjects with single *GJB2* coding region variants relative to the background carrier frequency. Untested or uncharacterised *DFNB1* alterations are likely to account for the excess. We investigated the significance of two well-documented *DFNB1* changes, the large deletion g.(GJB6_D13S1830)del and the splice site mutation c.-23+1G>A (also known as IVS1+1G>A or 1-3170G>A) of the non-coding exon of *GJB2*, in a large mixed stream of hearing loss referrals from the UK. Our set comprised 1425 apparently unrelated index subjects with a 80:20 ratio of Caucasians to non-Caucasians (predominantly British Asians). We developed and validated fluorescent assays for medium-throughput typing and analysed, prospectively and retrospectively, the vast majority of appropriate cases. In our Caucasian subgroup, the contribution of g.(GJB6_D13S1830)del to the detectable *DFNB1* mutation spectrum is 5.5% (95% CI: 2.9% - 9.4%) while the relative frequency of c.-23+1G>A is 1.4% (95% CI: 0.3% - 4.0%). g.(GJB6_D13S1830)del is absent in our non-Caucasian subgroup, but c.-23+1G>A is detected in around 10% of all pathological genotypes, including homozygous occurrence in consanguineous pedigrees. Concentrating on the c.-23+1G>A mutation we discuss genotype-phenotype correlations, impact on *GJB2* expression, and evolutionary origins.

P07.038

The investigation of dermatoglyphic samples in patients with Parkinson

A. Ozbinar¹, H. Samli², S. Cetin³, T. Fistik¹, A. Ozgoz², M. Solak¹, T. Aydemir³, F. Ozer³;

¹Afyon Kocatepe University, School of Medicine, Department of Medical Biology, Afyonkarahisar, Turkey, ²Afyon Kocatepe University, School of Medicine, Department of Medical Genetics, Afyonkarahisar, Turkey, ³Haseki Education and Research Hospital, Clinic of Neurology, Istanbul, Turkey.

The irregularities in the number and the shape of chromosomes destroy dermatoglyphic samples expressed by minor-effective genes and helping diagnosis of the hereditary diseases.

The most valid idea for the reason of Parkinson is that, both genetic and environmental factors associate in the formation of the disease.

The aim of this study is searching the relation between Parkinson and dermatoglyphics. Due to this, dermatoglyphic samples of 55 cases with Parkinson were evaluated by comparing the samples of the control group including 48 healthy people.

Investigating samples from the patient and the control group by "Rontgen Film method, an increase in the number of the knots and a decrease in the number of the loops at the I. finger of the right hand; a decrease in the number of triradiuses at the left hand interdigital regions I and III and the right hand interdigital region I; decrease in the number of triradiuses located on the right and the left hand tenar region and on the right hand hipotenar region; a decrease in the number of right hand a-b lines were detected. In our study, significant differences were found in the finger tip and palm samples of the Parkinson patients ($p < 0.05$). Even though data were related to a limited number of cases, they were found to be interesting due to giving a clue to the genetic predisposition of Parkinson. Being easy to perform, fast and cheap, not causing trauma, dermatoglyphic analyse methods suggest taking place in the scanning tests of Parkinson patients.

P07.039

The Accumulated Number of Risk Variants (=Risk Value) Rather Than Anyone of Them Determines Risk of Diabetes Mellitus Type II

A. A. AlAshtar¹, J. Vassallo^{2,3}, J. Azzopard³, J. Borg¹, M. Debono^{2,3}, C. Scerri¹, A. E. Felice¹;

¹Laboratory of Molecular Genetics, Faculty of Medicine, University of Malta, and Section of Molecular Genetics, Mater Dei Hospital, Msida, Malta, ²Diabetes and Endocrine Centre, Mater Dei Hospital, Msida, Malta, ³Department of Medicine, University of Malta, Medical School, Msida, Malta.

We determined the distribution of selected SNPs along inflammatory and metabolic pathways among Diabetic (DM2) patients from two different Mediterranean populations, one Southern European (Malta; N = 200) and one North African (Libya; N = 200). The reference populations were pools of DNA from consecutive newborn from the Malta BioBank (N = 200) and from Tripoli (N = 200) respectively. Significant differences between patients and reference groups in both populations have been found in ADRAB β 2 (51.1% vs 23.4%) FABP2 (32% vs 8.6%) UCP1 (26.4% vs 14.1%) and LEPTIN (35.8% vs 27.3%). Odds ratios were determined with respect to the inheritance of Sniplotypes, being defined as the non-random association of the 5 more significant non-syntenic genetic markers. The frequency of the wild sniplotype "1.1.1.1.1." (where 1 = wild type homozygote, 2 = heterozygote and 3 = mutant homozygote) and Leptin heterozygotes (1.1.1.2.1) were 1:10 compared to the reference populations. Additional statistical comparisons were confounded by the small number of cases falling in many categories. However, the distribution of relative risk / sniplotype suggested that the sniplotypes with increased 2s or 3s carried increased risk. In fact, it could be shown that relative risk increased exponentially with the number of inherited variant alleles ($R^2 = 0.97$; N = 800). Thus, it can be concluded that the probability or genetic risk of developing type II Diabetes is determined by the number of variant alleles rather than the pathophysiological impact of any one of them.

P07.040

Biological effect monitoring in cigarette smokers from the Kudankulam nuclear power project site area exposed to radiation, India

V. Balachandar¹, J. Malath², G. Brahmanandham³, B. LakshmanKumar¹, D. Khanna³, K. Sasikala¹, S. Selvasekarapandian³;

¹Human Genetics Laboratory, School of Life Sciences, Bharathiar University, Coimbatore, India, ²Universita degli studi di Padova, Department of Chemical Science, Padova, Italy, ³Solid state and Radiation Physics Laboratory, School of Physics, Bharathiar University, Coimbatore, India.

The chromosomal aberrations (CA) assay is important for monitoring the populations exposed to genotoxic agents because it allows the evaluation of the entire genome to identify mutagenic and carcinogenic chemicals. The focal aim of the present investigation was to identify the chromosomal alterations in cigarette smokers from Kudankulam nuclear power project site (KNPPS) areas located near to Kanyakumari. The levels of primordial radionuclides in Kanyakumari, a High Background Radiation Area (HBRA) exceeds 4.7 times than the normal (1 mSv).

In the present investigation, 72 smokers were selected in KNPPS area and equal numbers of smokers were selected in the normal level radiation area and it was used as a controls. After signing a consent form, volunteers provided blood samples (5 ml) to establish cell cultures at 52 h. For karyotyping, minimum 40 complete metaphase cells from each subject were evaluated.

Chromosomal and chromatid-types aberrations were observed in experimental subjects and controls. Some Dicentric chromosomes(DC) were particularly observed in experimental subjects. DC which are easy to identify also with classic Giemsa staining, represent an attractive biomarker, especially for assessment of radiation exposure. Statistical significant results were observed between experimental and control groups confirmed by Mann-Whitney U.

Information on the induction of radiation effects can be considered in the context of cancer risk by exposure to the radiation, this study gives potentially important information on the general health effects due to radiation exposure and the effect of cigarette smokers; it also helps people to understand the hazardous nature of chronic radiation exposure.

P07.041

Comparative study about digit ratio in two human populations of Bihor county

I. Tomulescu¹, E. Laslo¹, H. Vaida²;¹Faculty of Sciences, Oradea, Romania, ²Faculty of Socio-Human Sciences, Oradea, Romania.

In 1892 Sir Francis Galton published his classic treatises on fingerprints. Specifically, it is the ratio of the length of the index finger (digit 2, or "2D") and the ring finger (digit 4, or "4D") that is sexually dimorphic. We investigated 200 individuals. We measured the length of the 2nd, 3rd and 4th fingers of 100 from each locality (Oradea and Vascau). The Oradea locality has over two thousands of inhabitants, which means the variability of some phenotypical features must be a large one. The Vascau locality has not so many inhabitants, fifty thousand approximative. The individuals of Vascau were at random choosed and from Oradea are students. We measured the length of the fingers, from the finger basis to the superior bound of the phalanx. Then we calculated the digit ratio: 2D:4D, 2D:3D and 3D:4D. Also, we calculated z score and F distribution.

We compared the 2D:4D digit ratio of the studied localities ($F = 7.39$, $z \text{ score} = 2.95$). So, we may say the values proceed from two very different groups. So, the two studied groups are very different, the 2D:3D digit ratio of the two localities ($F=1.217$, $z \text{ score}=1.24$) and the 3D:4D digit ratio of the two studied localities ($F=2.06$, $z \text{ score}=1.73$).

We may conclude the two studied groups are very different. The variation coefficient demonstrated a very small variation of the values of 2D:4D, 2D:3D and 3D:4D values digit ratio in the each of the two studied populations.

Variants in DISC1 are associated with psychosis related traits in a large birth cohort

L. Tomppo¹, W. Hennah^{1,2}, J. Miettunen³, M. Järvelin^{4,5}, J. Veijola³, D. Lichtenmann^{1,6}, L. Peltonen^{1,7}, J. Ekellund^{1,8};

¹Institute of Molecular Medicine, National Public Health Institute, Helsinki, Finland, ²Medical Genetics Section, University of Edinburgh, Edinburgh, United Kingdom, ³Department of Psychiatry, University of Oulu, Oulu, Finland, ⁴Department of Public Health Science and General Practice, University of Oulu, Oulu, Finland, ⁵Division of Epidemiology, Public Health and Primary Care, Imperial College, London, United Kingdom, ⁶Café Ersatz, Bonn, Germany, ⁷Wellcome Trust Sanger Institute, Cambridge, United Kingdom, ⁸Department of Psychiatry, University of Helsinki, Helsinki, Finland.

DISC1 is among the most studied susceptibility genes to schizophrenia and other major mental illnesses. Based on the genetic studies performed it seems that the risk conferred by the variants of DISC1 is small even in the highly selected populations. We wanted to study the effect of previously identified risk variants of DISC1 on quantitative endophenotypes for psychosis in an unselected population sample. We utilized the large birth cohort collected in Northern Finland (NFBC66). This study included 4444 individuals born in the area during the year 1966. We genotyped 41 SNPs covering DISC1, both upstream and downstream of the gene. Principally, we tested an a priori hypothesis of the interplay between three SNPs, rs1538979, rs821577 and rs821633 that had previously been reported to affect risk to schizophrenia and bipolar disorder. The test variables were four psychometric instruments selected to function as proxies for both positive and negative aspects of schizophrenia. These were Revised Social Anhedonia Scale (SAS), Revised Physical Anhedonia Scale (PAS), Perceptual Aberration Scale and Golden and Meehl Schizoidia scale. The results strongly support an effect of SNP rs821577 on SAS ($P = 0.000021$) and PAS ($P = 0.021$). Most importantly, certain combinations of the genotypes of the three SNPs that modify the risk of schizophrenia dependent on the local genetic background in a previous study also correspondingly modify the measures of SAS (best $P = 0.0000022$) and PAS (best $P = 0.0075$) in the birth cohort studied here.

P07.043

Population study at STR loci Penta D and Penta E in Croatian population

V. Skaro¹, P. Projic¹, N. Pojskic², D. Primorac^{3,4}, D. Marjanovic^{1,2};

¹Laboratory for Forensic Genetics and Ancient DNA Analysis, Institute for Anthropological Research, Zagreb, Croatia, ²Institute for Genetic Engineering and

Biotechnology, Sarajevo, Bosnia and Herzegovina, ³Medical School, University of Split, Split, Croatia, ⁴Medical School, "Josip Juraj Strossmayer" University of Osijek, Osijek, Croatia.

In addition to our previous population studies of Croatian human population at 15 STR loci included in the AmpFISTR® Identifier® system we have also analyzed the allele frequency distribution at two additional STR loci Penta D and Penta E in the representative sample of Croatian population since these highly polymorphic pentanucleotide loci included in the PowerPlex® 16 enhance the discrimination power of that system, which is important in resolving paternity disputes, and are also ideal loci for evaluation of DNA mixtures often encountered in forensic casework. A total of 200 unrelated Caucasian individuals born in Croatia have been sampled for the analysis. Buccal swabs have been used as the DNA source. The QuiAmp DNA blood mini kit was used for DNA extraction. The PowerPlex® 16 System has been used to simultaneously amplify 15 STR loci: Penta E, D18S51, D21S11, TH01, D3S1358, FGA, TPOX, D8S1179, vWA, Penta D, CSF1PO, D16S539, D7S820, D13S317, D5S818 and Amelogenin. STR loci were amplified in ABI GeneAmp® PCR Thermal Cycler according to the manufacturer's recommendations. Electrophoresis of the amplified products was performed on an ABI 3130 genetic analyzer. Raw data have been compiled, analyzed and numerical allele designations of the profiles were obtained by using the accessory software: ABI 3130 Genetic Analyzer Data Collection v3.0 and GeneMapper™ ID Software v3.1. Deviation from Hardy-Weinberg equilibrium, observed and expected heterozygosity, power of discrimination and power of exclusion were calculated. We have also compared our data with data obtained from geographically neighboring European populations.

P07.044

Linkage disequilibrium and distribution of the variable number of tandem repeats (VNTR) polymorphism and 1342 A/G polymorphism in exon 9 of the dopamine transporter gene (DAT1) in populations of Northern Eurasia

A. V. Marusin¹, A. S. Gureev², S. A. Borinskaya³, N. K. Yankovsky³, V. A. Stepanov³;

¹Institute for Medical Genetics, Siberian Branch of the Russian Academy of Medical Sciences, Tomsk, Russian Federation, ²Tomsk State University, Institute of Biology, Ecology, Soil science, Agriculture and Forestry, Tomsk, Russian Federation, ³N.I. Vavilov Institute of General Genetics, Russian Academy of Sciences, Moscow, Russian Federation.

The DAT terminates dopaminergic neurotransmission and thus plays the important role in dopamine metabolism. Gene encoding the DAT (DAT1, SLC6A3) localized in the end of p-shoulder 5 chromosome. We've investigated two polymorphisms of this gene (VNTR in 3'-untranslated region and 1342 A/G polymorphism in exon 9) in seven populations: Buryat ($n=105$), Dungan ($n=44$), Persian ($n=36$), Kyrgyz ($n=188$), Tadjik ($n=39$), Ukrainian ($n=94$) and Uzbek ($n=50$). The observed genotype frequencies correspond to expected in Hardy-Weinberg equilibrium for both loci of all populations, excluding Tadjik population in exon 9-polymorphism. The alleles spectrum in VNTR polymorphism counted 6 alleles (from six tandem repeats to twelve), with 10 tandem repeats allele as prevalent in all groups (average frequency=0.834, variation from 0.707 in Ukrainians to 0.932 in Dungans). The prevalent allele in exon 9 was A allele (average frequency=0.817).

The largest expected heterozygosity in both loci was founded in Ukrainian and Persian populations (~0.4). The high interethnic differences were found by maximum-likelihood chi-square statistics: most populations significantly differ from each other for both loci. The total level of genetic differences measured by F_{st} statistics was 3.2% (4.54 for VNTR and 1.86% for 1342 A/G polymorphism).

The normalized linkage disequilibrium coefficient was fairly strong ($D' > 0.6$) for all population, exclude Ukrainian ($D' = 0.3725$), Persian ($D' = 0.3759$) and Tadjik ($D' = 0.4212$). This data may be explained by different level of isolation during the ethnic history of Caucasoid (Persian, Tadjik, Ukrainian) and Mongoloid (Kyrgyz, Uzbek, Buryat, Dungan) populations. This work was supported by the Russian Foundation for Basic Research (project no. 06-04-48274-à, 07-04-01629-à).

P07.045

Investigation of an effect of economic crisis on the prevalence of Down syndrome in St. Petersburg, RussiaN. V. Kovaleva¹, D. K. Verlinskaya², J. K. Morris³;¹St. Petersburg Medical Academy for Postgraduate Studies, St. Petersburg, Russian Federation, ²St. Petersburg Centre for Medical Genetics, St. Petersburg, Russian Federation, ³National Down Syndrome Cytogenetic Register, England and Wales, London, United Kingdom.

OBJECTIVE: To investigate changes in the prevalence of Down syndrome (DS) births during a global social transition. **DESIGN:** Data from St. Petersburg Down Syndrome Register were analyzed with a special attention to the period of high social expectations (1983-87) when the number of births had been increasing (69,406→73,275) and the period of a social frustration (1995-99) when the number of births had declined most dramatically (33,841→29,438). **STUDY POPULATION:** During 1980-1999, 1358 liveborn children with DS were identified among 1 046,932 births; a rate of 1.3/1000 births. Prenatal diagnosis had low impact on the birth prevalence. **METHOD:** The data obtained were compared with the expected rates and numbers based on the data from NDSCR, 1989-2002. **RESULTS:** Maternal age distribution in the general population had changed during the study period: proportion of mothers aged ≥ 35 yr increased from 6.8% in 1983-87 to 8.4% in 1995-99, however this has not resulted in corresponding increase in DS rate. In contrary, DS rate in 1995-99 was the lowest over the study period, being 1.18/1000. However, by the model applied, this figure does not differ significantly from the expected. The DS infant mortality rate had fallen from 39% in 1983-87 to 17% in 1995-99. **DISCUSSION:** There is no evidence for an effect of economic crisis accompanied with psychological stresses and with nutritional deficiency on chromosome segregation or on surviving of affected children. A suggestion that low DS rate might be explained by better welfare standards of reproducing fraction of the population is under the study.

P07.046

Skeletal Muscle Gene ACTN3 and Physical Performance:O. Kasımay¹, D. Sevinc², S. O. Iseri¹, K. Ulucan³, M. Unal¹, A. I. Guney⁴, H. Kurtel¹;¹Marmara University, School of Medicine, Sport Physiology Department, Istanbul, Turkey, ²Maltepe University, School of Medicine, Medical Biology and Genetics Department, Istanbul, Turkey, ³Marmara University, School of Dentistry, Medical Biology and Genetics Department, Istanbul, Turkey, ⁴Marmara University, School of Medicine, Medical Genetics Department, Istanbul, Turkey.

ACTN3 gene is responsible from the production of alpha-actinin-3 protein, which has force-generating capacity of muscle fibers, and which is restricted to fast fibers. Homozygosity for 577X in ACTN3 (R577XX) results in no production of α -actinin-3 protein. Recent studies show that elite sprint athletes had a higher frequency of the RR genotype. **Aim:** The purpose of the study was to investigate ACTN3 gene variations and their probable phenotypic reflection by using physiological methods, and to show ACTN3 polymorphism in Turkish soccer players (n=31). **Methods:** After determining the genotypes by analyzing the blood samples, three groups (XX,RR,RX) were formed. The groups were existing R577X variant in both ACTN3 genes (XX,n=4), not existing R577X variant in both ACTN3 genes (RR,n=22), or existing R577X variant only one of the two ACTN3 genes (RX,n=5), respectively. To determine aerobic performance, Bruce protocol was applied on treadmill and maximal oxygen consumption (VO₂max) was measured by metabolic analyzer. On a separate day, anaerobic performance was evaluated by Wingate test. Student's *t*-test or analysis of variance (ANOVA) was used for comparisons. **Results:** Thirteen % of the soccer players had homozygosity for R577XX codon. The VO₂max levels in XX group tended to be higher from RR ($p=0.09$) and RX groups ($p=0.05$). VO₂/HR (pulse oxygen) and VEmax (maximum ventilation) levels were not different between groups. Peak power values tended to be higher in RR group from the other groups. Our results evaluated the effect of genotypic variations on sprint and endurance performance of athletes contributing the understanding of genotype-phenotype correlation.

Polymorphisms of IL4 and IL4RA genes are associated with endometriosis

M. Kozlovskaya, G. Demin, M. Yarmolinskaya, S. Selkov, T. Ivashchenko, V. Baranov;

Ott's Institute of Obstetrics and Gynaecology RAMS, St.-Petersburg, Russian Federation.

Endometriosis is defined as a condition which displays features similar to malignancy, proliferation and growth. Typical endometrioid cells are characterized by increased cytokine activity. Cytokine genes are polymorphic that results in synthesis of proteins with various functional activities. The goal of the study focuses on the role of allelic variants of IL4 and IL4RA genes in pathogenesis of endometriosis.

DNA samples from the patients with endometriosis (n=82) and healthy women without gynecologic complications (n=69) were included in the study. Group of patients was divided into two subgroups according to severity of disease. Polymorphisms of IL4 (-590T>C) and IL4RA (1902A>G) were defined by PCR-RFLP assay.

The alleles and genotypes frequencies of IL4 gene did not differ between studied groups ($p>0.05$). The frequency of G/G genotype for IL4RA gene was significantly higher in endometriosis patients (19.5%) as compared to the control group (1.4%, $p<0.01$). Also the frequency of allele G was significantly higher in patients (27.6% and 17.4%, $p<0.01$ respectively). The relative risk for endometriosis when having G/G genotype of IL4RA gene was estimated by an odds ratio of 16.51 (95% CI: 3.57-76.41). Also it has been shown that the frequency of C/C or C/T genotype of IL4 gene in the subgroup with severe endometriosis is significantly higher than in control group ($p<0.05$). The presence of allele C may be responsible for increased risk of endometriosis (OR=3.05; CI: 1.05-8.83).

Our data suggests that polymorphisms of IL4 (-590T>C) and IL4RA (1902A>G) may be treated as prognostic genetic markers of endometriosis.

P07.048

Polymorphism C677T of the methylenetetrahydrofolate reductase gene and endothelial function in patients with essential hypertension of the Kazakh nationalityG. Junusbekova¹, M. Tundybayeva¹, G. Svyatova²;¹Scientific-research institute of cardiology and internal diseases, Almaty, Kazakhstan, ²Scientific centre of obstetrics, gynecology and perinatology, Almaty, Kazakhstan.

The purpose: to study association of polymorphic marker C677T of the methylenetetrahydrofolate reductase gene (MTHFR) with parameters of function of the endothelium in patients with essential hypertension (EH) of the Kazakh nationality.

Material and methods: A total of 118 patients (both males and females) of the Kazakh nationality were examined with EH of the IInd and IIIrd degrees average and high risk. We investigated endothelium - dependent vasodilation breakdown with reactive hyperemia by the method of D.Celermajer. The level of homocysteine (HC), endothelin-1, soluble intercellular adhesion molecule-1 (sICAM-1), soluble vascular cell adhesion molecule-1 (sVCAM-1) and production of sE-selectin in blood was determined by immunohistochemical test with use of commercial kits. MTHFR 677C→T genotyping was detected by polymerase chain reaction.

Results: Distribution of genotypes of polymorphic marker C677T of the MTHFR gene in patients with EH appeared the following: C/C -45,8 %, C/T- 39,8 % and T/T-14,4 %. The frequency of the allele C was 65,7 %, and of the T allele it was 34,3 %. When comparing patients with genotype C/T and T/T (n=64) with those patients, having genotype C/C, we observed a smaller value of a gain of diameter of a brachial artery on a background reactive hyperemia (6,56±1,08 and 9,86±1,32 % accordingly, $p=0,05$). Besides in patients of the second group a higher level of sVCAM-1 (504,5±23,11 and 596±31,71 ng/ml accordingly, $p=0,026$) was observed.

Conclusions: In patients with EH in the Kazakh population the C677T polymorphism of the MTHFR gene can be associated with development of endothelial dysfunction.

P07.049

Identification of point mutation pattern in the LDLR gene among Bulgarians with severe hypercholesterolemia

S. Bichev^{1,2}, L. Vladimirova-Kitova³, J. Genova², R. Kaneva², I. Kremenski⁴, V. Ganev⁵;

¹Medical University of Sofia, Sofia, Bulgaria, ²Molecular Medicine Center, Sofia, Bulgaria, ³Medical University of Plovdiv, Plovdiv, Bulgaria, ⁴National Genetic Laboratory, Sofia, Bulgaria, ⁵Sofia University, Sofia, Bulgaria.

Familial hypercholesterolemia (FH) is a common, autosomal dominant disorder of lipid metabolism and is a major risk factor for coronary vascular disease. FH affects approximately 1 in 500 individuals worldwide. Mutations in LDLR, APOB and recently described PCSK9 genes have been associated with this disease. The aim of the present study is to provide information about the spectrum of point mutations in the LDLR gene in sample of 200 Bulgarian patients with severe hypercholesterolemia. We applied Single Strand Conformation Polymorphism (SSCP) analysis to screen for sequence variations in the coding regions and splice sites of the LDLR gene. The detected samples with different SSCP patterns were sequenced. In 29 cases the diagnosis FH was genetically confirmed. We found 7 point mutations (ex.4bG>A at 590, ex.9G>A at 1195, ex.6C>A at 858, ex.8G>A at 1073 and T>C at 1061-8, ex.5A>C at 761, ex.11G>A at 1646) and 7 polymorphisms, one (ex.11C>T at 1705+23) not previously described. Our results have shown that exons 8, 9, 11 should be considered as "hot-spots" for Bulgarian population. In 3 out of 9 patients with determined mutations in the 11th exon we have observed in addition 2 different polymorphisms - C>T at 1705+23 and C>T at 1617. On the contrary, exons 16, 17, 18, 2, and the previously described as "hot-spots" exons 3 and 14 did not show aberrant profiles in the SSCP screening. Exons 7, 13 and 15 appear to be very polymorphic, however no mutations were observed in those exons.

P07.050

Distribution of FMR1 alleles in two populations with different ethnic background: Madeira (Caucasian) and Guinea-Bissau (Sub-Saharan African)

A. T. Fernandes¹, A. Ferreira¹, R. Gonçalves¹, R. Vasconcelos², A. Brehm¹;

¹Human Genetics Laboratory, University of Madeira, Funchal, Portugal, ²Pediatric Service, Central Hospital of Funchal, Funchal, Portugal.

The fragile X syndrome is the most common cause for inherited mental retardation. This syndrome results from an abnormal expansion of the CGG repeat in FMR1 gene which causes the inactivity of the gene, leading to the absence of the FMRP. The frequency of the alleles of FMR1 polymorphism was analyzed to the Madeira and Guinea-Bissau populations. Madeira and Guinea-Bissau population show significant differences ($P < 0,05$) but have some similar distributions, being the 29 repeats the most common allele followed by the 30 repeat CGG. These two alleles accounts for 51% of all alleles at this locus in a total of 19 different alleles varying between 7 and 38 repeats in the Madeira population and in the Guinea-Bissau population 22 different alleles varying in size from 8 to 43 repeats were identified and alleles 29 and 30 accounts for 45.2% of all alleles at this locus (table1). This population contains 89.6% of small alleles (≤ 35 CGG) and 10.4% of large alleles (> 35 CGG), a pattern similar to others observed in African populations but quite different from that of Caucasian populations. In the Madeira population ($n=141$) no intermediate or permuted alleles were identified while in Guinea-Bissau population ($n=104$) 4 intermediate alleles (prevalence: 1/26) were observed. These results can explain why there are no X-fragile reported patients in the Madeira population of 250.000 inhabitants.

The genome-wide patterns of variation confirms significant substructure in a founder population

K. Rehnström^{1,2}, E. Jakkula^{1,3}, T. Varilo^{1,2}, O. Pietiläinen¹, T. Paunio¹, N. Pedersen⁴, M. Järvelin⁵, S. Ripatti^{1,4}, S. Purcell⁶, M. Daly³, A. Palotie^{3,6}, L. Peltonen^{1,6};

¹National Public Health Institute, Helsinki, Finland, ²University of Helsinki, Helsinki, Finland, ³Broad Institute of Harvard and Massachusetts Institute of Technology, Cambridge, MA, United States, ⁴Karolinska Institute, Stockholm, Sweden, ⁵Imperial College, London, United Kingdom, ⁶Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

The genome-wide SNP genotyping platforms enable detailed association studies, but at the same time offer new insight into population genetics. Here we present an example of a founder population by scrutinizing nine geographically distinct Finnish subpopulations representing different eras in the population history to study the effect of bottlenecks and isolation using high-density SNP data. We demonstrate that population substructure and even individual ancestry are detectable at high resolution and support the concept of multiple historical bottlenecks resulting from founder effects.

We performed multidimensional scaling (MDS) of pairwise identity-by-state (IBS) sharing data to delineate population structure. Within Finland the two primary dimensions of the MDS-analysis correspond remarkably with the east-west and north-south directions, respectively, showing a distribution of individuals corresponding closely with the geographical distribution of parents' birthplaces. The youngest subisolates showed higher IBS similarity compared to other subgroups and separation using an extremely fine resolution. We analyzed linkage disequilibrium (LD) and extended regions of homozygosity (ROHs) to further explore the genomic structure of the subpopulations. Highest LD and the largest number of long (>10 Mb) ROHs was identified in the youngest regional population and showed a gradual decline of these measures in older and more outbred, subpopulations.

The study shows the power of GWA data to trace the population history and also exemplifies the power to identify stratification even within homogeneous populations. A deeper insight into fine-scale population substructure also emphasizes the importance of adjustment of GWA studies aiming at identifying smaller and smaller genetic effects to avoid confounding.

P07.052

Epidemiological study of Fraser syndrome in Europe

L. Odak¹, I. Barisic¹, V. Tokic¹, M. Loane², F. Bianchi³, E. Calzolari⁴, E. Game⁵, D. Wellesley⁶, H. Dolik²;

¹Childrens Univ. Hospital Zagreb, Zagreb, Croatia, ²EUROCAT Central Registry, University of Ulster, Newtonabbey, Co Antrim, United Kingdom, ³Unit of Epidemiology, CNR Institute of Clinical Physiology, Pisa, Italy, ⁴Department of

Experimental and Diagnostic Medicine, Division of Medical Genetics, University of Ferrara, Ferrara, Italy, ⁵Epidemiology, University of Southern Denmark, Odense, Denmark, ⁶Wessex Clinical Genetics Service, Princess Anne Hospital, Southampton, United Kingdom.

Fraser syndrome (FS) is rare autosomal recessive condition with classical features of cryptophthalmos, syndactyly, and genitourinary malformations. Abnormalities of the skull, ears, nose, and larynx are often present as well. Due to the rarity of FS, population-based epidemiological studies are lacking. We present the results of analysis of 24 cases of FS identified among 10 318 446 pregnancies registered in the EUROCAT network of congenital malformation registries in 1980-2004 period. This corresponds to a prevalence of 0.23/100000 or 1 in 429.935 births. Prenatal ultrasound examination detected abnormalities in 13/24 (54.2%) fetuses. Mean gestational age at discovery of an abnormality by prenatal ultrasound was 22.3±3.2 (18-27) gestational weeks. There were 2/24 (8.3%) fetal deaths, 9/24 (37.5%) pregnancy terminations and 13/24 (54.2%) were live born. One third of live births did not survive the first week of life. Male:female ratio was 3.4 (17/5). The mean birth weight in live births was 2363 ±622 g for males and 2133±413 g for females. The mean gestational age at birth was 37 weeks for both sexes. The most frequent associated congenital malformations were urogenital (81.8%; 18/22), eye (72.7%; 16/22), and limb (59.1%; 13/22) anomalies. The mean maternal age at birth was 28 ± 5 years and the mean paternal age 31±4 years. Parental consanguinity was present in 7/14 cases, and four families had already one affected child (4/13). All cases were registered in the Western part of Europe, 12/24 (50%) cases being from Great Britain and Portugal (prevalence 0.49/100000 or 1 in 202859 births).

P07.053

Analysis of frequencies of 35delG mutation in connexin 26 gene in different ethnic groups of Russia

E. I. Sharonova, S. P. Zinchenko, R. A. Zinchenko;

Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.

Mutations in the *GJB2* gene are a major cause of autosomal recessive and sporadic non-syndromic hearing loss in many populations. This study aims to determine the frequencies of 35delG mutation in different ethnic groups of Russia.

The patients with non-syndromic hereditary hearing loss from four ethnic groups (Chuvashs, Udmurths, Bashkirs and Russians from Rostov Regions) were analyzed for 35delG mutation in connexin 26 gene. Analysis of 60 patients with non-syndromic hereditary hearing loss from Chuvash Republic, 85 patients from Rostov Region, 36 patients from Republic of Bashkortostan, 58 patients from Udmurt Republic, showed that frequency for 35delG mutation was specific to Russian ethnic group (42.86%, 45%, 8.33%, 62.5%, respectively). Among the patients with non-syndromic hereditary hearing loss from other ethnic groups, frequencies of 35delG mutation were 5% for Chuvashs, 2.44% for Udmurths, 6.06% for Bashkirs.

More than 2574 healthy donors from five ethnic groups from Russia (Chuvashs, Marias, Udmurths, Bashkirs and Russians from Tver and Rostov Regions) were analyzed for 35delG mutation in *GJB2* gene. Significant differences in mutation frequencies between different ethnic groups were discovered. Analysis showed that frequency of 35delG mutation for Chuvashs ethnic group was 0.48% (5 chromosomes with mutation 35delG out of 1040 analysed (5/1040)), for Marias - 0.99% (8/804), for Udmurths - 0.25% (3/1184), for Bashkirs - 0.25% (2/792), for Russian - 1.44% (19/1320).

According to this research, contribution of 35delG mutation in connexin 26 gene to the development of non-syndromic hereditary hearing loss in various ethnic groups of Russia is different.

P07.054

N680S and -29 (G->A) FSH-R polymorphisms in Czech fertile male and female population

M. Macek sr.¹, H. Kluckova¹, P. Norambuena¹, T. Piskackova¹, M. Balasckova¹, M. Koudova¹, A. Stambergová¹, M. Macek jr.¹, J. GromolP;

¹Department of Biology and Medical Genetics, Charles University, Second Medical School and University Hospital Motol, Prague, Czech Republic, ²Institute of Reproductive Medicine, Muenster, Germany.

The aim of this study was the determination of the genotype characteristics of FSH-R polymorphism in position -29 (G->A) and exon 10

N680S in fertile couples in families indicated for prenatal diagnosis, or with risk of cystic fibrosis, risk of thrombophilic disorders and chronic pancreatitis disposition in male and female Czech population.

Polymorphism -29 (G->A) was examined in 318 females and 303 males, exon 10 N680S in 317 females and 304 males. The exon 10 and promotor polymorphisms were analyzed by allelic discrimination on ABI Prism 7000 detection system (Applied Biosystems).

The promotor polymorphism A/A in females was 5.03 %, in males 6.93 %; A/G in females 37.74 %, in males 35.31 %; G/G in females 57.23 %, in males 57.76 %. Exon 10 polymorphism Asn/Asn was 37.22 % in females, 27.96 % in males; Asn/Ser in 47.32 % for females, 50.33 % for males; Ser/Ser in 15.46 % in females and 21.71 % in males. It is apparent, that in both types of FSH-R polymorphisms no differences were disclosed between males and females.

The genotype 680 exon 10 polymorphism Asn/Asn, Asn/Ser, Ser/Ser are not different from so far published prevalence in Caucasian population.

These data provide possibility to compare the genotype characteristic of FSH-R polymorphisms for association studies in male and female reproductive disorders and for the pharmacogenetic strategy in hormonal treatment and stimulation in male and female patients.

Supported by grants NR9448-3/2007 and 00000064203.

Epidemiologic study of isolated gastroschisis in mexican population: 1978-2006

J. Arteaga, L. Luna, O. M. Mutchinick;

National Institute of Medical Sciences and Nutrition "Salvador Zubirán", Mexico city, Mexico.

Isolated gastroschisis (IGC) cluster in the offspring of very young mothers. Incidence reported range between 0.40 and 4.49 per 10000 births. Recently has been observed an increase in the frequency without a clear explanation, although several studies have identified consistent risk factors (RF). The increasing prevalence in newborns observed in a sample of the Mexican populations prompted us to analyze the secular trend for IGC and the following RF: maternal age, primigravidity, socioeconomic status, use of vasoactive medications and change of paternity. The information was obtained from the RYVEMCE; a hospital based multicentric case-control study. We studied IGQ in a sample of 1'066,542 newborns analyzing time trends prevalence from January 1978 to December 2006 and the mentioned RF in both, mothers of IGC cases and controls. P <0.05 was accepted as statistical significance. We observed a total of 151 cases with IGC, 49% were males and 51% females. The risk of having a baby with IGC was 2.4 times higher in very young mothers, <20 years (3.08/10000) than mothers ≥20 (1.17/10000), OR: 3.44, IC₉₅ 2.47-4.81. An evident time trend in the incidence of IGC starting in 1993 was observed, rising from an average of 0,50/10000 during 1978-1992 to an average of 2.44/10000 during 1993-2006 (p=1x10⁻⁶). Primigravidity was more frequent in cases than controls (66.2 and 41.1%). There were not statistical differences in the use of therapeutic drugs, socioeconomic level and change of paternity. Our results confirm an increasing trend for IGC particularly related to mothers of very young age.

P07.056

The peopling of North Asia: Y and X perspectives

V. A. Stepanov, V. Kharkov, I. Khitrinskaya, O. Medvedeva, M. Spiridonova, A. Marusin, V. Puzyrev;

Institute for Medical Genetics, Tomsk, Russian Federation.

To reconstruct the origin and evolution of human populations in North Asia we investigated the genetic diversity in 50 population samples (about 2000 individuals totally) using Y and X chromosome lineages. Y-chromosomal haplotypes were constructed with unique event polymorphisms (UEP) and STR markers according to Y Chromosome consortium (YCC) classification. SNP markers in a single 60 kb linkage disequilibrium region of ZFX gene was used to trace the X chromosomal population history.

The genetic diversity of Y haplogroups was quite high (0.70 - 0.95) in most populations except few very isolated groups. The proportion of inter-population differences in the total genetic variability measured by Fst statistics is 17% for binary haplogroups and 19% for YSTR. Multidimensional scaling and principal component analysis revealed four major components in North Asian Y gene pool, reflecting the presence

of Paleoasiatic (Q), Proto-Uralic (N3, N2), Eastern Asian (O, C), and Western Eurasian (R1, I, J) lineages.

X-chromosomal haplotypes in North Asia are less diverse (gene diversity within populations 0.65 - 0.80) and less differentiated ($F_{st} = 4\%$) compared to Y lineages.

The population clustering by X and Y gives, to a first approximation, a similar picture, and matrices of genetic distances between populations for X and Y haplotypes significantly correlates.

The age of genetic diversity generation and time of population differentiation demonstrates the Upper Paleolithic origin of major Y and X lineages and post-glacial population expansions.

This work is supported by RFBR grants ##06-04-48274 and 07-04-01629.

Genetic differentiation of ethnic groups of Russia evaluated by genes of hereditary disorders

R. A. Zinchenko, V. A. Galkina, E. K. Ginter;

Research Center for Medical Genetics, Moscow, Russian Federation.

On the basis of genetic epidemiological study the prevalence of autosomal dominant, autosomal recessive and X-linked recessive disorders in 10 regions of Russia (5 ethnic groups: Russians, Maris, Chuvashes, Udmurts, Adighes) was estimated. The size of the investigated population was more than 2.5 millions of persons. Genetic differentiation between populations of different hierarchical levels by estimated loads of hereditary diseases was established. The prevalence rate of all Mendelian disorders varied in the investigated populations from 1.34 to 5.92 per 1000 persons. Genetic diversity of hereditary diseases in the investigated populations was also under our study. 199 autosomal dominant, 165 autosomal recessive and 48 X-linked recessive diseases were revealed. Most of them were rare or very rare. There were some cases of local accumulations of hereditary disorders in the investigated populations. Simultaneously with medical genetic study the population genetic study was performed in the populations. By comparing both studies it was suggested that the genetic drift is a most important factor which determines genetic differentiation of populations by the prevalence and genetic diversity of autosomal disorders.

Age-dependent genetic polymorphism frequencies and Gene - Pass

V. S. Baranov¹, H. V. Baranova², O. S. Glotov¹;

¹Ott's Institute of Obstetrics & Gynecology, St.Petersburg, Russian Federation,

²European Institute of Personalized Prevention, Nice, France.

The report highlights the results of collaborative studies of personalized anti-aging medicine and its impact into longevity and aging. Special attention is paid to the gene nets of cardiovascular diseases, renin-angiotensin system, diabetes mellitus, osteoporosis etc. Polymorphic variants of at least some particular genes such as ACE, AGT, PAII, MTHFR, APOE, also as metabolic genes, like GSTs and other oxidative stress markers (NOS) are considered as the most plausible candidates of the genes crucial for aging. Molecular analysis of these particular genes supplemented with relevant metabolic genes testing, responsible for efficiency of detoxification system might have substantial contribution into personalized anti - aging medicine. The data on allele frequencies distribution for 10 different genes in newborns (106), 119 middle age and 148 old people over 69 are presented. Relevant gene testing supplemented with its adequate sophisticated interpretation and constructive recommendations might have substantial contribution to human health and should be considered as a new highly promising tool in anti-aging medicine "Gene - pass" term is suggested for the individual DNA data bank reflecting increased personal susceptibility to these common disorders. Tremendous impact to its practical application could be achieved through wide scale application of biochip technology. The latter are already available or are in progress for a number of multifactorial diseases. Special attention is paid to Genetic Pass of Reproductive Health - a version of Genetic Pass adjusted to the needs of pregnant woman. Life in harmony with personal gene makeup remains indispensable prerequisite of longevity and good health..

Genetic demography analysis in urban population in Buryatia Republic

E. R. Eremina;

Buryat Branch State Institution, Ulan-Ude, Russian Federation.

Ulan-Ude city is center of Buryatia Republic in Trans-Baikal region of Russia. It was founded about 300 years ago. From that time, both Russians and Buryats live there. We have studied genetic demography characteristics in the population of Ulan-Ude and have found some differences between these two ethnic groups. First of all, migrations pattern for Buryats is bordered mostly by Buryatia region, whereas for Russians migrants from distant regions of Russia are typical. However, fraction of homo-local marriages in Buryats is twice lower than in Russians. Frequency of homo-ethnic marriages in the two ethnic groups reflects their portions in the city population. Assortative marriage index by ethnicity was 87% for Russians, being slightly higher than for Buryats (81%). At the same time, assortative marriage indices by locality were similar for both ethnic groups. Total inbreeding estimated by isonymy index was 0.0007 for Buryats and 0.0005 for Russians. These estimates were lower than those indices for other Siberian peoples (Tuvians, Northern Khantys). Mean age of the first marriage was in Buryats 25.9 years for men and 24.72 years for women, whereas in Russians it was 24.86 and 22.69 years, respectively.

Genome-wide association analysis identifies multiple loci associated with normal variation in height

M. N. Weedon¹, H. Lango¹, G. Lettre², ... The GIANT Consortium^{1,2};

¹Peninsula Medical School, Exeter, United Kingdom, ²Broad Institute, Boston, MA, United States.

There are many single gene disorders that affect stature, but little is known about the genetic variants that explain normal variation of adult height. The availability of genome-wide association data offers new opportunities to identify the genes involved in normal growth.

Recent meta-analyses of genome-wide association studies (GWAS), using up to 16,000 individuals, have identified 22 independent loci associated with height ($p < 5 \times 10^{-8}$). The GIANT consortium has now extended these analyses, using imputation methods, to combine association results from 13 GWAS, with a total sample size of >32,000 individuals.

Initial meta-analysis identified 111 independent loci with $p < 1 \times 10^{-5}$ and 50 with $p < 5 \times 10^{-7}$. Confirmed loci implicate a wide range of molecular processes involved in normal growth. These include Hedgehog signaling (PTCH1, HHIP, IHH), chromatin remodeling (SCMH1, HMG2), and basic cell cycling (CDK6, ANAPC13). Some of the variants and genes have been connected to other diseases, including cancer, suggesting that variants associated with height may also influence disease susceptibility. Many of the associated loci include genes known to be involved in growth based on monogenic human studies. Other loci implicate genes previously unsuspected to have a role in growth, and represent excellent candidate genes for, as yet unexplained, growth-related single gene disorders.

Combining data from many genome-wide association studies is likely to result in the identification of hundreds of loci that influence adult height. These data should result in an unprecedented increase in our knowledge of the genetics of growth and development.

P07.061

Persons with greater individual genome-wide heterozygosity show lower increase of cortisol levels during acute psychological stress

L. Zgaga¹, C. Hayward², Z. Biloglav¹, I. Kolcic¹, O. Polasek^{1,3}, D. Rudan⁴, A. Vorko-Jovic¹, A. Wright², H. Campbell², I. Rudan³;

¹Medical School, University of Zagreb, Zagreb, Croatia, ²MRC Human Genetics Unit, Edinburgh, United Kingdom, ³Faculty of Medicine, Edinburgh, United Kingdom, ⁴Dubrava University Hospital, Zagreb, Croatia.

Aim: Genome-wide heterozygosity (GWH) was reported to affect a range of quantitative traits in humans, animals and plants. Several studies suggested that the underlying mechanism is increased compensation potential to environmental stressors in outbred individuals. In humans, psychological stress has been consistently linked to an increase in cortisol levels, which eventually impairs immune system function. We studied whether GWH status affects the increase in corti-

sol levels in persons reporting acute psychological stress.

Materials and methods: We studied 1,026 examinees from the Vis island, Croatia. Standardised multilocus heterozygosity (sMLH) was computed for each person from a genome-wide scan using 317,000 single nucleotide polymorphisms. Morning cortisol level was measured from the blood in all participants. Reported acute psychological stress was measured using General Health Questionnaire 30 (GHQ-30).

Results: GHQ-30 scores had a significant effect on the increase of cortisol ($p < 0.001$). All examinees were therefore categorized in 3 groups according to the increasing levels of reported psychological stress within GHQ-30. In all groups, the effect of sMLH on cortisol levels was investigated using general linear model with inclusion of potential confounding variables. In the group reporting mild stress the effect was weak and non-significant (Beta = -0.058, $p = 0.34$), but with increase of reported stress levels to moderate and strong, the effect became larger and statistically significant (Beta = -0.125, $p = 0.003$; and Beta = -0.188, $p = 0.04$, respectively).

Conclusion: This study implies that, in humans, the increase in individual GWH may buffer the effects of psychological stress on cortisol levels, thus protecting the physiological function of immune and endocrine system.

GLA mutations in young adult patients with a first stroke: The PORTYSTROKE study - screening genetic conditions in Portuguese Young STROKE patients

S. Ferreira¹, M. Viana-Baptista², I. Costa¹, M. Machado¹, J. M. Ferro³, J. P. Oliveira¹, & PORTYSTROKE Study Group⁴;

¹Faculdade de Medicina, Porto, Portugal, ²Hospital Garcia de Orta, Almada, Portugal, ³Hospital Santa Maria, Lisboa, Portugal, ⁴(NA), (NA), Portugal.

Background

Fabry disease (FD), an X-linked lysosomal storage disorder due to mutations in the alpha-galactosidase gene (GLA), is associated with the early onset of cerebrovascular disease (CVD), most commonly of the ischaemic small-vessel (ISV) type. Atypical phenotypes have been recognised and the disease is probably under-diagnosed in the stroke population.

Methods

Between 1/November/06 and 31/October/07, all patients aged 18-55 years presenting with a first stroke event to any of 12 major neurology hospital departments in Portugal were offered genetic screening for GLA mutations. Strokes were classified according to usual clinical and brain imaging criteria. Mutations were detected by cDNA analysis and confirmed on genomic DNA.

Results

Out of a total of 625 eligible patients, 493 (78.9%) consented to the genetic analysis. Of these, 74% had ischaemic strokes, of which 28.5% were cryptogenic. In 5 patients, RT-PCR was unsuccessful. Two previously described missense mutations were identified in 12 patients: p.R118C (n=6; 3 males) and p.D313Y (n=6; 4 males). Respectively 2 patients (males) with p.R118C and 3 patients (males) with p.D313Y had evidence of ISVCVD. Two patients (1 male) had a previously undescribed 5'UTR mutation (g.1136C>T). None of these patients had a diagnosis or family history of FD.

Conclusions

Overall, 1.23% (95%CI: 0.25-2.21) of the patients in this cohort had a recognised pathogenic GLA mutation. Despite having been described as a polymorphic allele causing a pseudo-deficiency in plasma alpha-galactosidase activity, the role of p.D313Y in ISVCVD should be further evaluated. The biologic relevance of the g.1136C>T 5'UTR mutation requires supplementary investigation.

P07.063

Identification of Ile105Val polymorphism for GST-P1 gene in five Iranian ethnic groups: Comparison with a mix-ethnic population from Tehran

F. Biramijamal¹, M. Soltani¹, S. Tanhaef², M. Sheidaei², M. Sanati³;

¹National Institute for Genetic Engineering & Biotechnology, Tehran, Islamic Republic of Iran, ²Shahid Beheshti University, Tehran, Islamic Republic of Iran.

The glutathione S-transferase P1 (GST-P1) protect cells from chemical injury and has a function in detoxification of carcinogenic compounds. The polymorphism at site of codon 105 in GST-P1 enzyme has been described, this site lies in close proximity to substrate bind-

ing for electrophilic molecule. It is demonstrated that single nucleotide polymorphisms (SNP) in various genes revealed a correlation between the presence of specific allelic variants and cancer susceptibility in diverse malignancies. Furthermore, it is shown that GST-P1 polymorphism is involved in risk of development of different types of cancer. In this study, we investigated the distribution of GST-P1 polymorphism, at codon 105, among different Iranian populations. The samples were collected from healthy population from five different ethnicity groups (Fars, Mazandarani, Kurd, Turk and Turkmen). We assessed the genotype patterns of GST-P1 among Iranian ethnic groups in five regions. Then, the data was compared with the allele distribution for above gene among Tehran population (52 samples), a mix-ethnic population. The GST-P1 genotypes, Ile105Val, were determined by polymerase chain reaction-restriction fragment length polymorphisms (PCR-RFLP) analysis in 269 Iranian healthy individuals. Allele frequency of GST-P1 genotype, Ile105Val, for above populations were similar, and there is only significant difference among Fars and Turkmen populations.

P07.064

Contribution of environmental and genetic modifiers to severity of the typical HFE-related haemochromatosis: a multivariate analysis

G. Le Gac¹, V. Scotte², I. Gourlaouen¹, C. Thèze¹, B. Chanu¹, A. Mercier¹, M. Mérou¹, C. Férec^{1,2};

¹Etablissement Français du Sang-Bretagne, Brest, France, ²Inserm U613, Brest, France.

Background/aim: Expression of the common p.C282Y/p.C282Y HFE-related haemochromatosis genotype depends on a balance between accentuating and reducing factors. Some of these factors have been identified, but they have mainly been analyzed independently. Here, we aimed to determine contribution of different environmental and genetic modifiers to total body iron overload.

Method: We studied 365 p.C282Y/p.C282Y patients (195 men and 170 women), and we used the iron removed by phlebotomy as quantitative trait (log transformed). We tested the influence of age, gender, alcohol abuse, body mass index, as well as six common variants: the 16189 T>C variant in mtDNA, the -308G>A variant in the TNF-alpha promoter, the well known duplication of the haptoglobin gene (genotypes Hp1-1, Hp1-2 and Hp2-2), and 3 SNPs located in genes involved in regulation of hepcidin synthesis (BMP2 rs23756, BMP4 rs4901474 and HJV rs16827043).

Results: Univariate analyses first highlighted the relation between each potential modifiers and severity of the body iron overload. Factors with a p-value lower than 25% were included in a same multiple linear regression model. Then, stepwise elimination procedures were successively performed until a model presenting only significant predictors was found. Predictors of this last model were the male sex ($p < 0.0001$), the greater age at diagnosis ($p < 0.0001$), the alcohol abuse ($p = 0.0008$) and the Hp2-2 genotype ($p = 0.0186$).

Conclusion: Our results underline the predominant influence of non-genetic modifiers in expression of the p.C282Y/p.C282Y genotype. Future investigations should address the influence of other genetic modifiers, and further look for gene/gene and gene/environment interactions.

P07.065

Investigation of polymorphisms in non-coding region of human mitochondrial DNA in 31 Iranian Hypertrophic Cardiomyopathy (HCM) Patients

M. Montazeri¹, M. Houshmand¹, M. Eftekhrazadeh², E. V. Zaklyazminskaya³; ¹NRCGEB, Tehran, Islamic Republic of Iran, ²Tehran Arrhythmia Clinic, Tehran, Iran, Tehran, Islamic Republic of Iran, ³Russian Research Center of Medical Genetics, Laboratory of DNA Research, Moscow, Russia., Moscow, Russian Federation.

The D-loop region is a hot spot for mitochondrial DNA (mtDNA) alterations, containing two HyperVariable Segments, HVS-I and HVS-II. In order to identify polymorphic sites and potential genetic background accounting for Hypertrophic CardioMyopathy (HCM) disease, the complete non-coding region of mtDNA from 31 unrelated HCM patients and 45 normal controls were sequenced. The sequences were aligned upon the revised Cambridge Reference Sequence (rCRS) and any incompatibilities were recorded as numerical changes in homoPolymeric C Tract (PCT), single base substitutions (SBS), insertions and

deletions (Indels). Nucleotide substitutions were found to make up the majority of the mutations, rather than indels. We drew significantly high transition rate (81.8%) versus lower frequency of transversions (18.2%). 12 polymorphisms were identified in this study which had not been published in the MitoMap database. PCT changes at position 303-309 were detected in 83% of our samples. Our results suggest that an increased level of HVS-I and HVS-II substitutions may be an indicator of mitochondrial DNA instability. Furthermore, mtDNA mutations may play an important role in pathogenesis of cardiac arrest which has remained unexplained for long.

P07.066

Frequency of the Hemochromatosis gene mutations in patients with Hereditary Hemochromatosis and in control subjects from Serbia

M. Saric¹, L. Zamurovic¹, M. Keckarevic-Markovic¹, D. Keckarevic¹, M. Kecmanovic¹, D. Savic-Pavicevic¹, J. Jovic², S. Romac¹;

¹Faculty of Biology, Belgrade, Serbia, ²Military Medical Academy, Belgrade, Serbia.

The most common form of hereditary hemochromatosis (HH) is HH type 1. It is an autosomal recessive iron-overload disorder associated with mutations in the hemochromatosis gene (HFE). The aim of this study was to determine the frequency of the C282Y, H63D and S65C mutations of HFE gene in the group of unrelated HH patients (n=28) and in the healthy population of Serbia (n=318).

The C282Y, H63D and S65C mutation frequencies in the healthy population were 1.6%, 15.7% and 1.6%, respectively and in the population of HH patients 25%, 19.6% and 1.8%, respectively. The frequency of C282Y homozygotes was estimated on approximately 1:3900 indicating the prevalence of HH type 1 in Serbia. Our results support previously documented gradient distribution of the C282Y mutation, in northwest to southeast Europe. They also confirm that the frequency of C282Y mutation is not related to the origin of particular population but it is more related to the geographical position of the population. This finding could be considered as yet further evidence in favor of the Viking or Celtic origin of C282Y mutation.

The frequency of the C282Y homozygotes (10.7%) is considerably lower than the frequency reported for HH patients in other European populations. It is possible that some of the analyzed HH patients carry other mutations in HFE gene, mutation in some other genes already related with HH or in some other yet not identified genes.

These results have important clinical implications for the detection and management of HH type 1 in Serbia.

P07.067

Hereditary hemochromatosis and multiple sclerosis. Frequency of common HFE mutations in Czech patients with multiple sclerosis

M. Tomková¹, P. Strachotová¹, L. Barnincová¹, E. Krasulová¹, L. Pospíšilová¹, D. Horáková¹, E. Havrdová¹, J. Horák², P. Martásek¹;

¹1st School of Medicine, Prague, Czech Republic, ²3rd School of Medicine, Prague, Czech Republic.

Hereditary hemochromatosis is an autosomal recessive disorder frequently found in Caucasian population and caused by iron overload (mutations in HFE gene). There have been several reports of a relationship between HFE gene polymorphisms and multiple sclerosis (MS). MS is an inflammatory demyelinating disease of the central nervous system. In the etiology of MS, both environmental and genetic factors play a role. In this study we investigated whether HFE polymorphisms is associated with Czech MS patients. We therefore genotyped 410 MS patients and 481 healthy controls for the C282Y, H63D, and S65C mutations by PCR-RFLP analysis. None of the MS patients were identified as homozygous for S65C or C282Y mutation, and seven (1.70%) for H63D mutation. Twenty eight (6.83%) MS patients were C282Y heterozygous, seventy seven (18.78%) were H63D heterozygous, and eight (1.95%) were S65C heterozygous. Among them, we have found four (0.97%) compound heterozygotes; three patients were C282Y/H63D compound heterozygous and one was found H63D/S65C compound heterozygous. Our results showed no significant differences in the distribution of C282Y and S65C HFE mutations between MS patients and controls. However, the allele frequency of the H63D mutation was significantly lower ($p < 0,05$) in the MS patients than in the control group. (Supported by grant IGA MZ 1A8713 and MSM 0021620806).

P07.068

Comparison of genome-wide homozygosity-by-descent estimates in human isolated population

O. Polasek^{1,2}, I. Kolčić², L. Zgaga², Z. Biloglav², A. Vorko Jović², D. Rudan³, I. Rudan⁴, A. Wright⁵, H. Campbell¹, A. Leutenegger^{6,7};

¹Public Health Sciences, University of Edinburgh, Edinburgh, United Kingdom,

²Andrija Stampar School of Public Health, Medical School, University of Zagreb, Zagreb, Croatia,

³Clinical Hospital Dubrava, Zagreb, Croatia, ⁴Centre for Global Health, University of Split, Split, Croatia, ⁵Human Genetics Unit, Medical

Research Council, Edinburgh, United Kingdom, ⁶Inserm U535, Villejuif, France,

⁷Univ. Paris-Sud, Villejuif, France.

The aim of this study was to investigate several methods of marker based genome-wide homozygosity estimation. The study sample consisted of 118 members of a single extended family living on the Adriatic Croatian island of Vis, where no pedigree based inbreeding was observed, and therefore no homozygosity by descent, HBD, was expected. Individuals were genotyped for 810 microsatellite markers and a 317k Illumina chip. Five approaches were compared: the proportion of heterozygous loci (multilocus heterozygosity, MLH), two methods of moments approaches that use different weighting approaches (ADC and PLINK), and finally 2 maximum likelihood approaches, one singlepoint and the other multipoint, using a hidden Markov model for marker dependencies (FEstim). The latter is the only existing multipoint method for HBD estimation and gives estimates the closest to the true HBD values, as shown previously in a simulation study. The results indicated that the two methods of moments approaches correlated highly with MLH and hence did not bring much information about HBD. On the other hand, the two maximum likelihood approaches exhibited zero value estimates when homozygosity was likely due to chance. A total of 68 individuals (57.6%) had no HBD as defined by the FEstim, while a total of 4 individuals (3.9%) had FEstim values over 0.0625 indicating inbreeding closer than first cousins. These methods can be used to differentiate homozygosity by chance vs. HBD, which may be important in investigation of the genome-wide heterozygosity effects on quantitative and health related traits.

P07.069

A medium-throughput assay for the genotyping and primary screening of useful polymorphisms using High Resolution Melting analysis

X. Muñoz, F. Marín, N. García, N. Sala;

Catalan Institute of Oncology - Translational Research Laboratory and Unit of Nutrition, Environment and Cancer, L'Hospitalet de Llobregat, Spain.

The High Resolution Melting (HRM) analysis uses highly sensitive fluorescent dyes specific for double stranded DNA and the Post-PCR melting curve, to characterize gene fragments and identify small sequence variants such as SNPs. The purpose of this study was to determine the performance of *LightCycler® 480 High Resolution Melting master* and the *LightCycler® 480 Gene Scanning Software*, for genotyping and gene scanning purposes in the *LightCycler® 480 (LC480) System*. For this we setup protocols for the analysis of the *MTHFR c.677C>T*, *FII c.20210G>A*, and *F5 Leiden* variants in 60 samples previously genotyped using hybridization probes. Among these samples 20 there were heterozygotes for *MTHFR c.677C>T*, 10 for *FII c.20210G>A* and 4 for the *F5 Leiden* variant. The remaining samples were wild-type homozygotes. We have also developed a protocol for the mutational scanning of *Trefoil factor 2 gene (TFF2)*. Post PCR HRM resulted in the expected different melting profiles that efficiently discriminated between homozygotes and heterozygotes for the different polymorphisms tested in all samples. HRM scanning of *TFF2* exon 4 in 50 control samples from our population, allowed for the identification of a previously described SNP (rs225334; MAF: 0.39) and a novel insertion, c.68_69insCTT (MAF: 0.05) in the 3'-UTR region. Both variants could be genotyped simultaneously in the same amplicon melting analysis.

We conclude that HRM may be an efficient and cost-effective method for the simultaneous amplification, mutational scanning and genotyping of amplicons up to 200bp, in a single step and in sets of 96 or 384 samples.

P07.070**Development of new genetic methods for predictive testing of multifactorial diseases and maximum prolongation of the human active life (analysis of 14 genes)**

O. S. Glotov, A. S. Glotov, G. S. Demin, M. V. Moskalenko, N. U. Shved, V. G. Vakharlovsky, T. E. Ivashchenko, V. S. Baranov;
Ott's Institute of Obstetrics and Gynecology RAMS, St-Petersburg, Russian Federation.

It is well-known that diagnostics on early stages and prophylaxis of different diseases is one of the most actual problems of modern medicine. Patient usually consults a doctor on the stage when disease is already in progress. At the same time the cause of pathological process often remains unclear. In this case intensive treatment can improve state of health of patient only for sometime and makes him dependent on symptomatic drugs. Diagnostic of predisposition to the multifactorial pathologies nowadays becomes an important tool that is necessary for solution of the predictive medicine problems. The basic directions of these researches are connected to genes of cancerogenesis and cardiovascular diseases. Using pharmacy biochip specially constructed for population studies, 13 polymorphisms of 7 genes: *CYP1A1*(C4887A, A4889G, T6235C), *CYP2D6*(G1934A, DelA2637), *CYP2C9*(C430T, A1075C), *GSTM1*(del), *GSTT1*(del), *NAT2*(C481T, G590A, G857A), *CYP2C19*(G681A) and using RFLP method 7 polymorphisms of genes: *AGT*(M235T), *ACE*(I/D), *AGTR1*(A1166C), *PAI1*(4G/5G), *GPIIIa*(C1565T), *MTHFR*(C677T), *NOS3*(4/5) were investigated in 3 age-specific groups from North-West Region of Russia. The frequencies of same genotypes and alleles of *CYP2C9*, *GSTM1*, *GSTT1*, *NAT2*, *AGT*, *ACE*, *AGTR1*, *PAI1*, *MTHFR*, *NOS3* genes were different between studied groups. In our investigation was demonstrated that people who have certain genotypes of studied genes for men and for women have some metabolic advantages for their longer survival. Further, it is necessary to perform studies on various groups of different age, taking into account meta-analysis data to estimate the role of age-regulating genes and multifactorial diseases in aging.

P07.071**Genetic structure of rural population of Kazakhstan**

G. M. Berezina, G. Svyatova, A. Baysbekova, M. Kirikbaeva;
Scientific Center of obstetrics, gynecology and perinatology, Almaty, Kazakhstan.

The study of genetic structure of modern populations of the man is one of key problems of genetics. Genetic and demographic information for the Kazakhs population living in the Republic of Kazakhstan is presented. The marital-migrational structure of eight districts of Kazakhstan was studied on the basis of marital recodes. The average value of ethnic marriage assortativeness was found to be 1,78. The genetic structure of rural populations of Kazakhstan is formed by respective districts and region. The mean number of children per woman constituted 4,71. Crow index of total selection (I_{tot}) and its components (I_m , I_f) were 0,36, 0,08 and 0,26 respectively. The size of the portion of the population of reproductive age (34,4% of the total), family size (4,71), and the predominance of the portion of the population (49,8% of the total) under reproductive allow us to classify this population as growing. The parameters of isolation of Malecots distance and index endogamy in eight districts of Kazakhstan are counted up. Highest local inbreeding is found out in the district of Abai (0,00103). The index of endogamy is 53,6% A significant correlation between effective population size, endogamy and ethnic diversity with a level of local inbreeding was revealed ($r = -0,896; 0,585; -0,658$). Recent social and economic changes have led to an increase in general and ethnic isolation of rural populations of Kazakhstan.

P07.072**Ethnic-Pathology: distribution of disease, in Colombian indigenous groups, genetic and environmental aspects.**

A. Ordonez, F. Suarez;
Instituto de Genetica Humana, Bogota. D.C., Colombia.

Ethnic-Pathology: distribution of disease, in Colombian minority groups, genetic and environmental aspects.

The frequency of disease varies among populations, the reasons for this variation may be social, cultural or due to environment, but the incidence, prevalence, response to treatment and natural history of disease are also influenced by genotype, and although distinction be-

tween genetic variation and the genetic variation associated with the disease is not absolute, the phenotypic expression of certain abnormal variations in the DNA depends mainly of the environment. Colombia is a multi-ethnic country with a variety of geographical areas, therefore, the behavior of the disease does not maintains a uniform epidemiological profile in all human groups, and is likely to be established according to specific profiles frameworks that define the ethnic groups. The ethnic-pathology would be defined, as the study of disease according to the affinities of a human community framed on its own aspects biological and cultural. This paper aims to describe the demographic distribution of the disease in the Colombian indigenous groups, according to their biological determinants, and to analyze how the expression of the disease varies depending on the development of the cultural and genetic determinants of a population.

P07.073**Male infertility risk evaluation in inhabitants of radiation polluted territories of Ukraine**

A. V. Klepko, S. Andreychenko;

Scientific Center for Radiation Medicine, Kyiv, Ukraine.

Reproductive system has been shown to be highly sensitive to radiation. Consequently continuous low dose ionizing irradiation may cause severe sexual disorders. In this connection present research aims in evaluation quality and fertility potential of human sperm from radiation-polluted regions of Ukraine, the role of radiation component in sperm damaging being assessed.

Freshly ejaculated semen was obtained from volunteers by masturbation after 3 days of sexual abstinence. Then sperm motility, morphology and concentration were analyzed by light microscopy in accordance with WHO protocol. Although light microscopy is routinely applied for the diagnosis of male infertility, however the limitations of such analysis are well recognized. Therefore flow cytometry (FCM), which allows the simultaneous measurement of several biological characteristics at the single cell level in several thousands of cells, was used as a complementary approach for rapid identification of sperm chromatin and membrane disturbances.

The following parameters, namely apoptosis development (AD), mitochondrial membrane potential ($\Delta\Psi_m$) and nuclear DNA ploidy (DP), were identified on flow cytometer PAS (Partec, Germany). AD was followed by Annexin V - Apoptosis detection Kit I (BD Pharmingen, USA), $\Delta\Psi_m$ was measured by means of Rhodamin 123 dye and DP was quantified using propidium iodide staining.

The data received have shown the existence of specific correlations between the radiation dose accumulated by donors and the quantitative distribution of spermatozoa in subpopulations of apoptotic, necrotized, immobile and viable cells. Furthermore, the increase of sperm DNA aneuploidy and DNA fragmentation proved to be concomitant to infertility growth

P07.074**Iranian Population Data on sixteen Short Tandem Repeat loci: STR Multiplex Assays**

M. A. Saremi^{1,2}, M. Tavallaei (Ph.D.)¹, M. Sajedifara², S. Zeinali (Ph.D.)³;

¹Baqiyatallah Medical Sciences University – Human Genetics Research Center, Tehran, Islamic Republic of Iran, ²Kawsar Human Genetics Research Center, Tehran, Islamic Republic of Iran, ³Pasteur Institute, Tehran, Islamic Republic of Iran.

A population study on sixteen new short tandem repeat (STR) loci D8S1179, D21S11, D7S820, CSF1PO, D3S1358, TH01, D13S317, D16S539, D2S1338, D19S433, vWA, TPOX, D18S51, D5S818, FGA and AMEL(X/Y) was performed on 1511 unrelated Iranian.

These individuals were randomly sampled, interviewed and with their informed consent added to the sample each donating 5 ml of whole blood. Whole blood was collected into EDTA tubes which were transferred for storage at 4-8 °C.

DNA was extracted from whole-blood specimens using the standard salting out method and precipitated with ethanol. The multiplex PCR was performed using approximately 2 ng of genomic DNA in a total reaction volume of 25 µl by the multiplex kit AmpFISTR Identifier.

DNA quantified by spectrophotometry. The DNA was amplified by PCR and separation and detection by the ABI 3130 capillary system instrument (Applied Biosystems).

All loci meet Hardy ±Weinberg expectations. The results demonstrate

that these loci can be useful for human identification in forensic cases in Iran. We must pay attention that typing success in loci ranges from 100 ± 150 base pairs is better especially with degraded DNA samples.

P07.075

Identification of a geographic area characterized by "reproductive longevity" in the Sardinia Island

P. Astolfi¹, G. Caselli², O. Fiorani³, R. M. Lipsi⁴, A. Lisa⁵, S. Tentoni⁶;

¹Dept. Genetics and Microbiology, University, Pavia, Italy, ²Dept. Demographic Sciences, University, Rome, Italy, ³IGM, CNR, Pavia, Italy, ⁴IMATI, CNR, Pavia, Italy.

Sardinian population differs from the Italian mainland and other European populations in demographic and biological traits, resulting from the socio-economic structure and the geographical and historical isolation. Its reproductive behaviour is characterized by the historical and still present tendency to late maternity. We hypothesize that areas of "reproductive longevity" exist throughout the island, where a higher incidence of elderly mothers combines with a lower risk of perinatal death. Data regard all 1980-96 births (n=299,793), occurred in 363 Sardinian municipalities. Through a smoothed isopleth mapping procedure, we explored the spatial distributions of a late maternity indicator (proportion of 35+year-old mothers), and a perinatal mortality indicator (proportion of deaths within the 1st week of life) associated with late maternity. We drew critical isopleths to highlight "excess" areas, where the late maternity indicator exceeds the average Sardinian value and approaches its upper limit. With respect to the "non excess" area (23% of 35+year-old mothers), in the "highest excess" area (27% of 35+year-old mothers) the Odds Ratio of perinatal death was lower (1.38 vs 1.78), and the proportion of consanguineous marriages and the inbreeding coefficient were respectively from 3 to 2.4 fold higher. In conclusion we suggest that such area, located in the central part of the island and qualified for "reproductive longevity", can be target of further investigations on eventual protective mechanisms against adverse perinatal outcomes in late maternity, and of studies on the possible association between reproductive longevity and achievement of an extended life span.

P07.076

High frequency of LCHAD deficiency carriers in the northern Poland

D. Piekutowska-Abramczuk¹, R. K. J. Olsen², J. Wierzbą³, E. Popowska¹, D. Jurkiewicz¹, K. Czornak¹, P. Kowalski¹, M. Borucka-Mankiewicz¹, E. Ciara¹, J. Sykut-Cegielska¹, W. Gradowska¹, M. Krajewska-Walasek¹, N. Gregersen², E. Pronicka¹;

¹Children's Memorial Health Institute, Warsaw, Poland, ²University Hospital, Skejby Sygehus, Aarhus, Denmark, ³Medical Academy, Gdansk, Poland.

Long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD) deficiency is an autosomal recessive disorder of mitochondrial fatty acid oxidation. It is the most common defect of the mitochondrial trifunctional protein (MTP) complex which catalyzes the last three steps of the β -oxidation spiral of long-chain fatty acids. The gene *HADHA* for the α -subunit of MTP carrying LCHAD activity is located on chromosome 2p23. 60-86% of reported patients with isolated LCHAD deficiency have a prevalent c.1528G>C mutation.

Our earlier screening of urinary GC-MS organic acid profile and MS-MS blood acylcarnitines profile in Polish children revealed the presence of 40 patients (37 families) with LCHAD deficiency. The common c.1528G>C substitution was observed on 89% of mutated alleles. A tendency for clustering the LCHAD deficient patients in northern part of Poland, especially in Pomeranian voivodeship, was found.

The aim of our study was to identify carrier frequency of the common mutation in various districts of northern Poland to verify the probability of correlation between high number of Pomeranian patients and expected high carrier frequency of the c.1528G>C mutation carriers.

Up to now, 1096 blood samples collected on anonymous Guthrie cards, have been screened. Seven heterozygotes for c.1528G>C mutation (including 4 carriers from the Pomeranian region) were detected. No samples homozygous for the c.1528C allele were identified. The preliminary study suggests that LCHAD deficiency carriers are more prevalent in the areas around the Baltic sea than in other parts of the world.

The study was partly supported by the Polish Ministry of Science Project 0678/B/P01/2007/33

P07.077

Association analysis of G-2548A and A19G polymorphisms in the human leptin gene with obesity

Z. Tomas¹, N. Smolej Narancic¹, M. Barbalic¹, M. Zajc¹, T. Skaric-Juric¹, P. Rudan¹, I. Rudan², H. Campbell³, A. F. Wright⁴;

¹Institute for Anthropological Research, Zagreb, Croatia, ²"Andrija Stampar" School of Public Health, School of Medicine, University of Zagreb, Zagreb, Croatia, ³Department of Public Health Sciences, University of Edinburgh, Medical School, Edinburgh, United Kingdom, ⁴MRC Human Genetics Unit, Western General Hospital, Edinburgh, United Kingdom.

Leptin is a protein hormone which plays an important role in the regulation of body adiposity, lipid metabolism and reproductive function. It is primarily secreted by the adipocytes and its concentration in the blood is proportional to the amount of body fat. Many leptin gene polymorphisms have been found, but their association with obesity is still controversial. We tested the polymorphisms G-2548A in promoter region and A19G in intron 1 of leptin gene for association with leptin concentration in the blood and obesity. A population-based association study was conducted in the population isolate of the Eastern Adriatic island of Vis, Croatia. Three hundred and twenty randomly selected subjects from the Vis population were genotyped. Obesity was defined as BMI \geq 30 kg/m². The results revealed significant association of G-2548A variant and leptin concentration in a codominant pattern (p=0.026). The ancestral G allele which displays as a minor allele in the Vis population (frequency of 0.44) was associated with higher leptin levels. The leptin concentration was significantly higher in the obese (60.1 ng/ml, N=244), than in the non-obese group (20.7 ng/ml, N=76) and it was more than three times higher in women (44.0 ng/ml) compared to men. However, no association of G-2548A and A19G polymorphisms with obesity was found (with leptin concentration, sex and age as covariates). The results indicate that the studied polymorphisms are not relevant markers for common obesity in this isolated population, but were found to influence the leptin concentration which is an obesity-related phenotype.

P07.078

High level of genetic differentiation in Siberian populations demonstrated by ZFX haplotypes

I. Khitrinskaya, V. Kharkov, V. Stepanov;

Institute for Medical Genetics, Tomsk, Russian Federation.

X-Chromosome is considered as a convenient instrument used to study genetic history of populations. Firstly, since men have only one copy of X-chromosome it is easy to determine haplogroups. Linkage disequilibrium is also greater on the X-chromosome, because only two-thirds of this chromosome manages to recombine in each generation. The size of regions with a single genetic history is expected to be larger than in autosomes, once more making it ideal for human population genetic studies. In our study we have analyzed 5 SNP (rs2238925, rs2238926, rs2238928, rs2704843 and rs2704849) in ZFX gene located in Xp21.3 locus on the X-chromosome. Human populations belonging to 11 ethnic groups residing in Siberia and Middle Asia (Russians, Altaians, Buryats, Kets, Khants, Kirghizes, Komis, Tajiks, Tuvians, Uzbeks and Yakuts) have been studied. Altogether 1073 male individuals were analyzed. Genetic differentiation of the ethnic groups under study was estimated using AMOVA analysis. General level of genetic differentiation for the investigated populations at the level of ethnic groups amounted to 3.6%. The North Siberian population (Kets, Yakuts and Khants) is most highly differentiated ($F_{ST} = 11.2\%$), for the other groups (Central Asia, South Siberia and East Europe) a degree of genetic differentiation does not exceed 1%. Structural analysis of the selected SNP revealed 19 haplotypes. Median networks demonstrate the occurrence of two haplotype clusters, which may be conditionally determined as "Mongoloid" and "Caucasoid". Linkage analysis revealed a high LD level for 9 groups, excluding Ket and Uzbek populations.

P07.079**Population study at fifteen Short Tandem Repeat loci in the Sarajevo (B&H Capitol) residents**L. Kovacevic¹, N. Bakal¹, N. Pojskic¹, D. Marjanovic^{1,2};¹Institute for Genetic Engineering and Biotechnology, Sarajevo, Bosnia and Herzegovina, ²Institute for Anthropology, Zagreb, Croatia.

In our previous population studies of B&H human population, we used 17 STR loci included in the *PowerPlex 16® System* and *AmpFISTR®/Identifiler®*, twelve Y-chromosomal short tandem repeats loci incorporated in the *PowerPlex® Y System*, as well as 28 Y-chromosome NRY bi-allelic markers to generate Bosnian referent database. Wishing to test our database in order to obtain specific results in various DNA analysis for the local population of Bosnian Capitol - Sarajevo, we have decided to test unrelated healthy 150 individuals (situated in Sarajevo) at fifteen autosomal short tandem repeats loci. Qiagen Dnaeasy™ Tissue Kit was used for DNA extraction from buccal swabs and bloodstains and *PowerPlex 16® System* for amplification and detection. Amplification was carried out as described previously. The total volume of PCR reaction was 5µl. PCR amplifications were carried out in PE GeneAmp PCR System Thermal Cycler. Electrophoresis of the amplification products was performed on an ABI PRISM 310 genetic analyzer (ABI, Foster City, CA). The raw data were compiled and analyzed using Genemapper® v3.2. Deviation from Hardy-Weinberg equilibrium, observed and expected heterozygosity, power of discrimination and power of exclusion were calculated. In addition, we compared obtained Sarajevo data with the data obtained from the global Bosnian and Herzegovinian population, isolated human population from the Bosnian mountain area as well with geographically closer (neighboring) European populations. The results of this study will be used as guidelines in additional improving of investigation of recent local B&H populations, both isolated and open, initiated in our previous researches.

P07.080**Study on a possible effect of four longevity candidate genes (ACE, PON1, PPAR-gamma, APOE) on human fertility**R. M. Corbo^{1,2}, L. Ulizzi¹, L. Piombo¹, R. Scacchi²;¹La Sapienza University, Rome, Italy, ²CNR Institute of Molecular Biology and Pathology, Rome, Italy.

A possible effect on fertility of four genes [angiotensin 1-converting enzyme (ACE), paraoxonase (PON1), peroxisome proliferator-activated receptor gamma (PPAR-γ), and apolipoprotein E (APOE)] previously found associated with longevity was sought in order to determine whether they have a pleiotropic action at different life ages. The study population was 151 Italian subjects whose reproductive life took place at the beginning of the demographic transition (declining fertility and longer life expectancy) and who had produced a mean number of children (3.6±2.3) such as to be still useful to detect a differential reproductive efficiency associated with different genotypes. Of these four longevity candidate genes, only PPAR-γ and APOE appeared to have an effect on fertility, indicating their possible influence on reproductive efficiency. The PPAR-γ Pro/Ala genotype, which in a previous study (Barbieri et al. 2004) showed a positive association with longevity only in men, was found associated with a higher number of children (6.1 ± 3.3) than Pro/Pro genotype (3.3 ± 1.9, p=0.001) only in men. Compared with the other APOE alleles, the APOE*2 allele, considered as an allele favouring a longer life-span, was confirmed to be associated with the lowest fertility (p=0.03). The logistic regression analysis indicated that APOE and PPAR-γ polymorphisms act as independent determinants of reproductive efficiency. These data suggest that the APOE*2 allele may follow the model of antagonist pleiotropy, whereas the PPAR-γ Pro/Ala genotype seems to exert beneficial effects both early in life and in advanced age in a gender-specific way.

P07.081**Polymorphism of some genes in connection with age gradation**

V. V. Pauk, I. Tuktarova, T. Nasibullin, O. E. Mustafina;

Institute of Biochemistry and Genetics, Ufa, Russian Federation.

The aim was to evaluate age dynamics of alleles and genotypes of APOE (C112R, R158C), ACE (I/D), PON1 (Q192R), PON2 (C311S), CAT (-262C/T), GPX1 (L198P) and MSRA (-402T/C) gene polymorphisms in group of 1627 Tatars in age of 1-109 years old.

Differentiation of total group on certain age groups was carried out by

means of CHAID algorithm from SPSS Answer Tree (v.13.0). Genotyping was performed using PCR and PCR-RFLP. Fisher's two-tailed exact test (Statistica v. 6.0) was used for age groups comparison.

In group 36-61 years increase of CAT *C allele frequency was observed (P=0.004). Persons in the age of 55-77 years have significantly higher GPX1*L allele frequency (P=0.016). APOE*3, ACE*D, ACE*D/*D, PON2*C, PON2*C/*C, CAT*T, CAT*C/*T, GPX1*P and GPX1*P/*P alleles and genotypes frequencies were considerably higher in senile group (P<0.05). ACE*I/*D genotype and PON1*R allele carriers were more frequent among long-livers (P=0.026 and 0.004 accordingly).

Thus, we have demonstrated diversity of APOE, ACE, PON1, PON2, CAT and GPX1 genes polymorphisms genotypes and alleles frequencies between different age groups. Possibly, the same polymorphic variant plays a protective role for an organism at its different age stages.

P07.082**Generation of lymphoblastoid cell lines from frozen whole blood**

N. Baker, J. Cooper, E. Burnett, J. Biggins, P. Bracegirdle;

European Collection of Cell Cultures, Salisbury, United Kingdom.

The manufacture of a lymphoblastoid cell line from a single donor blood sample is a means of securing a permanent, expandable and renewable source of genetic and other cellular material. Once a single donor cell bank is available, study material can be widely distributed and will be available many years after the initial study for follow-on studies that may not have been originally anticipated, or which may not be possible with existing technologies. In many respects a cell bank can be regarded as a means of immortalising a very valuable study cohort and is the soundest means of underpinning a biobank and maximising its value in the long term. However, the majority of biobanks participating in organisations such as the Public Population Project in Genomics (P3G) Consortium do not currently store samples for future cell line generation.

ECACC Human Genetic Services has approximately twenty years experience in providing strategic support to genetic research throughout the UK and Europe, through the provision of a blood processing and EBV transformation and cell banking service.

In this presentation we describe the development of a new process for the generation of EBV transformed lymphoblastoid cell lines from cryopreserved aliquots of whole blood which represents a cost effective alternative to current methods involving separated peripheral blood lymphocytes.

P07.083**No significant contribution between M470V and 5T polymorphisms and cystic fibrosis phenotype in Iranian patients**F. Mirzajani¹, F. Mirfakhraie², F. Asad³, M. Raftae⁴, H. R. Kianifar⁵;¹National Institute for Genetic Engineering & Biotechnology, Tehran, Islamic Republic of Iran, ²Shahid Beheshti Medical University, Tehran, Islamic Republic of Iran, ³Islamic Azad University of Tehran, Science & Research Campus, Tehran, Islamic Republic of Iran, ⁴Tabriz Children Hospital, Tabriz, Islamic Republic of Iran, ⁵Ghaem Children Hospital, Mashad, Islamic Republic of Iran.

The most common CFTR polymorphism, M470V, has been shown to be relatively frequent among Iranian Cystic Fibrosis patients. Whether M470V polymorphism and 5T variant have CF causing contribution in Iranian population is not clear yet and it may increase difficulties in genetic counseling. In order to compare the frequencies of these variations, 100 CFTR alleles from normal controls and symptomatic Iranian CF patients were analyzed for the presence of 5T and M470V polymorphisms using PCR-RFLP method. The frequencies obtained for M470V and 5T variants were almost the same in the studied groups, suggesting that these two polymorphisms do not have strong indication of being a disease causing polymorphism. The variation in distribution of such common polymorphisms among very diverse Iranian population deserves more investigation with higher number of samples.

P07.084**Male infertility induced by mtDNA/Y unfavorable combination? An association study on human mitochondrial DNA**S. C. Gomes¹, S. Fernandes², R. Gonçalves¹, A. T. Fernandes¹, A. Barros³, H. Geadá⁴, A. Brehm¹;¹Human Genetics Laboratory, University of Madeira, Funchal, Portugal, ²Genetics Department, Faculty of Medicine, University of Porto, Porto, Portugal, ³Centre of Reproductive Genetics A Barros, Porto, Portugal, ⁴Faculty of Medicine,

University of Lisbon, Lisboa, Portugal.

There is growing evidence that certain mtDNA haplogroups determine a genetic susceptibility to various disorders bringing out the interest in the possible role of mtDNA background on the phenotype expression of mitochondrial genetic disorders. An association between haplogroup T and asthenospermia has been reported and several sub-lineages of haplogroup U were associated with differences in sperm motility and vitality. The deletion of some DAZ copies gene in 10-15% of azoospermic and oligospermic patients has been reported but also present in fertile men belonging to certain Y-haplogroups. The findings of one study have rarely been replicated by studies in other populations and conflicting associations have been reported. Our focus in this case-control study is to investigate the existence of other influences, besides a weak mtDNA background, promoting male infertility. The occurrence of a specific mtDNA variant associated to a certain Y-chromosome haplogroup could represent a vital link that will compromise the sperm function and be responsible for male infertility. A group of 99 infertile men and other one composed by 90 subjects with proven fertility were selected and analysed. The frequency of the combination mtDNA-haplogroup H (especially with the CRS sequence) and Y-haplogroup R was higher in fertile than in infertile men seemingly to be favorable to fertility. On the other hand, a considerable number of infertile men belonging to mtDNA-haplogroup H (CRS) and to Y-haplogroup I, associated to a specific DAZ gene deletion pattern- 2+4d, suggests a non favorable combination to male fertility.

P07.085

Genetic risks factors for melanoma development in Latin America

F. Cuellar^{1,2}, A. Larre-Borges^{3,4}, B. Carlos^{5,6}, J. Puig-Butille^{1,2}, V. Godinez^{7,6}, J. Salas^{8,6}, Z. Ogbah^{1,2}, J. Malveyh^{1,2}, S. Puig^{1,2};

¹Hospital Clinic, IDIBAPS, Barcelona, Spain, ²GenoMEL, Barcelona, Spain, ³Hospital de Clinicas, Montevideo, Uruguay, ⁴GenoMEL, Latinamerica, Uruguay, ⁵Centro Medico Nacional IMSS, Mexico City, Mexico, ⁶GenoMEL, Latinamerica, Mexico, ⁷Facultad de Medicina UNAM, Mexico city, Mexico, ⁸Hospital Universitario UANL, Monterrey, Mexico.

Introduction: Genetics of Melanoma network (GenoMEL) is focused in melanoma genetic susceptibility in Europe, Australia, North America and Israel. Nowadays GenoMEL is obtaining samples and data from Latin America.

Objective: To Study well-known genes for melanoma (MM) susceptibility (*CDKN2A/p14arf*, *CDK4*, *MC1R*) in familial and multiple primary MM in Latin America.

Methods: In a total period of three years (2001-2009) patients with genetic susceptibility for MM from Latin America.

Results: Until now we have analysed 16 pedigrees (25 individuals) from Mexican and Uruguayan pedigrees and identified the I49T, M52T *CDKN2A* mutations in Mexico and E88X, -34G>T, G101W in Uruguay. The percentage of *CDKN2A* mutation was 100% in families with 4 MM cases (1/1 family), 25% in 3 MM (1/4), 55.5% in 2 MM (5/9), and no mutation in 2 MPM without familial history.

Conclusion: *CDKN2A* mutations are responsible of MM susceptibility in familial MM in Latin America. *CDKN2A* mutations with founder effect (G101W, -34G>T) were detected in Uruguay. Nonsense germline E88X *CDKN2A* mutation was detected in two unrelated Uruguayan families. M52T mutation detected in Mexico was not previously described. One MPM Mexican patient was believed homozygote for I49T by sequencing but later MLPA showed deleted exon 1 alfa.

P07.086

Variants in the Vitamin D Receptor Gene and Melanoma Etiology

L. P. Fernandez¹, E. Barroso¹, R. L. Milne¹, G. Pita¹, M. Tanic¹, J. A. Aviles², P. Lazaro², J. Benitez¹, G. Ribas¹;

¹Spanish National Cancer Research Centre (CNIO), Madrid, Spain, ²Hospital Gregorio Marañón, Madrid, Spain.

The aetiology of malignant melanoma (MM) remains unclear but it is known that both genetic and environmental factors influence the development of sporadic disease. The main reason for the increasing incidence of MM in the general population is greater sun exposure. Epidemiologic studies confirm that UV radiation is the main factor involved in the pathogenesis of the disease. Among phenotypic factors, fair pigmentation and low tanning ability are the most important risk factors. In recent years there has been an increasing interest in the

role of vitamin D and its active metabolites in MM susceptibility. Sunlight induces production of vitamin D that has been associated with antiproliferative and pro-differentiative effects in both melanocytes and cutaneous melanoma cells mediated through the vitamin D receptor. In this study we explore the interaction between sunlight exposure and vitamin D receptor gene polymorphisms in the etiology of MM.

This case-control study included 131 consecutive Spanish MM patients from the Dermatology Unit of the Gregorio Marañón Hospital and 245 control subjects frequency matched for sex and age. Phenotypic information was collected using a standardized questionnaire.

Four SNPs in the vitamin D receptor gene (VDR) were genotyped. SNPs on exons or in the putative promoter region were selected. We were able to identify several individual SNPs and haplotypes associated with tumoral characteristics such as breslow index and melanoma location. We also discuss the role of VDR variants as possible markers for MM and its aggressiveness.

P07.087

An Empirical Comparison of Meta-Analyses of Published Gene-Disease Associations Versus Consortium Analyses

A. C. J. W. Janssens¹, A. M. González-Zuloeta Ladd¹, S. López-Léon¹, J. P. A. Ioannidis², B. A. Oostra¹, M. J. Khoury³, C. M. van Duijn¹;

¹Erasmus MC, Rotterdam, The Netherlands, ²University of Ioannina School of Medicine, Ioannina, Greece, ³Centers for Disease Control and Prevention, Atlanta, GA, United States.

Background: Consortia of investigators currently compile sufficiently large sample sizes to investigate the effects of low-risk susceptibility genetic variants. It is not clear how the results obtained by consortia compare with those derived from meta-analyses of published studies. We performed meta-analyses of published data for 16 genetic polymorphisms investigated by the Breast Cancer Association Consortium and compared sample sizes, heterogeneity, and effect sizes.

Methods and findings: PubMed, Web of Science, and HuGENet databases were searched for breast cancer case-control association studies. Summary odds ratios (ORs) and 95% confidence intervals were calculated for three genetic models (homozygotes, heterozygotes, and per-allele comparisons), using random effects analyses. The strength of the epidemiological evidence was evaluated on the basis of recently proposed criteria. We found that meta-analyses of published data and consortium analyses were substantially based on different data. Published data by non-consortium teams amounted on average to 26.9% of all available data (range 3.0%-50.0%). The correlation coefficient of the I2 heterogeneity estimates of the two approaches was 0.47 (p=0.001), and that of the OR estimates was 0.44 (p=0.002). The meta-analyses of published data and the consortium analyses both showed statistically significant decreased breast cancer risks for CASP8 D302H, and all meta-analyses were graded as having "strong" evidence.

Conclusion: Meta-analysis of published gene-disease associations may still have an important role in the synthesis of knowledge on the genetic basis of human diseases. The expense and complexity of consortium-based studies should be considered vis-à-vis the potential methodological limitations of synthesis of published studies.

P07.088

Recessive congenital methemoglobinemia type I in Yakutia: the frequency of disease gene and age of the mutation

N. Galeeva, V. Spitsin, A. Polyakov;

Research Centre for Medical Genetics, Moscow, Russian Federation.

Recessive congenital methemoglobinemia (RCM) type I is defined by cyanosis due to methemoglobinemia and an isolated deficiency of NADH-cytochrome b5 reductase (b5R) in erythrocyte. This disease is rare in the world but frequent in Sakha Republic (Yakutia) of Russia. In research based on clinical evidence frequency of RCM in Yakutia amounted to 1:5677.

In previously investigation has been showed that all RCM cases here were caused by single mutation c.806 C>T in *DIA1* gene that suggested presence founder effect for this disease in Yakutia. Allelic frequency of the mutation amounted to 0.025 and calculated frequency of disease amounted to 1:1600.

The date of diffusion of the mutation has been calculated by linkage disequilibrium between disease locus and markers closed to it. The age of mutation is approximately 310 years.

P07.089

Population genetics study of three Microsatellite Markers (D3S1358, TH01 and FGA) in two Romanian groups and their genetic relationships to European populationsA. Rodewald¹, A. Kroll¹, G. Cardos^{2,3}, C. Tesio³, C. Tesio³, D. Banica⁴;¹Department of Human Biology of University, Hamburg, Germany, ²"Victor Babes" National Institute, Bucharest, Romania, ³Faculty of Biology, University of Bucharest, Bucharest, Romania, ⁴"Marius Nasta" Institute of Pulmonary Diseases, Bucharest, Romania.

In this study three different DNA-Microsatellites (D3S1358, TH01 and FGA) have been analysed in a sample of 200 individuals from the Romanian capital Bucharest; this data was compared with the data from a sample of 110 individuals from Prahova Valley (Carpathian Mountains) and with other European, Asian and African populations. Further, we investigated the possible extent of genetic influences by migrations of European neighbour populations on the Romanian genetic pool.

The results reveal that there were not any significant differences in the allele frequencies from the three microsatellite markers between the panmictic population of Bucharest and the slight isolated population from Prahova Valley.

Genetic distance analysis showed a close genetic relationship with Greek population as well as Slavic populations from Poland and Slovenia.

Historically this could be the result of intense trading activities of old Thracian and Daco-Gethic tribal groups from Romanian territory and Greek population groups, who established trading colonies at the west coast of the Black Sea (actually East-Romania) during the 6th-8th century. The Slavic influence is thought to be the result of the migrations of Slavic groups in the 6th-9th century across the Danube and Carpathian regions.

The study showed a more significant genetic distance from Romanian populations to the Croatian, Austrian, Hungarian and German populations.

This data can also be used for paternity and forensic analyses in the Romanian population.

P07.090

Evolutionary process of disease-associated oligonucleotide repeats until their expansion in humansS. Martins¹, V. C. N. Wong², P. Coutinho³, J. Sequeiros^{4,5}, A. Amorim^{1,6};¹IPATIMUP, Porto, Portugal, ²Dept Paediatrics and Adolescent Medicine, The Univ of Hong-Kong, Hong-Kong, China, ³Hosp S Sebastião, Santa Maria da Feira, Portugal, ⁴IBMC- Instituto de Biologia Molecular e Celular, Porto, Portugal, ⁵ICBAS, Porto, Portugal, ⁶Fac Ciências, Univ Porto, Porto, Portugal.

More than 40 neurological and neuromuscular disorders have been identified as caused by the expansion of repetitive sequences. The study of these *loci* over an evolutionary timescale becomes especially relevant to understand better the mechanisms behind these human-specific pathogenic expansions. In a previous study of the *ATXN3* locus, responsible for Machado-Joseph disease, we found evidence for an alternative, multi-step mechanism promoting allelic variation within the normal range, either by slippage replication of multiple CAGs or gene conversion. To gain insight into the wild-type alleles that might have been involved in the expansion process, we have now compared the flanking STR-backgrounds of different normal-sized alleles with the ancestral expanded haplotypes from the same SNP-based lineage, in 67 MJD families (42 from the GTGGCA and 25 from the TTACAC haplotypes), analysed as before. Pairwise comparisons did not show a direct correlation between the size of wild-type haplotypes and its genetic distance to expanded alleles. For lineage TTACAC, the genetic background of expanded alleles was identical to those with 20 and 28 CAGs ($R_{ST}=0$); for GTGGCA, a close relationship was found between expanded chromosomes and (CAG)₂₃ and (CAG)₂₇ alleles. These results led us to propose the possibility of a multi-step mutational mechanism, underlying also the process of *de novo* expansions in MJD. Assuming that similar mechanisms may be driving other repetitive tracts, we plan to study the evolutionary dynamics at the *ATXN1*, *DRPLA*, *ATXN7*, *KLHL1AS*, *PPP2R2B*, *TBP*, and *FMR1* loci. Selection was based on different allelic distribution, consensus motif and repeat configuration.

P07.091

On the epidemiology of the *MTHFR*-C677T gene variant in Mexico: A multiregional and multiethnic study

O. M. Mutchinick, M. A. López, B. E. Sánchez;

Instituto Nacional de Ciencias Médicas y Nutrición, México, D.F., Mexico.

It is well known the worldwide prevalence differences of the *MTHFR* gene C677T variant. Also is well known that the homozygous for the T allele, produce a deficient metylenetetrahydrofolate reductase enzyme with less than 50% activity, being this considered a risk factor for some birth defects, cardiovascular disease, thrombosis and cancer, among other health problems. In 1999 we reported a very high T allele prevalence in adult healthy Mexican female sample.

Herein we report the allelic and genotypic prevalence of the *MTHFR*-C677T variant found in 800 healthy newborns (HNB) from eight different provinces of the North, East, West, Centre and South and 440 indigenous people from five different ethnic groups (DEG) of the country.

In HNB the T allele prevalence and TT genotype range from 0.37% to as high as 0.71% and from 17.0% to 52.0% respectively, with a clear North to Southeast increasing gradient. In the DEG, remarkable differences were also observed, with the lower T allele (0.58%) and TT genotype (33.3%) prevalence in *Tojolabales* Indians, to the highest prevalence of 0.81% and 68.6%, in the *Mazateco* ethnic group. The same was observed when HNB from distinct provinces were compared. All groups studied were in Hardy-Weinberg equilibrium. The higher prevalence of the T allele in HNB in the Southeast provinces concurs with the natural setting of the ethnic groups studied. Our findings suggest that the very high prevalence of the T allele and TT genotype observed may be the result of inbreeding and advantage selection of the variant.

P07.092

Mutation 35delG and M34T screening in *GJB2* (connexin 26 gene) in Estonian populationR. Teek^{1,2}, T. Temberg², M. Kõiv², E. Raukas², N. Tõnisson², M. Kull¹, K. Õunap^{2,3};¹Department of Oto-Rhino-Laryngology, University of Tartu, Tartu, Estonia,²Department of Genetics, United Laboratories, Tartu University Hospital, Tartu,Estonia, ³Department of Pediatrics, University of Tartu, Tartu, Estonia.

Hearing loss is the most common sensory disorder worldwide. Mutations in *GJB2* (connexin 26) gene are a major cause of autosomal-recessive non-syndromic hearing loss in Caucasian population. Mutation 35delG in this gene is the most common cause for early onset hearing loss. The purpose of our study was to find out the carrier frequency of 35delG and M34T mutation among Estonian population.

We have screened 524 consecutively born neonates (the investigation is planned for up to 1000 newborns born in one month in whole Estonia). Our study uses anonymous random samples of dried blood spots on Guthrie cards from mass newborn screening program. We've found one homozygote and 29 heterozygotes for 35delG mutation. We've also detected 31 heterozygotes for M34T mutation, but no M34T homozygote so far. The carrier frequency for 35delG was 1 in 18 and 1 in 17 for M34T. The theoretical incidence of homozygotes for 35delG is 1:1296 and 1:1156 for M34T. Previous studies have shown 1 in 35 35delG carrier frequency in South-Europe, 1 in 79 Central and Northern Europe, and 1 in 22,5 in Estonia on 113 samples only (Gasparini *et al.*, 2000). Our study shows similarly the high carrier frequency of mutation 35delG among Estonian newborns. The incidence of mutation M34T is similar to mutation 35delG and it correlates well with results of our patients with early onset hearing loss. M34T is the second frequent mutation in our patient group.

P07.093

Physiological splicing variants in the *NIPBL* gene

B. Puisac, M. Ciero, M. C. Gil, M. Arnedo, M. P. Ribate, J. C. de Karam, J. Gomes, S. Menao, A. Pie, F. J. Ramos, J. Pie;

University of Zaragoza Medical School, Zaragoza, Spain.

Mutations in a regulator of the cohesin complex, the *NIPBL* gene, located in 5p13.1, are responsible for Cornelia de Lange Syndrome 1 (CDLS1, MIM 122470). CdLS is an inherited multisystem developmental disorder characterized by distinctive dysmorphic facial features,

growth and cognitive impairment, limb malformations and occasional multiple organ defects. The NIPBL gene encompasses 47 exons and produces a 9.5 kb transcript, which appears in several tissues with different level of expression. Besides, the identification of multiple transcripts in this gene suggest the presence of alternative splicing, a feature that has not been yet studied. Here, we report the first systematic analysis of the NIPBL splicing variants in human normal tissues.

NIPBL cDNA from adult brain, fetal skeletal muscle and leukocytes was amplified in various overlapping fragments, spanning exons 1 to 47. PCR products were separated by electrophoresis on agarose gel. Additional bands of different length than expected were sequenced. Several novel splicing variants bearing one or more skipped exons were found, but only the variant with skipped exon 12 was found in all tissues analyzed. This finding was subsequently confirmed by cloning. The variant with deletion of exon 43 was present only in adult brain. Our results provide a basis for more detailed studies of functional significance of these transcripts and might expand our knowledge of CDLS1.

This work is supported by a grant from the Ministry of Health of Spain (Ref. PI061343) and from the Diputación General de Aragón (Ref. B20).

P07.094

NOTCH3 mutations in young adult patients with a first stroke: The PORTYSTROKE study - screening genetic conditions in Portuguese Young STROKE patients

S. Ferreira¹, M. Viana-Baptista², I. Costa³, J. M. Ferro⁴, J. P. Oliveira³, & PORTYSTROKE Study Group⁵;

¹Faculdade de Medicina, Porto, Portugal, ²Hospital Garcia de Orta, Almada, Portugal, ³Faculty of Medicine, Porto, Portugal, ⁴Hospital Santa Maria, Lisboa, Portugal, ⁵(NA), (NA), Portugal.

Background

Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy (CADASIL), a genetic disorder due to mutations in the *NOTCH3* gene, is associated with early onset of small-vessel ischaemic cerebrovascular disease. The clinical spectrum of CADASIL varies widely and the disease is probably under-diagnosed in stroke patients.

Methods

Between 1/November/06 and 31/October/07, all patients aged 18-55 years presenting with a first stroke event to any of 12 major neurology hospital departments in Portugal were offered genetic screening for CADASIL. Strokes were classified according to usual clinical and brain imaging criteria. Mutational analysis was limited to PCR amplification and sequencing of *NOTCH3* exons 4, 11, 18/19, as these have been previously shown to contain ~80% of the mutations identified in Portuguese patients with CADASIL.

Results

Out of a total of 625 eligible patients, 493 (78.9%) consented to the genetic analysis. Of these, 74% had ischaemic strokes, of which 28.5% were cryptogenic. Seven different missense mutations in the *NOTCH3* gene were found in 8 patients (prevalence=1.6%; 95%CI: 0.8-3.1%): p.R163W; p.P167S; p.T577A; p.G595S; p.S978R (n=2); p.H981Y; p.R1036Q. There was no significant association with any particular type of stroke. None of these patients had a previous diagnosis or family history of CADASIL.

Conclusion

The minimal estimate for the prevalence of *NOTCH3* mutations among Portuguese young adults presenting with first stroke is at least 1000 times higher than the estimated population prevalence of CADASIL. The spectrum of pathogenic *NOTCH3* mutations may be more varied than previously recognised.

P07.095

Neuropeptide Y gene variation and association with alcohol consumption in a Spanish Mediterranean population

F. Frances, J. V. Sorli, O. Portolés, P. Guillem-Sáiz, J. I. González, D. Corella; Preventive Medicine Dept. and CIBER obn, Valencia, Spain.

Background and objective: Neuropeptide Y (NPY) is a neurotransmitter widely distributed in the central nervous system. Both intraamygdalar injection and overexpression experiments in animals have demonstrated that increases of NPY in the amygdala reduces alcohol

intake and anxiety manifestations in anxious rats. In humans, some studies have associated the Leu7Pro polymorphism in the NPY with alcohol consumption, but the evidence is scarce. In the Spanish Mediterranean population, the Leu7Pro variant is not polymorphic. Thus, our aim was to identify novel exonic variants in the NPY as well as the study previously described intronic variants, and their association with alcohol consumption in this population.

Methods: 911 subjects (321 men and 590 women) from the Spanish Mediterranean population were recruited. Alcohol consumption and demographic and lifestyle variables were measured. Nucleotide sequence determination and SNP analyses were carried out.

Results: Only one exonic SNP was detected by direct sequencing (1258G>A or rs9785023; allele frequency 0.47). From the intronic markers chosen (483A>G or rs13235938, 2517A>G or rs4722342 and 7065A>G or rs 4722343), only the last ones were polymorphic (allele frequencies 0.46 and 0.40 respectively), and none of them were associated with alcohol consumption. However, the 1258G>A SNP was associated (recessive pattern) with higher alcohol intake in drinkers. This association was particularly relevant in men with a moderate intake (40±9 g/d in GG, 41±8 g/d in GA and 59±5 g/day in AA; p<0.05).

Conclusions: The 1258G>A in the NPY is associated with alcohol consumption in the Mediterranean population.

P07.096

Splitting of large and complex pedigrees for linkage analysis of quantitative traits

A. V. Kirichenko, T. I. Axenovich;

Institute of Cytology and Genetics, Russian Academy of Science, Novosibirsk, Russian Federation.

Pedigree splitting is applied when large pedigrees are used for linkage analysis. Several algorithms of pedigree splitting have been proposed. They are adapted to MCMC, but not to Lander-Green based methods. The latter methods are sensitive to the pedigree size. None of the existing methods restrict the fragment size, and thus, they do not guarantee that all of the resultant sub-pedigrees can be efficiently analyzed by the Lander-Green algorithm. Earlier we proposed a fast automatic algorithm for splitting large pedigrees for subsequent Lander-Green based analysis (Liu et al, 2008). The algorithm is specifically aimed to deal with pedigrees obtained in disease-oriented studies in genetically isolated populations, where affected individuals are remotely related to each other through multiple lines of descent.

In contrast to pedigrees with rare diseases, in the pedigrees collected for quantitative trait analysis many close relatives having measured phenotypes and genotypes are considered as individuals of interest. We present a graph theory based algorithm for automatic splitting such pedigrees on the fragments of restricted size. This algorithm iteratively selects the clique with maximum weight of its edges from the cliques of restricted size. Weight of edge is defined as kinship between two individuals corresponding to clique nodes. The algorithm is implemented in a software package PedStr (<http://mga.bionet.nsc.ru/soft/index.html>).

We compared our program PedStr and the Greffa (Falchi et al, 2004) program and demonstrated that linkage power calculated on the base of sub-pedigrees obtained by PedStr was higher than for sub-pedigrees obtained by Greffa.

P07.097

Association of interleukin-1 polymorphisms with periodontal disease in mentally retarded

F. S. Bayoumi, E. H. A. Abouel-Ezz, H. M. Goumaa;

National Research Center, Cairo, Egypt.

Association between Interleukin (IL-1) gene polymorphisms & increased susceptibility to periodontitis were suggested. The intent of this study was determining prevalence of IL-1 α & β genotype polymorphisms among normal & mentally retarded Egyptian individuals.

Thirty normal volunteers (NV) (15-30 y) & 25 mentally retarded individuals (MR) (6-16 y) were subjected to dental examination with recording Gingival index scores (GI). IL-1 α and IL-1 β loci were genotyped by standard PCR restriction fragment length polymorphism assay. Ten of (NV) showed good GI scores (70% were healthy & 30% had initial periodontitis); The remaining (20) had fair GI score (15% with initial periodontitis, 35% had moderate periodontitis & 50% with severe

periodontitis); among these individuals, 30% were genotyped positive for IL-1 (26.6% were genotyped positive for IL-1 α & 3.3% for IL-1 β). Non (MR) had good GI score while 13 were fair GI (23.1% had initial periodontitis, 53.8% with moderate periodontitis & 23.1% with severe periodontitis) & the rest (12) had bad GI score (41.7% had moderate periodontitis & 58.3% had severe periodontitis). From all MR 36% were genotyped positive for IL-1 (24% were genotyped positive for IL-1 α and 12% for IL-1 β).

Data concluded the important role of polymorphism in genes of IL-1 (IL-1 α (+4845) & IL-1 β (+3953)) alleles presence with periodontitis either in normal or MR individuals & recommended their detection to determine patient's susceptibility for periodontitis. Evaluation of role of other potential candidate genes as contributors to periodontitis are needed.

P07.098

Frequency of the R229Q NPHS2 functional variant, associated with increased risk for microalbuminuria, in Bulgarian Roma population

O. Belcheva¹, P. Botev¹, B. Zaharova², A. Savov², R. Kaneva¹, I. Kremensky²; ¹Molecular Medicine Center, Medical University, Sofia, Bulgaria, ²National Genetics Laboratory, Medical University, Sofia, Bulgaria.

The cardio-vascular diseases are one of the leading causes for morbidity and mortality in the Western societies. Their major social and health-care system impact warrants the extensive efforts for identification of the genetic factors contributing to the predisposition to cardiovascular events. Microalbuminuria, defined as urine albumin-to-creatinine ratio of 0.03 to 0.299 mg/mg, is one of the recently recognised factors associated with increased risk of developing cardiovascular disorders in the general population. Multiple genetic epidemiological studies have shown that there are genetic causes associated with predisposition to the excretion of abnormal amounts of albumin in the urine. One of these is the R229Q functional variant in the podocin gene, NPHS2. Pereira and co-authors have shown that R229Q is associated with a 2.77-fold risk for developing microalbuminuric state even after adjustment for age, ethnicity, hypertension, obesity, and diabetes (Pereira et al., 2004). Since the distribution of this NPHS2 variant in the general population differs depending on ethnicity, we wanted to evaluate its frequency among Bulgarian Roma - an isolated population, with unique genetic background. We genotyped Roma and Bulgarian population control samples from the collection of the National Genetics Laboratory and the Molecular Medicine Center. Our results indicated that the allele frequency of the R229Q variant in Roma (3.4%; number of alleles, n=204) was not significantly different from the one we saw in Bulgarians (1.3%; n=238) and from that previously shown for Caucasians (3%, Franceschini et al. 2006).

Investigation of the polymorphism of eight genes among Russian population

S. E. Khalchitsky¹, M. O. Mkheidze²;

¹Saint-Petersburg Scientific research institute of physical culture, St. Petersburg, Russian Federation, ²Medical Academy for postgraduate study, St. Petersburg, Russian Federation.

Investigation of the polymorphic human genes sheds light on genetic structure of the different populations. Our study included eight polymorphic genes (CNB, NFATC4, PGC1A, PGC1B, TFAM, VEGF, UCP2, and UCP3). Well-known standard methods for DNA analysis were used. The study population consisted of 1057 residents of Russian Federation (female individuals - 574 aged from 16 to 19 yr, male individuals - 483 aged from 17 to 20 yr). Rates of alleles investigated are the following: CNB I - 91.5 per cent, NFATC4 Gly - 43.6 per cent, PGC1A Gly - 64.9 per cent, PGC1B Pro - 4.9 per cent, TFAM Thr - 9.1 per cent, VEGF C - 24.5, UCP2 Val - 36.4 per cent and UCP3 T - 23.8 per cent

P07.100

Associations between serotonin transporter gene SLC6A4 polymorphism and level of intellectual development (IQ) of the person

O. Gumerova, E. V. Lekontsev, V. Y. Gorbunova;

Bashkir State Pedagogical University it. M. Akmulla, Ufa, Russian Federation.

INTRODUCTION: Serotonin transporter gene SLC6A4 (17q11.1-12) is one of the basic genes, which define an overall performance of serotonergic neuromediators system. Its functional condition can be reflected on some aspects of intellectual activity of the person.

METHODS: The level of intellectual development (IQ) is certain at 250 unrelated individuals in the age of 18-35 years by nonverbal Kettel test.

According to parameters IQ examinees are divided into three groups: with a normal level of intellectual development (IQ within the limits of 90-110 points), high (above 110 points) and low (below 90 points). The analysis of genetic polymorphism 5-HTTLPR is carried out by a method PCR. RESULTS: Genotypes 1)*L*/L, 2)*L*/S, 3)*S*/S met frequency 1) 28%, 2) 42%, 3) 30% in group of comparison, 1) 21.4%, 2) 59.5%, 3) 19.1% in group with high parameters IQ and 1) 33.3%, 2) 41.67%, 3) 25% in group with low level IQ. The analysis of associations has shown statistically significant distinctions in distribution of frequencies genotypes of gene SLC6A4 between group of comparison and group with high parameters IQ ($\chi^2=8.313$; $P=0.017$), owing to increase of frequency of genotype SLC6A4*L*/S (59.5% against 42% in group of comparison; $P=0.030$; OR=1.418; 95%CI 1.069-1.836) in group of persons with high parameters IQ.

It is known, that the presence in genotype of allele SLC6A4*L provides high level expression of serotonin transporter gene and the high intensity of metabolism of serotonin, that is accelerating the process of pulse transmission through carrying intensification of serotonin from synaptic trough in presynaps.

P07.101

Genetic variation at nine STR loci in Russian Siberian population

O. Odinokova;

Institute of Medical Genetics, Tomsk, Russian Federation.

STR loci represent a rich source of highly polymorphic markers for medical, forensic and population studies. There are notable differences in allele frequencies and heterozygosities between population groups. We present here characteristics of the allelic polymorphism for nine STRs loci: D7S820, D3S1358, D5S818, D13S317, HumVWA, HumTHO1, HumF13B, HumLPL and HumCD4 in Russians (Caucasians) living in South-West Siberia.

Allele typing was performed using PCR and subsequent high-resolution PAAG electrophoresis. We have analysed 320-378 DNA samples from unrelated individuals for each STR-system. Nine alleles were identified in HumVWA (13-21 repeats, 139-171 bp), D5S818 (7-15 repeats, 134-166 bp) loci; eight alleles were noted in D3S1358 (13-20 repeats, 118-146 bp), D13S317 (8-15 repeats, 169-197 bp), HumTHO1 (5-11 and 9.3 repeats, 179-203 bp), HumCD4 (7-14 repeats, 130-165 bp) loci, and seven alleles - in D7S820 (7-13 repeats, 219-243 bp), HumF13B (6-12 repeats, 169-193 bp) and HumLPL (8-14 repeats, 109-133 bp) loci. The frequency data obtained can be used for comparison to other populations.

Genotype frequency distributions were consistent with Hardy-Weinberg equilibrium for every STR-systems. The levels of observed heterozygosity were high: 0,842 (HumTHO1), 0,828 (D13S317), 0,813-0,812 (HumVWA, D7S820), 0,778-0,770 (D3S1358, D5S818), 0,701 (HumCD4), 0,694 (HumF13B) and 0,666 (HumLPL).

Polymorphism information content (PIC), discrimination power (pD), power of exclusion (W) and matching probability (pM) were performed for each locus as indicators of their discrimination potential in human identification and paternity analysis. Forensic efficiency data suggest that investigated markers are very discriminating in Russian Siberian population.

P07.102**Comparative studying of polymorphism 3' UTR genes-candidates multifactorial diseases in the Siberian populations**

N. P. Babushkina, L. A. Koneva, A. A. Rudko, E. Y. Bragina, A. N. Kucher, V. P. Puzyrev;

Institute of Medical Genetics, Tomsk, Russian Federation.

Polymorphisms in 3' UTR in *TNFR* (rs36188382), *IL4RA* (rs2074570), *IL12B* (rs3212227), *IL12RB1* (rs3746190) and *IL12A* (rs568408) have been studied in several Siberian populations (Russians, Buryats, Tuvinians, Yakuts, 383 individuals in total). Deletion in 3' UTR gene *TNFR* has not been revealed in all investigated groups. This can suggest that the deletion has either very low polymorphism level, or it is a mutation. For other loci, Hardy-Weinberg equilibrium was observed for all genes except *IL12A* (rs568408) in Buryats (heterozygotes excess). Russians vs all other (Mongoloid) ethnic groups have shown significant differences in allele frequencies of three SNPs: in Russians, minor allele frequencies were 0.042, 0.229, 0.189 for *IL4RA*, *IL12A*, *IL12B* accordingly, where as in Buryats they were 0.105, 0.195, 0.380; in Tuvinians 0.109, 0.292, 0.359; in Yakuts 0.177, 0.174, 0.286. The maximum difference was observed between Russians and Yakuts and minimum difference was between Tuvinians and Buryats. In contrast, locus *IL12RB1* (rs3746190) has shown maximum differences between Tuvinians and Buryats (minor allele frequency 0.495 and 0.274 accordingly). This is additional evidence once again about complex ethnogeny and different contributions of European and Asian components in their gene pools.

P07.103**The analysis of CFTR mutation frequencies in different populations of Russia**

N. V. Petrova, E. E. Timkovskaya, R. A. Zinchenko;

Research Center for Medical Genetics, Moscow, Russian Federation.

3739 healthy donors from eight regions of European part of Russian Federation were analyzed for seven CFTR mutations (CFTRdele2,3(21kb), F508del, 1677delTA, 2143delT, 2184insA, 394delTT, 3821delT) accounted for 67% of CF alleles. 15 carriers of F508del mutation, 1 carrier of CFTRdele2,3(21kb) mutation and 1 1677delTA carrier were identified in the samples of 1324 Russians from Rostov, Tver, Pskov and Kirov provinces. Three F508del carriers and one CFTRdele2,3(21kb) carrier were revealed among 780 Chuvashes from Chuvashia, two F508del carriers - among 613 Udmurts from Udmurtia and one CFTRdele2,3(21kb) carrier - in 517 Bashkirs from Bashkortostan. In the sample of 505 Maris from Mary El none of the analyzed CFTR mutations was found. The population frequency of F508del mutation is 0,00525 (0,00401÷0,00676) in Russians from European region, 0,00112 (0,00006÷0,00530) in Udmurts, 0,00192 (0,00052÷0,00496) in Chuvashes, low than 0,00458 in Bashkirs and low than 0,00296 in Maris. The differences in F508del mutation frequencies between Russians and Maris, Russians and Chuvashes, Russians and Bashkirs are significant at 5% degree, between Russians and Udmurts - at 10% degree.

P07.104**L162V polymorphism of PPAR-alpha gene in patients with abdominal obesity**

O. D. Belyaeva¹, **A. E. Garanina¹**, V. V. Ugnolnikov¹, O. A. Bercovich¹, V. I. Larionova²;

¹*IP Pavlov State Medical University of Saint-Petersburg, Saint-Petersburg, Russian Federation*, ²*State Pediatric Medical Academy of Saint-Petersburg, Saint-Petersburg, Russian Federation.*

Aim. To evaluate the frequency of V162 allele of PPAR- α gene and determine the distribution of L162V genotypes in patients with abdominal obesity.

Methods. 26 males (BMI 30,58±0,80 kg/m², waist circumference (WC) 105,56±2,23 cm), 53 females (BMI 30,28±0,59 kg/m², WC 92,11±1,14 cm) entered the study (44,48±0,99 years). Genotypes were determined by polymerase chain reaction with subsequent restriction analysis. Biochemical components were measured by enzymatic methods.

Results. Polymorphisms were determined in 79 participants. The V162 allele frequency was 0,076. Plasma lipids, CRB, glucose, BMI and WC did not differ in man and woman regardless of PPAR- α genotype (woman: total cholesterol (tCh) 5,66±0,17, HDL 1,54±0,06 mmol/l, LDLP 3,80±0,17 mmol/l, TG 1,48±0,09 mmol/l, CRP 5,82±0,69 mg/l, glu-

cose 5,62±0,19, BMI 30,28±0,59 kg/m², WC 92,11±1,14 cm; man: tCh 6,24±0,25 mmol/l, HDL 1,24±0,08 mmol/l, LDLP 4,13±0,25 mmol/l, TG 3,17±0,86 mmol/l, CRP 6,82±2,62 mg/l, glucose 6,41±0,51 mmol/l).

Careers of V162 allele have higher tCh, LDLP and lower HDL values, but the difference did not reach statistical significance. The V162 carriers had higher glucose levels, but the difference did not reach statistical significance (LL162 - 5,93 mmol/l, LV162 - 5,41 mmol/l, $p > 0,05$). No difference between the genotypic groups was observed for CRP (LL162: 6,24±1,05 mg/l; LV162: 4,69±1,40 mg/l; $p > 0,05$).

Conclusion. The V162 allele frequency was 0,076, similar to that reported in ischemic heart disease and diabetes mellitus patients and healthy European man. No significant differences were observed between the presence of V162 allele and changes in blood lipids, glucose levels and body fatness measurements.

P07.105**Minor CYP1B1 involvement in the molecular basis of primary congenital glaucoma in Bulgarian Gypsies**

K. N. Kamenarova¹, P. Sivadova², S. Cheminkova³, S. Bouwer², D. Angellcheva², P. Seeman⁴, K. Hollingsworth⁵, V. Mihaylova⁶, A. Oscar³, G. Dimitrova³, R. Kaneva¹, I. Tournev³, L. Kalaydjieva²;

¹*Molecular Medicine Centre, Sofia, Bulgaria*, ²*Centre for Medical Research and WA Institute for Medical Research, The University of Western Australia, Perth, Australia*, ³*Department of Neurology and Department of Ophthalmology, Alexadrovsk Hospital, Medical University, Sofia, Bulgaria*, ⁴*Department of Child Neurology, 2nd School of Medicine, Charles University, Prague, Czech Republic*, ⁵*Neurodegenerative Disorders Centre, Queen Elizabeth II Medical Centre, Perth, Australia*, ⁶*Department of Neurology, Alexadrovsk Hospital, Medical University, Sofia, Bulgaria.*

Primary Congenital Glaucoma (PCG) is characterised by locus and allelic heterogeneity. Mutations in the cytochrome P450 1B1 (*CYP1B1*) gene contribute between 20-30% in cases from ethnically mixed populations and between 50-80% in populations where consanguinity is common. The Roma/Gypsies are considered to be a rare example of a founder *CYP1B1* mutation, with E387K (identified in a Slovak Roma), accounting for 100% of disease alleles. In the current study of 21 Gypsy PCG patients from Bulgaria and of 715 unscreened controls from the general Gypsy population unusual genetic heterogeneity was revealed. In the sample of affected subjects from 16 families, we identified five different *CYP1B1* mutations - four known (E229K, R368H, E387K and R390C) and one novel and potentially pathogenic (F445I), which together account for ~30% of disease alleles. Three of the mutations have been previously found in PCG patients from India. E387K was rare in both the patient and the control group (carrier rate 0.56%), indicating that its high frequency in the Slovak Roma is most likely a product of local founder effect. Sequencing of *MYOC* and genotyping polymorphisms linked to GLC3B and GLC3C did not support the involvement of these loci, previously implicated in PCG pathogenesis. The genetic basis of PCG in the Gypsies thus remains not completely resolved. The characteristics of the Gypsies as a founder population could facilitate the identification of novel unidentified PCG gene yet.

P07.106**Evaluation of a powerful screening tool for hereditary prosopagnosia**

I. Kennerknecht¹, H. Wang², T. Elze³, B. Welling⁴, V. Wong⁵, J. Liu⁶;

¹*Institute of Human Genetics, Westfälische Wilhelms-Universität Münster, Münster, Germany*, ²*Social Science Department, Chang Chun Taxation College, Jilin, China*, ³*Max Planck Institute for Mathematics in the Sciences, Leipzig, Germany*, ⁴*Institute of Human Genetics Westfälische Wilhelms-Universität Münster, Münster, Germany*, ⁵*Department of Paediatrics & Adolescent Medicine, The University of Hong Kong, Queen Mary Hospital, Hong Kong, China*, ⁶*State Key Laboratory of Cognitive Neuroscience and Learning, Beijing Normal University, Beijing, China.*

Prosopagnosia (PA) or face blindness is characterized by a highly selective impairment in recognition of faces. Longest and best known is the acquired form after e.g. brain injuries, strokes or atrophy of the right-occipito-temporal cortex. Recently, we could show that (1) the congenital form, in the absence of any traumatic event, is highly frequent, with a prevalence of around 2% worldwide, that (2) it almost always runs in families, and that (3) most surprisingly segregation pattern is fully compatible with autosomal dominant inheritance. We therefore coined the term hereditary PA (HPA, Kennerknecht et al.

2006 AJMG 140A1617ff).

Diagnosis of PA is generally established by in-depth testing with standardized test batteries for visual cognition. As these time consuming tests are not suitable for large scale screening, a questionnaire based screening was introduced. In a pilot study in India and Hong Kong we could show that only a few selected questions easily identify subjects highly suspicious for PA (Kennerknecht et al. 2007, JHG 52:230ff).

These tools were then applied at two Chinese Universities (Beijing Normal University, Chang Chun Taxation College). 2,000 questionnaires with a five-point-rating scale for 21 test items regarding facial and object recognition as well as some distractors were distributed. Those students with the highest scores were then invited for diagnostic interview. When starting with the highest scores, every 2nd student was a prosopagnosic. Among a total of 40 students who scored above 2 S.D. more than 1/4 (n=11, 27.5%) were prosopagnosics.

P07.107

A new approach concerning the registries for rare diseases

A. Tarniceru, M. Puiu, M. Serban;

University of Medicine and Pharmacy, Timisoara, Romania.

The registries for rare diseases follow to obtain epidemiological information useful to understand the dimension of the problem. Knowing the prevalence of rare diseases is an essential aspect for establishing the most adequate methods for detection, prevention and management to guide the health policy and the need for specialized personnel in different regions. In addition the registries for rare diseases represent data bases useful for research. It is necessary to ask for a well-informed consent which will allow using the recorded data in registers and also for future researches. The informed consent must be obtained after a previous preparation and notification of the patient and/or his family. In this way they will have all the information connected to the research in which they are involved: results, risks, limits and benefits.

The registries for rare diseases have to be adapted, the criteria and the tracking data have to be standardized in all European countries in order to have as many cases possible. For this reason it is absolutely necessary to create a new codification system approved by all countries, which will encode all known rare diseases.

P07.108

Genetic Characterization in 301 Spanish Families Affected by Autosomal Recessive Retinitis Pigmentosa

A. Avila-Fernandez, E. Vallespin, D. Cantalapiedra, R. Riveiro-Alvarez, J.

Aguirre-Lamban, A. Gimenez, M. Lopez-Martinez, I. Lorda-Sanchez, M. Trujillo-Tiebas, C. Ayuso;

Fundacion Jimenez Diaz-CIBERER, Madrid, Spain.

Introduction. Retinitis pigmentosa (RP) is a genetically heterogeneous disorder characterized by progressive loss of vision. We used a genotyping microarray (Asper) to study proved or possible recessive cases of RP, in order to optimise the molecular diagnosis of the disease.

Patients and Methods. 301 unrelated Spanish families containing 10 patients diagnosed as LCA, 96 as early onset Autosomal Recessive Retinitis Pigmentosa (onset <10 years of age) and 195 as non early-onset ARRP (onset >10 years of age). The families were also divided by genetic classification (138 autosomal recessive cases and 163 sporadic cases). All of them were analysed by a genotype microarray specific for arRP (Asper), which tested more than 500 mutations in 16 recessive RP genes: *CERKL*, *CNGA1*, *CNGB1*, *MERKT*, *PDE6A*, *PDE6B*, *PNR*, *RDH12*, *RGR*, *PLBP1*, *SAG*, *TULP1*, *CRB1*, *RPE65*, *USH2A* and *USH3A*.

Results. No mutation was found in LCA group. The mutation frequency was slightly higher in non early-onset (21,5%) than in early onset (16,6%) families but these differences weren't significant. The allele frequencies were: *CERKL* 2,9% (18/602), *CNGA1* 0,9% (6/602), *PDE6A* 0,6% (4/602), *PDE6B* 0,3% (2/602), *RLBP1* 0,3% (2/602), *SAG* 0,5% (3/602), *CRB1* 0,6% (4/602) and *USH2A* 7,8% (47/602). There weren't significant differences between autosomal recessive and sporadic cases.

Conclusion. The using of the genotype microarray is the first step in molecular diagnosis in Spanish families with Autosomal Recessive Retinitis Pigmentosa. *USH2A* is the main gene responsible followed by p.Arg257ter mutation in *CERKL* gene in Spanish population. 95% sporadic cases are inherited as an recessive form.

P07.109

RETN polymorphisms (-420C>G and IVS2+181G>A) in the Turkish population

N. Erginel-Ünaltona¹, M. Poda¹, A. Onaf², N. Coban¹, F. Guclu-Geyik¹, G. Can³;

¹Istanbul University, DETAE, Genetics Dept., Istanbul, Turkey, ²Turkish Cardiology Association, Istanbul, Turkey, ³Istanbul University, Cerrahpasa Medical Faculty, Dept. of Public Health, Istanbul, Turkey.

Resistin hormone (RETN) plays an important role in the insulin resistance mechanism. The effects of the two variants in the resistin gene (RETN -420C>G and IVS2+181G>A) on metabolic syndrome and cardiovascular events have been studied in the Turkish population. 208 healthy individuals, 360 with metabolic syndrome and 75 subjects with heart disease were genotyped. The genotype and allele frequencies of the RETN polymorphisms in the Turkish population have been determined for the -420C>G (CC: 47%, GC: 44%, GG: 9%) and IVS2+181G>A (GG: 52%, GA: 39%, AA: 9%) polymorphisms. The genotype and allele distributions have been found to be similar to other European populations.

In our study group the IVS2+181AA genotype has been found to be associated with low HDL-cholesterol levels (p=0.035). The AA genotype and dyslipidemia showed an association in both obese (p=0.012) and non-obese men (p=0.016). In the obese group, the carriers of IVS2+181AA and AG genotypes had higher triglyceride levels (p=0.044) than the GG genotype. In men, higher triglyceride levels have been associated to -420GG genotype (p=0.029). Furthermore, in obese men, the -420GG genotype has also been associated with dyslipidemia (p= 0.036). On the other hand, the IVS2+181A (p=0.0001) and -420G (p=0.009) allele carriers had lower log folate levels in the whole study population.

This study indicates that the variations in the RETN gene (-420C>G ve IVS2+181G>A) may effect lipid and the folate levels. Particularly, dyslipidemia was present more frequently in IVS2+181AA and -420GG genotype-carrying obese men, hence they may further contribute to MI risk.

P07.110

The Bayash Roma: phylogenetic dissection of Eurasian paternal genetic elements

I. Martinovic Klaric, M. Pericic Salihovic, L. Barac Lauc, B. Janicijevic;

Institute for Anthropological Research, Zagreb, Croatia.

The Bayash consist of numerous and small Romani groups speaking different dialects of the Romanian language and living dispersedly in Croatia, Hungary, Bosnia and Herzegovina, Serbia, Romania, Bulgaria, and to the lesser extent in Macedonia, Greece, Ukraine, Slovakia and Slovenia. Larger Bayash groups migrated to Croatia most likely during the 19th century, after abolition of slavery in Romania. Molecular architecture and the origin of the Croatian Bayash paternal gene pool was addressed by analysing 151 Bayash Y chromosomes from two Croatian regions, 332 Y chromosomes from Romani populations across Europe, 814 Y-chromosomes from non-Romani host populations living in Southeastern, Southern and Eastern Europe as well as with 1680 Y-chromosomes from South Asian populations. The Bayash in Croatia represent one population of largely shared paternal genetic history characterized by substantial percentage (44%) of common H1-M82 and E3b1-M78 lineages. Relatively ancient expansion signals and limited diversity of Indian specific H1-M82 lineages imply descent from closely related paternal ancestors who could have been settled in the Indian subcontinent between 7th and 9th centuries AD. Minimal time divergence of the Bayash subpopulations is consistent with their putative migratory split within Romania towards Wallachia and Transilvania. Substantial percentage of E3b1 lineages and high associated microsatellite variance in the Bayash men is a reflection of significant admixture with majority populations from the Vardar-Morava-Danube catchment basin - possibly a common paternal signature of Romani populations in Southeastern Europe. Additional traces of admixture are evident in the modest presence of typical European haplogroups.

P07.111**Analysis of Polymorphism of the CAG Repeats in the Spinocerebellar Ataxia type 1 (SCA1) Gene in Human Populations of the Volga-Ural Region***E. Mingazova, E. Khusnutdinova, I. Khidiyatova;**Institute of Biochemistry and Genetics, Ufa, Russian Federation.*

Spinocerebellar Ataxia type 1 (SCA1) is a neurodegenerative disease, is characteristic at the molecular level by CAG repeat expansions on 6p23 in the SCA1 gene. Distribution of normal alleles of CAG repeats in SCA1 gene was analyzed in populations of the Volga-Ural region, including Tatars, Russians, Maris, Udmurts, Komis, Chuvashes, three ethnogeographical groups of Bashkirs and two ethnogeographical groups of Mordovians. 13 alleles (8-12 in different populations), containing 24-37 trinucleotide repeats were found as a result of 956 DNA samples analysis. The allele frequency distribution showed two the most frequent alleles corresponding to 31CAG repeats with the frequency varied from 0,161 in Tatars to 0,328 in Chuvashes, and 32CAG repeats - from 0,152 in Mordovians erza to 0,425 in Chuvashes. Allele with large number of repeats (CAG)₃₇ was found in Bashkirs from the Abzelilovskii, Burzanskii regions, Mordovians erza with frequency of 0,008, 0,005, 0,022. Transitional alleles with number of repeats (CAG)₃₇₋₃₉ are unstable triplet repeats and can given subsequent mutation. Allele frequency distribution of SCA1 gene is significantly heterogeneity. The observed heterozygosity was the highest (99%) in Bashkirs from the Abzelilovskii region and the lowest (44%) in Mordovians erza; the average heterozygosity was 73,6%, and allows to consider this polymorphic DNA locus to be a highly informative genetic marker for populations. At present in the Bashkortostan Republic (Russia, South Ural, population 4069784 people) 10 families with progressive autosomal-dominant spinocerebellar ataxias were revealed, and in 2 of the examined families revealed the expansion of (CAG)_n-repeats in SCA1 gene.

P07.112**DNA copy number analysis in a case-control study of schizophrenia***F. Torri¹, S. Lupoli², S. Potkin³, E. Salvi¹, J. Turner³, G. Guffanti¹, A. Orrò⁴, J. Fallon³, C. Barlassina¹, D. Cusi¹, F. Macciardi¹;**¹University of Milan, Milan, Italy, ²INSPE, Milan, Italy, ³Dept. of Psychiatry & Neuroscience, UCI, Irvine, CA, United States, ⁴CILEA, Segrate, Milan, Italy.*

Recent studies have highlighted DNA copy-number variations (CNVs) as a largely under-explored source of human genetic variation, which could be responsible for the development of complex disorders. According to this hypothesis, evaluation of DNA copy number in schizophrenia may yield insights into the discovery of genetic risk factors for this disease (as aberrations in genes involved in glutamate signalling suggested in a recent report¹), as CNVs can also be transmitted as mendelian traits².

We have assayed 317.511 SNPs in 172 DNA samples from a case-control study of schizophrenia, including 91 controls and 82 schizophrenics, representing the first wave of a much larger sample, using the Illumina HumanHap300 Genotyping BeadChip®. In an effort to examine individual chromosomes for structural mutation, we used two different classes of algorithm: cnvPartition (circular binary segmentation algorithm) implemented in BeadStudio v3.0.22 and quantiSNP3 (Objective Bayes Hidden Markov Model).

Statistical analyses performed on genotyping data-sets of our study revealed that the overall distribution of CNV assignments is significantly different between schizophrenic patients and controls, with the main difference observed for duplications, which are more frequent in schizophrenics than in controls.

P07.113**Analysis of Y-chromosomal STR haplotypes in two ethnic groups and one cosmopolitan population from Tunisia***K. Fadhlou-Zid¹, I. Mendizabaf, H. Khodjet Eil Khill¹, B. Martinez-Cruz², M. Ben Amor¹, A. Ben Ammar Elgaaeid¹, D. Comas²;**¹Laboratoire de Génétique, Immunologie et Pathologies humaines. Faculté des Sciences de Tunis. Université Tunis El Manar, Tunis, Tunisia, ²Unitat de**Biologia Evolutiva. Universitat Pompeu Fabra. Doctor Aiguader 88, 08003, Barcelona, Spain.*

Human Y-chromosome short tandem repeat (Y-STR) markers show a high level of polymorphism and a significant degree of discrimination between individuals. Analysis of human Y-STR polymorphism has become a very useful tool both in evolutionary studies and in forensic casework, due in part to the loci being recombination free during meiosis and paternally inheritance. In order to define the Y-chromosome genetic structure in Tunisian population, 17 Y-STRs were typed in 159 unrelated healthy males in two ethnic groups ("Andalusians" and Berber) and one cosmopolitan population (Tunis) from Tunisia, using AmpFLSTR® Yfiler™ PCR Amplification Kit (AB Applied Biosystems). Allele and haplotype frequencies, standard diversity indices, pairwise genetic distances (RST) and analysis of molecular variance (AMOVA) were calculated with the software Arlequin version 2.000. A total number of 111 haplotypes were identified by the 17 Y-STR loci in our study sample and 91 haplotypes were unique. All the groups analysed showed high haplotype diversities, the highest value being observed in the "Andalusians" sample: 0.9924 +/- 0.0104 for "Cosmopolitan"; 0.9765 +/- 0.0132 for Berbers from Sened; 0.9886 +/- 0.0131 for Berbers from Chenini-Douiret; 0.8367 +/- 0.0547 for Berbers from Jeradou and 0.9940 +/- 0.0095 for Andalusians. The highest diversity revealed for Chenini-Douiret using this Y-STR is not expected, as compared to mtDNA or autosomal markers analysis. The hierarchical analysis of variance carried out between the Berber and Arabic-speaking groups failed to demonstrate any significant differentiation between them. These results corroborate the absence of overall genetic differentiation between Berbers and Arabs in Tunisia.

P07.114**Population data on the X chromosome short tandem repeat loci DXS9895, GATA172D05, DXS6810, DXS6803 and HPRT in Croatia***K. Crkvenac Gornik¹, K. Štingl², Z. Grubić², I. Tonković Đurišević¹, L. Letica¹, M. Burek¹, R. Lasan¹, D. Mužinić¹, D. Begović¹;**¹Division of Metabolic and Genetic Diseases, Clinic of Pediatrics, University Hospital Centre Zagreb, Croatia, Zagreb, Croatia, ²Tissue Typing Centre, University Hospital Centre Zagreb, Zagreb, Croatia.*

Due to its high polymorphism, the analysis of Short Tandem Repeat (STR) markers using the PCR method has become a widely applied technique in forensic individual identification, rapid detection of chromosome aneuploidies in prenatal and postnatal diagnosis and paternity testing. Until now a large number of autosomal and Y-chromosomal markers has been forensically evaluated and used for various purposes, but the application of X-chromosomal markers has played only a minor role in forensic practice so far. The X-STR loci (DXS9895, GATA172D05, DXS6810, DXS6803 and HPRT) were investigated in male (N=90) and female (N=93) population samples from Croatia. Samples were collected from randomly selected unrelated healthy individuals. No deviation from the Hardy-Weinberg equilibrium could be detected and allele frequencies showed similar distribution in male and female samples. With the exception of DXS6810 locus for which only 6 alleles were observed and PIC value lower than 0.75 was calculated, all other loci have demonstrated sufficient polymorphism and PIC value to be considered valuable in future forensic analyses.

P07.115**Epidemiology of monogenic hereditary skeletal diseases in Rostov region of Russian Federation***R. A. Valkov¹, T. I. Valkova², S. S. Amelina², R. A. Zinchenko³;**¹Railroad clinical hospital, Rostov-on-Don, Russian Federation, ²Rostov regional clinical hospital, Rostov-on-Don, Russian Federation, ³Research Center for Medical Genetics, Moscow, Russian Federation.*

Monogenic hereditary skeletal diseases have many various clinical forms and characterized by genetic heterogeneity. The main purpose of our research was determination of hereditary factor's role in common structure of skeletal diseases, and their prevalence at population of Rostov region of Russian Federation. 320925 people of eight area of Rostov region were examining. All hereditary skeletal diseases were dividing into isolated and syndromic forms. In the results 336 patients of 226 families are had hereditary skeletal diseases. It was 36% of all patients with hereditary diseases. The total prevalence rate of hereditary skeletal diseases in Rostov region was 1:950 persons. At that, the prevalence rate of isolated forms was 1:2700, and syndromic

forms - 1:1600. The most frequently autosomal dominant diseases were Ehlers-Danlos' syndrome - 1:6400, Marfan's syndrome - 1:20000, idiopathic scoliosis - 1:20000, polydactylia postaxialis - 1:21400, syndactyly, type I - 1:26700, osteogenesis imperfecta - 1:32000. In autosomal recessive, it was Spondiloeiphysial dysplasia Tarda - 1:64200, Spondiloeiphysial dysplasia with mental retardation - 1:80200, Langer type mesomelic dysplasia - 1:107000. In X-linked, it was Aarskog syndrome - 1:53500, Coffin-Lowry syndrome - 1:53500, Proud syndrome - 1:80200. Therefore, our research is enabling to improve genetic consultation's activity, directed to decrease of hereditary disease's pressure in Rostov region of Russian Federation.

P07.116

Smith-Lemli-Opitz Syndrome mutations in recurrent miscarriage

E. Dimitriadou¹, I. Lalou¹, S. Kalantaridou², M. Pavlou², A. Sotiriadis², M. Tzoufi³, I. Georgiou⁴, M. Witsch-Baumgartner⁴, M. Syrrou¹;

¹Genetics Unit, Laboratory of General Biology, Medical School, University of Ioannina, Ioannina, Greece, ²Department of Obstetrics and Gynaecology, Medical School, University of Ioannina, Ioannina, Greece, ³Child Health Department, Medical School, University of Ioannina, Ioannina, Greece, ⁴Department for Medical Genetics, Molecular and Clinical Pharmacology, Innsbruck, Austria.

Recurrent miscarriage (RM) is defined as >3 (or >2) consecutive pregnancy losses before 20 weeks of gestation and affects 1-3% of all women. More than 40% of RM are of unknown etiology and assumed to be genetic in origin.

Smith-Lemli-Opitz Syndrome (SLOS, MIM270400) is an autosomal recessive disorder of cholesterol biosynthesis caused by mutations in the gene DHCR7. The prevalence of SLOS ranges between 1:15000 and 1:60000 in European populations, but there is a discrepancy between expected and observed incidence of SLOS mutations that might be in part explained by first trimester miscarriages of affected fetuses. Aim: 1. To compare the prevalence of common SLOS mutations in Greek women with unexplained RM and in a control group. 2. To correlate common SLOS mutations with RM in order to conclude if screening for common SLOS mutations in couples with >2 spontaneous miscarriages should be added in the evaluation of RM.

Study group: 124 women aged <41 years, with >2 consecutive first trimester miscarriages. Controls: 75 healthy age-matched women, with proven fertility. The three most common for the Greek population mutations of the DHCR7 gene (IVS8-1G>C, p.Trp151X and p.Thr93Met) were studied using allele-specific PCR.

Two out of 124 women with unexplained RM were heterozygous for null IVS8-1G>C mutation. No carriers were found among the control group. This is an ongoing study.

P07.117

Prevalence of functional SNPs in candidate genes for common diseases in four Siberian populations

M. V. Golubenko¹, M. S. Nazarenko¹, A. N. Kucher¹, E. Y. Bragina¹, N. P. Babushkina¹, I. A. Goncharova¹, V. V. Pogrebenkova¹, O. Y. Bychkova¹, O. G. Ivanova¹, T. V. Zheykova¹, I. V. Saltykova², A. R. Simakina², L. A. Koneva¹, S. V. Buikin¹, O. A. Makeeva¹, V. P. Puzyreva^{1,2};

¹Institute for Medical Genetics, Tomsk, Russian Federation, ²Siberian State Medical University, Tomsk, Russian Federation.

Genetics of common diseases deals with common polymorphisms (in most cases SNPs). There are differences in the common diseases prevalence between human populations which may be explained in part by variation in frequencies of some predisposing SNPs depending on population descent. Furthermore, linkage disequilibrium is also known to be different in diverse populations. We studied twelve known candidate genes for common diseases of cardiovascular and immune systems, in four Siberian populations of different ethnic origin, namely Tuvinians, Yakuts, Buryats, and Russians (384 individuals in total). *ACE*, *AGTR1*, *NOS3*, *GNB3*, *TNF* and *LTA*, *TNFRSF1A*, *ADRB2*, *IL4*, *IL4RA*, *IL12A*, *IL12B*, *IL12RB1* genes were studied. Few SNPs in each gene were picked for genotyping on the basis of known associations with common diseases and/or possible functional effect. We have found significant differences between populations in both frequencies and LD estimates for most of genotyped SNPs. Few SNP positions were not polymorphic in our samples. We confirmed the fact that some SNPs within *ACE*, *NOS3*, *TNF*, *IL4RA* genes are in strong linkage disequilibrium. Taking into account that significant differences were found between related populations of Asian origin, as well as between

Russians and other European populations, our results emphasize need for further investigations of prevalence of candidate SNPs for common diseases in different populations. Differences in functional SNPs frequencies suggest population specific character of genetic structure of predisposition to common diseases which should be taken into account during development of genetic tests for common diseases predisposition in different regions.

P07.118

Application of MLPA in multiplex SNP genotyping for genetic epidemiology

C. Brasch-Andersen^{1,2}, L. Christiansen^{3,2};

¹Clinical Pharmacology, Institute of Public Health, University of Southern Denmark, Odense, Denmark, ²Dept. of Biochemistry, Pharmacology and Genetics, Odense University Hospital, Odense, Denmark, ³Epidemiology, Institute of Public Health, University of Southern Denmark, Odense, Denmark.

A method for simple and cost-effective medium-scale genotyping in large epidemiological studies is often needed, for instance when investigating the entire genetic variation in a single or a few genes.

The multiplex ligation-dependent probe amplification assay (MLPA) was initially developed for detection of DNA deletions or duplications, but is also suitable for genotyping single point polymorphisms (SNPs). We designed an allele discrimination assay for simultaneous genotyping of at least 10-20 SNPs in a large number of samples using the MLPA technology. Based on the MLPA probe design protocol we constructed 3 probes per SNP: 2 allele specific and 1 locus specific, which after ligation were PCR amplified and size-separated using capillary electrophoresis. In addition to the template specific sequence each of the MLPA probes contain a variable length stuffer sequence enabling both SNPs and alleles to be discriminated by size, and a primer specific sequence common to all probes, thus permitting multiplex PCR using only one primer set.

We applied the method on two genes for which the genetic variation was covered by 12 and 19 tagging SNPs, respectively. Genotyping results were verified using CEPH controls with known genotypes.

Applying the MLPA method will enable most labs to genotype SNPs in a medium scale without investing in new lab equipment as the method only requires a PCR machine and a capillary electrophoresis system.

P07.119

Large scale screening for spinal muscular atrophy (SMA) - effect of ethnicity on frequency of exon 7 deletion v.s duplication

R. Sukenik-Halevy^{1,2}, R. Pessó³, N. Garbani³, N. Magal^{1,2}, M. Shohat^{1,2,3};

¹Recanati Institute of Medical Genetics, Petach Tikva, Israel, ²Rabin Medical Center, Petach Tikva, Israel, ³Maccabi Health Insurance Genetic Institutes, Rehovot, Israel.

Approximately 95% of SMA patients have homozygous deletions of exon 7 and/or 8 of the SMN1 gene and 5% are compound for deletion of exon 7 and a point mutation. The carrier frequency varies between 1:150 and 1:35.

We undertook a survey to assess the carrier rate among healthy individuals with no family history, evaluate the false negative rate (individuals with three copies of exon 7), and determine any ethnic differences.

We analysed data from two medical centres in Israel that conduct carrier screening among the normal population using the MLPA kit. We studied the copy number of exons 7 and 8 and divided the subjects into six ethnic groups: Ashkenazi, North African, Iranian/Iraqi, Yemenite, Balkan, other Jewish. Statistical analysis was performed using chi-square.

Between February-October 2007, 7308 subjects were tested in Maccabi clinics and 1729 at Rabin Medical Center. The carrier rate (deletion of exon 7) was 1:62 and was not statistically different among the various ethnic groups.

Duplication of exon 7 was found in 1 in 9 individuals - a false negative rate of 5.5%. There was a significant difference between the ethnic groups: 12% among Ashkenazim, 4.4% among North African Jews and 6%-8% in other groups (p<0.001). This difference was also found for duplication of exon 8.

This study emphasizes the importance of determining the false negative rate for each ethnic group as it may vary markedly. The discrepancy between the rates of exon 7 deletions vs. duplications may be explained by the genetic disadvantage of deletions.

P07.120

Prevalence of CAT-interruptions in (CAG)n-repeat region in the gene for SCA1 in Siberian populations.

L. A. Koneva¹, N. P. Babushkina¹, M. S. Kuharskiy¹, N. R. Maksimova², A. N. Kucher¹;

¹Institute of Medical Genetics, Tomsk, Russian Federation, ²Yakuts Scientific Centre, Yakutsk, Russian Federation.

Spinocerebellar ataxia type 1 (SCA1) is a rare autosomal-dominant neurological disorder caused by expansion of an unstable (CAG)-repeats in gene for ataxin-1 (6p22-23). Normal repeat tract (in healthy people) consists of 6-37 triplets with 1-3 CAT-interruptions whereas mutant alleles contain pure repeat tracts from 39-70 CAG. CAT-interruptions are thought to serve as stabilizing factor.

We have studied frequency of alleles without CAT-interruptions among normal size alleles from different Siberian populations (855 individuals): Yakuts (the highest level of SCA1 accumulation) and Buryats, Tuvinians, Russians, Tatars, Kirghiz, Altaians and Khantys (without SCA1 accumulation). It is the first estimation of prevalence of homogeneous (CAG)n of normal length in SCA1 gene in different ethnic groups of Siberia with distinct contribution of European and Asian components in the their gene pools. *Sfa*NI restriction method was used to identify the interruptions. High frequency of chromosomes with normal homogeneous CAG repeat in Yakuts (15.66%), Tuvinians (17.9%), Kirghiz (13.57%), Altaians (9.56%), Buryats (9.51%) and rather low prevalence of such individuals among Tatars (7.15%), Russians (3.75%) and Khantys (2.83%) is revealed. Thus, high frequency of individuals without CAT-interruptions in normal length alleles in the populations without SCA1 accumulation has been shown. This finding puts a question concerning role of CAT-interruptions in (CAG)n-expansion in the gene ataxin-1.

The study was supported by RFBR grant N 06-04-49086.

P07.121

Simulation of dynamic spread of Triplet Repeat Expansion Diseases in human populations on example of spinocerebellar ataxia type I

L. Koneva, A. Konev, A. Kucher;

Institute of Medical Genetics, Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation.

Spinocerebellar Ataxia Type I (SCA1) is an autosomal-dominant neurodegenerative disorder caused by expansion of unstable CAG codon in *Sca1* gene that leads to abnormally long polyglutamine chains in nuclear matrix protein ataxin 1. SCA1 is frequent in Yakut populations, with 1.2% and 0.3% prevalence in Abyisky uluses (northern Yakutia) and Ust-Aldansky uluses (central Yakutia), respectively, in 2003. We developed the computational model in RAD environment Borland Delphi 7 for simulation of dynamics of SCA1 in population, and verified it with the epidemiological data from the two separate Yakutia regions.

The program is designed for simulation of SCA1 evolution in interactive mode. The user defines the initial parameters, such as population size and number of mutation carriers, as well as the interactive variables (demographical coefficients) - birth rate, death rate, migration and nuptiality, which can be adjusted during simulation. Other variables include: threshold number of CAG repeats, probabilities to inherit the mutation from mother/father, average expansion of trinucleotides tract during inheritance and reduction in number of mutant progenies due to genetic counseling. The model enables prediction of the length of CAG repeats, age of onset and life expectancy in individual mutation carriers in the lineage, and the prevalence of disease in population. Comparison of the data produced in simulation with the real values in existing populations was used to verify the computational model. This program provides flexible and highly visual way to predict dynamic changes in prevalence and spectrum of clinical characteristics of SCA1 in population in different demographic scenario.

P07.122

Association analysis of Tryptophan Hydroxylase-1 gene (TPH1) and suicidal behavior in Russian population

Z. Khalilova¹, D. Gaysina², A. Kazantseva¹, E. Khusnutdinova¹;

¹Russian Academy of Sciences, Ufa, Russian Federation, ²Institute of Psychiatry, King's College London, London, United Kingdom.

Suicide is an important public health problem, ranking among the top 10 causes of death for individuals of all ages. There is strong neurobiological evidence showing that serotonergic system dysfunction predisposes to suicidal behavior. Tryptophan hydroxylase, the rate limiting enzyme in serotonin biosynthesis, is one of the most important regulating factors in the serotonergic system. The aim of our study was to examine the association of four single nucleotide polymorphisms (rs 4537731, rs211105, rs1800532 and rs7933505) of TPH1 gene and attempted suicide. DNA samples of 312 cases (101- male, 152- female), who had suicide attempts, and 346 control subjects (194- men, 152- women) from Bashkortostan (Russia) were genotyped using PCR-RFLP technique. The distribution of allelic and genotype frequencies was in accordance with the Hardy-Weinberg equilibrium. No significant differences in either allele or genotype frequencies of rs1800532 and rs7933505 polymorphisms of TPH1 gene were found between suicidal and control groups. In a male group there was a tendency of underrepresentation of the *G/*G genotype of rs 4537731 polymorphism in suicide group compared to that in control group (11% vs 21%; $X^2 = 3.81$; $p = 0.05$; $df = 1$). For the females *G/*G genotype of rs211105 polymorphism was reported to be protective marker of suicidal behavior ($X^2 = 5.66$; $p = 0.017$; $df = 1$; $OR = 0.226$; $95\%CI 0.06-0.85$). The results suggest sex-related differences in the contribution of the TPH1 gene to susceptibility for suicidal behavior.

The work was supported by RSCI grant 06-06-00163.

P07.123

New candidate gene *B4GALNT1* is not associated with type 1 diabetes

T. Zemunik¹, V. Torlak², V. Škrabić², Z. Kačić³, J. Jakšić⁴, G. Stipančić⁵, A. Špehar⁶, A. Markotić¹, V. Boraska¹;

¹School of Medicine, Split, Croatia, ²Clinical hospital Split, Split, Croatia, ³General Hospital Dubrovnik, Dubrovnik, Croatia, ⁴General Hospital Šibenik, Šibenik, Croatia, ⁵University Hospital "Sestre Milosrdnice", Zagreb, Croatia, ⁶University Hospital Rebro, Zagreb, Croatia.

Monosialo-ganglioside (GM2-1) can be found on the pancreatic β -cell membrane. GM2-1 has recently been shown to be a target for ICA and GAD autoantibodies associated with type 1 diabetes mellitus (T1DM) development. Beta-1,4-N acetyl-galactosaminyl transferase 1 (GalNAc-T) is the enzyme involved in the biosynthesis of GM2 gangliosides. GalNAc-T catalyzes the transfer of GalNAc into GM3 by beta-1,4 linkage resulting in the synthesis of GM2. Enzyme beta-1,4 GalNAc-T is coded with *B4GALNT1* gene located on chromosome 12. The purpose of this study was to examine the relation of *B4GALNT1* gene tag single nucleotide polymorphisms (tagSNP) with susceptibility to T1DM. Two analyzed *B4GALNT1* tagSNP-s, rs1008314 and rs715930, capture 100% of *B4GALNT1* common variation at the $r^2=0.8$, based on the HapMap data. We performed case-control (213 patients and 199 control subjects) and family-based (202 families) studies in Croatian population. Case-control study did not observe an association with T1DM (rs1008314, $p=0.3001$; rs715930, $p=0.5256$). Also, transmission disequilibrium test did not detect any discrepancy from the expected minor allele transmission (rs1008314, $p=0.6547$; rs715930, $p=0.4986$) nor from the haplotype transmission from parents to affected child. This is the first ever reported association study to examine *B4GALNT1* gene polymorphisms with T1DM. We did not find any evidence to support our hypothesis of *B4GALNT1* T1DM association.

P07.124

Quantitative Epidemiology of the Haemoglobinopathies Suggests a Molecular Model of Complex Disease Based on Variability in the Assembly of Hetero-Dimeric Molecules

A. E. Felice, R. Galdies, W. Cassar, M. Pizzuto, M. Farrugia, B. Cauchi, M. R. Caruana, C. A. Scerri;

Laboratory of Molecular Genetics, Faculty of Medicine, University of Malta, and Section of Molecular Genetics, Mater Dei Hospital., Msida, Malta.

Between 1998 and 2008 we conducted a comprehensive population based Haemoglobin testing programme. Lately we integrated the

phenotypical based testing with genotyping using low cost DNA sequencing. During this period of time, the birth rate declined from 11.7 / 1,000 to 10.3 / 1,000 and the immigrant population of Malta increased ten fold. Two α globin variants Hb St. Luke and Hb Setif have been found among 0.2% of Maltese. The proportion of the variants was between 3.9% and 17.5%, depending on the effect of the mutation on the assembly and the co-current α or β thalassaemia; α thalassaemia is found among 1.3 % of neonates. Several β globin variants were detected including Hb Marseilles and Hb S. The Hb Valletta was always found in very tight linkage disequilibrium with the γ globin variant Hb F Malta I although a presumed "hot spot" of recombination has been assumed in between them. β Thalassaemia heterozygotes amount to 1.8% the population with 4 β globin gene mutations accounting for over 95%. The quantitative data suggested a model based on the differential assembly of molecular subunits into hetero-dimers albeit from non-syntenic variant genes that accounted for a broad range of variant allele expression between less than 5% as in Hb S combined with an α thalassaemia or around 100% as in Hb S homozygotes or the Hb S- β^0 Thalassaemia compound heterozygosity. The globin model appears broadly applicable to a variety of possibly complex conditions associated with multiple variant genes having quantitative effects.

Genetic analysis of a large French Canadian Tourette Syndrome family

J. Riviere¹, J. St-Onge¹, C. Poulin¹, F. Riche², P. Lespérance¹, G. Tellier³, S. Chouinard¹, G. A. Rouleau^{1,3};

¹CHUM Research Centre, Montreal, QC, Canada, ²Université du Québec à Montréal, Montreal, QC, Canada, ³Sainte Justine Hospital, Montreal, QC, Canada.

Tourette Syndrome (TS) is a complex neurodevelopmental disorder principally characterized by chronic motor and vocal tics and often associated with other behavioral abnormalities. Despite evidence of a strong genetic component, little is known about the genes predisposing to TS. We conducted a genome-wide linkage analysis in a large French Canadian (FC) TS family comprising nine affected individuals and exhibiting an apparent autosomal dominant mode of inheritance of the disorder. Five-hundred markers with an average marker density of 8cM were genotyped. Multipoint linkage and haplotype analyses were performed using GENEHUNTER and SIMWALK2 programs. Multipoint linkage analysis of the genome-wide scan revealed four chromosomal regions (2q, 6q, 8q and 13q) with LOD scores greater than 1.5 using an "affected-only" approach. Subsequent fine-mapping of these regions resulted in a single significant linkage peak (LOD>3.0) on chromosome 2q. Screening of candidate genes is needed in order to identify the causative TS gene in this family.

P07.126

The sex specific effects of UCP2 and 3 promoter polymorphisms in Turkish population

M. Poda¹, G. Can², A. Onat³, E. Bayrak¹, G. Hergenç⁴, S. E. Humphries⁵, N. Erginel-Ünaltna¹;

¹Istanbul University, DETAE, Genetics Dept., Istanbul, Turkey, ²Istanbul University, Cerrahpasa Medical Faculty, Dept. of Public Health, Istanbul, Turkey, ³Turkish Cardiology Association, Istanbul, Turkey, ⁴Department of Biology, Yildiz Technical University, Istanbul, Turkey, ⁵Centre for Cardiovascular Genetics, BHF Laboratories, Royal Free and University College London Medical School, London, United Kingdom.

UCP2 and UCP3 genes are highly homologous, yet they are expressed in different tissues. UCP2 is expressed in white adipose, heart, pancreas and kidney, whereas UCP3 is expressed in skeletal muscle and heart preferentially. Promoter region polymorphisms in UCP2 and UCP3 genes (-866G/A and -55C/T respectively) have been previously associated with obesity, diabetes and lipid profiles in different cohorts. To clarify the contribution of these polymorphisms to dyslipidemia and related conditions, we investigated the associations with the lipid, blood pressure and anthropomorphic measurements, with regard to diabetes and sex status. The study population consisting of a large (n=1975) representative cohort of Turkey ("Turkish Adult Risk Factor Study"-TARF study, mean age=54.6 ±11.5), was genotyped using sequence specific Taqman probes. The ANOVA t-test was used to compare the differences in continuous variables among study subjects subdivided by sex and/or diabetes status. Continuous variables (having P values

≤ 0,05 in NOVA t-test) were tested further by univariate analysis using Bonferroni correction.

The genotype distributions for both UCP3-5C/T and UCP2-866G/A were in accordance with Hardy-Weinberg equilibrium. The resulting frequencies were 0,75 for UCP2 -866G allele, whereas 0.78 for UCP3-55C. After Bonferroni correction the statistical results were as follows: In male subjects, UCP3-55TT genotype was associated with decreased total cholesterol (p=0,028) and diastolic blood (p=0,024) pressure levels, while it was associated with higher fasting glucose (0,0001) and logHOMA-R (p=0,032). In female subjects, UCP2-866AA genotype was associated with decreased levels of triglyceride (p=0,021) and ApoB levels (p=0,027).

In conclusion, the UCP3-55C/T and UCP2-866G/A promoter polymorphisms have gender specific phenotypic effects on human metabolism.

P07.127

UGT1A genetic polymorphisms in São Miguel population (Azores): implications for pharmacogenetic studies

M. J. Brilhante¹, P. R. Pacheco^{1,2}, F. Sigallat¹, H. Polena¹, R. Cabral^{1,2}, C. C. Branco^{1,2}, L. Mota-Vieira^{1,2};

¹Hospital of Divino Espírito Santo of Ponta Delgada, Azores, Portugal, ²Instituto Gulbenkian de Ciência, Oeiras, Portugal.

UGT enzymes are responsible for glucuronidation and detoxification of endogenous and exogenous compounds. Homozygosity for a polymorphism in the UGT1A1 TATAA box promoter causes Gilbert's syndrome. This sequence contains six TA repeats (UGT1A1*1), whereas seven repeats (UGT1A1*28) imply reduced gene expression. In UGT1A6, two missense mutations result in three alleles: UGT1A6*1 (T181-R184), UGT1A6*2 (A181-S184) and UGT1A6*3 (T181-S184). UGT1A1*28 and UGT1A6*2 are associated with reduced enzymatic activity.

Here, we determined UGT1A1 and UGT1A6 polymorphisms prevalence in São Miguel population (n=469 healthy individuals), and investigated UGT1A1 association with UGT1A6 polymorphisms. In UGT1A1, we identified five genotypes: 0.4% (TA)₆/(TA)₆, 50.5% (TA)₆/(TA)₆, 39.7% (TA)₆/(TA)₇, 9.2% (TA)₇/(TA)₇, and 0.2% (TA)₈/(TA)₈. Five and eight TA repeats are found only in African-ancestry individuals. These alleles confirm our previous results on Sao Miguel genetic ancestry, an admixed population composed of European, Jews and Africans. UGT1A*6 genotype frequencies were 47.5% (*1*1), 36.2%, (*1*2), 7.5% (*2*2), 4.7% (*1*3) and 4.1% (2*3). A strong association between UGT1A1*28 and UGT1A6*2 alleles was observed, since 81.4% homozygous for UGT1A1*28 were also homozygous for UGT1A6*2. Overall, 6.7% were homozygous for both UGT1 polymorphisms, and 39% had at least one variant allele for UGT1A1*28 and UGT1A6*2. These highly prevalent polymorphisms result in modified expression and activity of UGTs, may influence susceptibility to cancers and predispose to side effects of drugs, such as irinotecan. Currently, we are analyzing three missense mutations in UGT1A7, to evaluate the extension of linkage disequilibrium between UGT1A1, UGT1A6 and UGT1A7. Funded by Azorean Government (M1.2.1./003/2005). PRP has PhD grant SFRH/BD/27453/2006.

P07.128

Identification of the rare UGT1A1*36 allele in a Caucasian family of the Azores (Portugal)

M. Soares^{1,2}, M. R. Santos^{1,2}, A. R. Couto^{1,2}, J. P. Pinheiro^{1,2}, I. Dutra^{1,2}, V. Rodrigues³, J. Bruges Armas^{1,2};

¹SEEBMO - Hospital de Santo Espírito, 9700-856 Angra do Heroísmo, Portugal, ²IBMC - Instituto de Biologia Molecular e Celular da Universidade do Porto, Porto, Portugal, ³Centro de Saude de Santa Cruz da Graciosa, 9880-320 Santa Cruz da Graciosa, Portugal.

The role of UDP-glucuronosyl transferase 1A1 (UGT1A1) as a predictor of toxicity in cancer patients receiving irinotecan lead to the identification of a rare UGT1A1 genotype in a 69 years old female of Azorean ancestry.

The genotype UGT1A1*36/UGT1A1*28 (TA)₅/(TA)₂₈ was identified in the index case and after informed consent, three siblings (2 females-F and 1 male-M) were investigated. DNA extraction was performed from peripheral blood cells. Amplification of region of interest was performed by PCR using specific primers; forward primer was labelled for subsequent fragment analysis. Genotyping of (TA) repeats in this region

was performed submitting PCR products to capillary electrophoresis. Analysis revealed the following genotypes: TA_5/TA_6 (1F; 1M) and TA_6/TA_7 (1F).

TA_5 allele frequencies of 0.044, 0.017 and 0.000 have been identified for African-American, Caucasian and Japanese, respectively. To our knowledge, there is only one Portuguese report with the identification of an individual with this genotype. Due to the low frequency of the TA_5 allele on Caucasian population, HLA typing was performed in order to evaluate putative ethnic influences. HLA alleles for loci A, Bw, Cw, DRB1 and DQB1 were typed for all the individuals (SSP, SSO and SBT). HLA extended haplotype inferred for the proband: A*0102-B*5801-Cw*1802-DRB1*1301-DQB1*0603 revealed alleles that are extremely rare in Caucasians (e.g. Cw*1802) suggesting that this family may have had influences from other ethnic groups. The Azores archipelago was populated mainly by the Portuguese however, settlers from other European, African and possibly Asian countries, are well known in these islands history.

P07.129

Are the Moravian Valachs of Czech Republic the Aromuns of Central Europe? Model population for isolation and admixture

E. Ehler^{1,2}, V. Vančata²;

¹Department of Anthropology and Human Genetics, Charles University in Prague, Faculty of Science, Prague, Czech Republic, ²Department of Biology and Ecological Education, Charles University in Prague, Faculty of Education, Prague, Czech Republic.

Moravian Valachs of Czech Republic are one of the most distinct ethnic groups from Central Europe. Related to similar populations in Poland and Slovakia, they emerge at the end of 15th century, as the north-westernmost prominence of migration that started 250 years earlier in northern Romania. Being predominately highland sheep herders and of putative Romanian origin, they represent a Central European analogue of Balkan Aromanian populations. We have gathered Y-chromosomal, linguistic, ethnographic and historical data for this population and compared them with surrounding as well as with east European populations.

Linguistic data show specific parts of shared vocabulary of Romanian origin between several pastoral groups in Central and Eastern Europe. Comparing genetic and linguistic pairwise distance matrices (Mantel test) in these populations did not revealed any significant correlation. Thus we confirmed that plain geographical distance still plays the major role in genetic distances between populations in Europe. From our further analysis it is clear, that the Moravian Valachs, after at least five centuries of admixture, are not overly genetically different from surrounding populations. On the other hand, from the point of view of intra-population diversity, they are much more similar to isolated Balkan populations (e.g. Aromuns) than to Central European populations.

P07.130

Haplotype profile of vitamin K epoxide reductase (VKORC1) as determinant of warfarin sensitivity in Roma population

C. Sipeky¹, V. Csöngéi¹, B. Faragó¹, K. Horvatovich¹, L. Járomi¹, P. Kisfalvi¹, A. Maász¹, L. Magyari¹, E. Sáfrány¹, I. Takács², B. Melegh¹;

¹Department of Medical Genetics and Child Development, University of Pécs, Pécs, Hungary, ²2nd Department Institute of Internal Medicine and Haematology, Semmelweis Teaching Hospital, Miskolc, Hungary.

Oral anticoagulants, including warfarin and acenocoumarol, are the most widely prescribed drugs for treating of thromboembolic disorders. Complications with coumarin therapy include the narrow dosage window, the broad variation of interindividual and interethnic drug requirement, and the relatively high incidence of bleeding. Coumarins target blood coagulation by inhibiting the vitamin K epoxide reductase complex (VKORC). Recently, three main haplotypes of VKORC1 *2, *3, *4 have been observed, that explain most of genetic variability in warfarin dose among Caucasians. The aim of the work was to study the VKORC1 haplotype profile of Roma population in Hungary, and compare with results of the average Hungarian Caucasian population. G-1639A, G9041A, C6009T single-nucleotide polymorphisms were determined for VKORC1 haplotype-tagging. A total of 455 unrelated Roma and 237 Hungarian controls were haplotyped. The genotypes were analyzed by PCR-RFLP assay and direct sequencing. Our study revealed significant difference in the prevalence of VKORC1*2 and VKORC1*3 haplotypes between the Roma and average Hungarian

population ($p < 0.01$). The H7 and H8 haplotypes, requiring high warfarin doses are predominant in Roma population were 49% together, while H1 and H2 haplotypes, requiring low warfarin dose were the predominant in Hungarian average samples. Furthermore, 21.8 % of Romas were homozygous for the H7 and H8 haplotypes and an addition 3% were accounted to H9 haplotype. Results presented here shown high variability of the Roma people, which can have therapeutic consequences.

P07.131

High prevalence of Wilson disease in a small mountain village in Romania

F. Raicu^{1,2}, R. Cocos¹, A. Şendroi², D. Neagoş¹, R. Creţu¹, C. Glavce², L. Bohilţea¹, I. Şendroi²;

¹Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, ²Francisc I Rainer Anthropological Research Institute Romanian Academy, Bucharest, Romania.

Wilson disease (WD) is an autosomal recessive disorder caused by a defect in ATP7B gene, coding for a metal transporting P-type ATPase, resulting in copper overload mainly in liver and brain. Increased number of Wilson disease patients in a small mountain village next to Bran region led us to initiate a population screening. We firstly screened for mutation in five WD patients from five apparently unrelated families. Direct sequencing of all 21 exons within ATP7B gene was performed for all five WD patients. Mutation analysis revealed that each of them was homozygotes and compound heterozygotes bearing three mutations, one was frameshift mutation (P767P-fs) and two were missense mutations (H1069G and K832R). Up to now we screened 20 relatives of the five WD patients and we will screen a total of 152 autochthonous inhabitants to the third generation originating from the same village, in order to find the total number of carriers for these mutations. The high number of mutations and the homozygous/compound heterozygous state made correlation between genotype and phenotype difficult. The high prevalence WD indicates the need for health education intervention, genetic counselling and newborn screening for Wilson disease in this region.

P07.132

Allele frequencies for CYP1A1, CYP2D6, CYP2C9, CYP2C19, GSTT1, GSTM1, MTHFR, MTRR, NQO1, NAT2, HLA-DQA1 and ABO genes in native Russians

O. A. Gra^{1,2}, O. N. Mityaeva¹, Z. M. Kozhekbaeva², A. S. Glotov³, D. O. Fesenko¹, I. V. Goldenkova-Pavlova², T. V. Nasedkina¹;

¹Engelhardt Institute of Molecular Biology Russian Academy of Sciences, Moscow, Russian Federation, ²Vavilov Institute of General Genetics Russian Academy of Sciences, Moscow, Russian Federation, ³Ott's Institute of Obstetrics and Gynecology Russian Academy of Medical Sciences, Saint-Petersburg, Russian Federation.

Xenobiotic-metabolizing genes (e.g. Cytochromes P450, GST, NAT2, and NQO1), folate metabolism genes (e.g. MTHFR, MTRR) and major histocompatibility complex genes (e.g. HLA-DQA1) play multiple role in the organism functioning. In addition, ABO is the most clinically significant high-polymorphic gene in transfusion and transplantation medicine. Epidemiological data shows that allele frequencies of these genes exhibit ethnic and geographic diversity. Besides, little is known about frequency distribution of the major polymorphic variants in native Russians.

We developed biological microchips which allow to analyze a spectrum of allelic variants in twelve different genes such as CYP1A1, CYP2D6, CYP2C9, CYP2C19, GSTT1, GSTM1, MTHFR, MTRR, NQO1, NAT2, HLA-DQA1 and ABO. Using this composite methodological platform we have studied 352 DNA samples from healthy native Russian volunteers. For the first time we have received the allelic frequencies of above mentioned genes. The allelic frequencies of gene polymorphisms that we studied are close to allelic frequencies observed in some European populations, as published earlier. These data were used in comparative studies to determine predisposition to psoriasis, colorectal cancer, lymphoma and leukemia in adults and to childhood leukemia. The HLA-DQA1 and ABO allele frequencies were used to estimate forensic population parameters for these loci.

P07.133**The frequency of XRCC1 DNA repair gene A399G polymorphism in the Western Anatolia**

T. Sever, S. Pehlivan;

University of Gaziantep, Faculty of Medicine, Department of Medical Biology, Gaziantep, Turkey.

The aim of our studies, to determine of XRCC1 gene at codon 399 region frequencies of polymorphisms in healthy Western Anatolia population. We aimed XRCC1-399 polymorphism frequencies and the genotype distribution, with respect to the polymorphic codon 399 of XRCC1 gene by PCR-RFLP (Msp I Restriction Endonuclease enzyme) in 100 healthy individuals from the region of Izmir, Turkey. The following genotype frequencies were observed in the Western Anatolia population: A/A 44%, A/G 41% and G/G 15%. The frequency of A allele is 64.5% and the frequency of G allele 35.5%. The presence of the Adenin and Guanine allele frequencies in various populations such as USA, England, Caucasians, Korean and Chinese populations are similar to our results according to the published data.

P07.134**Phylogeography of the human Y chromosome haplogroup E3a**F. Cruciani¹, B. Trombetta¹, D. Sellitto², C. Nodale¹, R. Scozzari¹;¹Sapienza Università di Roma, Rome, Italy, ²Consiglio Nazionale delle Ricerche, Rome, Italy.

The Y chromosome specific biallelic marker DYS271 defines the most common haplogroup (E3a) currently found in sub-Saharan Africa. A sister clade, E3b (E-M215), is rare in sub-Saharan Africa, but very common in northern and eastern Africa. On the whole, these two clades represent more than 70% of the Y chromosomes of the African continent. A third clade belonging to E3 (E3c or E-M329) has been recently reported to be present only in eastern Africa, at low frequencies.

In this study we analyzed more than 1,600 Y chromosomes from 55 African populations, using both new and previously described biallelic markers, in order to refine the phylogeny and the geographic distribution of the E3a haplogroup.

The most common E-DYS271 sub-clades (E-DYS271*, E-M191, E-U209) showed a non uniform distribution across sub-Saharan Africa. Most of the E-DYS271 chromosomes found in northern and western Africa belong to the paragroup E-DYS271*, which is rare in central and southern Africa. In these latter regions, haplogroups E-M191 and E-U209 show similar frequency distributions and coalescence ages (13 and 11 kyr, respectively), suggesting their involvement in the same migratory event/s.

By the use of two new phylogenetically equivalent markers (V38 and V89), the earlier tripartite structure of E3 haplogroup was resolved in favor of a common ancestor for haplogroups E-DYS271 (formerly E3a) and E-M329 (formerly E3c). The new topology of the E3 haplogroup is suggestive of a relatively recent eastern African origin for the majority of the chromosomes presently found in sub-Saharan Africa.

P07.135**Genetic variability of Madeira archipelago inferred from Y chromosome, mtDNA and HLA system**

A. C. N. Lemos, H. Spinola, R. Gonçalves, A. Fernandes, A. Brehm;

Human Genetic Laboratory, Funchal, Portugal.

The Madeira Archipelago is composed by two inhabited islands, Madeira and Porto Santo. The first settlers of these islands came from north and south of Portugal and Europe (Flandres, France and Italy), jointly with some African slaves.

Three geographic groups were defined within the Archipelago: Funchal (FX), Southwest (SW) and Northeast (NE - including Porto Santo). The Y chromosome haplogroup followed the *Y Chromosome Consortium* and comparison with both mtDNA and HLA-A, HLA-B and HLA-DRB1 genes was performed. *Arlequin* was used to compare the three geographic groups within the archipelago and to calculate genetic diversity of Y chromosome SNPs, mtDNA and HLA systems between and within each group.

No significative haplotypic differences were found regarding the Y chromosome SNPs for these three groups, opposite to mtDNA and HLA systems encountered between Southwest and Funchal. We also found major European influence although some African traces are present. The highest level of genetic diversity was found in Funchal for

both mtDNA and HLAs.

The aim of this study was to determine the genetic background of the Madeira population, to search for differences within the Archipelago and find out the influence of the colonization in the actual genetic structure of this population.

P07.136**Prehistoric migrations out of East Europe: phylogeography of Y-chromosome haplogroups N2 and N3a**V. Kharkov¹, O. Medvedeva², K. Khamina², V. Stepanov¹;¹Institute for Medical Genetics, Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation, ²Tomsk State University, Tomsk, Russian Federation.

To reveal the structure and phylogeography of N2 and N3a Y-chromosomal haplogroups and to reconstruct their origin, the analysis of YSTR-haplotypes was carried out using seven YSTR loci of NRY (*DYS389I*, *DYS389II*, *DYS390*, *DYS391*, *DYS392*, *DYS393* and *DYS394* (*DYS19*)). A total of 234 samples belonging to N2 and 903 belonging to N3a from different ethnic population samplings of Europe, Siberia, Central Asia and Far East were analyzed. The results of the analysis evidenced a higher genetic diversity for N2 and N3a haplogroups in European populations as compared with Asian ones. Median networks showed the occurrence of different haplotype clusters for Europeans and Asians. Age of STR variation for N3a haplogroup was 14.2 thousand years (12.3 only for Europe and 8.6 for Siberia) and for N2 haplogroup it was 12.6. A high frequency of N2 and N3a haplogroups in some Siberian populations is the consequence of strong founder effect events, the age of which reached 3-5.5 thousand years. Pairwise values of *F_{st}* showed that, in Siberia, neighboring populations were characterized by a higher level of genetic differentiation than European ones. Cluster analysis also revealed relative proximity of European populations to each other as compared to Asian populations. These results suggest that an isolation of the regional group of populations occurred soon after the origin of the N2 and N3a haplogroups. Evenks and Yakuts displayed highly specific overlapping N3a haplotype spectra, atypical for other Siberian ethnic groups. Thus Eastern Europe is the most probable place of N2 and N3a haplogroups origin.

P07.137**Y-chromosome lineages in Xhosa and Zulu Bantu speaking populations**

R. P. A. Gonçalves, H. Spinola, A. Brehm;

Human Genetics Laboratory, Funchal, Portugal.

Y-chromosome Single Nucleotide Polymorphisms have been analysed in Zulu and Xhosa, two southern Africa Bantu speaking populations. These two ethnic groups have their origin on the farmer's Bantu expansion from Niger-Congo border towards sub-Sahel regions on the southern tip of the continent, during the past 3000 years.

Seven different Y-chromosome haplogroups were found in Zulu contrasting with only two in Xhosa. E3a, a common haplogroup among West sub-Saharan associated to Bantu migration was the most prevalent in both populations (56.9% in Zulu and 90% in Xhosa). The second most common haplogroup was E2 (29.3% in Zulu and 10% in Xhosa), present both in West and East African populations.

The present-day Zulu and Xhosa paternal legacy is essentially of West sub-Saharan origin. Zulu population shows a most diverse genetic influence comparing to Xhosa, revealing some pre-Bantu expansion markers and East African influences. Zulu presents 8.6% Y-chromosome haplogroups (A, B, J1) of non-Bantu influence that could indicate gene flow from other populations, particularly Khoisan.

P07.138**Y-chromosome lineages and kinship relation in Central Eastern Sardinia**P. Rizzu¹, L. M. Pardo¹, G. Piras², K. J. van der Gaag³, D. Sondervan¹, M.Monne², A. Gabbas², N. Bradman⁴, P. de Knijff⁴, A. Ruiz-Linares⁴, P. Heutink¹;¹Department of Clinical Genetics, Section Medical Genomics, Amsterdam, The Netherlands, ²Biomolecular and Cytogenetic Center, Dept. of Hematology and Oncology, San Francesco Hospital, Nuoro, Italy, ³Forensic Laboratory for DNA Research, Leiden University, Leiden, The Netherlands, ⁴The Galton Laboratory, Department of Biology, University College London, London, United Kingdom.

Genetic isolates have been successfully used in the study of complex traits, mainly because they allow a reduction in the complexity

of the genetic models underlying the trait. Prior knowledge of the genetic structure of the isolate is therefore a fundamental prerequisite for designing and carrying out successful association studies of complex disorders.

Sardinians has long been the object of study by geneticists by virtue of their ancient origin and long-standing isolation. Some studies suggest that the Sardinians are a relatively homogenous population with no significant heterogeneity among sub-regions. These reports are however in contradiction with several others demonstrating the existence of differentiated sub-regions, molded by natural, cultural barriers and historical events.

Our aim is to determine the extent of homogeneity in the Central-Eastern Sardinia that includes the archaic area as defined by archeological, linguistics and genetic studies. We determined Y-chromosome lineages in 256 unrelated Sardinian males from this area using a panel of informative biallelic markers (SNPs) and microsatellite (STRs). In addition to sex-specific markers we also used autosomal SNPs (500K Affymetrix chips) in 100 of the DNA samples to determine accurately kinship values.

Our analysis shows that the frequency of the major Y haplogroups clearly sets this population apart from the rest of the Europeans haplogroups.

Our results allow to evaluate how past peopling and demographic events might impact genome wide association study design for complex disorders that show a high incidence or a founder effect in this part of the island such as Diabetes type-1 and Breast-cancer.

P07.139

Characterization of the mitochondrial haplogroups of two Andean populations (Aymaras and Quechuas) from the Bolivian Altiplano: Comparison to other South-American populations

M. Gayà-Vidal¹, N. Saenz², A. Sevin², C. Coudray², C. Thèves², G. Athanasiadis¹, E. Esteban¹, M. Villena², A. Rodriguez², R. Vasquez², J. M. Dugoujon², P. Moral¹;

¹Unitat d'Antropologia, Dpt. de Biologia Animal, Facultat de Biologia, Universitat de Barcelona, Barcelona, Spain, ²Centre d'Anthropologie UMR 8555 CNRS, Toulouse, France, ³IBBA, La Paz, Bolivia.

Mitochondrial DNA has been widely used in human population genetic studies. It has been used to treat the colonization process of the New World. Particularly, in South-America, the Andean region with its geographic, environmental and historical particularities is an important area for these studies.

We have analyzed the mitochondrial DNA diversity of two Amerindian populations from the Andean Altiplano belonging to the two main Amerindian linguistic groups in Bolivia, namely Aymaras and Quechuas. The Aymara population is situated between La Paz and the Titicaca Lake and the Quechua population located in the Potosi department. Our aim is to provide new mtDNA data from these two Andean Altiplano populations.

Haplogroup (A, B, C, and D) and sub-haplogroup determinations have been carried out through RFLP analysis in the coding region, as well as through DNA sequencing of the HV1 and HVII regions (16020-250) in 190 non-related individuals.

After the determinations, the allele frequencies have been calculated and compared to other South-American populations for which data are available in the literature. Statistical analyses have been carried out in order to assess the genetic relationships between just the two populations of this study and also regarding three geographical levels: South-America, Central Andes and Bolivia.

P08. Genomics, technology, bioinformatics

P08.01

DECIPHER (DatabasE of Chromosomal Imbalance and Phenotype in Humans using Ensembl Resources) - <http://decipher.sanger.ac.uk>

S. M. Richards¹, R. M. Pettett¹, P. A. Bevan¹, S. Van Vooren¹, H. Fiegler¹, H. V. Firth², N. P. Carter¹;

¹Wellcome Trust Sanger Institute, Cambridgeshire, United Kingdom, ²Cambridge University Dept of Medical Genetics, Addenbrooke's Hospital, Cambridge, United Kingdom.

DECIPHER is a web-based, interactive database which provides a link between phenotype and chromosomal rearrangement utilising the En-

sembl genome browser and other bioinformatics resources.

DECIPHER provides the architecture for international collaborative effort identifying new syndromes and genes involved in human development and disease, for interpreting array CGH data and improving medical care for patients with congenital abnormalities. The DECIPHER Consortium has grown considerably over the last four years with database entries of over 1500 patients from approximately 90 centres worldwide.

In DECIPHER, molecularly defined rearrangements (e.g. from array-CGH) are mapped on to the reference sequence for viewing in Ensembl. Genes within the affected region are identified and prioritised according to their relevance to the phenotype. Clusters of rearrangements within the same region in patients with comparable phenotypes enable new syndromes to be defined and published.

Other features in DECIPHER which aid in the interpretation of microarray data include:

Trio analysis tool - A trio of an affected individual and parents are analysed to determine de novo or familial/inherited conditions.

Gene prioritisation tool - advanced text mining searches PubMed for associations between highlighted genes and phenotypes.

Search tool - a search engine for 'consented' data within DECIPHER to facilitate the identification of rearrangement clusters and links between phenotype and genomic location.

DECIPHER enables international collaborative research on developmental disorders and provides a powerful knowledge base for clinical diagnosis and management of patients with congenital abnormalities.

P08.02

3C on FOXL2.

D. Beysen¹, J. Dostie², B. D'haene¹, A. De Paeppe¹, J. Dekker², E. De Baere¹;

¹Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, ²Program in Gene Function and Expression, University of Massachusetts Medical School, Worcester, MA, United States.

Defective long distance gene regulation is an emerging mechanism underlying human disease. Blepharophimosis syndrome (BPES), an autosomal dominant condition affecting eyelid and ovary development, is caused by mutations in the *FOXL2* gene. Its expression is strictly regulated, which was illustrated by the recent identification of deletions upstream and downstream of its transcription unit as underlying cause of BPES. We demonstrated that these rearrangements remove several conserved non-coding sequences (CNCs) harbouring potential long-range *cis*-regulatory elements.

Here, we used Chromosome Conformation Capture (3C) to identify long-range interactions of *cis*-regulatory elements with the *FOXL2* promoter in two adult *FOXL2* expressing cellular systems. We found that in adult ovarian granulosa cells and fibroblasts three long-range *cis*-regulatory sequences located 177 kb, 283 kb and 360 kb upstream of *FOXL2* come in close vicinity to the *FOXL2* core promoter. Noteworthy, 3C in human fibroblasts derived from a BPES patient with a heterozygous deletion of the region encompassing the regulatory element at 283 kb, revealed decrease of interaction of the deleted element and the *FOXL2* core promoter and the two other regulatory elements. Interestingly, the element at 283 kb corresponds to a sequence deleted in the Polled Intersex (PIS) goat, which is an animal model for BPES. In conclusion, we hypothesize that the interaction between the *cis*-regulatory element located at 283 kb and the *FOXL2* core promoter is essential to establish efficient transcriptional regulation of *FOXL2* expression.

P08.03

Study of the antisense transcript to AFAP1 human gene

A. V. Marakhonov^{1,2}, A. Baranova^{1,2}, T. Kazubskaya³, S. Shigeeva¹, M. Y. Skoblov¹;

¹Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation, ²Molecular and Microbiology Department, College of Science, George Mason University, Fairfax, VA, United States,

³Blokhin Cancer Research Centre, Russian Academy of Medical Sciences, Moscow, Russian Federation, ⁴Department of Forensic Medicine, Faculty of Medicine, People's Friendship University of Russia, Moscow, Russian Federation.

Antisense regulation of gene expression is a widespread but not well-understood mechanism of gene expression regulation. Recently we have carried out a whole genome *in silico* search of *cis*-antisense

clusters of transcripts in humans. The developed database revealed a significant number of sense—antisense pairs consisting of one EST cluster expressed predominantly in normal tissues and another cluster with tumor-specific expression. The role of antisense transcripts in the regulation of oncogenes and tumor suppressor genes warrants functional research. Here we describe and characterize an antisense mRNA asAFAP overlapping human AFAP1 gene.

AFAP1 encodes for an actin filament binding protein, which serves as a modifier of actin filament structure and integrity. It also is able to relay a signal from receptor tyrosine kinases through PKC α to Src protein kinase. It has been shown that AFAP1 is overexpressed in prostate cancer and contributes to tumorigenic growth. We hypothesized that the transcription of asAFAP antisense mRNA may lead to suppression of sense AFAP1 gene expression and a compensatory restraint added to one of the mitogenic signaling pathway that is unlikely to be supported by natural selection in the tumor cell population. To study the intriguing phenomenon of tumor-specific asAFAP antisense expression we performed detailed *in silico* analysis of asAFAP sequences and experimentally quantified this transcript in normal and tumor human tissues.

We have specified the exon-intronic structure of asAFAP antisense transcript and carried out the expression analysis of AFAP1 sense—antisense pair in normal and tumor human tissues.

P08.04

High-resolution breakpoint mapping of human chromosome 21 segmental aneuploidies for genotype-phenotype correlation and identification of underlying genomic architecture

A. Hoischen, B. van Bon, L. E. L. M. Vissers, C. F. H. A. Gilissen, S. Keijzers-Vloet, N. de Leeuw, B. B. A. de Vries, H. G. Brunner, J. A. Veltman; Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands.

As part of the European FP6-sponsored AnEUploidy consortium we are involved with work package 2: Genotype-phenotype correlations in human aneuploidies. The objective of this work package is to study the phenotypic consequences of gene dosage imbalance in the human population.

One of our roles in this project is the characterization of segmental aneuploidies of HSA 21. Until now we collected 19 cases with detailed clinical information, enabled by using a standardized phenotypic list. Cell lines and/or DNA are available for all patients. Karyotyping as well as additional analysis (FISH, microarray-based high-resolution genome profiling) were performed for the majority of cases. We have used a chromosome 21 specific oligo-array with 385,000 oligonucleotides to further delineate the genomic rearrangements in this cohort. Breakpoint fine mapping of approximately 1kb accuracy has been performed for the most cases, enabling breakpoint sequencing as a next step. For one case with a partial chromosome 21 deletion (46,XY,del(21)(q11.2q21.3)) the rearrangement coincide with bordering segmental duplications (SDs) that have identical orientation and high (>95%) similarity. This suggests that recurring deletions and/or corresponding duplications of similar size that are mediated by NAHR (non-allelic homologous recombination) may exist. These analysis of the underlying genomic-architecture are enabled by in-house developed software tools.

Detailed genotype-phenotype correlations are ongoing for all patients to get a better insight into the underlying gene dosage imbalances. Expansion of the patient cohort and transcriptome analysis are planned as joined efforts of the consortium.

P08.05

Artificial intelligence applied in finger prints identification

E. Laslo, I. Tomulescu; Faculty of Sciences, Oradea, Romania.

In this paper we propose a new database search method with results in finding the most nearest existing data. The searching method is based on the artificial intelligence concepts named Genetic Algorithms combined with polynomial approximation.

In the first stage of the process for each record in the database we create an algebraic polynomial named characteristic function and we update the database with the polynomial coefficients.

For the second stage we process the input data also to create an algebraic polynomial approximation. This method was used in our previous research in numerical approximation with Genetic Algorithms.

In the last stage we search all the polynomials created in the first stage which approximate the minimum requirement of the polynomial representing the input data.

If the difference doesn't satisfy the minimal requirement, we consider this data inexistent in the original database and we could save this data like a new record.

We applied this method to interpret the 2d coordinates of the points which represent the particularities of the finger prints.

P08.06

Genomic profiling to identify novel genetic risk factors for Behçet's disease

J. M. Xavier¹, T. Krug¹, B. V. Fonseca¹, F. Barcelos², G. Jesus³, A. Bernardino³, M. Coutinho³, C. Neves³, J. Vedes⁴, M. Salgado⁵, J. Crespo³, J. Vaz Pato², S. A. Oliveira¹;

¹Instituto Gulbenkian de Ciencia, Oeiras, Portugal, ²Instituto Portugues de Reumatologia, Lisboa, Portugal, ³Hospital Infante D. Pedro, Aveiro, Portugal, ⁴Hospital de Sousa Martins, Guarda, Portugal, ⁵Hospital Pediatrico de Coimbra, Coimbra, Portugal.

Introduction: Behçet's disease (BD) is a multisystemic immuno-inflammatory disorder characterized by a generalized vasculitis, particularly at oral and genital mucosa and eye (uveitis). Although there is evidence for environmental risk factors, epidemiological and family studies strongly support the existence of genetic risk factors for BD. The only established genetic predisposition for BD is the HLA-B*51 allele on chr. 6p21, which explains only 19% of its overall genetic susceptibility. Furthermore, a recent linkage study on Turkish families found strong evidence for linkage with BD at 6p22-24 and 12p12-13. Case-control association studies on biological candidate genes have so far mostly been inconclusive. To identify new susceptibility genes for BD, we are conducting the "genomic convergence" approach, which combines data from whole genome linkage screens with expression studies to determine which genes will be tested in association studies.

Methods & Materials: We performed gene expression profiling in peripheral blood mononuclear cells of carefully matched cases and controls using Affymetrix GeneChip Human Genome U133 Plus 2.0 microarrays.

Results: Preliminary analyses identified 131 genes differentially expressed among 11 cases and 11 controls (1.2 fold-change cutoff and p-value<0.05), 18 of which map to the linkage peaks in Turkish families.

Conclusions: These 18 genes differentially expressed among BD patients and controls constitute excellent candidate genes for association studies in this disease. We are currently confirming the expression studies in a larger dataset.

P08.07

The centralized DNA-extraction, quality control, storage and sample logistics center for EU-project Genetics of Healthy Aging

O. M. Törnwall, M. Jussila, P. Laiho, L. Peltonen, M. Perola; National Public Health Institute, Helsinki, Finland.

The National Public Health Institute of Finland (KTL), Department of Molecular Medicine (MLO) has over the past decade developed an infrastructure for handling an extensive number of biological samples collected in large epidemiological and population based studies (www.nationalbiobanks.fi). The biobank consists of centralized DNA-extraction, quality control, storage and sample logistics and has developed a database and sample logistics system applicable to any biobank handling DNA samples. The center is equipped with state of the art bar coding system, automated DNA extraction equipments, liquid handling robots, storage facilities and tailor made data management tools. The biobank has served as a DNA logistics center for several research projects, including the EU funded project; Genetics of Healthy Aging (GEHA) (www.geha.unibo.it).

The aim of the GEHA consortium is to collect DNA samples from 2650 long-lived 90+ sib pairs and controls from 15 European countries. The samples are shipped to Helsinki, DNA is extracted, stored, quality checked and distributed to the genotyping laboratory CEPH in France. By the end of 2007, 9813 samples from 6867 individuals had been extracted. The method of choice for nearly all of the GEHA samples has been the automated extraction equipment Autopure LS. The failure rate of extraction has been very low < 1%. Average yield for blood samples is 31,4µg/1ml of blood and 1,8µg for cheek swab samples.

From all the subjects 4745 samples have been tested for PCR-functionality and monitored in case of sample mix-ups or contamination. During QC only 0,8% of the samples had to be excluded.

P08.08 Using the bioinformatic tools to choose the SNPs with highly possible phenotypic effect

D. Ozhegova¹, M. Freidin¹, V. Puzyrev²;

¹Siberian State Medicin University, Tomsk, Russian Federation, ²Research Institute of Medical Genetics, Tomsk, Russian Federation.

Common polymorphisms, such as SNPs, in human gene promoters are the significant factors influencing differential gene expression underlying natural phenotypic variation. A number of bioinformatic tools were developed recently, which are useful in prediction of "on its own" functionally important SNP in promoters utilizing the knowledge about transcription factors binding the DNA. We used such the resources for a pilot search of functional SNPs in seven immune response modifying genes: STAT1, IL10, IL12B, IFNG, IFNGR1, MCP-1, TLR-2. Firstly, all 61 the SNPs were chosen in the promoters of these genes using dbSNP (<http://www.ncbi.nlm.nih.gov/SNP>), and Ensembl (<http://www.ensembl.org>). Then, the selection of a minimal sufficient number of SNPs was done using SNPselector (<http://www.snpselector.duhs.duke.edu>) and PupaSNPfinder (<http://www.pupasnp.org>). Finally, Genomatix MathInspector (<http://www.genomatix.de/matinspector.html>) was utilised to predict a possible transcription factors (TFs) binding efficiency change due to the SNPs chosen. Eighteen SNPs in promoter region of seven genes were analyzed by MathInspector and it was found that the nucleotide substitution in seven SNPs caused new binding sites for TFs. The potential functionality of these SNPs is under current experimental validation in our group. Thus, bioinformatic approaches to the analysis of gene promoters allows reducing the search space for candidate SNPs and focusing on the SNPs with specific characteristics. Such in silico analysis facilitate understanding of specific features of gene promoters under the study and provide information on the genes functional variability.

P08.09 Breast cancer diagnostics: CSCE screening using the BioNumerics® software.

K. Janssens, B. Pot, L. Vauterin, P. Vauterin;

Applied Maths NV, Sint-Martens-Latem, Belgium.

INTRODUCTION. CSCE technology can be used for indirect mutation scanning (e.g. BRCA1/2 mutation detection). The method is sensitive and more rapid than full gene sequencing and is therefore time and cost saving. By the use of multi-capillary sequencers, high throughput routine screening becomes feasible, but requires the availability of reliable automatic mutation detection software.

DATA ANALYSIS is performed directly on the ABI .FSA files. Files are imported in batches through the use of a BioNumerics® plugin, a script based dynamic extension of the software that uses a file naming strategy to automatically import up to 200 traces with up to 20 samples each. BioNumerics® provides an adapted database environment to store all imported data and takes care of all data management activities. The plugin offers a proper analysis tool for the mutation detection: Peak matching is done using a proprietary algorithm that uses five user-adjustable curve parameters allowing to compare normalized peak shapes. The result is a fast, sensitive and reliable peak matching that can be used to discriminate typical 'wild type samples' from 'heterozygous mutants'. For each target PCR product, one or more target variants can be defined, allowing the creation of polymorphic variants. The result is displayed in a clear overview report with color indication of reference peaks, positive matches, mismatches, failed peaks and problem cases for which verification is required. For the latter click and zoom functions are available to quickly evaluate all matching parameters on the screen.

P08.10 High Quality Mutation Detection

L. Xu, S. Jankowski, E. Fraser, E. Vennemeyer;

Applied Biosystems, Foster City, CA, United States.

Accurate mutation calling and quality data have been identified as key components of direct sequencing by many clinical researchers. We used a new bioinformatics software, Variant Reporter™ to detect muta-

tions in large volume of data sets. This analysis tool provides improved algorithm for SNP detection that are trained to discover accurate sequence variations and report review status for traceability. It helps to create expressive Quality Control Data reports for large data sets and create annotated projects that contain trace files and data annotation. Data sharing abilities between users, such as between a bioinformatics team and end users, will be demonstrated. The guided workflow gives a new or advanced user confidence in a short period of time. In this poster we will highlight how core team can use the new Quality Control metrics and how end users can share the accurate results.

P08.11 Prevalence of mutations in Troponin T (TNNT2) and Troponin I (TNNI3) in Czech hypertrophic cardiomyopathy (HKMP) patients.

L. Benesova¹, K. Curila², M. Penicka², D. Zemanek³, P. Tomasov³, M. Minarik¹;

¹Laboratory for molecular genetics and oncology, Genomac International, Ltd., Prague, Czech Republic, ²Cardiocenter, Charles University, Prague, Czech Republic, ³Cardiovascular center, Faculty Hospital Motol, Prague, Czech Republic.

Hypertrophic cardiomyopathy (HCM) is a serious cardiovascular disease with autosomal dominant inheritance, caused by mutation of genes coding for structural or regulation proteins of sarcomeres of the heart muscle. Troponin T (TNNT2) and Troponin I (TNNI3) are important part of sarcomere of heart muscle and mutations in their genes are responsible for development of HCM.

We have performed complete sequencing of TNNT2 and TNNI3 genes in 100 HCM patients, previously diagnosed by Electrocardiography. We have recorded a total of 4 positives. Of the different mutation types detected, there was 1 novel mutation, which, to date, was not recorded in any of the major HCM databases. A wide variability of the mutation malignancy was recorded with respect to the disease manifestation for different mutation types.

This project was supported by the Czech Ministry of Health Grant Agency project no.NR9164.

P08.12 Disentangling molecular relationships with a causal inference test

J. Millstein, B. Zhang, J. Zhu, E. E. Schadt;

Rosetta Inpharmatics LLC, wholly owned subsidiary of Merck & Co., Inc., Seattle, WA, United States.

There has been intense effort over the past couple of decades to identify loci underlying quantitative traits as a key step in the process of elucidating the etiology of complex diseases. However, a stumbling block has been the difficult question of how to leverage this information to identify molecular mechanisms that explain quantitative trait loci (QTL). We have developed a formal statistical test to quantify the strength of a causal inference pertaining to a measured factor, e.g., a molecular species, which potentially mediates the causal association between a locus and a quantitative trait. We applied the test to infer causal relationships between transcript abundances and obesity traits in mice and also to reconstruct transcriptional regulatory networks in yeast. We treat the causal inference as a 'chain' of mathematical conditions that must be satisfied to conclude that the potential mediator is causal for the trait, where the inference is only as good as the weakest link in the chain. This perspective naturally leads to the Intersection-Union Test framework in which a series of statistical tests are combined to form an omnibus test. Using computer simulated mouse crosses, we show that type I error is low under a variety of non-causal null models. We show that power under a simple causal model is comparable to other model selection techniques as well as Bayesian network reconstruction methods. We further show empirically that this method compares favorably to TRIGGER for reconstructing transcriptional regulatory networks in yeast, recovering 6 out of 8 known regulators.

P08.13 Identification of a potential regulatory element forming a hairpin structure within the 3'UTR of CDK5R1

M. Venturin¹, S. Moncini¹, P. Zuccotti¹, A. Nicolini², P. Riva¹;

¹Department of Biology and Genetics for Medical Sciences, University of Milan, Milan, Italy, ²Department of Pharmacology, Chemotherapy and Medical Toxicology, University of Milan, Milan, Italy.

CDK5R1 encodes for p35, a regulatory subunit of CDK5 kinase, which is fundamental for normal neural development and function. CDK5R1

has been implicated in neurodegenerative disorders and proposed as a candidate gene for mental retardation. The remarkable size of CDK5R1 3'UTR, which is highly conserved in mammals and contains AREs and miRNA target sites, suggests a role in post-transcriptional regulation of its expression. The insertion of CDK5R1 3'UTR into luciferase gene causes a decreased luciferase activity in four transfected cell lines. A 3'UTR region (named C2) leads to a very strong luciferase mRNA reduction, owing to a significantly lower half-life, indicating accelerated mRNA degradation. This fragment was dissected into smaller regions and a 65 bp sequence (C2.11), in which no known regulatory elements were predicted, has been identified to be responsible of the decreased gene expression. A stable structural motif (forming a hairpin) of C2.11 fragment was predicted by RnaProfile and SFold programs, both starting from the isolated fragment and considering it within the whole 3'UTR. Lowering of luciferase levels for the construct with an intact hairpin structure in contrast with unchanged levels for four mutated/deleted structures suggests that this putative element might really have a regulatory role. Since complementary mutations restoring the hairpin did not affect luciferase activity, we suggest that both the sequence and the structure are essential for the ability of C2.11 fragment to reduce transcript stability. Further mutagenesis experiments, binding assays and RNase protection assays will disclose the function of this novel CDK5R1 3'UTR regulatory element.

P08.14

Computational analysis of structural and non-structural proteins of chikungunya virus - mosquito borne disease as potential target for vaccine

K. R. Rupesh¹, K. Mahdieh²;

¹IFREMER, Plouzane, France, ²Special Medical Center, Tehran, Islamic Republic of Iran.

Chikungunya virus (CHIK), an alphavirus borne by *Aedes* mosquitoes that produces dengue-like illness in humans, characterized by fever, rash, painful arthralgia, and sometimes arthritis throughout sub-Saharan Africa, Southeast Asia, India, and Western Pacific. Recent widespread geographic distribution, recurrent epidemics, and infection of military personnel, travelers and laboratory staff working with CHIK have indicated need for more understanding and to have safe and efficacious vaccine. In our present study we have analyzed the characteristics of structural and non-structural proteins synthesized by CHIK using computational tools and predicted the potential vaccine candidates. CHIK contains two proteins - non-structural and structural. Computational analysis of non-structural protein revealed that it is 275.65 kDa hydrophilic protein, pI 6.841, while that of the structural protein revealed a 138.88 kDa hydrophilic protein of pI 8.88. Antigenic prediction sites on non-structural and structural proteins predicted were examined for their use as vaccine candidates for effective control of the disease. Positions of alpha helix and b-sheets in the secondary structure of the proteins were predicted which laid the path for 3D structural characterization of the target proteins. On analyzing hydrophathy plot, structural protein and non-structural protein were found to be hydrophilic. Using nucleotide sequences of the proteins, degenerate primers were designed for its use in PCR based diagnostic identification of the CHIK. Primers designed could find its use as a diagnostic tool for identifying CHIK infected patients specifically. The predicted antigenic sites could be used as potential vaccine candidates.

P08.15

CHDWiki: a comprehensive tool to gather and manage cardiogenetic data

J. Breckpot¹, R. Barrio², B. Thienpont¹, S. Van Vooren², L. Tranchevent², B. Coessens², M. Gewillig³, Y. Moreau², K. Devriendt¹;

¹Center for Human Genetics, Leuven, Leuven, Belgium, ²Department of Electrical Engineering (ESAT), Catholic University of Leuven, Leuven, Belgium,

³Paediatric Cardiology Unit, Catholic University of Leuven, Belgium, Leuven, Belgium.

We present a Wiki based information system designed for the collaborative annotation of genes involved in congenital heart defects (CHD). In this context, a Wiki has many appealing features such as collaborative user-friendly publication. However, a major obstacle for its use is that, unlike databases, it lacks structure and semantics, which prevents the use of further computational knowledge discovery approaches. To benefit from both the Wiki flexibility and the databasing advan-

tages, we extended the MediaWiki platform to allow the inclusion and the interaction with external data and programs. The current online project contains: (i) genes and gene mutations associated to CHDs (local curated database), (ii) links from CHD genes to related patient case reports (local cytogenetic database), (iii) links from CHD genes to publicly available descriptions of copy number variants, (iv) an interactive view of this information on chromosomes. Moreover, CHD candidate genes can be prioritized (Endeavour¹) based on easily selectable training genes associated to CHD types. CHDWiki promises to be the central resource/reference for CHD genetics. It can be viewed as a dynamic review of all the knowledge published in this field. Additionally, the Wiki goes further by managing information on promising candidate genes. The CHDWiki will be the most comprehensive resource available on genes associated to CHDs with 48 genes, 40 CHDs and 135 manually curated associations. While initially dedicated to this concrete project, the system is generic and allows the rapid development of Wikis augmented by structured data and analysis results.

P08.16

Copy number variants and gene expression in the mouse

E. A. C. Chaignat¹, C. N. Henriksen¹, N. Vinckenbosch¹, S. Pradervand¹, M. Ruedi², S. Zoellner³, H. Kaessmann¹, A. Reymond¹;

¹Center for Integrative Genomics, Lausanne, Switzerland, ²Department of Mammalogy and Ornithology, Natural History Museum, Geneva, Switzerland, ³Department of Biostatistics, University of Michigan, Ann Arbor, MI, United States.

Copy number variants (CNVs), defined as large stretches of DNA that vary in number of copies among phenotypically normal individuals, are a source of phenotypic variation. To achieve a more complete mapping of mouse CNVs, we used whole-genome oligonucleotide array comparative genome hybridization to identify CNVs in 13 inbred strains and in 21 wild mice. Using a hidden Markov model, we predicted some 3800 CNV candidate regions, which we subsequently validated using a custom-made array. Thus multiplying by more than three the number of copy-number variable regions previously reported in the mouse genome.

To address whether CNVs affect gene expression, we assessed the expression levels of 45'037 transcription units in liver, kidney, brain, heart, lung and testis of six inbred mouse strains. We found that the variance of the expression levels for each of the recorded tissues is significantly larger for genes mapping inside than for genes mapping outside of CNVs, suggesting that copy number variation affects the variability of gene expression and must be taken into account when considering phenotypic differences between strains. Similarly, the genes mapping on the flanks of the CNVs, despite their not varying in copy numbers, display a modification of their relative expression levels. This phenomenon is effective over several hundreds of kilobases away from a breakpoint. It is present in all assessed tissues and persistent throughout mouse development. Thus our results demonstrate that changes in genome structure influence not only gene dosage but also the expression of neighboring genes.

P08.17

Development of TaqMan® Copy Number Assays for Copy Number Analysis

K. Li, A. Broome, Y. Wang, C. Xiao, F. Wang, I. Casuga, M. Xia, X. You, M. Bozzini, T. Hartshorne, G. Janaway, J. Tan, P. White, A. Toepfel, E. Spier, C. Chen;

Applied Biosystems, Foster City, CA, United States.

Copy number variation is an important polymorphism in the human genome that can be associated with genomic disorders or various diseases. Accurate detection of copy number differences is critical for understanding how copy number variation may play roles in diseases such as cancer, immune diseases, and neurological disorders, and also drug response. Although array-based technologies are powerful for genome-wide CNV discoveries and micro-deletion/micro-duplication syndrome studies, more quantitative technologies with high accuracy, specificity, and sample throughput are necessary to validate identified copy number changes and to detect deletions and duplications for large sample sizes in candidate regions or genes.

Here we report our progress on the development of TaqMan Copy Number Assays. High quality targets for assay design are selected across the whole human genome. A proprietary assay design pipe-

line generates assays for genomic DNA targets, and includes genome specificity checks and screens to minimize oligo interactions. TaqMan Copy Number Assays are run together with a reference assay and gDNA in a duplex real-time PCR. The TaqMan Copy Number Assay detects the target gene or genomic sequence of interest and the reference assay detects a sequence that is known to be present in two copies in a diploid genome. Relative quantification is achieved using a data analysis tool which has been developed for copy number determination. We will discuss progress in development of the assay design pipeline, and data analysis tool, and assay development including studies of reference assays, gDNA input titration, and the accuracy and precision of TaqMan CN assays.

P08.18

In silico search for the cryptic RSS in repetitive elements of human genome

A. Y. Gubsky¹, V. G. Zinkovskiy²:

¹Odessa National I.I. Mechnikov University, Odessa, Ukraine, ²University of Opole, Opole, Poland.

Cryptic recombination signal sequences (cRSS) are targets sites of RAG1/2 proteins when the V(D)J-recombination system gets out of control. Early, we showed that in the human genome (outside the Ig and TCR loci) there are 5649 cRSS which supposedly have high recombination potential (their heptamers and nonamers corresponded to CACAGTG and ACAAACC sequences or differed from them for 1-2 not functional nucleotides). Some of them can hypothetically participate in the formation of intragenic deletions and inversions. At present, having matched coordinates of such cRSS with coordinates of 9933066 known in the human genome repetitive elements in silico, we observed that 3500 (61 %), 265 (5 %), 102 (2 %), 51 (1 %) 7 (0,1 %) cRSS are the structural elements of non-LTR retrotransposons (AluY, AluX, L1, MIRb, etc), endogenous retroviruses and LTR retrotransposons (LTR1B, MLT1C, ERVL-E, etc), DNA transposons (Charlie1, MER58A, Tigger1, etc), simple repeats ((CA)_n, (CAAAA)_n, etc) and other repeats (not identified) respectively. Having researched the localization of such cRSS, we observed that in 85 % cases the nucleotide sequences of motives are fully localized inside repeats and in 15 % cases are localized partly. In whole, cRSS were found in structure of 414 unique types of repeats of 16 families. We consider, that many types of repetitive elements can participate in spreading of motives which can theoretically mediate instability in human genome when the V(D)J-recombination system gets out of control.

P08.19

Development of a TaqMan® Cytochrome P450 Panel Array and Positive Controls

T. Hartshorne, D. Merrill, S. Desai, T. Ceccardi;

Applied Biosystems, Foster City, CA, United States.

The Cytochrome P450 enzymes: CYP2D6, CYP2C9 and CYP2C19 metabolize the majority of currently prescribed drugs. Pharmacogenetic analysis of polymorphic alleles of their genes has demonstrated numerous links between functional polymorphisms, having absent or altered enzyme activity, and cases of non-response or adverse drug reactions. Genotyping these variants can have a significant role in predictive drug metabolism and safe, efficacious drug therapy.

Applied Biosystems offers over 2600 TaqMan® Drug Metabolism (DME) Genotyping Assays that detect polymorphisms in coding and regulatory regions of over 220 DME genes. To facilitate pharmacogenetic research, TaqMan® DME Assay panels on TaqMan® Arrays were developed including a P450 array containing 48 assays to important CYP2D6, CYP2C9 and CYP2C19 variants. Arrays are 384-well microfluidic cards that are pre-loaded with assays, greatly reducing experimental preparation time and eliminating the need for liquid-handling robots or multi-channel pipettes. Benchmark tests conducted to compare the performance of assays run on arrays to data from 384-well plates showed that assays on arrays can be genotyped with the same high success rate as on plates. An interactive data analysis tool, AutoCaller™ software, enabled overlaying and viewing cluster plots from multiple arrays and facilitated genotyping analysis. Synthetic positive control templates for each assay were run on arrays in pools to represent all 3 genotypes; controls demonstrated assay functionality for each probe and aided genotype calling. TaqMan® DME SNP

Arrays and positive control templates (available through Gene Link™) offers an easy to use platform for accurate, reliable genotyping of drug metabolism and response variation.

With disease studies and genomics research producing ever larger datasets, there is an urgent need for advanced informatics solutions that can handle such extensive information. Launched in January 2008, the GEN2PHEN project (Genotype-To-Phenotype Databases: A Holistic Solution) aims to help address this need.

The GEN2PHEN consortium (<http://www.gen2phen.org/>) involves 19 research and company partners; including 17 from Europe, one from India, and one from South Africa. Funding of 12 Million Euro from the European Commission (7th Framework Programme) is bolstered by additional funds provided by the partner institutions. Being a key European program, GEN2PHEN is intimately connected with other major infrastructure projects such as BBMRI and ELEXIR.

The main objective of GEN2PHEN is to establish the technological building-blocks needed to evolve today's diverse databases into a seamless genotype-to-phenotype (G2P) biomedical knowledge environment, tied into genome browsers like Ensembl.

The project's specific objectives include:

- 1) Analysis of the current G2P informatics
- 2) Analysis of ethical aspects that need to be addressed
- 3) Development of key standards
- 4) Creation of generic database components and integration solutions
- 5) Creation of search modalities and data presentation solutions
- 6) Facilitation of data flows into G2P databases
- 7) Creation of a 'G2P Knowledge Centre' providing information exchange solutions, search/analysis tools, and support for primary data and comment deposition
- 8) Deployment of GEN2PHEN solutions to the community
- 9) Addressing questions of system durability and long-term financing

The research leading to these results has received funding from the European Community's Seventh Framework Programme (FP7/2007-2013) under grant agreement n° 200754.

Two-Dimensional Electrophoresis of Nucleic Acids to Assess Quality of Samples and Efficiency of Molecular Methods

J. J. Jonsson^{1,2}, H. G. Thormar^{1,3}, G. H. Gunnarsson^{1,3}, F. S. Eiriksdottir³, B. Gudmundsson³, S. Sigurdardottir^{1,2}, P. Estibeiro³;

¹Univ. of Iceland, Reykjavik, Iceland, ²Genetics and Molecular Medicine, Landspítali, Reykjavik, Iceland, ³BioCule Inc., Reykjavik, Iceland.

Two-dimensional (2D) electrophoresis allows separation of molecules based on different characteristics. Although widely used in proteome studies, 2D electrophoresis of nucleic acids has so far only had limited applications mostly in studies on DNA metabolism. We have invented several new techniques of 2D electrophoresis of nucleic acids. These techniques can be used to simultaneously assess length distribution and strandness i.e. amount of single-stranded DNA, double-stranded DNA (both A and B forms) and RNA-DNA hybrids in various samples. DNA lesions detected with our technology include nicks, double-stranded breaks, base modifications and drop outs leading to

compromised base pairing or even generation of single-stranded DNA molecules. Various lesions in DNA can happen *in vivo* and *in vitro*. We have observed extensive damage to DNA due to various types of lesions formed *in vitro* upon storage of biosamples and under conditions simulating various laboratory procedures. These lesions in the original samples influence the efficiency and quality of complex molecular procedures such as quantitative amplifications and random labelling reactions. 2D Strandness-Dependent Electrophoresis can also be used to assess efficiency of cDNA synthesis, a critical step in genomic expression studies. Typical yield of double-stranded DNA is again very variable reflecting the poor control of such a complex procedure. To make these techniques easily available to investigators, BioCule Inc. is marketing a dedicated automated instrument using 2D microgels.

P08.22

The acidic environment as essential attribute for the DNA functioning

T. M. Partskhaladze, T. J. Mdzinarashvili, T. I. Lomidze;
Tbilisi State University, Tbilisi, Georgia.

Experimental results were obtained that give the possibility to conjecture mechanisms by which the proteins (RNA polymerases) carry out promoter melting, which is important step in transcription process. We suppose that process of melting (opening of specific sites of ds-DNA) is induced by acting of acidic residues enriched regions of proteins. Experimental investigations of the DNA molecule in acidic environmental condition unambiguously have indicate that acidic area (pH<5.0), induces despiralization of DNA and process is reversible. The calorimetric measurements performed under different acidity condition have shown, that ds-DNA structural flexibility greatly depends on the value of solvent pH. It is shown that, by the increase of environmental acidity (in contrary to the alkaline environment), DNA structure undergo considerable destabilization. We have demonstrated that if DNA destabilised under acidic treatment (for which stability of double helix considerably is reduced and most of its sites lack helical structure) is transferred in the neutral physiological environmental condition (pH 7.0), DNA restores its nature helical structure throughout.

P08.23

The stochastic description of DNA hybridization

A. Arakelyan¹, V. Arakelyan²;

¹Center of Medical Genetics and Primary Health Care, Yerevan, Armenia, ²Yerevan State University, Yerevan, Armenia.

There are a lot of works devoted to DNA hybridization problem, however practically in all works the process of hybridization is described deterministically. Such description is not full. The full description of DNA hybridization process should be done in the framework of stochastic model. For the stochastic description of DNA hybridization, let us introduce the conditional probability function, that there are a certain number of DNA duplexes on substrate at moment of time, provided that at a preceding moment of time on substrate there were another number of DNA duplexes. Let us consider DNA hybridization process as a discrete Markov process. We obtained equation for the change of conditional probability in time. Using this equation it is possible to calculate not only an average number of DNA duplexes, but also dispersion, correlation function and spectral density of DNA duplexes number on substrate. It is shown, that with raising the concentration of single-stranded DNA in solution the dispersion of DNA duplexes on substrate increases, and then passing through a maximum decreases, and at a very high concentration of single-stranded DNA the dispersion approaches zero. The results we have obtained can be used in DNA-chip technology. In many cases, the basic source of random variations of a signal during information read-out from DNA-chip is fluctuation of concentration of immobilized DNA, and this is result of chip production technology. Our calculations indicate that another source of fluctuation is present, which is connected to the stochastic nature of DNA hybridization process.

P08.24

Meta-analysis in the technology of DNA microarrays

A. Kastrin, B. Peterlin;

Division Of Medical Genetics, Ljubljana, Slovenia.

With the explosion of microarray technology, an enormous amount of data is being generated. Limited overlap among the published lists of discovered genes between similar studies makes it difficult to determine which, if any, exhibit truly effect of differential expression and prompting the question of whether microarray studies are inherently reliable. To address this issue it is of special interest to combine results across multiple studies of various research groups working on similar clinical entities. Systematic integration of gene expression data from different sources increases reliability of detecting differentially expressed genes. The challenge, however, is in designing and implementing efficient analytic methodologies for combining high-throughput genomic data from several related studies. We consider the meta-analysis of different microarray data sets using a fixed and random effect paradigm and demonstrate how relatively standard statistical approach yield promising results. We illustrated proposed method by integrating gene expression profiles from three different prenatal trisomy 21 studies based on Affymetrix microarray technology. We identified a novel set of 14 transcripts of potentially candidate genes, which are active in development of human embryo with trisomy 21 (Table 1). Our results show that this approach would serve as a plausible method for analyzing microarrays beyond the specific implications for trisomy 21.

Multi-copy amplification of the exon 2 of the dystrophin gene in a Duchenne muscular dystrophy patient: A new approach by Oligo-Array-CGH

H. Gabriel¹, M. Kukuckova², A. Utkus³, V. Kucinskis³, A. Lott¹, M. Gencik^{1,2};

¹Zentrum fuer Medizinische Genetik, Osnabrueck, Germany, ²Medgene,

Bratislava, Slovakia, ³University of Vinius, Vilnius, Lithuania.

Duchenne muscular dystrophy (DMD) and Becker muscular dystrophy (BMD) are the most common inherited disorders of muscle.

Deletions are found in 55% of patients with BMD and 65% of patients with DMD. Point mutations account for ca. 30% of mutations, while duplications can be found in 5-10% of DMD patients.

MLPA (multiplex ligation-dependent probe amplification), is widely used as a reliable method to detect both deletions and duplications of dystrophin exons.

Here we describe a 5 years old male patients from lithuania with suspected Duchenne muscular dystrophia. He had a positive Gower sign and pseudohypertrophy of calf. Muscular biopsy showed muscular dystrophy with lipomatosis and fibrosis. CPK tests revealed a value of >22.000 U/L.

Analysis of the dystrophin gene by multiplex PCR excluded deletions. MLPA showed a single amplification of the exon 2 of the dystrophin gene. Surprisingly, calculation of the MLPA data revealed the presence of 4 to 5 copies of the exon 2. To validate this finding quantitative real-time PCR was performed giving also evidence for 4 to 5 copies of exon 2

MLPA testing of the patients mothers demonstrated that the amplification was de novo.

To identify the exact range of the amplification a new approach by oligo-array-CGH was conceived. Shortly, a customer-designed 44k

Oligo-Array (Agilent) was created. Multiple probes on this array spanning the amplified region of exon 2 of the dystrophin gene. In a next step Array-CGH data will provide a basic for the design of PCR systems for exact determination of the amplification limits.

P08.26

Role of the kinase DYRK1A in cerebral cortex development: effects on the transcriptome

E. Balducci^{1,2}, M. J. Barallobre^{1,2}, M. C. Ruiz de Villa³, A. Sánchez², M. L. Arbonés^{1,2};

¹Center for Genomic Regulation (CRG), Barcelona, Spain, ²Centre for Biomedical Research on Rare Diseases (CIBERER), Barcelona, Spain, ³Statistics Department, University of Barcelona, Barcelona, Spain.

DYRK1A is a dual-specificity protein kinase involved in brain development. Human DYRK1A is located in the Down Syndrome (DS) Critical Region of chromosome 21 and its overexpression has been associated to the neurological defects observed in DS. Nevertheless, DYRK1A function at the molecular level remains poorly understood. As DYRK1A substrates include several transcription factors, we have analyzed the impact of Dyrk1a dose reduction on the transcriptome of mouse cerebral cortex at postnatal day 0 (P0) and 7 (P7). To this end, global gene expression of Dyrk1a^{-/-} and Dyrk1a^{+/+} cortices were compared using Affymetrix chips.

Microarray results revealed deep changes in gene expression extending into the set of 3169 genes analyzed. Among those, 22% and 5% showed different expression levels between genotypes at P0 and P7 respectively (adj-p<0.05). Despite this global perturbation, changes in the expression of individual genes were subtle: only 1% (at P0) and 3% (at P7) of the differentially expressed genes showed a fold-change >2. Gene Ontology analysis revealed enrichment in transporters within the down-regulated genes and in DNA binding molecules within the up-regulated genes both, at P0 and at P7. Among the genes deregulated between genotypes, 61 were common to both developmental stages. Interestingly, their regulation showed a similar trend at P0 and P7 but always opposite to the developmental trend (defined by the expression of such genes in Dyrk1a^{+/+} mice at P7 vs P0).

These results suggest that DYRK1A plays a pivotal role in cerebral cortex development acting on the regulation of the transcriptome.

P08.27

Re-examining the human genome

R. J. Kinsella, I. Barnes, C. Snow, A. Frankish, J. Mudge, L. Wilming, J. Loveland, D. Carvalho-Silva, J. Rajan, E. Hart, L. Gordon, J. Gilbert, S. Trevanion, T. Hubbard, J. L. Harrow;

Wellcome Trust Sanger Institute, Hinxton, Cambridgeshire, United Kingdom.

Recent improvements in sequencing technologies enable the routine sequencing of large complex genomes. However the annotation of such genomes is still complex and there is no higher eukaryote that has all its coding sequences predicted to 100% accuracy. The HAVANA group (<http://www.sanger.ac.uk/HGP/havana/>) at the Wellcome Trust Sanger Institute is involved in manually annotating all the coding transcripts within the human genome through various international collaborations. The team is involved in the scale up of the ENCODE pilot gene annotation project (GENCODE) to the whole human genome. The project includes seven other partner institutes and will integrate computational approaches, expert manual annotation and targeted experimental approaches to generate a reference gene set. This will include analysis of pseudogenes, experimental validation of putative/novel genes and examination of the protein-coding potential of genes using comparative and structural analysis.

In addition, the Havana group collaborates with RefSeq at NCBI, UCSC and Ensembl to produce a core set of human and mouse coding genes for the Consensus CDS (CCDS) project. Any CCDS candidate transcripts where there is disagreement between WTSI/EBI and NCBI annotation are manually re-inspected, discussed and, where possible, an accord is reached on a structure (18293 human CCDS agreed to date). The end result is a combined, non-redundant gene set agreed by several of the major genome centers.

All annotation is displayed on the Vertebrate Genome Annotation (VEGA) database, a central repository for high quality manual annotation of finished vertebrate genome sequence with a three monthly release cycle (<http://vega.sanger.ac.uk/index.html>).

P08.28

An in vivo unbiased screen for enhancer activity using lentivector-mediated transgenesis

M. Friedli¹, I. Barde², C. Attanasio¹, M. Arcangeli¹, A. Quazzola², S. Verp², F. Spitz³, J. Zakany⁴, D. Duboule^{4,2}, D. Tronc², S. E. Antonarakis¹;

¹University of Geneva, Department of Genetic Medicine and Development, Geneva, Switzerland, ²EPFL, School of Life Sciences, Lausanne, Switzerland, ³EMBL, Heidelberg, Germany, ⁴University of Geneva, Department of Zoology and Animal Biology, Geneva, Switzerland.

Finding sequences that control spatial and temporal expression of genes is important to understand genome function. Here, we present an in vivo screen for enhancers in a contiguous 200-kilobase DNA fragment using lentivector-mediated transgenesis. Previous studies have used evolutionary conservation as an indicator of regulatory potential, but increasing evidence suggests that this criterion systematically overlooks functional sequences. We thus designed our study without any bias towards a particular sequence feature. We chose a mouse BAC corresponding to a region of Hsa21 because it contains the olig1 and olig2 genes that are expressed specifically in the CNS. In order to screen this fragment systematically for enhancer activity, we generated a library of 121 overlapping clones (sizes: 2-4kb) in a LacZ reporter lentiviral construct containing a minimal promoter. We generated lentivectors individually for each segment and injected them in pools of 10 or 20 in mouse oocytes. LacZ staining was performed on E11 embryos to identify expression patterns. The first six pools tested yielded 60 of 242 LacZ positive embryos with ~2.5 transgenes per embryo. To date, 7 fragments of 52 assessed were identified that potentially contain gene expression regulators. To confirm regulatory activity, 4 sequences were re-injected individually, 2 (one evolutionary conserved) of which were confirmed as tissue specific enhancers with stainings in the spinal chord and trigeminal ganglion compatible with olig expression. The method could be scaled up to cover large chromosomal regions, and determine what fraction of the constrained and non-constrained genome has regulatory potential.

P08.29

Enhanced workflow for sequencing PCR products by capillary electrophoresis

P. Kotturi, E. Currie-Fraser, S. Pickrell, M. Johnson, P. McNamara; Applied Biosystems, Foster City, CA, United States.

Since the introduction of Sanger dideoxy sequencing, significant efforts have been directed toward increasing throughput by streamlining workflow. We describe here further enhancements for a PCR product resequencing workflow capable of reducing the total time, from beginning PCR reactions through completion of basecalling, to 6 hours or less. The workflow shown employs a new AmpliTaq Gold[®] Fast PCR Master Mix in conjunction with modified thermal cycler conditions to substantially reduce the time required for PCR amplification. Process time is further reduced through optimization of cycle sequencing (BDT v1.1) conditions. We have coupled these improvements with an efficient sequencing reaction cleanup protocol and decreased CE run time using the fast plates on a 3130xL. Overall data quality compares favorably with data obtained using previously documented methods. The increased efficiency and generation of high quality results is vital to both clinical and research applications in reducing time to discovery.

P08.30

Analysis of copy number variation using formalin-fixed paraffin-embedded (FFPE) samples on BAC microarrays

D. Postma, S. Snoeijsers, M. Lacombe, **S. Schoenmakers**; Kretech Diagnostics BV, Amsterdam, The Netherlands.

Array-based comparative genomic hybridization (aCGH) has become a powerful tool to analyze DNA copy number changes. Especially in combination with archival tissue samples with well-documented follow-up data, it enables the analysis of genomic changes underlying tumour development. Unfortunately, DNA isolated from archival, formalin-fixed, paraffin-embedded (FFPE) material, is often degraded and therefore difficult to label. In theory, labelling techniques that skip the use of enzymes would be the best option. Therefore, we compared the non-enzymatic Universal Linkage System (ULS) and conventional random priming to label DNA isolated from FFPE material. Testing of FFPE samples that had been stored for up to 17 years showed

that ULS-labelling yielded satisfying degrees of labelling (DoL~1.5%), while the ones for random priming were ~0.2%. Reproducibility of the analysis of these samples on BAC arrays was better as well (R²=0.96 for ULS vs R²=0.88 for random priming).

In addition, aCGH applications involve substantial amounts of genomic DNA, while the amount of DNA available is often limited, requiring whole-genome amplification (WGA). Recently, Qiagen's REPLI-g has been optimized for degraded samples. Therefore, we compared BAC aCGH experiments using 100ng of FFPE DNA, labelled using either direct random priming or a combination of REPLI-g and ULS or REPLI-g and random priming. Correlation with data obtained using conventional microgram amounts of input DNA data was best for the REPLI-g/ULS combination (R²=0.84 vs 0.70 for random priming), as was reproducibility.

In conclusion, ULS allows aCGH analysis of archival DNA, while minimizing labelling-induced bias.

P08.31

Functional SNP candidates identified by genome wide ChIP analyses

A. Ameur¹, A. Rada-Iglesias^{2,3}, O. Wallerman², M. Motalebipour², S. Enroth¹, J. Komorowski^{1,4}, C. Wadelius²;

¹The Linnaeus Centre for Bioinformatics, Uppsala, Sweden, ²Rudbeck Laboratory, Uppsala, Sweden, ³Current address: The Linnaeus Centre for Bioinformatics, Uppsala, Sweden, ⁴Interdisciplinary Centre for Mathematical and Computer Modelling, Warsaw, Poland.

Disease-associated SNPs identified in large association studies are often located in non-coding regions and it is possible that some SNPs affect the interaction between transcription factors and DNA. In HepG2 cells we mapped binding sites for the transcription factors USF1 and USF2 along the genome using ChIP-chip. Using the novel BCRANK algorithm, we detected 1754 binding sites for USF1 with the predicted binding motif. In dbSNP, we found 140 candidate functional SNPs in these motifs. Eight of the SNPs were heterozygous in at least one of four human cell samples. In 5 of 6 cases where the SNP was inside the core predicted USF1 binding motif CACGTGAC, ChIP and sequence analysis of the enriched DNA showed that USF1 was, with statistical significance bound to the allele containing the USF1 consensus and less to the other. We detected significant allelic differences for USF2, POLR2A and H3K27me3. As a negative control, we analyzed 2 cases where the SNP was located just outside USF1 core sequence and saw no differences for any investigated factor. By high resolution genotyping in the HepG2 genome we have a dense map of potential functional SNPs. We have mapped additional factors along the genome using ChIP-sequencing, identified individual binding motifs containing hundreds of SNPs. Furthermore, we found significant enrichment of one allele at heterozygous positions as indication of allele specific DNA-protein interactions. Thus, individual binding sites can be defined at base pair resolution and large numbers of candidate functional SNPs can be predicted in genome wide experiments.

P08.32

TaqMan® Express: A format for easy mRNA quantification using pre-plated TaqMan Gene Expression Assays

K. Poulter, F. Chan, J. Rappleye, P. Hegerich, D. N. Keys, K. Y. Lee, G. Marcus, S. Koepf, C. Chen;

Applied Biosystems, Foster City, CA, United States.

TaqMan® Express Plates contain up to 96 pre-spotted and dried TaqMan Gene Expression Assays on an optical 96-well plate. Pre-plated assays simplify, accelerate and help error-proof mRNA quantification experiments. This is especially important when there is more than one operator in a lab, when a study is being done across multiple labs, or when a study is extended over a period of time. The assays in TaqMan® Express plates are user-selected from a catalogue of >50,000 Taqman assays targeting human, mouse, rat, Rhesus and dog genes. Here, we show that TaqMan assays which are aliquoted and dried for storage perform comparably to standard wet assays aliquoted immediately before use. Dynamic range for dried assays showed >6 logs of linearity, detection of 2-fold discrimination with 99.7% confidence was demonstrated, and limit of detection was <10 copies. When the wet vs dry performance of a defined set of assays was compared, the difference between the normalized CT values (ddCT) was <0.3. The data also shows strong reproducibility for replicates within and

across plates and across manufacturing lots. For assays with CT<32 the StDev was <0.3 for all of these comparisons. Finally, data showing reproducibility for plates run by different individuals at different sites will be presented.

P08.33

EUREXpress, a transcriptome atlas of the developing mouse embryo: a valuable resource to study mechanisms of gene expression

G. Diez Roux, EUREXpress consortium;

Telethon Institute of Genetics and Medicine, Napoli, Italy.

Genome-wide expression analyses have a crucial role in functional genomics. The EU-funded EUREXpress consortium has generated a transcriptome-wide acquisition of expression patterns by means of ISH and established a web-linked, interactive digital transcriptome atlas (www.eurexpress.org). To date we have generated over 12000 expression patterns, which have been thoroughly annotated. This interface includes 1420 anatomical structures and correlative trees regarding ontological (embryological) and topological relations allowing advanced queries. In order to perform more global analysis we divided the genes studied into two main categories, based on their annotated expression patterns, namely a) "regional", i.e., genes with clearly detectable patterns which however were not widespread to all the tissues, and b) ubiquitous/undetectable, i.e., genes which either did not give any clearly detectable pattern in any tissue or were detected in all tissues. The analysis of the data has determined that 35-40% of genes at E14.5 present a restricted/regional expression pattern. We sought to establish possible correlations between the genomic properties of regional genes vs. undetectable/ubiquitous genes including gene size, number of annotated alternative transcripts, and degree of evolutionary conservation. Statistical analysis revealed that regional genes have a) an average genomic length considerably higher than undetectable/ubiquitous genes, a) a higher number of alternative splice isoforms and c) are conserved in a higher number of species across evolution as compared to undetectable/ubiquitous genes. In addition, the data has also allowed performing detailed molecular characterization of the CNS and has identified, for example, novel molecular regionalization of the thalamus, diencephalons and the telencephalic pallium.

P08.34

Functional exploration of the fibrinogen gene landscape to identify new regulatory mechanisms

A. Fort¹, L. Palumbo¹, R. J. Fish¹, M. Neerman-Arbez^{1,2};

¹University Medical Center, Geneva, Switzerland, ²Division of Angiology and Haemostasis, University Hospital, Geneva, Switzerland.

The transcription of the three fibrinogen genes is coordinately regulated and previous studies have described cis-acting elements situated in each of the 5'-promoter regions. Recent advances in vertebrate genome sequencing and annotation allowed us to search for more distant cis-/trans-regulatory elements involved in the regulation of the fibrinogen gene cluster and investigate the molecular mechanisms by which these elements participate in transcriptional regulation. Multi-species genome comparisons revealed remarkable conservation of the fibrinogen gene cluster structure as well as a conserved adjacent syntenic gene desert region (130kb). We therefore speculate that regulatory element of the fibrinogen gene cluster have also been conserved throughout the vertebrates' evolution and reside in the syntenic regions including the cluster. Analyses of the conserved block of synteny bearing the fibrinogen cluster (200kb), using the VISTA browser, revealed 33 conserved non-coding sequences (CNC). We tested the regulatory potential of 17 of the CNCs in a reporter assay, by inserting each CNC upstream of a Luciferase gene. Regulatory activity was measured in hepatoma cell lines (Huh7, HepG2) and in HEK-293T cells. We identified 3 CNCs with hepatocyte-specific enhancer activity, one residing between FGB and FGA and two situated in the adjacent syntenic non-coding region. We are also performing chromosome conformation capture (3C) experiments to identify cis or trans DNA-DNA interactions between the proximal fibrinogen gene promoters and currently unknown sequences.

Future work will focus on the functional characterization of these newly identified cis-regulatory elements.

P08.35

Complete sequencing of the CFTR gene using the new generation GS-FLX sequencing technology

H. Cuppens, L. Vliegen, J. Cassiman;

Center for Human Genetics, Leuven, Belgium.

In most genes involved in genetic diseases, a broad spectrum of mutations is found. Even for diseases such as cystic fibrosis, genetic testing can be very challenging. Indeed, routine CFTR genetic tests only screen for the most common mutations (88-92% sensitivity in most European countries).

New generation sequencing technology, such as picotiter pyrosequencing on a GS-FLX system, has been recently introduced. However, this technology was initially developed for whole genome sequencing purposes.

We adopted this technology for complete sequence analysis of the CFTR coding region, and its exon/intron junctions.

To this aim we have developed a robust multiplex amplification assay in which biotinylated amplicon-specific primers are locally restricted through streptavidin/biotin crosslinking. Indeed, 30 amplicons should be analyzed for the CFTR gene, which can be only economically feasible if amplified in one, or a limited number, PCR multiplex reaction(s). For a 50x coverage, only half a million nucleotides are needed for CFTR sequence analysis, i.e. 0.5% of the full capacity of the GS-FLX system. Therefore, 100-200 samples should be pooled in order to use the full capacity of the GS-FLX system. We therefore also developed an universal sample tagging approach allowing the pooling of more than 100 samples with one set of 260 primers (60 amplicon-specific and 200 tagging primers). This compares to 6000 primers if amplicon-specific PCR primers are tagged as such.

This technique is readily transferable to any gene, allowing sequencing of more than 100 samples for the same gene, or even different genes, in an economically feasible way.

P08.36

Nuclear localization of SM22 alpha during heart development

E. Bregant¹, R. Lonigro¹, N. Passon¹, A. Scaloni², G. Renzone³, M. Pandolfi⁴, C. Di Loreto⁴, G. Damante⁵;

¹*Department of Biomedical Sciences and Technologies, Udine, Italy,* ²*Proteomics and Mass Spectrometry Laboratory, ISPAAM, Napoli, Italy,* ³*Proteomics and Mass Spectrometry Laboratory, ISPAAM, Napoli, Italy,* ⁴*Department of Medical Morphological Research, Udine, Italy,* ⁵*Department of Biomedical Sciences and Technologies, Udine, Italy.*

The molecular mechanisms that control heart development have been the subject of intense investigation. The transition of embryonic to adult cardiomyocytes is associated to changes in the expression patterns of different proteins.

Aim of this study is the identification of nuclear proteins whose expression is modified during cardiac differentiation. A proteomic approach, based on two-dimensional electrophoresis was utilized. The experimental model is the H9C2, a myoblast cell line derived from embryonic rat ventricle. These cells proliferate in medium with 10% serum, instead low serum and stimulation with retinoic acid induce differentiation versus cardiomyocytes.

We have analyzed the nuclear extracts of H9C2 that are grown in proliferation medium and in differentiation medium by proteomic approach.

Seven different proteins have been identified as differentially expressed after MALDI-TOFF, LC-ESI-MS/MS mass spectrometry. An interesting protein is SM22 alpha (transgelin), a 22-KD cytoskeletal protein that is a marker of smooth muscle cells.

The level of the SM22 alpha is reduced at 20th day of differentiation condition. These data are confirmed by Western-Blot analysis and quantitative RT-PCR.

By immunocytochemistry, we confirmed the nuclear localization of the protein in H9C2 cell line. Furthermore, in histological section of human embryonic heart we show that SM22 alpha is located at nuclear level in heart vessels and in myocytes of the cardiac outflow.

Thus, our data indicate that SM22 alpha can be localized in the nucleus and suggest that this localization is regulated during development

P08.37

Methylation-sensitive High Resolution Melting Analysis as a diagnostic tool for Beckwith-Wiedemann and Silver-Russell syndromes.

M. Alders, J. Blik, K. vd Lip, R. vd Boogaard, M. Mannens;

Academic Medical Center, Amsterdam, The Netherlands.

The Beckwith-Wiedemann syndrome (BWS) and Silver-Russell syndrome (SRS) are caused by disturbed imprinting at 11p15. This region harbors two independently regulated clusters of imprinted genes. The first cluster is under control of the IC1 upstream of the H19 promoter, which is methylated only at the paternal allele. The second cluster is controlled by IC2 upstream of the KCNQ1OT1 promoter and is methylation on the maternal allele only.

BWS is an overgrowth syndrome. The majority of the patients display hypermethylation of IC1, hypomethylation of IC2 or both. SRS is a growth retardation syndrome and in a subset of patients a hypomethylation of IC1 is found, opposite to the aberration found in BWS patients.

Molecular confirmation of BWS and SRS is done by methylation analysis of IC1 and IC2. Since the methylation defects in BWS and SRS are mosaic the test must be quantitative.

We set out to validate High Resolution Melting Analysis (HRMA) for methylation analysis in BWS/SRS diagnostics. Advantages of this method are that it is fast, cost effective and requires no post PCR handling. We tested a group of 17 BWS/SRS patients with different levels of hyper- and hypomethylation at IC1 and/or IC2 and 45 normal controls. All patients showed a melting profile different from the normal controls and the degree of deviation was consistent with the degree of hypo- or hypermethylation as determined by southern blotting. In conclusion, HRMA analysis proves to be a fast, reliable and sensitive diagnostic tool for BWS and SRS.

P08.38

Calibrator improves methylation-sensitive high resolution melting results

C. N. Gundry¹, M. Wall¹, J. McKinney¹, J. D. Phillips², M. K. Yu³, D. H. F. Teng¹;

¹*Idaho Technology, SL, UT, United States,* ²*University of Utah, SL, UT, United States,* ³*Myriad Genetics, SL, UT, United States.*

High resolution melting has been shown to be a sensitive method for methylation detection of CpG sites. In high resolution melting, multiple CpG sites within the same PCR fragment can be detected homogeneously. Unlike the common real-time methylation-specific PCR technique (MethylLight Taqman probe detection) hi-res melting provides more information with fewer PCRs. As 5-methylcytosines are resistant to conversion to uracils, there can be substantial sample-to-sample melting differences depending on the number of CpG dinucleotide sites and the sequence context within the fragment. However, depending upon fragment and the exact number of 5-methylcytosines actually converted during the bisulfite treatment, there can be both variation in replicate conversions of the same sample and very subtle melting differences between samples. Both of these problems are resolved with calibrated melting. Calibration has especially been helpful to increase accuracy of genotyping when melting differences are subtle. This technique improves hi-res melting reproducibility and genotyping calls via synthetic oligonucleotide probes. We used melt calibration in conjunction with amplicon methylation analysis to improve our detection in a highly methylated region. We obtained excellent resolution of amplicon fragments within a hypermethylated region of the miRNA-195 genomic sequence. Sequence verification showed that our homogeneous technique is comparable to this gold standard in accuracy.

P08.39

Interlaboratory validation of High Resolution Melting (HRM) for BRCA1 and BRCA2 on the LightCycler® 480

T. Janssens¹, N. van der Stoep², R. Buser³, G. Michils¹, A. Corveleyn¹, E. Dequeker¹, P. Maille³, E. Bakker², G. Matthijs¹;

¹*Center for Human Genetics, Leuven, Belgium,* ²*Center for Human and Clinical Genetics, Leiden, The Netherlands,* ³*Laboratory of Oncogenetics, Geneva, Switzerland.*

High Resolution Melting (HRM) was selected as a technology for which a thorough validation would be very timely. In a collaborative EuroGen-test study, we extensively tested it on the LightCycler® 480.

HRM is a fast, simple and cost-effective high-throughput scanning

method to detect sequence variations. PCR is performed in the presence of a saturating dsDNA binding dye. Single-base variations in the amplicon result in altered melting behaviour after heteroduplex formation, visualised by HRM plots. The LightCycler® 480 performs both PCR and HRM in one run.

BRCA1 and BRCA2 were chosen as target genes, because their size and mutation spectrum represent a challenge in molecular diagnostics. Current methods, like dHPLC and DGGE, despite their good performance, are limited by throughput or labour-intensity.

HRM is potentially useful for solving these problems. However, it needs to be shown that the sensitivity and the user-friendliness are at least as good as the current state of the art. We set up an extensive validation in 3 laboratories.

The first objective was to design a complete primer set for BRCA1 and BRCA2. Indeed, the performance of HRM is largely depending on PCR quality. Critical criteria were specific banding patterns after gel electrophoresis, sigmoid curves on real-time PCR plots and less than 3 melting domains per amplicon.

About 300 known variations are being tested in a blinded way. This will allow us to determine whether HRM reaches a sensitivity close to 99%, which would make it a suitable new method for diagnostic use.

P08.40

Interlaboratory validation study of High Resolution Melting Curve Analysis for mutation scanning of BRCA1 using the LightScanner (IT)

N. van der Stoep¹, C. D. M. van Paridon¹, A. Stamberгова², P. Norambuena², M. Macek², T. Janssens³, G. Matthijs³, E. Bakker¹;

¹Center for Human and Clinical Genetics, Leiden, The Netherlands, ²Institute of Biology and Medical Genetics, Prague, Czech Republic, ³Center for Human Genetics, Leuven, Belgium.

The current set up for mutation scanning of BRCA1 occurs through sequence analysis, DGGE, PTT and dHPLC. All these techniques are time consuming and expensive. Therefore we have evaluated the High-Resolution Melting Curve Analysis (HR-MCA) as a high-throughput mutation-scanning tool for the BRCA1 gene using LightScanner from Idaho Technology (IT) and the LightScanner-MasterMix. This study was implemented in the EuroGentest evaluation program for new techniques in genome diagnostics. Investigations were carried out using a panel of >189 variants and 327 wt controls. We optimized and evaluated 58 primer-sets that cover BRCA1. All heterozygous variants could be detected using the Call-IT-1.5 software resulting in a 100% mutation-detection sensitivity. These variants also include small DNA deletions and insertions. Out of 327 wts we observed 3,7% false positive curves (FP) resulting in a specificity of 96%. Re-evaluation of ten BRCA1-amplicons in the two other diagnostic laboratories gave rise to identical results. Moreover using unlabeled probes we were able to identify many frequent occurring polymorphisms, omitting unnecessary sequence analysis. Finally we selected a set of 41 best-performing primers that encompass the entire BRCA1 gene using stringent criteria and performed 2 blind tests on 27 patient DNA samples that were sequenced in parallel. Optimal HR-MC analyses setting were fixed based on the results obtained with our large set of known control samples. In both series we detected all heterozygous variants and observed a FP-score of 1,8%. In conclusion, HR-MCA with the LightScanner appears to be a rapid and sensitive method for mutation scanning.

P08.41

Isolation and transcriptional profiling of embryonic human neural crest cells

S. Thomas¹, M. Thomas¹, P. Wincker², P. Xu³, M. C. Speer³, A. Munnich¹, S. Lyonnet¹, M. Vekemans¹, H. C. Etchevers¹;

¹INSERM U781, PARIS, France, ²GENOSCOPE (CEA) and UMR 8030 CNRS-GENOSCOPE-Université d'Evry, Evry, France, ³Center for Human Genetics, Department of Medicine, Duke University Medical Center, Durham, NC, United States.

Developmental and stem cell biology ask the common question of how functionally distinct cell types arise from one self-renewing founder population. Human neural crest cells (hNCC) form in the embryo at the end of the first month of pregnancy, although the precise dates have remained elusive. Most NCC differentiate completely into melanocytes, all components of the peripheral nervous system, certain endocrine cells and connective and structural tissues in the head, although par-

tially competent NCC progenitors continue to reside in many tissues in animal models. Due to their inaccessibility and despite their developmental importance, the original properties and restriction of hNCC potential over time have never been examined. Here, we demonstrate when and how to isolate self-renewing hNCC and report the resultant study of their transcriptome by serial analysis of gene expression (SAGE). In addition to highlighting candidate disease genes, we have identified novel markers that distinguish hNCC from other human cell types and distinguished between evolutionarily conserved and species-specific NCC properties. Genome-wide analysis, using multiple statistical criteria, demonstrates that the global molecular signature of early migratory hNCC is remarkably similar to that of pluripotent human embryonic stem cells. We show that most cell types of the human pharyngula express a number of genes in situ that, individually, do not autonomously confer pluripotency but taken within the context of the transcriptome, may be permissive for the unique plasticity of hNCC over time. Our findings pave the way for further studies of hNCC therapeutic potential in neurocristopathies such as peripheral demyelinating disorders.

P08.42

Human Leukocyte Antigen (HLA) Typing and Sequence-Based Typing (SBT) for Blood Stem Cell Transplants

N. Cereb¹, L. L. Xu², E. Vennemeyer², S. Jankowski², S. Y. Yang¹;

¹HistoGenetics, Ossining, NJ, United States, ²Applied Biosystems, Foster City, CA, United States.

Human leukocyte antigens (HLA) are protein markers that are found on most of the body's cells. The immune system uses HLA to recognize which cells belong in your body and which do not. These protein markers help identify a person's tissue type. The HLA proteins are important in matching patients and donors for a bone marrow, peripheral blood cell (PBSC) or cord blood transplant. When a transplant center looks at the match level, it is looking at how alike the HLA tissue types of the patient and the donor are to each other.

We will demonstrate that directed sequencing of over 40 PCR-amplicons (including forward/reverse) in the HLA-Class I region provides a complete test result for each patient. Even one amino acid variation in each HLA gene between the donor and recipient increases transplant mortality risk by 10%. Using an exact sequencing match will greatly improve the patient's chances of transplant success.

Direct sequencing for HLA typing gives the accurate and ultimate answer, without a timely screening step prior to sequencing. Using state-of-art automated capillary electrophoresis instrumentation and bioinformatics tools to deliver these results saves lives by reducing time before a donor is located, increasing successful transplant outcome and lowering subsequent healthcare cost.

P08.43

Conserved and non-conserved transcription regulatory elements associated with SINEs in mammalian promoters

N. V. Tomilin;

Russian Academy of Sciences, St.Petersburg, Russian Federation.

About half of promoters of protein-coding genes in the mouse and human genomes contain sequences of interspersed repeats which can effect gene expression. Recent estimations suggest that some of these sequences are evolutionary conserved and may represent >5% of all constrained nonexonic elements which are under strong purifying selection in mammalian genomes. However, major fraction of important regulatory elements is not constrained in evolution. These elements can be recruited from a large pool of lineage-specific dispersed repeats. For example, human Alu and mouse B1 repeats contain short conserved segments with potential binding site for transcription factor PitX2 (binding motif YTGGGATTANW) which is important for establishment of left-right asymmetry in development of multiple organs. Alu-associated binding sites for PitX2 regulate expression of human PLOD1 and ANF genes but most of downstream target genes for PitX2 is not established. Our results indicate that >1000 of mouse or human genes contain Alu/B1 associated PitX2 binding sites and these genes are expressed in almost all tissues. >100 of these promoters also have potential binding site for transcription factor Nkx2.5 (motif TYAAGTG) which frequently cooperates with PitX2 in gene regulation. Among PitX2 and Nkx2.5 targets in the mouse genome we found promoters of SMARCD3, PRKCZ and NIPA1 genes expressed at high level in

brain. However, in human genome other brain-expressed genes having SINE-associated PitX2/Nkx2.5 sites are identified (e.g. KIF17). It is likely that SINEs contributed to regulatory evolution of brain-expressed genes through their associated binding sites for PitX2 in a lineage specific manner.

P08.44

KingFisher® Flex - Versatile automated nucleic acid, protein and cell purification

S. Suomalainen, M. Partanen, V. Puro, A. Lamberg;
Thermo Fisher Scientific, Vantaa, Finland.

Sample preparation is often a limiting step for genomics and proteomics studies. Rapid and efficient isolation of nucleic acids, proteins and cells from complex biological matrixes is needed to get high quality starting material for various experiments. KingFisher, the magnetic bead based, automated purification system from Thermo Fisher Scientific, provides a quick and easy solution to achieve high quality and reproducible results in purification of nucleic acids, proteins and cells with minimal hands-on time. The technology is based on magnetic rods which move particles through the various purification phases - binding, mixing, washing and elution. The KingFisher is an open and flexible system, letting the user to choose any available magnetic particle based purification kit suitable for the application.

Thermo Scientific KingFisher family consists of three instruments with different throughput and working volume capacities. The latest member of the family is KingFisher Flex, which is truly flexible solution for different types of sample processing needs. There are four magnetic heads available for the instrument depending of the needed processing volumes. With the 24-rod configuration the processing volume can be raised up to 5 ml and with the 96-rod configuration it is possible to achieve the highest throughput in working volumes 20-1000 µl. The instrument is compatible with robotic platforms providing a high throughput automated solution for all biotech and pharmaceutical laboratories. The data from different applications shows that KingFisher Flex provides a rapid method for purification of high quality and quantity biological molecules.

Diagnosis optimization by using MLPA in the investigation protocol in mentally retarded children - Romanian experience

A. Sireteanu¹, E. Neagu², G. Schobers³, V. Bica⁴, C. Skrypnik⁵, M. Puiu⁶, V. Creț⁷, L. Barbari⁸, C. Rusu¹;

¹Department of Human Genetics, University of Medicine and Pharmacy, Iasi, Romania, ²"Mina Minovică" Forensic Medicine Institute, București, Romania, ³Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, ⁴Institute for Mother and Child, București, Romania, ⁵Faculty of Medicine and Pharmacy, University of Oradea, Oradea, Romania, ⁶University of Medicine and Pharmacy, Timisoara, Romania, ⁷Children's Hospital, Cluj, Romania.

Mental retardation (MR) is a heterogeneous entity, genetic causes being involved mainly in moderate/severe forms. Subtelomeric rearrangements (SR) play an important role in idiopathic MR determination. Recently introduced MLPA (Multiplex Ligation Probe Amplification) technique seems to provide good results in SR's identification. We have used MLPA to identify SR in children with idiopathic MR, the protocol consisting of the following sequence: clinical selection based on de Vries score; karyotype; antiFMRP test for Fragile X syndrome screening; PCR for Fragile X syndrome diagnosis; MLPA testing using 2 independent kits in order to separate polymorphisms. Parents were tested if an abnormality was detected in their child (by karyotype/MLPA).

The study group was formed of 223 children that had a de Vries score of 3/more. All patient data were recorded in a database specially designed. In 28 of them (12.5%) the karyotype revealed different abnormalities. 17 cases (7.6%) presented speech delay/ autism, but anti-FMRP test and PCR were normal. Out of the 195 MLPA tests done: 168 cases (86.1% were normal, 13 (6.7%) abnormal and 14 (7.1%) had polymorphisms. The most frequently involved SR were 1p del and 7q del. Clinical features of the cases identified with different SR will be illustrated with photos and discussed.

In conclusion, we appreciate that the diagnostic score is useful in case selection for further testing, MLPA proves to be efficient in diagnosing SR and the frequency of SR as a possible cause of idiopathic MR is similar to other studies in the literature.

P08.46

Confocal morphometry of the transfected human mesenchymal stem cells

A. V. Lavrov¹, T. V. Karamysheva², N. B. Rubtsov²;

¹Research Center of Medical Genetics RAMS, Moscow, Russian Federation,

²Institute of Cytology and Genetics SB RAS, Novosibirsk, Russian Federation.

Transfected human stem cells (SC) demonstrate great potential for clinical applications. They are extensively investigated to elucidate their efficiency and safety. We focused on studying the reaction of SC on the introducing the genetic construction. Morphometry of nuclei of the transfected mesenchymal stem cells (MSC) was performed.

Materials and methods: The culture of MSC at the "late" passage (12) was used. Lipid-mediated transfection was performed with a non-viral vector based on ps415 containing VEGF121 using UF-56 as the lipid media. After 90 minutes media was changed. Cells were washed and cultivated for two days, then seeded on cover-glasses and cultivated 24 hours more. Cells were fixated with paraformaldehyde. Nuclei were contrasted with DAPI. Scanning was performed using confocal microscope Axiomager A1.

Results: average nucleus dimensions of the transfected human mesenchymal stem cells: 14,6x8,7x8,3µm and of control MSC - 14,8x8,9x8,3µm.

Conclusions: transfected MSC have the same nucleus dimensions as the control MSC. Additional studies should be performed to check chromatin structure and the form of the nuclei which appeared slightly different in our study. Objective formal criteria should be formulated to perform such analysis. The integrity of the nucleus may prove the stability of MSC after transfection forming the basis for further application of the transfected MSC in clinical trials.

RMetaWeb: Meta-analysis online tool

A. Kastrin;

Division Of Medical Genetics, Ljubljana, Slovenia.

Meta-analysis is a statistical procedure that integrates the results of several independent studies. The number of papers published on meta-analyses in biomedical domain has increased sharply in the past 15 years. The merits and perils of the somewhat mysterious procedure of meta-analysis, however, continue to be debated in the medical community. Given the increasing pace of published meta-analysis studies, their methodological quality, however, still leaves much to be desired. We have developed RMetaWeb, an online system for comprehensive, fast, and reliable research synthesis analysis. The web interface is based on a Perl CGI script that communicates with R using the CGIwithR library. An interactive viewer provides straightforward navigation through various procedures. Output is exported to an HTML and PDF, which offers convenient views on the results in both tabular and graphical formats. RMetaWeb is intended to serve to the scientific community and it is hoped that it will become a useful tool on conducting reliable meta-analysis in biomedical research. The RMetaWeb is freely available from <http://genepark.mf.uni-lj.si>.

P08.48

Optimizing bisulfite DNA conversion method for methylated CpG island discovery and screening

E. Currie-Fraser, B. Finkelnburg, S. Jankowski, L. Xu;

Applied Biosystems, Foster City, CA, United States.

DNA methylation at the 5' position of cytosine in promoter CpG islands plays a critical role in regulating gene expression. Typically methylation is inversely correlated with the transcription status of the gene.

Bisulfite DNA conversion is one of the most used techniques for methylation studies because of its relative simplicity, whereas other methods are frequently cumbersome and require significant optimization. The bisulfite conversion method allows precise analysis of methylation in a target region by converting all nonmethylated cytosines into uracils, while methylated cytosines remain unchanged. The workflow described here provides an effective solution for methylation analysis with straightforward protocols. We recognize that bisulfite conversion rate and primer design are the most critical steps in this approach. In this presentation, we demonstrate that a promoter region's methylation status can be identified with confidence using an optimized approach, which requires small amounts of genomic DNA and generates high quality data. This workflow, therefore, is very useful for the analysis of

clinical samples, where the amount of material is limited and analysis time is an important factor.

P08.49

Combined analysis of altered promoter methylation and gene expression changes in non-small cell lung cancer

N. Tönisson^{1,2,3}, K. Fellenberg⁴, R. Kuner⁴, M. Meister⁵, T. Vooder^{2,1}, K. Välik¹, K. Kirotar¹, A. Metspalu^{1,3}, J. D. Hoheisel⁶;

¹University of Tartu, Tartu, Estonia, ²Tartu University Hospital, Tartu, Estonia, ³Estonian Biocentre, Tartu, Estonia, ⁴German Cancer Research Center (DKFZ), Heidelberg, Germany, ⁵Thorax Clinic, Heidelberg, Germany, ⁶University of Tartu German Cancer Research Center (DKFZ), Heidelberg, Germany.

Combined analysis of promoter methylation and gene expression helps to reveal causative links between the epigenotype and phenotype of malignant tumours. Methylation changes in cancer are frequent and relatively stable, therefore they're also attractive biomarkers for tumour profiling, as well as potentially for monitoring the efficiency of anticancer therapy.

We have performed an analysis of 48 genes in 60 surgically treated lung adeno- and squamous cell carcinoma patients, using in situ synthesized oligonucleotide microarrays. The samples were analysed for promoter methylation, as well as the corresponding gene expression changes. The analysis included known and putative tumour suppressor genes, genes controlling cell growth and differentiation, antiangiogenic factors and genes participating in cell to cell and cell to extracellular matrix connections. A panel of tumour-free lung tissue was used as the negative control. The dual level data was analysed with M-CHIPS platform and showed clear differences between cancer and cancer-free tissue.

A similar study with more complex setup is underway in a different clinical center.

P08.50

The new MLPA based approach for HLA-DQA1, -DQB1 typing

E. Bliznetz, N. Galeeva, A. Polyakov;

Research Centre for Medical Genetics, Moscow, Russian Federation.

The genetic complexity of the human major histocompatibility complex (MHC) has required the using of various molecular typing methods to identify specific alleles. Sequence specific primers (SSP), sequence specific oligonucleotide probes (SSOP) and sequence-based typing (SBT) are a few of the methods that have been utilized in the HLA community at present. We have designed Multiplex ligation-dependent probe amplification (MLPA) method based system for HLA-DQA1 and -DQB1 loci typing. Such MLPA advantages by comparison against others molecular method as cheapness and simplicity of the technique and a possibility to determine chromosome haplotype are governing for HLA typing method. Our MLPA based system reveals 8 DQA1 alleles in one tube and 19 DQB1 alleles in one tube. A working procedure is consisting of three steps; the site-specific oligonucleotide probes ligation, multiplex amplification with common primers pair and PCR fragments assessment. For comparison, our earlier SSP based system reveals the same alleles; the working procedure includes 2-4 PCR/Multiplex PCR during HLA-DQA1 typing and 5-8 PCR/Multiplex PCR during HLA-DQB1 typing per person. In our option MLPA method is excellent additional molecular HLA typing method.

NASBA product labeling for following microarray experiments

O. Scheler¹, B. Glynn², S. Parkel^{1,3}, M. Maher², A. Kurg^{1,3};

¹University of Tartu, Institute of Molecular and Cell Biology, Department of Biotechnology, Tartu, Estonia, ²National University of Ireland, The National Diagnostics Centre, DNA Diagnostics Laboratory, Galway, Ireland, ³Estonian Biocentre, Tartu, Estonia.

DNA microarrays that enable quick and simultaneous investigation of many different biological targets are steadily becoming everyday tools in genetics and molecular diagnostics. Environmental and medical samples can easily be identified and investigated by specific probe microarrays that are complementary to the suitable marker sequences in analyzed solution. Biological markers of interest are usually amplified and labeled prior to the microarray hybridization experiment. RNA targets can efficiently and exclusively be amplified using nucleic acid sequence based amplification (NASBA), even in the presence of genomic DNA. NASBA is an isothermal method that has previously

been applied for the detection of different pathogens and mRNAs. Several labeling protocols for many amplification methods have been described in literature previously, but none of them are for NASBA amplification products. Commercial NASBA amplification method was modified to meet the needs of microarray experiment. Extra amino-allyl-UTPs were added to the NASBA solution in order to add fluorescent marker Cy3 to the aminoallyl modified RNA products after the reaction. Two different commercial aaUTP reagents (aaUTP-Na and aaUTP-Li salts) were investigated over wide concentration range (0,125mM to 8mM). Strongest microarray signal intensities were achieved with 2mM final concentration of aaUTP-Li salt used in NASBA reaction. Modified NASBA method enabled accurately detect pathogens from solution containing total RNA from as low as 0,1-1 CFU.

P08.52

Identification of mir-21 (MIRN21) targets in breast cancer cells by gene expression profiling

D. Selcuklu^{1,2}, M. Donoghue¹, C. Spillane¹, C. Yakicier³, E. Erson²;

¹University College Cork, Cork, Ireland, ²Middle East Technical University, Ankara, Turkey, ³Bilkent University, Ankara, Turkey.

Increasing numbers of microRNAs have been shown to target cancer related genes. Our aim was to identify mir-21 targets which are regulated through mRNA cleavage, deadenylation, or other processes that can lead to mRNA up- or down-regulation. Our experimental approach involved silencing of endogenous mir-21 expression by 2'-Ome-inhibitors (anti-mir-21) in MCF7 cells. Total RNAs from anti-mir-21 transfected, control oligo transfected and untreated cells were further processed and hybridized to Affymetrix Human Genome U133 Plus 2.0 arrays. Statistical and clustering analyses were conducted using Bioconductor to identify the effects of mir-21 silencing on the transcriptome. Using $p < 0.05$ and fold change > 1.5 as cut-off values, 134 transcripts were differentially expressed only in anti-21 treated samples. The transcriptome responsive to mir-21 silencing was analysed further by GO (gene ontology) based clustering of functionally related genes and biochemical pathway analysis (GO, KEGG) to gain better understanding of mir-21 function in cancer pathways. Over 25 % of the mir-21 sensitive genes were involved in regulation of transcription, 9.62 % in apoptosis and regulation of programmed cell death, while the rest were involved in a range of other biological processes. Amongst these, some genes were linked to apoptosis by insulin signalling, cell cycle regulation by TGF-BETA and MAPK signalling pathways suggesting a potential involvement of mir-21 in regulatory control of these cancer-related pathways. Further studies are underway for verification candidate targets identified. These studies will facilitate the identification of new cancer biomarkers regulated by microRNAs that could be used for better diagnostic and therapeutics for breast cancer.

P08.53

A Pipeline for Designing Custom TaqMan® Assays for Small RNA Genes

L. Wong, Y. Wang, Y. Liang, D. Ridzon, C. Chen;

Applied Biosystems, Inc., Foster City, CA, United States.

MicroRNAs (miRNAs) are a new class of non-coding RNAs that mediate post-transcriptional gene silencing. A growing number of novel miRNAs and other small RNA genes are being discovered and there is a significant need for custom assays to determine the level of their expression. An automated bioinformatics pipeline has been developed to design TaqMan® MicroRNA Assays to allow quantitation of miRNA expression by real-time PCR. To date, over 2,000 assays have been designed using the pipeline for miRNAs listed in miRBase (release 10.0). The pipeline has been wet-lab validated for mammalian miRNAs showing assay performance success of greater than 90% based on assay linearity and no template control (NTC) background signal. As research interest in small non-coding RNAs is rapidly expanding beyond miRNAs, the capability of the pipeline to design assays for other small RNAs including small interfering RNAs (siRNAs), short hairpin RNAs (shRNAs), and PIWI-interacting RNAs (piRNAs) is extremely valuable. Assays for over 100 endogenous siRNAs have been designed using the same design pipeline as for miRNAs. Preliminary data shows similar performance as miRNA assays with minimal background in the presence of tissues and cell lines for these siRNA quantitation assays. In conclusion, we have developed a robust pipeline to successfully design TaqMan miRNA assays. Recent data demonstrates the ability

of the pipeline to design TaqMan assays for quantitation of siRNAs as well as the potential for designing assays for other small RNA genes.

P08.54

Human mitochondrial DNA data integration with the semantic web

J. S. Moilanen^{1,2};

¹Institute of Medical Technology, University of Tampere, Tampere, Finland,

²Department of Clinical Genetics, University of Oulu, Oulu, Finland.

Human mitochondrial DNA (mtDNA) is a 16.5 kb circular genome in which numerous polymorphisms have been detected in thousands of sequenced genomes from various populations and patient groups worldwide. Evolutionary data and the lack of introns in mtDNA suggest that many of these polymorphisms have functional significance, and there are many reports suggesting that some polymorphisms or continent-specific mtDNA lineages (haplogroups) are associated with an increased risk of certain complex diseases or traits. Association data, haplogroup definitions, sequences, polymorphisms and structural and functional features of mtDNA-encoded genes form an immense body of knowledge which is currently scattered around different databases and resources. Current mtDNA databases have been designed principally to be viewed by human researchers and do not provide uniform access to all data and are therefore not optimal for data mining or other purposes where hypotheses are tested against huge amounts of heterogeneous data.

The semantic web is an emerging technology which allows integration of almost any kind of data in a framework which also makes it possible for computers to perform inference tasks in an unified and standardized manner. Mitochondrial Information Integration Initiative (Mitol3) aims at developing an open resource that will collect data on available human mtDNA sequences, polymorphisms, haplogroup definitions and other aspects of mitochondrial genomics. The data are stored as RDF (Resource Description Framework) statements in a RDF triple store which can be accessed with semantic web browsers and which also provides a SPARQL interface for performing complex queries over the data.

The effects of the *MTHFR* gene variations for drug response in rheumatoid arthritis and psoriatic arthritis patients treated with methotrexate

N. Horelli-Kuitunen¹, M. Kaistamaa², P. Onkamo², A. Nenonen³, L. Ahola¹, J. Ihalainen¹, K. Laiho³, M. Kauppi³, M. Nyström²;

¹Medix Laboratories Ltd, Espoo, Finland, ²University of Helsinki, Helsinki, Finland, ³Rheumatism Foundation Hospital Heinola, Heinola, Finland.

Methotrexate (MTX) is a folic acid antagonist widely used to treat immunosuppressive disorders such as rheumatoid arthritis (RA). The enzyme 5,10-methylenetetrahydrofolate reductase (*MTHFR*) is involved in maintaining folate and homocysteine homeostasis and common genetic variations, c.677C>T and c.1298A>C, in the *MTHFR* gene are associated with decreased enzyme activity and altered folate levels, which may predispose to increased susceptibility to the anti-folate effects of MTX therapy. Here, we studied the effects of these variations for MTX response in a total of 298 Finnish patients who had either rheumatoid (218) or psoriatic arthritis (80). Together with genotyping we also analyzed folate, homocysteine, ALAT, and B12 vitamin levels as well as clinical patient data concerning toxicity and efficiency of the MTX treatments. Finally, statistical analyses were done to evaluate possible associations between the *MTHFR* gene variations and MTX toxicity and efficiency. Our results show that the patients with two normal alleles (677TT/1298AA) are less likely to experience side effects during MTX therapy although, no statistically significant association between variations and methotrexate toxicity was found. Remarkably, *MTHFR* 677TT was recognised to be a risk genotype for elevated ALAT as well as a serious risk factor for low folate and accordingly elevated homocysteine levels both during and after MTX treatment. In addition, the state of the disease stayed remarkably more often active in patients having 677TT genotype and low folate levels suggesting that *MTHFR* c.677C>T is critical genotype and should be taken into account in patient treatment strategy.

Denaturing electrophoresis on Lab-on-Chip Agilent BioAnalyzer platform: A novel approach for rapid screening of DNA mutations

M. Minarik¹, R. Chudoba², B. Belsanova¹, B. Gas², L. Benesova¹;

¹Genomac International, Prague, Czech Republic, ²Charles University, Prague, Czech Republic.

Recent expansion in genome research brought a number of new analytical technologies for detection of DNA mutations and polymorphisms. Although many exciting approaches are presented in scientific environment, only a relatively small fraction subsequently finds its way to practical application in routine diagnostic testing. Among the most widely used methods are either enzymatic methods such as RFLP, OLA, TaqMAN, etc. or methods based on separation due to secondary DNA structure effects such as DGGE, TGGE, SSCP, dHPLC and others.

Over the past several years, many of the electrophoresis-based techniques have been adapted to capillary electrophoresis DNA sequencers utilizing separation under partial denaturing conditions at either constant-temperature or in temperature gradients settings.

In the current work we introduce a DNA melting separation on an electrophoresis chip platform. We adapt Agilent 2100 Bioanalyzer for detection of common point mutations in Factor V Leiden and Factor II Prothrombin genes. The technique employs denaturing temperature gradients on the chip to reliably separate homo- and hetero-duplex forms.

This work was supported by the Czech Ministry of Industry grant FI-IM3/215.

Web-based collection of gene-specific sequence variants and their phenotypic consequences

I. F. A. C. Fokkema, G. B. van Ommen, J. T. den Dunnen, P. E. M. Taschner; Human and Clinical Genetics, Leiden, The Netherlands.

Soon it will be possible to sequence a human genome for a reasonable price, making medical and clinical application of human genome sequencing a realistic option. However, as highlighted by the Human Variome Project meeting in Melbourne (2006), when we want to understand the consequences of all the variation we will see, we need to improve significantly in reporting and cataloguing the variants and their consequences we identify at the moment. To facilitate the collection of sequence variants and their phenotypic consequences we have developed the Leiden Open-source Variation Database (LOVD) software (www.LOVD.nl). LOVD provides a free, open-source, platform-independent and fully web-based tool to build, curate and share Locus-Specific mutation DataBases (LSDBs). In addition, to facilitate error-free reporting of variants we have developed the Mutalyzer nomenclature checker (www.LOVD.nl/mutalyzer) and coupled it to LOVD. Mutalyzer names sequence variants following the HGVS mutation nomenclature recommendations, using a GenBank accession number, a HGCN gene symbol and the variant as input. Currently, our Leiden server hosts over 70 gene variation databases, with data collected for more than 20,000 patients contributed by 150 submitters world-wide, the largest series covering gene variants in relation to neuromuscular disorders.

P08.58

Next Generation Sequencing

K. A. Stangier;

GATC Biotech AG, Konstanz, Germany.

The next generation sequencing technologies, embodied by the Roche Diagnostics/454, Illumina/Solexa and Applied Biosystems sequencing machines, provide the opportunity to generate huge amounts of sequence information for de novo and resequencing of genomes. GATC uses all three leading high throughput sequencing machines in house: the GS FLX from Roche Diagnostics, the Illumina Genome Analyzer and the SOLiD system of Applied Biosystems, providing the flexibility to tailor sequencing projects to meet customer requirements. The bioinformatic analysis of the huge amount of data is still a challenge, especially for the human genome (3 GB). In addition, many questions regarding cancer research or disease related topics, can be addressed by sequencing just the area of interest of the human genome. Often these areas are too big to be amplified out of the whole genome. GATC

will present data from enrichment studies of the human genome of sequence areas related to different diseases. The paired-end method for the technologies provides additional information about large scale variations in the genome allowing an accuracy approaching classical Sanger sequencing. Comparison of the next-gen sequencing data to a reference genome provides a mapping that takes advantage of the high coverage to identify SNPs and other structural differences and variations. The results can be imported into other assembly programs (e.g. SeqMan™ of the Lasergene™ suite from DNASTAR Inc., USA).

P08.59

A novel approach for miRNA profiling and discovery using massively parallel ligation-based dibase sequencing technology

R. R. Samaha, C. Barbacioru, J. Gu, S. Kuersten, R. Setterquist, M. Barker, R. Wicki;

Applied Biosystems, Foster City, CA, United States.

Next-generation sequencing (NGS) platforms produce 10-100's of millions of short reads (25-50bp) in a single run which makes them particularly suited for tag counting application including gene expression profiling. With Applied Biosystem's new platform, sequencing is carried out *via* dibase sequential rounds of ligation with high fidelity and high read quality. Using a newly developed library protocol which requires low sample input and results in sequence ready samples in less than a day, we explored the expression profiles of small non-coding RNAs in two normal tissues, using the SOLiD™ system. The frequency and distribution of miRNAs, isomiRNAs and miRNA* were evaluated and the fold changes generated from these tissues were compared to those of 380 TaqMan® miRNA assays. Significant correlation levels were observed confirming the applicability of this approach for small RNAs expression profiling. Moreover, more than 3000 potentially novel miRNAs or non-coding RNAs were discovered. These potential novel small RNAs are currently being further validated.

This new library approach coupled with the SOLiD™ System provides a high throughput method for digital gene expression that enables the discovery of novel small ncRNAs and miRNAs as well as profiling their expression levels, without the probe bias of microarrays. Because of the SOLiD™ System's throughput which is greater than 100M reads per slide, it is particularly suited for the analysis of gene expression being able to deliver the dynamic range required to detect genes expressed at very low levels and to accurately measure fold changes at the same low expression levels.

P08.60

Cloning and construction of mouse PEP cDNA chimera with EGFP under regulation of CMV promoter

M. Ostadsharif^{1,2}, K. Ghaed^{2,3}, S. Tanhaei², K. Karbalaee², M. Nasr-e-Esfahan²;

¹Islamic Azad University, Research & science campus, Tehran, Islamic Republic of Iran, ²Royan, Isfahan Research Campus, Isfahan, Islamic Republic of Iran,

³Biology Dept., School of Sciences, The University of Isfahan, Isfahan, Islamic Republic of Iran.

Peroxisomes are tiny organelles in almost all eukaryotic cells. They exhibit various functions including β -oxidation of very long chain fatty acids and metabolite peroxidation which is essential for the cell function and differentiation. We have cloned (Peroxisomal Protein) PEP cDNA in a mammalian expression vector in a chimeric cDNA type, encompassing PEP with EGFP cDNA. Amino acid alignment analysis revealed two hydrophobic domains. The First Comprises twenty amino acid residues between 12-31 residues and the second one, is located at 152-169 residues. There is a tripeptide (SKI) at carboxy terminus responsible for sorting of this protein to the matrix of peroxisome. There is a fibronectin type III domain between residues 31-114 in pep. In order to see the importance of above sorting signal, we performed a site-directed mutagenesis to delete SKI tripeptide. Amplified Pep cDNAs either containing SKI or deleted ones were constructed downstream of EGFP cDNA under regulation of CMV promoter in pEGFP-C1 vector and were sent for sequence. Transfection of plasmids containing chimera of EGFP-PEP cDNAs in to the CHO-K1 showed several punctuate structures presumably peroxisomes while, SKI deletion showed a cytosolic pattern like EGFP-C1. Taken together, these data strongly suggest that SKI, which is located at the C- terminus of protein is required for sorting of this protein.

P08.61

The Mouse Genome Informatics (MGI) resource: translating mouse phenogenomics into models of human disease

A. V. Anagnostopoulos, H. Dene, S. M. Bello, H. Onda, T. F. Meehan, M. N. Knowlton, D. L. Burkart, I. Lu, L. L. Washburn, M. Tomczuk, R. P. Babiuk, B. A. Richards-Smith, C. L. Smith, J. T. Eppig;

The Jackson Laboratory, Bar Harbor, ME, United States.

The mouse is universally considered a premier model system for studying human development and disease. The MGI resource (<http://www.informatics.jax.org>) provides free access to integrated data on the genetics, genomics and biology of the laboratory mouse, facilitating navigation through sequence, polymorphism, spatiotemporal expression, mapping, biochemical function and process, sub-cellular topology, mammalian homology, phenotype and disease model data. MGI curates aberrant mouse phenotypes in the context of mutations (spontaneous, induced or genetically engineered), strain variations, QTLs, and complex traits that serve as credible models of human genetic disorders, incorporating phenotype-related images as available. Robust querying parameters include standardized terms from the Mammalian Phenotype Ontology, a hierarchically-structured vocabulary that supports morphophysiological annotations to background-specified allelic genotypes at varying degrees of granularity. Parallel use of key bio-ontologies, including the Anatomical Dictionary, GO, and OMIM, fosters innovative approaches to peruse expression profiles, map functional features of gene products to complex pathophysiological states, and establish associations between observed mouse phenotypes and orthologous human gene mutations or distinct nosological entities for which defined mouse genotypes phenomimic the human condition. MGI advances translational research through an integrated data platform which optimizes retrieval and semantic interpretation of multi-parametric, genome-scale datasets, and permits disease model mining from a genotype, phenotype or computational perspective. Recent enhancements include a redesigned homepage and site-wide navigation paradigm, and an image-rich "Phenotype, Alleles & Disease Models" portal, as one of several mini-homepages, each encapsulating a different MGI biodomain along with content-specific access instructions, statistics, FAQs, and news announcements. Supported by NIH grants HG000330, HG002273, HD033745.

P08.62

Characterization of post-transcriptional regulation of the human chromosome 21 transcriptome

S. I. Nikolaev^{1,2}, S. Deutsch^{1,2}, R. Genolet³, C. Ucla¹, L. Parand¹, B. Conne¹, J. Vassalli¹, J. Curran³, S. E. Antonarakis¹;

¹Department of Genetic Medicine and Development, Geneva University,

Geneva, Switzerland, ²Authors contributed equally to the work, Switzerland,

³Department of Microbiology and Molecular Medicine, University of Geneva, Geneva, Switzerland.

To characterize the post-transcriptional regulation of transcriptional units in human chromosome 21 (HSA21), we performed a sucrose gradient separation of RNA in 3 cell lines (GM06990, HeLaS3 and SKNAS). We generated fractions according to ribosome content to separate (i) RNA undergoing active translation (associated with at least 2 ribosomes) and (ii) a pool of all fractions representing total RNA. Each pool was hybridized to a 22bp resolution tiling array comprising the entire non-repetitive sequence of HSA21 (18 Mb).

We observed that approximately 5% of HSA21 is transcribed in each cell line, and a total of 8.5% is transcribed in at least 1 line. On average 51.6% of signals correspond to annotated regions, whereas the remaining have been previously referred to as Txfrags.

We performed RT-PCR (with RT-minus control) and/or 5 and 3' RACE for 100 random Txfrags, and sequenced positive bands. In all cases the sequences correspond to known exons elsewhere in the genome but also with high homology to HSA21. This strongly suggests that these signals result from cross-hybridisation.

To identify genes with significant levels of post-transcriptional regulation, we performed a paired-rank analysis of all detected exons. We observed that 86 out of 247 HSA21 genes demonstrate a significant shift in their rank distribution, suggesting post-transcriptional control.

Our data suggest that 1) there is a considerable posttranscriptional control of gene expression and 2) a substantial fraction of Txfrags result from cross-hybridization with exons mapping elsewhere in the genome.

P08.63**Prader-Willi Syndrome: Multiplex Ligation Dependent Probe Amplification Diagnosis (MLPA) and Microsatellites**

A. Rodriguez, M. Miramar, M. Calvo, F. Lorente, E. Barrio, S. Izquierdo, N. Martinez;

Molecular Genetics, H.U. Miguel Servet. University of Zaragoza, Zaragoza, Spain.

Introduction: PWS is a neuroendocrine genetic disease, with a global frequency estimated between 1/10.000 - 1/25.000 livebirths. Clinical symptoms are characterized by hypotonia, hyporreflexia, lack of movements and deglutatory alterations. Typical dismorphic and behavioural phenotype include hyperphagia-obesity, hypogonadism, hypogonadism, mental retardation and bone maturation retardation.

Lack of paternal contribution results in PWS either by paternal deletion in 15q11-q13 region (70%) or from maternal disomy (25%). A few cases (2-5%) are due to imprinting center mutations.

Aims: We have performed a mutational screening of large deletions in 15q11-q13 region and the methylation analysis of *SNRPN* gene in 37 patients with PWS clinical features. The aim of this study is to confirm clinical diagnosis, to evaluate the main genetic alterations in our population and provide supportive genetic counselling to the families.

Material and Methods: Patients DNA was obtained by robotic extraction (EZ1, Qiagen). The MLPA technique was performed by the commercially available PWS Kit from MRC Holland. This kit allows large deletions screening in 15q11-q13 region genes in two PCR reactions and the methylation study of *SNRPN* by *HhaI* enzyme digestion. Analysis was performed with an ABI PRISM 310 sequencing analyzer (Applied Biosystems) and further data Excel normalization. In abnormal methylation cases microsatellites D15S10, D15S11, D15S113, D15S128, GABRA3, GABRB5 were studied.

Results and Conclusion: The MLPA genetic analysis has allowed PWS diagnostic confirmation in 16.2% patients with clinical criteria. Two deletions in 15q11-q13 region and 4 maternal uniparental disomy were found. We conclude that PWS is well characterized by the MLPA technique.

P08.64**ProSeeK: A web server for MLPA probe design**

L. Pantano, L. Armengol, S. Villatoro, X. Estivill;

Center for Genomic Regulation, Barcelona, Spain.

The technological evolution of platforms for assessing genome-wide copy number imbalances has allowed the discovery of an unexpected amount of human sequence involved in duplications and deletions (termed copy number variants or CNVs). In terms of sequence coverage, this is the most important type of human variation identified so far and can make an important contribution to human diversity and disease susceptibility. While different methods exist to assess genome-wide changes in gene dosage at high-throughput, methods for validating these findings are tedious and expensive. Multiplex Ligation-dependent Probe Amplification (MLPA) is one of the available technologies, used even in diagnostic settings, to assess copy number variation in the human genome. One of the dull and time-consuming steps of MLPA is probe design step. Because of the multiplexing capacity and the required specificity, the oligonucleotides targeting specific regions have to meet a large number of requirements for an efficient design of the experiment. ProSeeK is designed to perform all steps automatically and to provide the best candidate probes for each individual assay. ProSeeK is integrated as a user-friendly web server to ensure portability.

P08.65**The OpenArray™ platform: enabling high-throughput SNP genotyping and real-time PCR applications in nanoliter volumes**

S. Liu-Cordero, D. G. W. Roberts, E. Ortenberg, J. Cho, J. Hurley, M. Koczynski, K. D. Munnally;

BioTrove, Inc., Woburn, MA, United States.

BioTrove has developed the OpenArray platform based on through-hole technology, a broadly applicable nanoliter fluidics technology for parallel and low-volume solution phase reactions. OpenArray plates are coated with hydrophilic coatings on the interior of each through hole and hydrophobic coatings on the exterior of the through-holes. This

enables OpenArray plates to hold solutions in the open through-holes via capillary action. The OpenArray plate consists of 3072 through-holes that can be loaded with reagents to perform individual 33 nL reactions for use in both real time PCR applications as well as endpoint genotyping applications. The unique configuration of the through-holes enables the researcher to interrogate a large number of nucleic acid samples against a large number of assays in a flexible, configurable format. By altering the number of assays or the number of samples the researcher can easily customize the OpenArray to meet their changing needs. Researchers using this technology benefit from the parallelism of microarrays and the data quality of solution phase reactions.

P08.66**External cell control quantitative RT-PCR (eccPCR): A new technique for reliable detection of subtle changes in mRNA expression**

A. Bors¹, P. Ribiczey¹, G. Köblös², A. Brózik¹, Z. Ujjalud³, M. Magócsi¹, A. Várad², A. Tordai¹, T. Kovács¹, T. Arányi²;

¹Hungarian National Blood Transfusion Service, Budapest, Hungary, ²Institute of Enzymology, Hungarian Academy of Sciences, Budapest, Hungary, ³University of Szeged, Department of Biochemistry and Molecular Biology, Szeged, Hungary.

Quantitative RT-PCR (qRT-PCR) is a widely used method to determine relative gene expression levels. Quantification of the observed expression levels becomes reliable after normalization to the expression of an internal standard gene. If the mRNA level of the standard gene is altered during the experiment, small changes of target mRNA levels can be especially difficult to detect. However, the expression of commonly used internal standard genes is often unstable, which considerably bias quantification.

To overcome the drawback of unstable internal standards, we developed a new method, called external cell control PCR (eccPCR). This method is based on the addition of control cells to the studied cells before RNA extraction and qRT-PCR. Only the control cells express the reference gene, while only the studied cells express the gene of interest. This technique controls all steps of sample preparation and overcomes the uncertainty of normalization to internal standard genes.

We present the validation of the new method by detection of the changes of hSERCA3 mRNA expression in response to Na⁺-butyrate treatment of KATO-III gastric cancer cells using F4-6 mouse erythroleukemia cells as control and mPu.1 mRNA as the reference gene. In addition, we demonstrate the instability of the expression of a commonly used internal standard gene GAPDH by the eccPCR technique. The sensitivity analysis of the new method showed that a 1.5-fold gene expression level difference can be systematically detected with the eccPCR assay.

We conclude that eccPCR allows accurate quantification of small expression level differences of a gene of interest.

P08.67**An integrated custom design tool for PCR resequencing**

B. Turner, A. Sartori, S. Jankowski, L. Xu;

Applied Biosystems, Foster City, CA, United States.

Increasing attention has been devoted to SNP discovery and genotyping in an effort to associate disease/phenotypes with gene variations and mutations and to determine evolutionary relationships, but reliable primer design and data analysis remain two of the major challenges to overcome. Development of a flexible design tool that allows researchers to select PCR-sequencing primers for different genomic targets with user-defined parameters would greatly facilitate resequencing.

In order to help the scientific community to better use PCR and CE-sequencing for SNP discovery, we released the VariantSEQTM primer designs of 15K+ human genes to the public via NCBI's ProbeDB.

To improve upon this one-size-fits-all approach, we have developed an integrated web-based tool which incorporates target sequence selection/submission, primer design, and data analysis into a connected workflow. Users can choose genes, transcripts and other identifiers, select any region in the genome, or upload their own sequence as well as specify design parameters, e.g. amplicon length, primer T_m etc. The web interface then submits the job to a backend pipeline, which takes advantage of proprietary primer picking and predictive quality assurance processes that generated Applied Biosystem's VariantSEQTM primers. All currently known SNP/MNP sites in the genomic

sequence are avoided during primer design. The resulting primers are then checked for genomic redundancy and the probability of success in PCR. An exhaustive search is performed to produce the optimal tiling of the amplicons covering the target region. Utilization of this primer design tool can substantially reduce the effort required to design and optimize robust resequencing primers.

P08.68 Prescreen for *RB1* mutation identification using high-resolution melting analysis

E. K. Zhang¹, D. Rushlow¹, N. L. Prigoda¹, B. Piovesan¹, K. Vandezande¹, B. L. Gallie^{1,2};

¹Retinoblastoma Solutions, Toronto, ON, Canada, ²The Hospital for Sick Children, The Vision Science Research Program, University Health Network and Departments of Ophthalmology, Molecular and Medical Genetics and Medical Biophysics, University of Toronto, Toronto, ON, Canada.

Germ-line mutations in the *RB1* gene cause hereditary predisposition to retinoblastoma, a childhood eye cancer, but 90% of the tumors are caused by novel mutations. Since the *RB1* gene spans 180 kb and contains 27 exons, and *RB1* mutations have been observed in all 27 exons and promoter with few recurrent mutations, multiple modalities are required in addition to sequencing to attain high sensitivity for mutation detection. Amplicon melting with a saturating DNA intercalating dye was introduced as an attractive technique to genotype small sequence alterations. In order to investigate the efficiency of high-resolution melting analysis (HRM) in *RB1* mutation screening, we tested its sensitivity to detect known variants.

PCR products were prepared for routine sequencing. Resolight dye master mix was added post-PCR. Fluorescence melting curves were recorded using the LightCycler 480. All (10/10) heterozygous and 2/2 homozygous variants were readily discriminated from wild-type. A wide range of mutation types including heterozygous one base pair transitions and transversions and small deletions and insertions could be detected when compared with wild-type DNA. Our experiments showed that we were able to obtain different melting curves from wild-type DNA even for very low level mosaic variants which are detectable only by allele-specific PCR (AS-PCR) and not by sequencing. A good sensitivity can be expected when the assay is used to detect otherwise missed mosaic mutants. HRM analysis is a simple and rapid technique in prescreening of small sequence alterations in DNA diagnostics.

P08.69 The first serotonin receptor allelic variant database

B. Niesler, R. Röth, S. Wilke, C. Fischer, G. Rappold;
Institute of Human Genetics, Heidelberg, Germany.

Serotonin (5-hydroxytryptamine, 5-HT) controls a variety of physiological functions. 5-HT receptors mediating serotonin action are divided into seven main classes (5-HT₁R to 5-HT₇R). A multitude of candidate gene screenings has been published during the last years. We have started to structure this information in the first serotonin receptor allelic variant database using LOVD (Leiden Open Source Variation Database). Up to now, the database comprises data of 5-HT₃ receptor subunits. To date, five different human subunits are known (5-HT_{3A-E}), which are encoded by the serotonin receptor genes *HTR3A*, *HTR3B*, *HTR3C*, *HTR3D* and *HTR3E*. Different receptor subtypes seem to be involved in chemotherapy induced nausea and vomiting (CINV), irritable bowel syndrome (IBS) and psychiatric disorders. During the last years *HTR3* case-control and pharmacogenetic studies indicated that *HTR3A* and *HTR3B* polymorphisms may contribute to the etiology of psychiatric disorders and may predict CINV and medical treatment of psychiatric patients. Currently, the database is subdivided into five sub-databases, referring to the serotonin receptor genes. Within each sub-database we are collecting mutations, polymorphisms, demographic information as well as pharmacogenetic data. Every sub-database includes general information about the respective gene and is linked to other resources. The remote user is able to search the data and to submit new data. This central information pool should help clinicians as well as scientists to evaluate their findings and to use the information for subsequent studies. Data about functional consequences of variants will be integrated in future to enable specific drug design in the therapy of respective conditions.

P08.70 AutoSNP: an integrated graphical user platform of high-throughput SNP data analysis for disease gene mapping

C. C. Huang¹, Y. F. Liu², D. D. Lee³, C. T. Hsu⁴, Y. T. Chang³, T. T. Liu², S. F. Tsaï⁵, M. W. Lin^{1,6};

¹Institute of BioMedical Informatics, National Yang-Ming University, Taipei, Taiwan, ²VYM Genome Research Center, National Yang-Ming University, Taipei, Taiwan, ³Department of Dermatology, Taipei Veterans General Hospital, Taipei, Taiwan, ⁴Institute of Public Health, National Yang-Ming University, Taipei, Taiwan, ⁵Division of Molecular and Genomic Medicine, National Health Research Institutes, Zhunan Town, Miaoli County, Taiwan, ⁶Department of Medical Research & Education, Taipei Veterans General Hospital, Taipei, Taiwan.

Single nucleotide polymorphisms (SNPs) have become most common used marker in current human genetic studies. Researchers normally need to select a set of SNPs from an enormous amount of SNP of candidate genes or regions. Moreover, current platforms of high-throughput SNP genotyping will produce huge amounts of genotyping data with different output format. It is a trivial and time-consuming work to pick up SNPs and process different kinds of data format for specific linkage or association analysis program.

To ease the task of managing high-throughput SNPs data from two main platforms-Illumina and Affymetrix assays, we generated a graphical user platform named "AutoSNP" by using Perl language. In this platform, user can select SNP data source and then convert SNP genotyping data into appropriate format for specific genetic analysis program. We integrated both linkage analysis programs (Allegro, GeneHunter, Linkage, Merlin, SuperLink and SimWalk2) and association analysis programs (FBAT, PLINK, HaploView, PHASE, and WHAP) in this platform. Moreover, this platform also allows users to connect to Ensembl variation database, NCBI SNP database, and the TAMAL (Technology And Money Are Limiting) database to query information from their SNPs list. Finally, we use a skin disease "primary cutaneous amyloidosis (PCA)" genotyping data as an example to demonstrate our platform.

P08.71 New Methods for Sizing Large DNA Fragments on Capillary Electrophoresis Instruments

C. Davidson, S. Hung, S. Chen, S. M. Koepf, K. D. Jacobson, M. C. White, S. Lim, N. Patel, S. Berosik, S. Pistacchi, A. B. Shah, L. K. Joe, R. Santhanam, R. A. Padilla;
Applied Biosystems, Foster City, CA, United States.

Applied Biosystems is continually developing new fragment analysis size standards to better support existing and new applications. Recent developments have focused on improving sizing precision and accuracy and expansion of the sizing range, using Applied Biosystems' 5th dye technology. We present details about developing methods to take advantage of a new high performance, 68 peak size standard and illustrate its versatility, accuracy, flexibility, and precision when used on various capillary electrophoresis instrument platforms, different polymers and capillary array lengths. Methods described include DNA fragment sizing up to 1200bp in applications such as AFLP, T-RFLP, VNTR, mutation screening, MLST, and BAC fingerprinting.

P08.72 A statistical approach for predicting the clinical type of SMA using MLPA

A. Kastrin, **M. Zadel**, M. Volk, B. Peterlin;
Division Of Medical Genetics, Ljubljana, Slovenia.

Spinal muscular atrophy (SMA) is a common autosomal recessive disorder in humans, characterized by degeneration of the anterior horn cells of the spinal cord, causing symmetric proximal muscle weakness. SMA is classified in three clinical types, SMA I, SMA II, and SMA III, based on the severity of the symptoms and the age of onset. The purpose of this study was to build the prediction model evaluating the probability of a SMA type based on multiplex ligation-dependent probe amplification analysis with commercial probe mix (SALSA Probe Mix 021; MRC Holland). This mix contains 16 probes specific for the SMA critical region (5q12.2-5q13.3). Dosage ratio was chosen to form the basis of the analysis. We developed a multinomial logistic regression model based on the data of 65 SMA cases. Prediction model was constructed using all probes, and using stepwise probe selection algorithm by Akaike information criterion to remove irrelevant and redundant

probes while retaining or improving the predictive power. Validation of the model was performed using 10-fold cross-validation regime to avoid overfitting and assure statistical validity of results. The predictive model was evaluated on the basis of three performance measures: sensitivity, specificity, and the area under the receiver operating characteristics curve (Table 1). Proposed model confirm the known and indicate some novel patterns which may contribute to a better understanding of SMA.

Table 1. Performance measures.

	Model					
	Full			Stepwise		
	SMA I	SMA II	SMA III	SMA I	SMA II	SMA III
Sensitivity	0.471	0.679	0.700	0.571	0.719	0.737
Specificity	0.896	0.676	0.844	0.902	0.758	0.848
AUC	0.772	0.676	0.707	0.748	0.746	0.771

P08.73

SMRT arrays as a high resolution technique for detection of DNA microvariations

P. Armero, C. Maqueda, A. Hernández, S. Esteban, P. Madero;
Centro de Análisis Genéticos, Zaragoza, Spain.

Introduction: Nowadays, array CGH is one of the highest resolution techniques for genome-wide detection of chromosomal alterations. Genome screening using array CGH has great potential in the characterization of numerous unexplained chromosomal aberrations. The whole genome Sub-Megabase Resolution Tiling Array (SMRT array) is capable of identifying microamplifications and microdeletions at a resolution of 100 Kb.

The aim of this study was to show the utility of this SMRT arrays to provide precise information about the size and breakpoints of DNA copy number gains and losses.

Methods: We present a patient with microcephaly, epilepsy and mental retardation, with a female normal karyotype 46, XX. A SMRT array, (from Wan Lam Laboratory at the BC Cancer Research Centre) analysis was performed. Moreover, two MLPA kits (SALSA P096 and SALSA, from MRC-Holland) and fluorescent in situ hybridization (FISH) technique were carried out.

Results: The SMRT array analysis showed a 4p subtelomeric deletion of 1.25 Mb. MLPA study of the specific 4p16.3 subtelomeric region confirmed this microdeletion. Five of the sixteen specific probes of MLPA kit, located in the new defined WHSCR-2, were deleted. FISH assays showed a deleted pattern with the 4p subtelomeric probe but normal results were obtained when hybridization was performed with specific WHS probe.

Conclusions: The SMRT array study confirms the small deletion WHSCR-2 previously detected by MLPA and not detected by WHS FISH. SMRT array arises as an effective technique to detect DNA microvariations and provides more information about their size and precise breakpoints.

P08.74

Flexible and 640-multiplex array detection of nucleic acid variations

K. Krjtskov¹, R. Andreson¹, R. Mägi¹, A. Khrunir², A. Metspalu¹;
¹IMCB, Tartu, Estonia, ²IMG RAS, Moscow, Russian Federation.

DNA sequence variation detection is important in various biomedical applications such as gene identification of common diseases, disease diagnosis and -treatment, drug discovery and forensic analysis. Here, we describe an arrayed primer extension-based genotyping method (APEX-2) that allows multiplex DNA amplification (640-plex) and detection of single nucleotide polymorphism (SNP) or mutations on microarray through four-color single-base extension. The principle of multiplex PCR needs two oligonucleotides per SNP/mutation generating amplicons that contain the unknown base pair (studied position). The same oligonucleotides are used in the following step as attached single-base extension primers on a microarray. The call rate of 640-plex APEX-2 was 99.87%, the reproducibility was 99.92% and the coincidence between Illumina HumanCNV370-Duo v1.0 BeadChips and APEX-2 genotyping was 98.6%. The method described here may be very useful for a custom number of SNP- or mutation detection analysis, molecular diagnostics and in forensic analysis. APEX-2 has also the potential to fill the gap (up to 1500 positions) between expensive high-density platforms and low-multiplex level detection systems.

Transplantation of amniotic fluid-derived stem cells in a rodent model of stroke

I. Antonucci^{1,2}, M. Maki^{3,4}, S. Yu^{3,4}, T. Masuda^{3,4}, M. M. Alip^{3,4}, D. C. Hess^{3,4}, G. Palka¹, L. Stuppia^{1,2}, C. V. Borlongan^{3,4};

¹G. D'Annunzio University Foundation, Chieti, Italy, ²Aging Research Center, CESI, Chieti, Italy, ³Department of Neurology, Medical College of Georgia, Augusta, GA, United States, ⁴Research and Affiliations Service Line, Augusta Veterans Affairs Medical Center, Augusta, GA, United States.

The discovery of amniotic fluid (AF)-derived stem cells initiated a new and very promising field in stem cell research. These cells possess immune-privileged characteristics suitable for a successful transplantation. The purpose of this study was to reveal stemness of rat AF-derived cells and to test the effectiveness of transplantation of fresh as compared to cultured AF cells in a rodent model of stroke. Cells were characterized at day 25 of culture by immunohistochemical analysis to highlight the presence of embryonic stem cell markers. This analysis showed that cultured, i.e., adherent AF cells resembled a mesenchymal-like morphology and were positive for OCT4 and SSEA, typical embryonic stem cell markers. A parallel in vivo study subjected rats to middle cerebral artery (MCA) occlusion for 60 minutes and subsequently assigned to one of the following intravenous transplantation: i) freshly isolated AF cells; ii) cultured rat AF mesenchymal-like stem cells; iii) vehicle. Behavioral tests were performed prior to stroke surgery and repeated at day 2 post-stroke/post-transplantation to evaluate the functional consequences of the MCA occlusion and to quantify improvements in motor and cognitive function after transplantation. Transplantation of cultured, but not freshly isolated AF mesenchymal-like stem cells promoted significant recovery from stroke-induced motor and neurologic deficits compared to vehicle-infused stroke animals. The present study shows that cultured rat AF-derived cells are more therapeutically active than freshly isolated cells. The observed behavioral benefits demonstrate that AF stand as a highly potent alternative source of stem cells for therapeutic strategies in stroke and related neurological disorders.

e-infrastructure for thalassaemia research network (Ithanel)

M. Kleanthous;

The Institute of Neurology and Genetics, Nicosia, Cyprus.

The main objective of Ithanel (<http://www.ithanel.eu>) is to enhance the scientific potential of the haemoglobinopathies' research community using infrastructures and tools of European research networks. Ithanel aims to harmonise and develop these resources for the coordination of existing research activities as a base for future collaborative projects. The consortium comprises of all major European research institutions active in the field and a number of collaborating partner institutions from non-EU Mediterranean and Black-Sea countries. In total Ithanel associates 26 partners from 16 countries. In order to set-up and maintain interaction between the partners involved as well as to coordinate training and project management activities, Ithanel utilizes teleconferencing technology. Additionally Ithanel introduced media broadcasting and streaming technologies for conferences and teaching courses on haemoglobinopathies, contributing to the exchange and dissemination of good practices in the field of e-learning. Aiming to encourage a high level of interaction among members of the haemoglobinopathy community, a dedicated portal has been created (<http://portal/ithanel.eu>). Visitors to the Ithanel portal can quickly exchange information, share ideas, enhance the global awareness of pertinent issues, and help define critical areas of haemoglobinopathy treatment and research. The portal offers the latest news, techniques and information on haemoglobinopathies and also serves as a platform for the easy exchange of information and dialogues between interested groups, both patients and researchers. The portal is also used as a database of standard scientific protocols, methodologies, and repositories. It contains information on almost all Thalassaemia-related institutions and medical centres as well as patient and scientific societies.

Genomic regulation of gene-expression levels in the brain during human evolution

M. Cáceres^{1,2}, **L. Armengol**¹, **J. W. Thomas**², **T. M. Preuss**³, **X. Estivill**¹;

¹Genes and Disease Program, Center for Genomic Regulation (CRG-UPF) and CIBERESP, Barcelona, Spain, ²Department of Human Genetics, Emory University School of Medicine, Atlanta, GA, United States, ³Division of Neuroscience and Center for Behavioral Neuroscience, Yerkes National Primate Research Center, Atlanta, GA, United States.

For the last few years, several groups have used microarrays to compare transcript levels in humans and non-human primates and have identified hundreds of candidate genes with expression changes in the human brain. Here, a multidisciplinary approach, including experimental techniques and bioinformatic analysis of genome sequence and gene-expression data, is proposed to obtain a more profound understanding of the potential causes and effects of these gene expression changes. Preliminary sequence comparisons have yielded examples of diverse types of mechanisms that could account for the observed differences in mRNA levels, such as multiple gene duplications, insertion of transposable elements in 3' UTR or upstream regions, and a single nucleotide mutation in the polyA signal. In addition, as an example of the proposed strategy, a global analysis of the regulatory sequences of the thrombospondin 4 (*THBS4*) gene has been carried out. This gene is involved in synapse formation and shows a six-fold up-regulation in humans that is specific of the forebrain. Interestingly, an excess of nucleotide changes and an Alu insertion were found in the *THBS4* promoter region in the human lineage. However, *in vitro* gene reporter assays indicated that the human and chimpanzee promoter fragments have similar transcriptional activity, and computational prediction of transcription factor binding sites suggests that *THBS4* up-regulation could be due to changes in trans-acting regulators. Overall, these results provide insights into the regulatory mechanisms acting at various levels and the evolutionary role of gene-expression regulation, and could help us to determine the molecular basis of human-specific traits.

Using genome-wide pathway analysis to unravel the etiology of a complex disease like type 2 diabetes

C. C. Elbers^{1,2}, **K. R. van Eijk**¹, **L. Franke**^{1,3}, **F. Mulder**¹, **Y. T. van der Schouw**², **C. Wijmenga**^{1,3}, **N. C. Onland-Moret**^{1,2};

¹Complex Genetics Section, Dept. of Biomedical Genetics, University Medical Center Utrecht, Utrecht, The Netherlands, ²Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, The Netherlands, ³Department of Genetics, University Medical Center Groningen and University of Groningen, Groningen, The Netherlands.

Several genome-wide association studies (GWAS) have recently been published on a variety of complex diseases. However, 99.9% of GWAS data is currently discarded and not analyzed to its full potential. In this study, we took a different approach and aimed to evaluate alternative methods of obtaining valuable information on disease etiology from GWAS data. We assessed whether we could detect over-represented biological pathways in the GWAS datasets, by combining a network-based tool, 'Prioritizer', with a pathway-classification tool, 'PANTHER'.

As an example, we used publicly available data from two type 2 diabetes (T2D) GWAS; the Diabetes Genetics Initiative (DGI) and the Wellcome Trust Case Control Consortium (WTCCC). Of the 1,179 SNPs in the DGI dataset and the 1,712 SNPs in the WTCCC dataset that showed association with T2D with a p-value lower than 0.003, we were able to map 559 and 797 SNPs, respectively, to genomic loci that contained one or more genes. Prioritizer then selected the most promising gene(s) from each locus based on their functional interactions with genes on the other loci. We used PANTHER to assign each of the selected genes to a specific pathway and to test whether we saw more genes in each pathway than expected.

Our results showed that the 'inflammation mediated by chemokine and cytokine signaling' and 'Wnt signaling' pathways were consistently the most strongly overrepresented in the T2D data. By taking an alternative approach, we have shown it is possible to detect biological mechanisms in GWAS data.

Ultra-High-Throughput Sequencing in heterogeneous inherited heart disorders: a first experience in Hypertrophic Cardiomyopathy

S. Fokstuen¹, **C. Iseli**^{2,3}, **D. Roby**⁴, **A. Munoz**⁴, **S. E. Antonarakis**^{4,1}, **J. L. Blouin**¹;

¹Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland, ²Ludwig Institute for Cancer Research, Lausanne, Switzerland, ³Swiss Institute of Bioinformatics, Lausanne, Switzerland, ⁴Genetic Medicine, University of Geneva School of Medicine, Geneva, Switzerland.

During last decade, molecular genetics has provided new insights into the pathogenesis of inherited heart disorders and Hypertrophic Cardiomyopathy (HCM) represents the most common one (1/500). Genetic testing has a growing impact on the management of patients and their families. However, the extensive genetic heterogeneity of these disorders requires the use of high-throughput mutation detection strategies for clinical screening. We had developed a 30-Kb HCM-Custom-DNA-resequencing-array (HCM-RA) comprising all exons (n=160), splice-sites and 5'-UTR of 12 HCM genes. Although very efficient in detecting single nucleotide variants, this approach did not identify small indels, accounting for 14% of HCM mutations. Moreover, resequencing-arrays lack flexibility since gene additions requires a new design.

In order to overcome the shortcomings of microarray-resequencing we assessed the performance of the recently developed Ultra-High-Throughput-Sequencing (UHTS). We reanalysed these 12 genes in a total of 19 patients, hybridized previously on HCM-RA (8 positive-controls as a composite-pool and 11 DNA without mutation), in a single channel of a SOLEXA. Every single base of the sequence (570 fold coverage accounting for 24 alleles) was analyzed using a newly developed data analysis pipeline.

All the 8 control mutations and 18 SNPs previously identified by HCM-RA were also observed in UHTS. Furthermore sequence alterations and particularly indels were detected such as c.1028delC/p.Thr343fsX349, [c.2146-9C>A+c.2146-2delA], c.506-12delC in gene MYBPC3, c.53-15_-11delTTCTC in TNNT2. Although evolution and improvement in DNA target enrichment, specificity and data analysis are needed, UHTS holds considerable promises in mutation/variant analysis underlying highly heterogeneous or multigenic pathologic conditions in clinical practice as well.

Advantages of universal primers use in biochip analysis of thrombosis genes polymorphism

A. S. Glotov^{1,2}, **E. S. Vashukova**^{1,2}, **L. B. Polushkina**¹, **O. N. Mityaeva**³, **T. V. Nasedkina**³, **I. V. Goldenkova-Pavlova**⁴, **T. E. Ivaschenko**¹, **M. S. Zainulina**¹, **V. S. Baranov**¹;

¹Ott's Institute of Obstetrics&Gynecology, St.-Petersburg, Russian Federation, ²Saint-Petersburg State University, Saint-Petersburg, Russian Federation, ³Engelgardt Institute of Molecular Biology, Moscow, Russian Federation, ⁴Vavilov Institute of General Genetics, Moscow, Russian Federation.

Genetic testing of inherited predisposition to frequent multifactor diseases needs new screening methods of DNA-polymorphism analysis. The most advanced approaches in genetic testing of multifactorial diseases usually include multi-locus DNA amplification. The multiplex PCR method could be significantly improved by means of the universal sequences incorporated into locus-specific primers. We have selected such DNA sequences and used them for two-step PCR genotyping of *F2*, *MTHFR*, *F5*, *PAI1*, *GP1IIa*, *FGB* polymorphism with the subsequent hybridization on oligonucleotide biochips. Use of this technique opens an ample opportunity for the fast and reliable detection of inherited thrombosis. The method could be easily adopted in any molecular diagnostic laboratory.

The work was partly supported by BRHE Fellowship competition 2006 (Y4-B-12-02), Saint-Petersburg Personal grant for PhD (PD 07-1.4-129), and grant of Russian Foundation for Basic Research (N 07-04-12271-ofi)

P08.81**The Human Variome Project - plans and progress**R. G. H. Cotton^{1,2};¹Genomic Disorders Research Centre, Carlton South VIC, Australia, ²Convenor, The Human Variome Project, Australia.

The Human Variome Project (HVP; www.humanvariomeproject.org) was created to coordinate and curate the collection of all genetic variation, its phenotype and associated disease(s). This is because lack of up-to-date, complete and correctly curated information can lead to excessive web searching, misdiagnosis and wastes valuable health-care funds.

Work to obviate this problem began more than a decade ago with the Human Genome Variation Society (HGVS; www.hgvs.org) promoting collection and display of variants, producing recommendations and software.

At the launch of the HVP, 96 recommendations (www.nature.com/ng/journal/v39/n4/pdf/ng2024.pdf) were drawn up by over 50 world experts from over 20 countries to be implemented in the future. The task is large so countless people will need to be involved in a coordinated manner with specially developed tools and protocols.

What is needed is an automated, seamless system transferring clinical data (phenotype), genotype and pathological data to hospital records, as well as to databases curated by experts, in a de-identified and ethically acceptable way, initially to LSDBs and finally to central databases/browsers.

The International Society for Gastrointestinal Hereditary Tumours (In-SiGHT; www.insight-group.org) has volunteered to be a pilot for (a) collection of all mutations and phenotype for their four genes of interest and (b) from all countries.

Many components for this flow have already been developed, often multiple times around the world in an un-coordinated disconnected way. A planning meeting was held in May 25-29 2008 to review these and rationalise future planning (www.humanvariomeproject.org/HVP2008/).

P08.82**Teststrip-based genotyping to assist in the prediction of anticoagulant dose requirement**H. Puehringer¹, Q. Berisha², G. Klose³, B. Schreyer³, W. Krugluger², R. Lorch³, C. Oberkanins¹;¹ViennaLab Diagnostics GmbH, Vienna, Austria, ²Department of Clinical Chemistry, Rudolfstiftung Hospital, Vienna, Austria, ³Clinical Haemostaseology, Westpfalz-Klinikum GmbH, Kaiserslautern, Germany.

Coumarin derivatives, such as warfarin and phenprocoumon, are the most widespread oral anticoagulant drugs for the prevention and treatment of arterial and venous thromboembolic disorders. However, these vitamin K antagonists have a narrow therapeutic range and a wide interindividual variability in dose requirement. Despite adjustment for clinical variables, adverse events are frequently encountered during the initial phase of therapy. Genetic polymorphisms in the drug-targeted vitamin K epoxide reductase complex 1 (*VKORC1*) and in the drug metabolizing enzyme *CYP2C9* have been reported to account for the majority of variations in the therapeutic response to warfarin.

We have developed a genetic test (StripAssay) for the simultaneous detection of two *VKORC1* polymorphisms (-1639G>A, 3730G>A) and the functionally defective *CYP2C9* variants *2 and *3 determined by 430C>T and 1075A>C. Preliminary data from our ongoing clinical study, to date including 130 patients treated with phenprocoumon (MarcumarTM), allowed a classification of high, intermediate and low dose responders according to *VKORC1* and *CYP2C9* genotypes. The stable dosage required for therapeutic anticoagulation was considerably lower in carriers of a combined *VKORC1*-1639A and *CYP2C9* *2 or *3 genotype compared to carriers of a single variation or wildtype alleles. The *VKORC1* 3730G>A polymorphism seemed to have no additional predictive power for phenprocoumon dose variability.

The new diagnostic assay and the results obtained during our study will assist clinicians to achieve a safer and more individualized anticoagulant therapy.

P08.83**eSensor® genotyping test for CYP2C9, CYP4F2 and VKORC1 polymorphisms associated with warfarin sensitivity**

W. A. Coty, M. R. Reed, A. R. Jacobs, P. Naranatt, R. Hubert, S. Panuganti, Z. Wang, V. Headley, Y. Liu, M. Abedi, G. R. Gust, K. Olszewski, D. Canfield; Osmetech Molecular Diagnostics, Pasadena, CA, United States.

We have developed an eSensor® test to genotype 8 CYP450 2C9 polymorphisms known to affect enzyme activity (2C9 *2, *3, *5, *6, *11, *14, *15 and *16), as well as the *VKORC1* -1639G>A promoter polymorphism associated with warfarin sensitivity and the CYP450 4F2 rs2108622 (V433M) polymorphism recently found to correlate with warfarin dose. After multiplex PCR and exonuclease digestion, genotyping is performed using the eSensor® cartridge and XT-8 instrument within 35 minutes for up to 24 samples. In a reproducibility study performed with 20 genomic DNA samples and 3 plasmid controls (n = 345 tests), 100% first-pass call rate and agreement with DNA sequencing were obtained. A method comparison study with 105 genomic DNA samples extracted from blood gave 100% call rate and agreement with DNA sequencing after re-testing of no-call samples, as did an additional cohort of 145 genomic DNA samples from saliva and cell lines. The assay gave 100% first-pass call rate and agreement with DNA sequencing using input genomic DNA amounts between 10 and 1,000 ng per PCR. Testing of ethnic panels from the Coriell Cell Repository revealed elevated allele frequencies for 2C9 *5 (3%) and *11 (7.6%) in the African-American panel (n=33), and 2C9 *14 (2.2%) in the Gujarathi Indian panel (n=90). Initial feasibility has been demonstrated for PCR amplification directly from whole blood samples, with no interference observed from serum albumin, IgG, bilirubin, hemoglobin, triglycerides or excess EDTA.

P08.84**A multiplex detection assay for Warfarin dosing using Single Base Extension**A. J. Rai¹, N. Udar², C. T. Yu¹, M. Fleischer¹;¹Memorial Sloan Kettering Cancer Center, New York, NY, United States, ²Beckman Coulter, Fullerton, CA, United States.

Thromboembolic events in "at risk" individuals can be prevented by anti coagulation drug therapy. Warfarin is a commonly used anticoagulant prescribed to over one million patients in the US (2006). Individuals vary greatly in their response to warfarin therapy. This difference has a genetic basis. Two genes: cytochrome P450 2C9 (2C9) and vitamin K epoxide reductase subunit protein 1 (*VKORC1*) have been reported to account for 60% of these differences. There are two clinically important alleles of 2C9(*2 and *3) and one of *VKORC1* (-1639 G->A). We designed a multiplex assay for the simultaneous detection of these three alleles in a single reaction. Our assay entails a multiplex PCR amplification of the target gene fragments followed by a multiplex single base extension reaction. The single base extension reaction incorporates the target nucleotide which has a fluorescent tag attached to it. This tag is detected by separation on a capillary electrophoresis platform. The entire assay can be performed with in an eight hour day by a single technologist with minimal hands-on effort. We observe 100% concordance on twenty samples when our assay is compared to traditional DNA sequencing. We have optimized this assay for high-throughput screening of patient samples, allowing for analysis of two 96well plates on a single overnight run. Our multiplex SNP panel can be used as a stand-alone test for patients starting warfarin therapy, or its results can be combined in an algorithm with additional parameters (e.g. weight, age, sex, etc.) to provide dosing recommendations for initial warfarin administration.

P08.85**Whole Genome Amplification (WGA) in forensic SNP profiling**I. Pietrangeli¹, C. Martone¹, E. Giardina¹, I. m. Predazzi¹, P. Marsala², I. gabrielle³, c. pipolo³, o. ricci³, G. Solla³, A. Spinella³, G. Novelli^{1,4};¹Centre of Excellence for Genomic Risk Assessment in Multifactorial and Complex Diseases, School of Medicine, Tor Vergata University of Rome, Rome, Italy, ²Direzione Centrale Anticrimine, Servizio di Polizia Scientifica, Rome, Italy, ³Direzione Centrale Anticrimine, Servizio di Polizia Scientifica, Rome, Italy, ⁴Division of Cardiovascular Medicine, Department of Medicine, University of Arkansas for Medical Sciences, Little Rock, AR, United States. Whole genome amplification (WGA) is a technique developed for genetic analysis to obtain sufficient amount of DNA from small pools of cells or even single cells.

Presently, the usefulness of WGA in STR-based forensic analysis is limited because of allelic dropout (ADO) and bias in peak area ratios observed in low copy number (LCN) templates. Sequence polymorphisms (SNPs) are more sensible than length-polymorphisms (STRs) and less prone to ADO (allelic dropout) when WGA is applied. Thus, we recently validated a panel of TaqMan SNP assays selected to show an high sensibility in LCN templates. Here we evaluated the performance of multiple displacement amplification (MDA) applied to our optimized SNP assays starting from small amounts of genomic DNA (gDNA). A set of 100 samples were analyzed for 21 SNPs and a total of 1 ng, 100 pg and 10 pg of genomic DNA of each sample was used as template for the MDA. Concordance and amplification failure (AF) between gDNA and wgaDNA were extremely robust (100%) when WGA was performed on 1 ng and 100 pg of gDNA, whilst the concordance decreased to 99.2% for samples amplified from 10 pg of gDNA. The absence of a full concordance for 10 pg samples is referred as ADO occurring when a gDNA heterozygote genotype is scored as homozygote but it should not lead to mis-typing if only heterozygous genotypes are considered. The robustness of WGA applied to specifically selected SNP assays should suggest a reconsideration of WGA for forensic SNP profiling.

P08.86

Comparison of genotyping consistency between genomic and whole-genome amplified DNA using the Illumina GoldenGate and Infinium-II assays

S. Cichon^{1,2}, M. Alblas¹, K. Kämmerling¹, T. W. Mühleisen¹, M. M. Nöthen^{1,2}, P. Hoffmann^{1,2};

¹Life & Brain Center, University of Bonn, Bonn, Germany, ²Institute of Human Genetics, University of Bonn, Bonn, Germany.

High-throughput SNP genotyping has become an important research strategy in human genetics. Although most genotyping assays require minimal amounts of DNA, repeated use often leads to depletion of the samples. To address this problem whole-genome-amplification (wga) technologies have been developed and are meanwhile commercially available. Albeit the amplification seems to be mostly successful, it is controversially discussed whether the wgaDNA represents an exact copy of the genomic DNA (gDNA). In the present study, we aimed to assess the genotyping consistency between 45 wgaDNAs (generated using the REPLI-g DNA Amplification Kit, Qiagen, Hilden) and their corresponding gDNA samples. The gDNAs were of different age and quality. To compare genotype consistency 20 high-quality sample pairs were genotyped using Illumina's HumanHap550V3 BeadChips (565,000 SNPs). 25 sample pairs of different DNA quality were genotyped for 384 SNPs using Illumina's GoldenGate assay. All samples genotyped on the HumanHap550V3 performed well, with call rates >99%. The average consistency between gDNA and wgaDNA was 99.99% when comparing SNPs successfully genotyped in the corresponding samples. Of the 25 sample pairs genotyped with the GoldenGate assay, 22 performed well with call rates >99% (gDNA) and >98% (wgaDNA). Genotype consistency was 100% for corresponding samples. The remaining 3 sample pairs showed noticeably worse results with an average genotype call frequency of 99.8% (gDNA) versus 60.1% (wgaDNA) and a genotype consistency of only 89%. Possible explanations for the observed discrepancies include the age of gDNA, the extraction method as well as the presence of unknown inhibitors interfering with the amplification process.

P08.87

Comprehensive Desktop Software for Next Generation Sequencing Applications

S. Baldwin, D. Nash, K. Dullea, R. Nelson, T. Durfee, J. Engelking, F. Blattner; DNASTAR Inc., Madison, WI, United States.

Next Generation sequencing technologies provide the data generation tools for many large scale molecular biology applications including whole genome sequencing/resequencing, polymorphism detection, as well as gene expression and regulation. The cost effectiveness of these technologies makes them accessible to virtually any researcher. One of the lagging issues, however, has to do with the handling of the large quantities of data generated and gaining access to the tools required to analyze the data. To provide users with the ability to take advantage of the next-gen revolution, DNASTAR has developed fully scalable software capable of processing a wide range of resequenc-

ing and whole genome projects on a desktop computer. The software is fully compatible with Sanger, Roche 454, Illumina and ABI SOLiD sequence platforms. We will provide workflow examples of assembly within SeqMan Genome Assembler for rapid resequencing assembly projects along with the use of its companion, SeqMan Pro for finishing, analyzing and annotating whole genome assemblies. We will also present a workflow for using the software in digital gene expression applications comparing data from microarrays to data generated by next generation sequencing instruments.

Diagnostic and clinical validations in DNA-diagnostic laboratories: a BRCA example

D. Bodmer, M. R. Arjen, S. Hans, H. Nicoline, L. J. L. Marjolijn; Department of Human Genetics, Nijmegen, The Netherlands.

Clinical validations are used to assess the clinical sensitivity and specificity of genetic testing within DNA diagnostic laboratories and are an important instrument to monitor and further improve reliability and efficiency of molecular testing. However, for most indications the clinical information available to DNA diagnostic laboratories is too scarce to determine the a priori chance of a positive test result. In order to assess the sensitivity and specificity of genetic testing, we started with a so called diagnostic validation, in which the robustness of the method(s) to analyze a single gene or a set of genes for a genetic disease was determined. The parameter used is the mutation detection ratio (MDR) which is defined as the proportion of mutation-positive results. By comparing the MDR of a genetic test at different time intervals (e.g. years), the robustness of this test can be judged. This robustness depends on changes and variations that occur within a method (with or without preceding analytical validation) as well as method performance by different operators. Decrease of the MDR of a genetic test over time, should lead to critical evaluation of the different laboratory processes and assessment of putative alterations in the a priori risk of the diagnostic requests.

An example: The efficiency of BRCA1 and BRCA2 mutation analysis has decreased within years. To determine the cause of this decrease, e.g. whether this is due to technical issues or solely to an altered referral policy, we performed both a diagnostic validation as well as a clinical validation.

P09.02

Expanded newborn screening: Challenges for the provision of pre-newborn screening care

J. Allanson¹, F. A. Miller², R. Hajeems², J. Carroll³, P. Chakraborty¹, R. Christensen², J. Little⁴, B. Wilson⁴;

¹Children's Hospital of Eastern Ontario, Ottawa, ON, Canada, ²University of Toronto, Toronto, ON, Canada, ³Mount Sinai Hospital, Toronto, ON, Canada, ⁴University of Ottawa, Ottawa, ON, Canada.

Historically, newborn screening (NBS) aimed to identify serious childhood disorders for which treatment was available to reduce morbidity and mortality. Limited attention to pre-screening information provision was justified by the severity and treatability of the conditions screened. Yet technological advances allow NBS programs to identify disorders for which the promise of clinical benefit is uncertain as well as an array of "incidental" findings (benign variants, carrier status results). Given the contested value of such results, commentators argue that limited attention to pre-screening care is no longer justifiable. This paper reports survey data on attitudes and practices of a cross-sectional stratified random sample of five health care professional (HCP) groups in Ontario that are involved in prenatal care and/or care of newborns in the first days of life (obstetricians, midwives, nurses, family physicians, pediatricians). The majority of HCPs surveyed (68%) believe it is their responsibility to provide information about NBS to parents prior to the heel prick test. However, as many as 48% of these providers report that they do not consistently or usually do so. This paper explores the role of provider type, practice barriers (e.g. insufficient time, training, compensation) as well as knowledge and confidence of NBS in explaining the discrepancy between perceived professional responsibility and actual professional practice. Thus, while most HCPs perceive

a responsibility to provide information about NBS to parents prior to the heelprick, many challenges face the provision of this increasingly important pre-screening care.

P09.03

Increasing research through collaboration

J. D. Cody, C. D. Sebold, D. E. Hale;

Chromosome 18 Clinical Research Center, San Antonio, TX, United States.

One goal of lay advocacy groups is to encourage research into the condition of interest. However, advocacy groups face some unique challenges in the achievement of this goal. (1) The pool of potential research participants and funding opportunities are limited by the relative rarity of the condition. (2) Many conditions have multisystem involvement, meaning that specialists from multiple disciplines must be involved in the research. (3) For many conditions, the natural history is still unknown. However, studies delineating the phenotype of a condition are particularly challenging, as such studies require a methodical clinical assessments of every system, ideally performed by the same group of investigators.

The relationship between the Chromosome 18 Registry and Research Society and the Chromosome 18 Clinical Research Center is unique in that the Registry is affiliated with only one research center. This differs from the more traditional paradigm in which an advocacy group grants smaller amounts of funding to multiple investigators at different institutions.

In our experience, this relationship has been critical in addressing the above challenges. (1) The collaborative effort provides the Research Center both funding and a large pool of potential research participants. (2) The establishment of the Research Center in one institution allows for recruitment of multiple disciplines within the institution to aid in study design and execution. This paradigm also eliminates barriers to the sharing of data and samples between investigators. (3) The same investigators perform evaluations on patients using the same methods and tools, ensuring that the clinical data is reliable.

The international multidisciplinary Community Genetics Network

L. P. ten Kate¹, L. Hennemar²;

¹Dept Clinical Genetics, EMGO-Institute, VU University Medical Center, Amsterdam, The Netherlands, ²Dept Public and Occupational Health, EMGO-Institute, VU University Medical Center, Amsterdam, The Netherlands.

The International Multidisciplinary Community Genetics Network is an E-mail network aiming to facilitate communication among those working in the field of community genetics. This includes researchers, health professionals and others interested in genetic screening, genetic education, access and quality of genetic services or preconception care, genetics in primary care, genetic registries, genetics of disadvantaged populations, public consultation or epidemiological, economic,

psychosocial, ethical and legal issues.

The core activity is a monthly newsletter with a list of references to recent scientific papers of members and a continuously updated list of upcoming meetings. This allows a rapid spread of information among members, which is advantageous to the authors of papers or organizers of meetings, but also to readers who want to stay tuned on what others are doing. In addition members may present information on new activities in the newsletter, and publish calls for information (e.g. about validated research questionnaires or participants for a particular study).

The Network was launched at the ESHG annual meeting in Nice last year. Nine months later (mid February 2008) the Network has 245 members in 45 countries worldwide, growing at a pace of 25-30 new members each month. Just over 50% of the membership comes from Europe (20 countries). The country with the largest number of members is the USA. Updated numbers will be presented at the ESHG annual meeting in Barcelona.

Those who want to have more information or want to become a member and obtain the newsletter, should send an E-mail to commgenet@gmail.com.

Mainstreaming community genomics: the ECOGENE-21 initiative

D. Gaudet, M. Santure, F. Paradis, C. Belanger, D. Brisson;

Montreal University Community Genomic Medicine Center, Chicoutimi, QC, Canada.

ECOGENE-21 is a transdisciplinary initiative, driven by the specific needs of communities. ECOGENE-21 specifically refers to human communities, a cohesive social entity of individuals or families sharing the same environment and ecosystem within the context of the larger society. ECOGENE-21 aims to understand the role of genetic health determinants and new genetic technologies in global health issues, and integrate this knowledge into a comprehensive framework to improve health at the level of human communities. The aims are to: (1) develop, validate, apply and replicate cost-effective genome-based technologies and screening strategies to prevent Mendelian diseases at the community level; (2) generate, validate, apply and evaluate technologies and strategies in different communities of the world for the prevention and treatment of common diseases, based on the model of lipid disorders, the metabolic syndrome and associated risk of type 2 diabetes and cardiovascular risk factors; (3) develop the expertise and platforms needed to generate, apply, validate and replicate new knowledge issued from community genomics, population genomics, pharmacogenomics, nutrigenomics, epigenomics and environmental genomics research. Over a 5-year timeframe, ECOGENE-21 will deliver, apply and disseminate new applicable, cost-effective and exportable vanguard technologies, strategies and concepts for disease prevention in human ecosystems, as well as innovative knowledge transfer and training strategies, tools, platforms and expertise. The ECOGENE-21 framework and results obtained to date in the French-Canadian founder population based on analytic, clinical and public health validity and utility criteria will be presented. ECOGENE-21 is supported by the Canadian Institutes of Health Research (#CTP-82941).

P09.07

It's not just about competence: Why identifying organisational practice is an important step in developing a high quality genetic service

M. Bishop^{1,2}, Y. Bylstra¹, F. Cullinane³, C. Gaff¹, S. Metcalfe^{1,2};

¹Murdoch Childrens Research Institute, Melbourne, Australia, ²The University of Melbourne, Melbourne, Australia, ³The Royal Women's Hospital, Melbourne, Australia, ⁴Genetic Health Services Victoria, Melbourne, Australia.

While there have been numerous efforts to develop competences in genetics for non-genetic health professionals to support their practice, there has been minimal research to identify other factors that influence this role. As part of our study to examine how midwives provide a genetic service in Victoria, Australia, we identified the barriers and facilitators of this practice, using a mixed methods approach. Qualitative data were collected from nine focus groups with midwives (n=50) and two focus groups with experts in genetics (n=10), as well as 12 interviews with managers of hospital maternity services. Transcripts

were analysed, major themes identified and data triangulated. These findings were validated with quantitative data collected from midwives responding to a state-wide survey ($n=317$, response rate 45.4%). Our findings indicate that there is variation in the genetic practice of midwives. While each midwife's practice is contingent on their individual competence, the scope of their practice is heavily influenced by the organisation in which they work. For example, each hospital provides specific guidelines on what information needs to be collected to determine genetic risk, and what genetic tests should be discussed with each pregnant woman. These findings suggest that programs that only target midwifery competence will not be enough to effect practice change. Instead, for midwives to provide an effective and high quality genetic service, a two pronged approach targeting midwifery competence and addressing organisational policy is required.

Genetic counseling for newborn hearing screening in Nagano, Japan

S. Maruyama¹, A. Sakurai¹, S. Usami¹, Y. Takumi¹, H. Moteki¹, K. Hayashi¹, S. Nishio¹, M. Maeda², A. Mizuuchi¹, M. Arakawa¹, R. Kawamura¹, Y. Yamanouchi¹, H. Yamashita¹, M. Tama¹, T. Kosho¹, K. Wakui¹, T. Wada¹, Y. Sekijima¹, Y. Fukushima¹;

¹Shinshu University School of Medicine, Matsumoto, Japan, ²Support Center for Children with Hearing Loss, Matsumoto, Japan.

Congenital deafness is a disorder with high prevalence (1/1,000 birth) and that requires early diagnosis and medical intervention to minimize the morbidity of the affected infant. Since 50% of congenital deafness is caused by genetic defect and clinical phenotype and prognosis in part depend on genetic background, genetic testing for affected infants can provide useful information. In Japan, a newborn hearing screening has started as a government project in 2000. In Nagano prefecture of Japan (population 2.2 million), a screening program has started in 2002. In 2007, under the collaboration and coordination among medical-, educational- and administrative staffs, the Support Center for Children with Hearing Loss has opened to support both affected children and their parents. Division of Clinical and Molecular Genetics in Shinshu University Hospital also collaborates with this center as a provider of genetic counseling. Since 70% of genetic congenital deafness is an autosomal recessive disorder, most parents of affected children have normal hearing, thus do not consider the possibility of genetic causes on their affected children. This also suggests that the burden of patients could be more intense when they know the diagnosis of their children.

We performed a questionnaire-based survey to clarify psychological impact of parents and what they needed during hearing screening, before and during genetic testing, and after being informed a diagnosis. Results of this survey clearly indicated the importance of genetic counseling during screening program and intense collaboration between the Center and community medical staffs such as public health nurses.

P09.09

Development of a set of core competences in genetics for health professionals in Europe

H. Skirton¹, C. Lewis^{2,1}, A. Ken², D. Coviello³;

¹University of Plymouth, Plymouth, United Kingdom, ²Genetic Interest Group, London, United Kingdom, ³Fondazione IRCCS, Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena, Milan, Italy.

The increasing use of genomics within a wide range of health care settings requires health professionals to develop relevant expertise in genetics to practise appropriately. There is a need for common minimum standards of competence in genetics for health professionals in Europe. However, there are significant differences in professional education and practice across Europe and setting common curricula is not practical. It was agreed by the Expert group of the EuroGentest project Unit 6 that a pragmatic solution would be to describe and agree, by consensus, a set of core competences that could apply to health professionals in Europe, whatever their national setting.

The core competences were based upon existing frameworks, modified for the European context. They relate to i) professionals whose specialisation is in genetics and ii) professionals who are generalists or specialise in an area of health care other than genetics. Recommendations have been based on work that was developed in consultation with the particular group of professionals involved. The goal of this

work is not to be prescriptive, but to provide frameworks that can be adapted to national and professional need. Curricula for a range of health professionals, both pre-registration and post-registration, can be built or modified using the competences.

In this paper, the process of development, the competences and suggested learning outcomes will be discussed. The competences and a background document can be viewed on the website of the EuroGentest project [<http://www.eurogentest.org/>]. The project team invites feedback.

Genetic Counsellor : News from France

C. Cordier^{1,2}, N. Pasz², M. Voelckel^{3,2};

¹Department of Cytogenetics, Mulhouse, France, ²French Association of Genetic Counsellors, Marseille, France, ³Department of Medical Genetics, Marseille, France.

The Professional Master « Genetic Counselling and Predictive Medicine » made possible the education of the first French Genetic Counsellors, since 2005. Two years later, there are 34 graduated, 23 of them have a job and 4 of them have a job offer.

Thanks to the data from the French Association of the Genetic Counsellors; the AFCG (Association Française des Conseillers en Génétique), we suggest to present the interdisciplinary recruitment, the job progression in France, and the way managed to its valorisation.

We will specify the annual number of new graduated, and the Genetic Counsellors location in France and in a couple of countries. Then, we will insist on the processing action for a national, European, and international integration of these new French professionals.

P09.11

Genetics counseling:misdirection and misuse in some developing countries

M. Shariaty;

Cancer Research Institute, Tehran, Islamic Republic of Iran.

Practically genetics counselling began with Eugenic movement around 1910 in England,USA and some western countries with very negative and destructive effects on health and integrity of humankind. Fortunately ,the misuse of genetics was officially abandoned in 1944 though practically persisted up to 1960s.

Medical Genetics counselling based on dignity and equality was introduced by Sheldon Reed in 1944 and became an obligate branch of modern clinical and medical genetics settings.

In Islamic countries Genetics counselling was introduced by the author in 1968 based on the same principles thought by my mentor professors Reed,Vogel and Fuhrmann,and considering all of the humanitarian ,ethical,moral ,and religion issues concerning the clients.Since 1968 i have consulted more than 17000 couples,majority seeking consanguineous marriage. Only less than 2% of these young healthy couples seeking marriage actually needed karyotyping.

Unfortunately,in the last several years in some developing countries,genetics counselling has been misunderstood and misused due to financial interests of private centers.It is quite wrong but popular practice to order karyotyping for every marriage or every disease that carries the label of being due to genetics.s disease.I have seen many examples of ordering karyotyping for Duchene muscular dystrophy,thalassemia,hemophilia,phenylketonuria and cystic fibrosis .

Based on these facts I am proposing a universal medical guideline for every Genetics counselling center and every genetics counsellor based on medical,ethical,humanitarian ,and religion principles so that the needy clients could not be misused and financially and morally exploited.

P09.12

Cystic fibrosis cascade carrier testing in Victoria, Australia: an audit of clinical service

B. J. McClaren^{1,2,3}, M. A. Aitken¹, R. J. Massie^{1,4,2}, S. A. Metcalfe^{1,2}, D. J. Amor^{3,2,1};

¹Murdoch Childrens Research Institute, Melbourne, Victoria, Australia, ²The University of Melbourne, Victoria, Australia, ³Genetic Health Services Victoria, Melbourne, Victoria, Australia, ⁴Royal Children's Hospital, Melbourne, Victoria, Australia.

In Victoria, Australia, carrier testing for cystic fibrosis (CF) is performed by a single state-wide laboratory and counselling service. CF carrier

testing is offered free of charge to the relatives of babies diagnosed with CF through the newborn screening program. Although cascade testing is known to detect carriers of CF, its effectiveness has been questioned, in our clinical service and elsewhere, because most babies with CF are born to couples who do not have a family history; the uptake of cascade testing following a child's diagnosis of CF by newborn screening has not been previously reported.

We investigated CF cascade testing in the families of Victorian children with CF. We studied the uptake of cascade carrier testing by examining 53 pedigrees of newborns diagnosed with CF between 2001 and 2004, and performing data linkage to the laboratory database records. The uptake of carrier testing amongst adult first and second degree relatives was 16% (190/1160). Parents were the most likely relatives to have been tested, followed by aunts/uncles, then grandparents. We conclude that cascade testing, as currently offered, is not an effective strategy for detecting carriers for CF. An alternative is to offer population-based screening and this occurs in some countries but with quite variable uptake reported. Factors influencing uptake of CF carrier testing need to be explored. We are now conducting an evaluation of the barriers and facilitators to cascade testing to inform both clinical service delivery and population-based CF screening programs.

P09.13

Facing choices about genetic testing and assisted reproduction: developing an integrated care pathway to help health professionals meet the needs of infertile men with Cystic Fibrosis (CF) and congenital bilateral absence of the vas deferens (CBAVD)

A. Edwards¹, C. Phelps², A. Procter¹, I. Ketchell³;

¹All Wales Medical Genetics Service; Institute of Medical Genetics, University Hospital of Wales, Cardiff, United Kingdom, ²Institute of Medical Genetics, Cardiff University School of Medicine, Cardiff, United Kingdom, ³Adult Cystic Fibrosis Unit, Cardiff and Vale NHS Trust, Cardiff, United Kingdom.

Background The choices offered by assisted reproductive technologies (ART) and preimplantation genetic diagnosis (PGD) mean that genetics services need to be better integrated into the care pathway of infertile men with CF/CBAVD. This study explored how multidisciplinary healthcare professionals in one UK NHS Trust believe genetics services can be integrated into a common care pathway.

Methods Three focus groups were convened with health professionals involved in the care of men with CF/CBAVD (representing genetics, adult respiratory medicine, paediatrics, assisted reproduction and urology). The first two groups (5 & 7 participants respectively) explored awareness of genetics, ART and PGD. Concerns and training needs were identified. Following patient interviews, a final focus group was convened to identify a common care pathway.

Results. Much uncertainty existed amongst non-genetics specialisms regarding the role of genetics services in the CF/CBAVD care pathway. A lack of confidence was evident when talking about the genetics of CF/CBAVD, ART and PGD. Common concerns related to when to raise these issues and how to deal with parental pressure. Participants felt that although the in-depth discussion of these issues should be the main responsibility of the genetics service, their own basic knowledge could be enhanced.

Conclusions. There is a need for improved information exchange about the genetics of CF/CBAVD and assisted reproductive options between specialisms. Genetics services can improve awareness and become better integrated into the existing care pathway by facilitating professional workshops and training sessions, and producing leaflets and referral guidelines. An integrated care pathway is being developed.

P09.14

Challenges in establishing a population carrier screening program for cystic fibrosis

A. Bankier¹, M. Delatyck², J. Massie³, R. Forbes², B. Chong¹, D. DuSart¹, V. Petrou²;

¹Victorian Clinical Genetics Services, Parkville, Australia, ²Genetic Health Services Victoria, Parkville, Australia, ³Royal Children's Hospital, Parkville, Australia.

Cystic fibrosis is the commonest life shortening autosomal recessive condition among Caucasians due to mutations in the *CFTR* gene. The carrier frequency in this population is 4% with a disease incidence of 1:2,500. Carriers are healthy and the majority of people are unaware

of their carrier status. More than 95% of babies born with CF have no family history of CF. Most parents who have a child with CF elect to utilise reproductive technology for subsequent pregnancies by either prenatal diagnosis (PND) or pre-implantation genetic diagnosis (PGD). The US National Institutes of Health and American College of Obstetricians and Gynecologists recommend offering CF carrier testing to all couples.

We have introduced a fee paying prenatal screening program, initially offered through obstetricians in the private sector. Sampling is by cheek brush, testing for the twelve most common severe mutations in *CFTR*. In the first two years of the program 2975 people were screened of whom 64 were carriers (1:46) and 6 carrier couples (~1:500) were identified all of whom chose either PND if pregnant or PGD if non-pregnant at the time of testing.

The challenges and difficulties faced include difficulties of educating health care professionals and the public about CF, the requirement for sample recollection in 2.2% of patients screened, the correct collection procedure, patient anxiety regarding not being offered screening until pregnant, reluctance of health professional to offer screening primarily due to time constraints and equity of care when screening is currently only offered in the private health sector.

P09.15

EuroGentest Medical Genetics Quality Assurance Database

L. Desmet^{1,2}, A. Corveleyn^{1,2}, N. Nagels^{1,2}, V. Lanneau³, I. Caron³, B. Urbergo³, S. Aymé^{3,2}, E. Dequeker^{1,2}, M. A. Morris^{4,2};

¹Department for Human Genetics, Leuven, Belgium, ²EuroGentest, Leuven, Belgium, ³Orphanet, Paris, France, ⁴Service of Genetic Medicine, Geneva, Switzerland.

The outcome of genetic testing has a great impact on the life of patients and their entourage. The quality of genetic testing is thus of utmost importance. In July 2007, EuroGentest released a European Quality Assurance (QAU) database in collaboration with Orphanet, with reliable public information about the quality systems of laboratories offering medical genetic testing (<http://www.eurogentest.org/web/qa/basic.xhtml>). The database contains at present data from about 230 laboratories of 32 countries.

These data comprise besides laboratory contact details and a link to the Orphanet laboratory page, information about the quality manager, the accreditation status with a link to the accreditation scope if applicable, and about participation in genetic EQA schemes.

During 2004 and 2005, 152 of the 230 laboratories (66%) participated together in 87 different EQA schemes; mainly for CF testing (51% of the EQA participating laboratories), DNA sequencing (34%) and FRAXA (31%). Of the laboratories participating in EQA, 28% are also accredited according to standards ISO 17025 or ISO 15189. Another 23% of laboratories are preparing for accreditation in the near future.

The EuroGentest QAU database allows consumers (laboratories, doctors, etc) to identify a laboratory with a quality system for a particular diagnostic test. It benefits laboratories by encouraging and providing recognition of their investment in QAU as well as by giving them a better informed choice for referral of tests.

The database will be continually updated and participation in the database is freely open to all European laboratories offering human medical genetic testing. For more information, please contact QAUSurvey@eurogentest.org.

P09.16

Definitions of genetic testing in European and other national legislation (EuroGentest WP3.4)

O. Varga^{1,2}, J. Sequeiros^{1,3};

¹IBMC, Porto, Portugal, ²School of Public Health, Faculty of Public Health, UD MHSC, Debrecen, Hungary, ³ICBAS, Porto, Portugal.

We are comparing definitions of genetic testing among legislation from European institutions and individual Member States, as well that produced in the USA, Canada, Japan and Australia.

Investigation is based on documents collected from websites and databases, including governmental sources, as well as that gathered within WP3.1 and the series European Ethical-Legal Papers, being published by EuroGentest Unit 6.

We checked the present status and validity of all legislation used: only those still in force will be analyzed and compared; when validity check is currently not possible, due to unavailability or language incompat-

ibility, they will be noted as “unknown”.

Preliminary results (16 laws) come from 7 countries (Belgium, Hungary, Portugal; Australia, USA, Canada and Japan): 6 are compulsory and 10 soft laws.

Definitions of genetic testing in these documents vary significantly in length and comprehensiveness, depending on their general purpose and aims; jurisdiction source is also variable: general discrimination (Belgium and Canada), genetic information and discrimination in employment (USA), health care (Hungary), general privacy and confidentiality (Australia), health and genetic information (Portugal).

The expected results are an up-to-date and easy-to-search definitions database, focusing on legislation of European and other countries, with annotations regarding relevancy and reach of that legislation (compulsory or only soft law; source, and to which jurisdiction(s) does it apply; etc.).

Then, definitions of genetic testing in European and other legislation may be compared among countries and jurisdictions. This might be helpful for legislators and policy makers, the various professionals involved in genetic testing and the general public.

P09.17

What do judges need to know about human genetics? Judicial science education in the US

C. Skrzynia¹, F. M. Zweig², J. P. Evans¹;

¹University of North Carolina, Chapel Hill, NC, United States, ²Advanced Science and Technology Adjudication Resource Center, Washington, DC, United States.

The importance of genetics has grown in the past decades not only among other biological sciences but also throughout society in general. However knowledge about the subject lags. Efforts have been devised to fill this gap in high schools, in medical education and in the general public. We'd report here on judicial education programs as conceived and produced by the Advanced Science and Technology Adjudication Resource Center (ASTAR) in collaboration with the University of North Carolina in Chapel Hill.

ASTAR is a congressionally mandated educational effort with the mission of training the US judiciary in scientific matters in order to enhance scientific knowledge in US courts. Through the use of lectures and hands-on instruction a cadre of resource judges has been trained to serve at their home jurisdictions as resource persons who can offer consultation and expertise when cases involving scientific and technical matters arise.

We present aspects of the curriculum, which range from intense “basic science boot camps” to mock “adjudication clinics” and plenary discussions moderated by judges and scientists. We focus specifically on human genetics as this subject plays an increasing role in diverse court cases. The examples include genetics of addiction, cancer genetics, genetically engineered crops, inborn errors of metabolism and genetic discrimination. Out educational objective is to promote case management and settlement in controversies in which novel scientific evidence is likely to be introduced.

P09.18

Ethnicity and Genetics: a sensitive issue

N. J. Lescho¹, N. V. A. M. Knoers²;

¹Dept Clinical Genetics, Amsterdam, The Netherlands, ²Dept Human Genetics RadboudUniversity Medical Centre, Nijmegen, The Netherlands.

In our multicultural society registration of ethnicity is not allowed by law. We here present six “ethnicity issues”: in genetic counselling and diagnostic testing, population screening programs, association studies and pharmacogenetics, respectively.

- Testing for new mutations in the BRCA-1 gene is time-consuming. Patients with an Ashkenazi background have different mutations than other ethnic groups and therefore, it would be advantageous to know the ethnic background of patients to improve efficiency of mutation analysis.
- In prenatal screening for Down syndrome, background values for Beta-hCG and PAPP-A differ between Afro-Caribbean and West-European women.
- In neonatal screening 16 diseases are tested in all 180.000 newborns in the Netherlands each year, including sickle cell anaemia, while only 40.000 have an increased risk for that disorder.
- Consanguineous marriages are common in people originating from

North Africa, because of social advantages. The increased risk for autosomal recessive diseases in their offspring is mostly not known in the future parents.

- In association studies results can often not be reproduced by additional studies. Ethnicity is an important cause.

- Finally, ethnicity is an issue in pharmacogenetics, for instance in prescribing beta-blockers for heart failure in African-Americans. It is difficult to handle the issue of ethnicity in genetics correctly and little is done to change that attitude. Meanwhile, this attitude may be harmful for the patient and science in general.

P09.19

A comparison of criteria for clinical validity and utility in various national and international frameworks

P. Javaher¹, U. Kristoffersson², A. Kent³, A. Christianson⁴, R. Raouf⁵, C. Barreiro⁶, I. Nipper⁷, J. Schmidtko¹;

¹Medical School of Hannover, Hannover, Germany, ²Lunds University, Lund, Sweden, ³Genetic Interest Group, London, United Kingdom, ⁴University of the Witwatersrand, Johannesburg, South Africa, ⁵Ministry of Health, Cairo, Egypt, ⁶Hospital de Pediatría SAMIC, Buenos Aires, Argentina, ⁷Universitaetsklinikum Muenster, Muenster, Germany.

CAPABILITY is a 3-year model project developed jointly by Unit 3 (Clinical Genetics, Community Genetics and Public Health) and Unit 6 (Education) of the Network of Excellence (EuroGentest) and by leading experts from Argentina, Egypt and South Africa. CAPABILITY's overall objectives are to contribute to the efforts to establish and sustain a worldwide harmonisation process for quality standards for the integration of genetic test/genomic knowledge applications into practice and prevention and to serve as a model project for successful, sustainable collaboration between EU research centres and centres from developing countries.

In recent years a great deal of attention has been paid at national and international levels, to develop policies in the field of provision of clinical genetic testing services. The topic has been tackled by several different national and international organisations, each taking different approaches, depending on their primary objective. In various frameworks different groups addressed the determination of criteria for clinical validity and utility of genetic testing. As a preliminary outline in the context of CAPABILITY, this review aims to present the various frameworks and to draw a comparison of the different approaches.

P09.20

The cystic fibrosis external quality assessment scheme, monitoring the quality of laboratory performance

S. Berwouts¹, E. Girodon², M. Stuhmann³, M. Schwarz⁴, M. A. Morris⁵, A. Corveleyn¹, L. Desmet¹, E. Dequeker¹;

¹Centre of Human Genetics, University of Leuven, Leuven, Belgium, ²Service de Biochimie et Génétique, Groupe hospitalier Henri Mondor-Albert Chenevier, Créteil, France, ³Institut für Humangenetik, Medizinische Hochschule, Hannover, Germany, ⁴Department of Medical Genetics, St Mary's Hospital, Manchester, United Kingdom, ⁵Laboratoire de Diagnostic moléculaire, Service de Médecine Génétique, University Hospital, Geneva, Switzerland.

Given the potential serious health consequences of genetic test results, mechanisms should be in place to assure the quality of the tests and the interpretation of the data.

In this regard, the International Organization for Standardization ISO 15189 (5.6.4) and the Organisation for Economic Co-operation and Development (OECD) Guidelines for quality assurance in molecular genetic testing (2.C), contain requirements and recommendations for laboratories to participate in external quality assessment schemes (EQA). Participation in EQA schemes is useful not only to the laboratory, as a key element of its quality assurance processes, but also as a quality indicator to monitor the improvement of laboratory performance.

The Cystic Fibrosis (CF) Network has been providing EQA since 1996 and has performance data from more than 10 years. This study focuses on a group of about 100 molecular genetics laboratories that participated in the CF EQA scheme for each of the previous three years.

Reporting the correct genotype, provision of appropriate interpretation and additional elements required by ISO 15189 such as unique identification of the patient and sample type, are compared over these three years. In addition, comparable cases and samples with identical genotypes were included during the three-year period, which enabled

us to analyse performance of a laboratory more specifically and to survey if individual comments, provided by the assessors, were taken into account by the laboratory.

Regular participation contributes to continuous improvement and monitoring of internal quality in laboratory performance. Moreover, it is a relevant tool for assessors to educate laboratories.

P09.21

Fetal alcohol syndrome among grade-one children in the Northern Cape Province of South Africa: prevalence and risk factors

M. F. Urban¹, M. F. Chersich², L. Fourie³, C. Chetty³, L. Olivier⁴, J. Rosenthal⁵, D. L. Viljoen⁴;

¹University of Cape Town, Cape Town, South Africa, ²International Centre for Reproductive Health, Kenya and University of Ghent, Ghent, Belgium, ³Foundation for Alcohol Related Research, Johannesburg, South Africa, ⁴Foundation for Alcohol Related Research, Cape Town, South Africa, ⁵Centers for Disease Control, Atlanta, GA, United States.

Objective: To describe prevalence, characteristics and risk factors for fetal alcohol syndrome (FAS) and partial FAS among children attending grade one in the Northern Cape Province of South Africa.

Design: Cross-sectional study using a two-tiered method for active ascertainment of FAS/partial FAS cases. This comprised screening of growth parameters, and then diagnostic assessment for screen-positive children using clinical and neuro-cognitive assessments, and maternal history of drinking during pregnancy. Mothers or care-givers of children with FAS were interviewed, as well as matched controls.

Setting: Primary schools in De Aar (8) and Upington (15).

Subjects: Grade one pupils in 2001 (De Aar, n=536) and 2002 (Upington, n=1299).

Outcome measures: FAS or partial FAS.

Results: Prevalence of FAS/partial FAS was high: 64/536 (119.4/1000, 95% CI=93.2-149.9) in De Aar, and 97/1299 (74.7/1000, 95% CI=61.0-90.3) in Upington. Overall, 67.2 per 1000 children (95% CI=56.2-79.7) had full FAS features. Growth retardation was also common in this population: 66.6% (1181/1774) were underweight, 48.3% (858/1776) stunted and 15.1% had a head circumference <2S.D. for age. Interviews with cases and controls showed that mothers of children with FAS were less likely to have fulltime employment or have attended secondary school. These women also had lower body mass index and about 80% currently smoked. Over two-thirds of all pregnancies were unplanned.

Conclusions: Nearly one in ten pupils has FAS/partial FAS, with the rate in De Aar the highest yet described in South Africa. The epidemiological features described are important for designing essential preventive interventions.

P09.22

A study into the knowledge of inherited metabolic disorders among patients and parents in the Irish population

R. O'Shea¹, E. Treacy², A. Murphy², S. Lynch³, D. Lamber²;

¹Institute of Medical Genetics, Cardiff, United Kingdom, ²National Centre for Inherited Metabolic Disorders, Children's University Hospital, Dublin, Ireland, ³National Centre for Medical Genetics, Dublin, Ireland.

Galactosaemia and Maple Syrup Urine Disease (MSUD) are recessively inherited conditions detected by newborn screening in Ireland. Patients are treated at one centre and genetic information is provided by the specialist team. We assessed knowledge among parents and patients to see whether referral for formal genetic counselling would be beneficial, using a questionnaire including 4 demographic, 8 knowledge, 2 information and 5 disease impact questions. 27 families with galactosemia and 10 with MSUD were interviewed in clinic. All parents of children with galactosemia and MSUD answered >75% of questions correctly, but there were misunderstandings about the risk or implications of carrier status. There was a significant difference in knowledge between ethnicities. Adult patients with galactosemia had more misunderstandings in relation to inheritance, recurrence risks and carrier status than their parents. 83% of study participants requested more information about their condition and its transmission. 40% of affected adults with galactosemia identified a need to meet others with the same condition. While parents of children with MSUD or galactosemia are well informed, the majority expressed a wish for more information. Adult patients themselves and parents from an Irish Travelling back-

ground could especially benefit from further genetic counselling.

P09.23

Molecular testing for rare genetic disorders in Europe: hype or hope?

P. J. Willems;

GENDIA (GENetic DIAgnostic network), Antwerp, Belgium.

Currently, there are huge differences between various countries in accessibility, price and quality of molecular diagnostic testing. The bottlenecks include the vast number of genetic diseases (> 1000), the low number of samples per disease, the nature of the disease mutation often being a private mutation, the high cost of testing and lack of reimbursement by governments and insurance companies, and the lack of an international organised network of diagnostic labs combining their portfolio of tests. All these bottlenecks impair a cost-effective and reliable diagnostic service, thereby holding molecular testing in many countries in a preclinical era. However, the quality, accessibility and cost-effectiveness of diagnostic tests for rare genetic disorders could be substantially improved by the creation of an international network of diagnostic labs combining their portfolio of tests and exchanging samples for rare genetic disorders. The first network of diagnostic labs offering genetic tests internationally was incorporated four years ago, and is called GENDIA (for GENetic DIAgnostic Network). It consists of "referral labs" sending samples to GENDIA, "test labs" testing samples they receive from GENDIA, and a central GENDIA lab coordinating the network. Currently more than 2.000 different genetic tests are available through GENDIA. Such international network of genetic diagnostic labs results in greater access to a large spectrum of genetic tests performed with higher quality at lower cost.

P09.24

What is the impact of genetic counseling and prenatal diagnosis in genetic diseases prevention in an Arab Muslim population?

H. Chaabouni-Bouhamed¹, L. Kraoua¹, M. Chaabouni¹, M. Kharraf², L. Ben Jemaa¹, R. Mrad¹, F. Maazoul¹;

¹Department of Hereditary Disorders, Tunis, Tunisia, ²Department of Human Genetics, Tunis, Tunisia.

Tunisians are mostly of Arab and Berber origin, and nearly all are Muslim. Consanguineous marriages are prevalent. Tunisia is different from its neighbouring countries in its accomplishments towards women's rights. The nuptial evolution toward a belated marriage model reduced the progeny. Contraception is encouraged and abortion is legal in case of medical or acute social problem. Genetic disorders are common in Tunisia; more than 70% of the population are educated and most are receptive to health guidelines. Genetic counselling (GC) and prenatal diagnosis (PND) are performed as medical facilities in a limited number of genetic centres. To evaluate the real impact of GC and PND on genetic diseases prevention, we surveyed during three years 2862 couples /families who were referred to our center. We evaluated the impact of GC on parents' attitude by analyzing the occurrence of pregnancies and the acceptance of prenatal screening and PND. Parameters were correlated to parents' age, socioeconomic situation, and education level; and to the disease. Our results showed that people in Tunisia ask for GC and follow it in most cases. The response quality is variable depending on the patients' education and their socio-economic class. This is in some ways different from other Arab countries with similar cultural and religious backgrounds, probably due to social and legislative differences. At present, GC and PND seems to be the method of choice for prevention of genetic diseases in Tunisia and such services should be developed as a priority despite the financial costs of such a programme.

P09.25

Exploring the views of European clinical genetic professionals on new international recommendations for genetic counselling related to genetic testing

R. A. Pestoff¹, H. Kääriäinen², E. Rantanen³, M. Hietala³, L. Kerzin-Storarr¹;

¹Medical Genetics Research Group and Regional Genetics Service, CMMC and University of Manchester, Manchester, United Kingdom, ²Institute of Biomedicine - Department of Medical Genetics, Turku, Finland, ³Department of Medical Genetics, Turku, Finland.

EuroGentest: The main goal of the EuroGentest Network of Excellence is to improve and harmonise the quality of genetic testing in Europe.

Formulation of quality standards includes those for genetic counselling associated with genetic testing, and is the focus of this study.

Genetic Counselling Guidelines related to Genetic Testing: The recommendations for genetic counselling in connection with different testing situations aim to establish minimal criteria for genetic counselling and to improve patient's understanding of the results and consequences of genetic testing. These guidelines were formulated through analysis of published guidelines and synthesis during two workshops with experts from genetic practice and research. Comments from ESHG members and national societies have been received, and endorsement by ESHG Board will now be sought.

Study description: This study aims to investigate how colleagues in the clinical genetics community view these new professional guidelines, and to identify any attitudinal, cultural, or practical barriers (professional/societal, economic etc) which may inhibit them following these guidelines in practice. Furthermore, the best ways for dissemination of guidelines will be discussed, and potential barriers to this identified.

Study method: Guidelines and questionnaire surveys will be distributed to self-selected delegates at the ESHG conference and selected genetics centres in countries across Europe. Approximately 100 individuals involved in providing genetic counselling will be recruited.

Open invitation to obtain copy of guidelines and participate in study: ESHG delegates are invited to visit our poster to receive a copy of the recommendations and to register an interest in participating in the study.

P09.26

Importance of database reviewing before prenatal diagnosis

M. Alonso^{1,2}, J. J. Tellería^{1,2}, I. Fernández^{1,2}, A. Blanco^{1,2};

¹IBGM (Instituto de Biología y Genética Molecular), Valladolid, Spain, ²University of Valladolid, Valladolid, Spain.

Cystic Fibrosis (CF) is an autosomal recessive disorder having a frequency of 1:4000 in our population. So far, we had study more than 2000 samples, including about 1500 from neonatal CF screening since 1999.

Several families with affected members or carriers asked us for genetic counselling.

In 2000, four brothers and sisters of a CF patient's mother were analysed for the F508del mutation. One of them was found to be a carrier of this mutation (heterozygote) while the others were non CF carriers. Then, the carrier's partner was screened for 95% of the CF causing mutations in our population using the DGGE-GC Clamp method. We observed an anomalous DGGE pattern in exon 11, and by direct sequencing we confirmed that it was the change I539T, previously described as a CF mutation. We informed the couple that the risk for having affected children was ¼.

Eight years later, in 2008, the obstetrician called us for a prenatal diagnosis of this couple. We reviewed the database and there were some changes: in 2002 this "mutation" had been subjected to functional studies in mammalian cells showing that I539T not only does not decrease the CFTR activity, but in fact increased its activity. Therefore, the obstetrician and the couple were informed that prenatal diagnosis is not necessary.

Preconceptional carrier screening allows couples at risk to arrive at informed reproductive decisions. Still, the information given to them may have to be updated at the moment of choice between different reproductive options.

P09.27

Results of Genetic Counselling and molecular genetic testing of severe monogenic disorders in Hungary between 1993 and 2006.

L. Tímár¹, Á. Herczegfalvi², H. Píró³, K. Hajdu⁴, A. Tóth⁴, V. Karcag²;

¹National Institute of Child Health, BUDAPEST, Hungary, ²Bethesda Children's Hospital, BUDAPEST, Hungary, ³Dept. of Molecular Genetics, Natl. Institute of Environmental Health, BUDAPEST, Hungary, ⁴National Center of Health, BUDAPEST, Hungary.

During the genetic counselling of the severe monogenic genetic disorders it is very important to establish the exact etiological diagnosis. The molecular genetic examinations play outstanding role in this diagnostic procedure. Molecular genetic diagnosis provides effective possibility for prevention of serious genetic disorders by prenatal diagnosis and possible termination of pregnancy whenever treatment of diseases is unavailable. Moreover, genetic results provide accurate

differential diagnosis and proper medical care for this patients. Molecular genetic examinations on the following severe genetic disorders have been performed in our laboratory during the last 13 years: Spinal Muscular Atrophy - in 78 families with 98 prenatal diagnosis; FRAXA - in 38 families with 2 prenatal diagnosis; Charcot-Marie-Tooth disease type 1A - in 14 families; Duchenne/Becker Muscular Dystrophy - in 12 families; Congenital Myasthenic Syndrome - in 1 family; Facioscapulo-humeral Muscular Dystrophy - in 2 families; Limb Girdle Muscular Dystrophy - in 2 families; Angelman syndrome in 5 families. The detailed results will be reported in our presentation.

By performing the molecular genetic analysis effective diagnosis and correct genetic counselling was established in our genetic unit.

P09.28

Inventory and classification of genetic diseases: a new service of Orphanet

A. Rath, M. Georget, V. Lanneau, S. Aymé;

Inserm, SC11 / Orphanet, Paris, France.

Several nomenclatures and classifications of genetic diseases have been developed since 1990, which overlap at the level of cellular models, molecular assays and genomic testing, as biological and medical researchers rarely communicate among each others. Genomics represent one end of the scale of granularity. Electronic Health Record Systems reside in medicine and form the other end of the scale. Both have to be able to exchange information, for instance to make genetic diseases visible in the health care system, but also to allow communication within the community and permit the interfacing of different databases. Nomenclature of genetic diseases has evolved a lot during the past years, but no one knows how to establish the catalogue of human genetic diseases as a definition of what is a disease is lacking. To overcome this difficulty, Orphanet (www.orpha.net) has established a database of phenotypes and of genes with the possibility to query by disease name, by gene name or symbol or by sign. Every phenotype is also classified in the multiple possible classification systems to allow an understanding of its physiopathology or of its range of expression. Every phenotype has a unique identifier which will remain stable. Currently over 4,500 phenotypes are classified and indexed. This new service, available since March 2008, is expected to provide a bridge between clinicians and biologists for a mutual benefit.

Collaboration is key in the preliminary efforts of genetic education for health professionals in Chile for the welfare of patients with genetic diseases

S. A. Castillo Taucher^{1,2}, R. Pardo³, T. Aravena^{1,3}, M. Aracena^{4,5}, C. Villaseca^{6,7}, C. Mellado⁸, P. Sanz^{1,8}, F. Cortés^{9,10}, N. Unanue¹¹, M. Lagos⁵, M. del Campo¹²;

¹Genetic Unit Hospital Clínico Universidad de Chile, Santiago, Chile, ²Genetic Unit Clínica Alemana, Santiago, Chile, ³Genetic Unit Hospital Sótero del Río, Santiago, Chile, ⁴Genetic Unit Hospital Calvo Mackenna, Santiago, Chile, ⁵Genetic Unit Hospital Clínico P. Universidad Católica, Santiago, Chile, ⁶Genetic Unit Hospital Roberto del Río, Santiago, Chile, ⁷Genetic Unit Clínica Dávila, Santiago, Chile, ⁸Genetic Unit Hospital San Juan de Dios, Santiago, Chile, ⁹Genetic Unit Instituto de Nutrición y Tecnología de Alimentos, Santiago, Chile, ¹⁰Genetic Unit Clínica Las Condes, Santiago, Chile, ¹¹Genetic Unit Hospital Clínico San Borja Arriarán, Santiago, Chile, ¹²Genetic Unit Hospital Val d'Hebrón, Barcelona, Spain.

With all clinical geneticists in Chile(25), in 2003 we implemented a website for clinical consultations that serve urban and rural hospitals; Telegenética in Spain began simultaneously. Interchange of technical support financed by Agencia de Cooperación Iberoamericana allowed the Chilean website (www.teledismorfologia.cl). We have made preliminary efforts to use this site as a learning tool for postgraduate students in Clinical Genetics from Latin America.

During 2005 we developed a pilot course "Online Education in Clinical Genetics for Health Professionals" for those working in the only population-based registry of congenital birth defects in Chile. In 2006 and 2007 (57 and 71% MDs, 0 and 13% foreigners, respectively) we offered the program through www.medichi.cl, a net of digital learning from Faculty of Medicine Universidad de Chile, and are planning the third version 2008.

The website and the course should improve care for patients and their families by helping primary health care professionals understand ge-

netic influences on illness, and recognize and manage more effectively the most common genetic problems, with improving identification and description of children affected by birth defects.

Another challenge is facilitating the creation of support groups of rare diseases at a national level, demonstrating the needs of patients and groups; implementing access to the media, policymakers and the health systems. We struggle for the connection and interchange through an Ibero-American network of these alliances in each country. Chilean population is 15 million, infant mortality 8 per 1,000 live births, congenital malformations the second leading cause (33.6%). Abortion is prohibited by law.

P09.30

Estimation of patient's understanding of genetic information received at genetic counselling. Results of pilot study.

I. O. Sadellov¹, L. Y. Ivanova², I. V. Zhuravleva², V. L. Izhevskaya¹, E. K. Ginter¹; ¹Research centre for medical genetics, Moscow, Russian Federation, ²Institute of sociology, Moscow, Russian Federation.

The pilot study of the 71 families with hereditary disease in a child or in one of spouses was carried out. It has been shown, that about 72% of respondents (51/71) have completely understood the genetic information. In group of respondents with low (to 5%) repeated genetic risk correctly named value and category of risk 83% and 63% accordingly. The appreciable part of respondents in this group (36%) has overestimated the genetic risk. About 70% of respondents with high repeated risk could correctly specify the value, and about 75% of them - a category of risk; 24% of them underestimated the risk. The full satisfaction with the results of consultation was expressed by 76% (54/71) of respondents. A rate of coincidence of expectations of a family before consultation and the results of consultation was estimated. The respondent's satisfaction with the results of consultation was higher if their expectations were justified at least partially. This factor didn't influence the understanding of the information

P09.31

Capacity building for the transfer of genetic/genomic knowledge into practice and prevention: The CAPABILITY international collaborative network

I. Nippert¹, U. Kristoffersson², J. Schmidtke³, A. Kent⁴, A. Christianson⁵, R. Raouf⁶, C. Barreiro⁷;

¹Universitätsklinikum Muenster, Muenster, Germany, ²Lunds University, Lund, Sweden, ³Medizinische Hochschule Hannover, Hannover, Germany, ⁴Genetic Interest Group, London, United Kingdom, ⁵University of the Witwatersrand, Johannesburg, South Africa, ⁶Ministry of Health, Cairo, Egypt, ⁷Hospital de Pediatría SAMIC, Buenos Aires, Argentina.

The number of genetic tests is growing each year and increasing knowledge about gene-disease associations will lead to new opportunities to apply genetic/genomic knowledge in practice and prevention. Before genetic tests are introduced into general practice the benefits of their use must be evaluated. Worldwide, health care systems are facing the same challenges: 1) The need to develop an evidence-based evaluation process for genetic tests or other applications of genomic knowledge in transition from research into practice. 2) The need for capacity building to enable health care systems to make effective use of genetic/genomic applications with proven clinical utility.

CAPABILITY is a 3-year model project developed by the Network of Excellence: Genetic Testing in Europe - Network for test development, harmonization, validation and standardization of services (EuroGentest) and by leading experts from: Argentina, Egypt and South Africa, the latter being currently engaged in major development projects to integrate genetic services in primary care and prevention in their countries.

CAPABILITY will:

- develop an analytic framework for evidence-based genetic test evaluation,
- identify priorities for capacity building by a systematic needs assessment survey and
- validate the project's approach by means of demonstration projects in Argentina, Egypt, Germany and South Africa.

CAPABILITY's overall objectives are to contribute to the efforts to establish and sustain a worldwide harmonisation process for quality standards for the integration of genetic test applications into practice and prevention.

P09.32

The lay people attitude towards predictive genetic testing in Russia

V. V. Pogrebenkova, O. A. Makeeva, V. P. Puzyrev;

Research Institute of Medical Genetics, Tomsk, Russian Federation.

1400 Russian adults aged from 20 to 65 (73% women) were investigated through a specially developed questionnaire about their base knowledge and attitude towards predictive genetic testing. 66% of respondents indicated they would prefer to know about their future diseases; the share of respondents expressing the positive attitude towards predictive testing increased (up to 85%) when people were told that the necessary prophylaxis will be in principal available. 89% of respondents mentioned they are likely change their life style (give up with pernicious habits, keep to a diet or take medication) if they would be diagnosed as being at a high risk of a disease; the proportion of women was higher if compared to men (91% vs 81).

Among the main reasons which can force people to undergo predictive genetic testing for common diseases the people's concerns about their health status (39%) and practitioner's recommendation (23%) have been denoted; at the same time the more detailed information about genetic testing and curiosity have been accounting for 18 and 16% respectively, while 4% of respondents would follow the family member's or friend's advice.

When people were asked to range the particular common traits to which genetic testing could be mainly useful, they indicated oncological (17%), cardiovascular diseases (16%) and diabetes mellitus (11%) as the most advisable.

In general, the overestimation of expectations related to genetic testing for disease predisposition is obvious in lay people in Russia. The positive attitude for predictive genetic testing did not depend from the level of education, while the awareness about emerging genetic technologies did.

P09.33

Risky genes, risky trust? Framing risk through trust and credibility markers in direct-to-consumer online genetic tests

E. F. Einsiedel, R. M. Geransar;

University of Calgary, Calgary, AB, Canada.

This study looks at internet direct-to-consumer (DTC) advertising for genetic testing to assess the ways in which genetic risk information is framed to consumers, and examine the strategies employed to establish trust and credibility in this context. Representations of benefits and risks on 22 company websites were coded and themes were developed across advertisements for tests across a cross-section of health conditions. Two strategies were most frequently used by companies to frame risk: underlining the basis of the condition, often with genetic determinist and essentialist undertones, and stressing the commonality of the conditions. Major credibility and trust markers employed included indications of organizational professional accreditation and expertise (often through credentials of company executives and staff). The DTC ads examined provided limited, vague or inaccurate information about disease etiology and promoted tests for use in broader at-risk populations than is normally indicated in clinical practice. Implications of these trends for Canadian consumers and clinicians and for public policy are discussed.

P09.34

Information on genetic testing in Europe: new services from Orphanet

V. Lanneau¹, I. Caron¹, A. Rath¹, M. Georget¹, B. Urbero¹, L. Desme^{2,3}, A. Corveleyr^{2,3}, N. Nagels^{2,3}, M. A. Morris^{2,4}, E. Dequeker^{2,3}, S. Aymé^{1,2};

¹Orphanet, Paris, France, ²EuroGentest, Leuven, Belgium, ³Department for Human Genetics, University of Leuven, Leuven, Belgium, ⁴Service of Genetic Medicine, Geneva University Hospital, Geneva, Switzerland.

Genetic tests are offered internationally, through both public and private sectors. Doctors and biologists need to know which tests are available, where they are offered and whether the identified laboratories meet quality standards.

To fulfil this need, ten years ago, www.orpha.net started to set up a database of medical laboratories in the field of rare diseases. The data collection covered one country in 1997, 15 in 2003, 26 in 2006 and reaches 36 countries in 2008. This effort was possible thanks to collaboration with EuroGentest NoE and resources from the EC DG for

public health. Orphanet is accessed daily by over 20,000 users, 20% of whom are looking for information on genetic testing. Currently, the database includes data from 1,233 laboratories offering 16,336 tests for 1,504 diseases. Data collection is done at country level through partnerships with key leaders in the field. Information is updated yearly through an online questionnaire prefilled with existing information.

In March 2008, Orphanet launched a new website version to improve its user-friendliness and to provide expanded information. The new services include a possibility to query by gene in addition to the traditional query by disease name. It also includes the possibility to query by broad category of diseases, as all published classifications of rare diseases have been introduced in the database. Information on laboratories was enriched with quality management data, collected and validated by the QAU database team of EuroGentest. The new Orphanet website also includes information on networks in which laboratories participate.

P09.35

Genetic testing: can a consensus definition be achieved? A survey of EuroGentest participants and website registered users (WP3.4)

J. Pinto-Basto¹, B. Guimaraes¹, E. Rantanen², P. Javaher³, I. Nippert⁴, H. Kääriäinen⁵, J. Schmidtke⁶, U. Kristoffersson⁶, J. Sequeiros^{1,7};

¹UnIGENE and CGPP, IBMC, Porto, Portugal, ²Dept Medical Genetics, Univ Turku, Turku, Finland, ³Dept Medical Genetics, Hannover Medical School, Hannover, Germany, ⁴Universitätsklinikum Münster, Münster, Germany, ⁵Dept Medical Genetics, Univ Turku and National Public Health Institute, Helsinki, Finland, ⁶Dept Clinical Genetics, Univ Hospital, Lund, Sweden, ⁷ICBAS, Univ Porto, Porto, Portugal.

EuroGentest Unit 3 sent a questionnaire to all participants, experts, advisory board and users of its website, to assess the need and the feasibility of achieving a consensus definition of genetic testing or whether this should be context-dependant.

A total of 126 questionnaires were received, from 32 countries: 58 EuroGentest participants, experts and advisory board members, and 68 registered users of its website. Among all, 44 were physicians (24 clinical geneticists, 20 other), 82 non-physicians (58 geneticists, 24 other professionals - lawyers, ethicists, etc.).

The need for a consensus definition was acknowledged by all groups, though all were also less enthusiastic about the possibility of attaining one (non-physician, non-geneticist professionals felt less that need, and were more pessimistic about reaching it). Clinical geneticists were the most supportive for context-dependent definitions. Human geneticists uphold that it should be best reserved for DNA/cytogenetic testing, whereas other groups supported a wider definition. Medical applications (and scientific research for many) should always be covered, but most believed non-medical applications (paternity testing, criminal identification) should not. Monogenic and susceptibility testing gathered consensus, but about 50% thought non-disease linked polymorphisms should be excluded. For 3/4, somatic mutations belonged within the definition. DNA, chromosomes and gene products were almost unanimously seen within its scope; clinical pathology, imaging/physiologic tests, physical exams and family history were perceived by ~50% of clinical geneticists also as covered, but less so by the other groups.

At issue, may be more the distinction between the definition of genetic-material testing and of genetic information.

P09.36

IronXS: an Australian high school screening program for haemochromatosis

S. A. Metcalfe¹, M. Wolthuisen², E. Varley², V. Collins², I. Macciocca³, M. Aitken², L. Bond⁴, K. Allen^{1,4}, M. B. Delatycki^{1,3};

¹Murdoch Childrens Research Institute and Dept Paediatrics, University of Melbourne, Parkville, Vic, Australia, ²Murdoch Childrens Research Institute, Parkville, Vic, Australia, ³Genetic Health Services Victoria, Parkville, Vic, Australia, ⁴Royal Children's Hospital, Melbourne, Australia.

New research suggests that population genetic screening for hereditary haemochromatosis (HH), an easily preventable iron overload condition, should be reconsidered.¹ In the *HaemScreen* workplace-based study² we found high uptake of screening (>90%) for people attending the information session, but only 6% of those eligible actually attended. This led us to consider other strategies for offering screening.

We report our first year of data from *ironXS*, a screening program for the C282Y *HFE* mutation in high schools. A DVD-based information session was presented to 3638 year 10 and year 11 students at 19 schools. 1533 students had parental consent to participate (42% of eligible students; males:females = 45:55; mean age=15.7yr) of whom 1359 chose testing (37.4% overall uptake; 89% of attenders). This revealed 7 C282Y homozygotes (1 in 194), who were invited to clinic for genetic counselling, and 148 C282Y heterozygotes (1 in 9), who received their result in the mail. Students completed a baseline questionnaire (Q1). More than 90% of students answered all the knowledge questions correctly. A second questionnaire (Q2) was sent one month after results were received to all homozygotes and heterozygotes and a sample of wild-types (74% response rate). Knowledge retention was generally very high. There were no significant differences in general health perception scores, risk perception and anxiety levels between the three groups. Follow-up will include Q3 at 12 months and interviews with students, parents and teachers. We aim to screen 9000 students in total.

P09.37

Genetic Counselling challenges with a family with HDL2: From the bedside to the bench and back to the bedside

L. J. Greenberg;

University of Cape Town, Observatory, South Africa.

Huntington disease (HD) is a late-onset genetic disease characterised by involuntary movements and progressive mental deterioration. The condition was thought to be caused only by a CAG-repeat sequence in the huntingtin gene on chromosome 4. In 2001 however it was found that an African American family, presenting with similar symptoms to HD and no expansion in the HD gene, had a mutation in the junctophilin-3 gene on chromosome 16. This condition has been named Huntington disease like-2 (HDL2) and until recently, had only ever been reported to be associated with individuals of Black African ethnicity.

In 2007 one family of mixed ancestry from the Western Cape in SA was identified with HDL2. This finding came about as a result of a pilot study of 63 persons with clinical symptoms of HD who do not carry the HD-causing expansion. Two individuals tested positive for HDL2; one that was referred for diagnostic testing in 1995 and the other in 2005. It was then found that in 2006, a research project had been initiated in another research laboratory, to study this family in-depth and blood samples had been collected from a number of additional family members. In addition, the mother of an eleven year old child of one of the HDL2 patients, described as a "difficult child", had recently requested genetic testing.

A clear distinction between clinical practice and research is not always possible and geneticists often find themselves with discordant responsibilities to different members of the same family.

P09.38

The Human Genetics Historical Library

P. S. Harper¹, P. Keelan²;

¹Institute of Medical Genetics, Cardiff, United Kingdom, ²University of Cardiff, Cardiff, United Kingdom.

Although digitisation of historical sources represents a satisfactory solution to the accessing of many historic scientific journals and related works, for books, apart from a few classics, it is no substitute for availability of the printed works; yet many institutional and personal collections across the world are being dispersed or even destroyed.

The Human Genetics Historical Library represents an international resource, curated by Cardiff University Library Special Collections, that aims to create a definitive physical collection of books on or related to human genetics, covering the 20th century. Initiated in 2004, it now contains over 2000 volumes, almost all donated by individual workers or institutions.

The detailed catalogue records are becoming available online via Cardiff University Library catalogue (Voyager), <http://library.cardiff.ac.uk/>, while an interim listing is available on the project website (www.genmedhist.info/HumanHistLib), supported by Wellcome Trust. The books themselves are available for consultation. Donations are welcome. The Library, as it grows further, will become a valuable historical resource in documenting the progress of human and medical genetics during the course of the past century.

P09.39

Establishing a cardiogenetic service in Southern Sweden

C. Lundin¹, P. Platonov², E. Hertervig², B. Ekmehag², O. Kongstad², U. Kristof-fersson¹;

¹Dept of Clinical Genetics, Lund, Sweden, ²Dept of Cardiology, Lund, Sweden.

The genetic causes of several familial cardiac arrhythmias have been established in recent years, and thus the request for molecular genetic analyses as well as genetic counselling for these families has emerged.

The multidisciplinary cardiogenetic service in the South Swedish Health Care region was initiated in 2005, and the network now comprises cardiologists, pediatric cardiologists, clinical geneticists, and specialists in pathology and forensic medicine, respectively. Much effort is concentrated towards education of the stakeholders and on drawing up guidelines, whereby more uniform information and clinical management of at-risk family members is possible. So far, two guidelines have been completed, i. e., regarding families with an increased risk of hypertrophic cardiomyopathy (HCM) and long QT syndrome (LQTS), respectively.

We have adopted the model developed for our cancer genetic service, i.e., most families are seen by a clinical geneticist together with a cardiologist. This gives the possibility of discussing most aspects of the disease, although no clinical examination or investigation is performed.

Until December 2007, 28 families have been counselled in the cardiogenetic clinic, the majority having familial HCM (15 families). 3 families had LQTS, and the rest had various diagnoses. All HCM-patients with a positive DNA analysis have had various mutations in *MYBPC3*. In LQTS, only families with a known mutation have, so far, been referred to the cardiogenetic clinic.

The request for genetic counselling in hereditary cardiovascular diseases is increasing, and establishing multidisciplinary networks in this field in our health care region is essential for high quality care and cost-effectiveness.

P09.40

Should preconception genetic testing of infertile couples be any less rigorous than for gamete and embryo donors? A case report

C. Bancroft^{1,2}, T. El-Menabaway¹, M. Menabaway¹, A. H. Handyside^{1,2}, A. R. Thornhill^{1,2};

¹London Bridge Fertility, Gynaecology and Genetics Centre, London, United Kingdom, ²Bridge Genoma, London, United Kingdom.

A 36 year-old man presenting with primary male infertility (oligozoospermia) underwent in-vitro fertilisation treatment with intracytoplasmic sperm injection and transfer of two embryos resulting in healthy twins. The couple had surplus embryos cryopreserved, which they subsequently elected to donate to our embryo donation programme. To comply with Human Fertilisation and Embryology Authority (HFEA) Code of Practice for UK gamete and embryo donors, both partners underwent appropriate genetic screening tests, including karyotyping, which wasn't considered necessary when the couple were first evaluated at their local hospital. The man carried a 13;14 balanced Robertsonian translocation and was referred for genetic counselling.

Structural chromosome abnormalities cause infertility in both men and women, and many fertility centres have experienced similar cases. Owing to the increased incidence of balanced translocations among infertile people compared with the general population it is prudent to routinely offer preconception genetic counselling and karyotype analysis to couples with infertility. Such measures may improve (i) infertility diagnosis, (ii) follow-up treatment, (iii) risk assessment for future children and (iv) pregnancy management. Furthermore, appropriate genetic testing and evaluation may reduce numbers of failed IVF cycles, saving patients financial, physical and emotional costs. Current UK regulations require rigorous screening (including karyotyping) for gamete and embryo donors. However, routine karyotyping of couples with infertility is not UK standard practice and, this represents an inequality in patient care. Routine karyotyping should be offered to all couples presenting with infertility allowing them to make informed choices before undertaking the large investment required for assisted reproduction.

P09.41

Analysis of Machado-Joseph Pedigrees: Risk Assessment and Patterns of Segregation in Azorean Families

C. Bettencourt¹, C. Santos², T. Kay³, J. Vasconcelos⁴, M. Lima¹;

¹University of the Azores, Ponta Delgada - Azores, Portugal, ²Autonomous University of Barcelona, Bellaterra (Barcelona), Spain, ³Hospital of D. Estefania, Lisbon, Portugal, ⁴Hospital of Divino Espirito Santo, Ponta Delgada - Azores, Portugal.

Machado-Joseph disease (MJD) is an autosomal dominant neurodegenerative disorder of late onset (mean 40.5 yrs), whose causative mutation is a CAG expansion in the *ATXN3* gene, at 14q32.1. MJD presents clinical heterogeneity, with differences in onset between series of patients being reported. Since in MJD risk assessment is complicated by age dependent penetrance, these differences will have an impact in risk calculation for at-risk individuals who choose not to take the genetic test. In the Azores 32 extended MJD families were identified; in Flores Island the disease reaches the highest worldwide value of prevalence (1:103). Segregation ratio distortion (SRD) could be one of the factors behind high values of prevalence. The availability of an extended genealogical database for the affected Azorean families, associated to the thorough follow-up of patients provided the background to conduct a study aiming: a) to provide age dependent risk data, with impact on Genetic Counselling (GC); b) to analyse segregation patterns of normal and expanded *ATXN3* alleles. For risk assessment, the probability of gene expression, using onset data from 176 Azorean patients, was calculated; a Bayesian method to compute the probability of heterozygosity if asymptomatic at different ages was applied. Sixty-two sibships were selected for segregation analysis (330 meioses). This analysis produced mendelian ratios, not supporting the presence of SRD for expanded alleles. Globally, results obtained will allow a higher accuracy of risk assessment, an essential component of GC, which is critical for the decision making of at risk individuals, namely for reproductive choices.

P09.42

Science and Technology in the Muslim World: The Challenges

A. I. Al-Aqeel;

Riyadh Military Hospital/ King Faisal Specialist Hospital, Riyadh, Saudi Arabia. Muslim nations must take a big leap forward in developing science and technology to catch up with the rest of the world. But to flourish, science and technology need a cultural base that can only be acquired by science education, with an ethical background, and by undertaking research programmes. This effort requires that the mentality of political leaders must change to show more of a commitment to science between the 57 Islamic countries.

Saudi Arabia, Qatar and Kuwait spend about 0.2% of their gross domestic product (GDP) on science - less than one-tenth of the developed country average of 2.3%. The Emir of Qatar has created an endowment that generates millions of dollars in research funding every year. Saudi Arabia is making a slow start, having approved a new national science and technology development plan in 2002. Both Saudi Arabia and Kuwait are each investing around \$2 billion in higher education institutes that include research centers.

Inherited Genetic diseases are prevalent in the Muslim World. We will address the preventive health aspects of genetic problems in the Muslim world and provide guidelines to prioritize preventive strategies. Applications of various novel genetic techniques such as comprehensive neonatal screening, high throughput heterozygote detection, and pre implantation genetic diagnosis are discussed.

In conclusion; from the various genetic techniques available, each country should adopt strategies most suitable to its genetic needs and should prioritize the programs to be used in prevention, in the presence of the challenges of having resources and expertise, among others.

P09.43

Bases for genetic counselling in melanoma: benefits of specific surveillance programme

S. Puig^{1,2}, J. Puig Butille^{1,2}, F. Cuellar¹, S. Kroemer¹, C. Badenas^{1,2}, C. Carrera¹, P. Aguilera¹, M. González¹, P. Iglesias¹, D. Gabriel¹, M. Mila^{1,2}, J. Malvehy^{1,2};

¹IDIBAPS/HOSPITAL CLINIC, Barcelona, Spain, ²Centro Investigación Biomédica en Enfermedades Raras (CIBERER), ISCIII., Barcelona, Spain.

Introduction: *CDKN2A* and *CDK4* are two major susceptibility genes for melanoma (MM). Other genes involved in melanoma susceptibility

are *MC1R* and *c9orf14*.

Objectives: To describe the prevalence of germ line mutations in *CDKN2A* and *CDK4* in familial melanoma; to evaluate the modifying effect of *MC1R* polymorphism and *c9orf14* variants; to describe a specific surveillance programme.

Subjects: 70 families with at least 2 cases of melanoma (1 of 8; 17 of 3 and 49 of 2) were included.

Methods: Exon 1 α , 1 β , 2, 3 and IVS2-105, -34G>T at the *CDKN2A* promoter region and EXON 2 from *CDK4* were studied by PCR-SSCP analysis and sequencing; *MC1R* was studied by sequencing and *c9orf14* variants by SSCP analyses.

Results: *CDKN2A* mutations were detected in 24% of families being more frequent in families with multiple cases ($p < 0.05$). The polymorphism A148T was present in 18% of families, while this polymorphism is only present in 7.2% of sporadic MM ($p = 0.02$). *MC1R* variants are associated with melanoma risk, increased number of primaries and younger age of onset. 268 individuals from 133 families were included in a specific dermatological surveillance programme including total body photography with digital dermoscopy, total body exploration with digital dermoscopy or total body exploration with dermoscopy according to the phenotype of the patient. This specific programme allows the early diagnosis of 92 new melanomas from 407 excised lesions in a mean follow-up of 44 months.

The European Molecular Genetics Quality Network (EMQN)

O. Kämäräinen, S. Patton, R. Elles;

European Molecular Genetics Quality Network (EMQN), NGRL and Regional Molecular Genetics Service, St Mary's Hospital, Manchester, United Kingdom.

Molecular Genetics testing forms an increasingly important part of the diagnostic process in all branches of medicine. Studies of the reliability of such testing have indicated a significant level of inaccuracy in laboratory reports, arising from errors in sample identification, genotyping or interpretation. The European Molecular Genetics Quality Network (EMQN) aims to raise and maintain the quality of Diagnostic Clinical Molecular Genetics Testing by providing external quality assessment (EQA) schemes. In 2007 EMQN provided 18 disease specific and 2 technique specific EQA schemes. The EMQN's schemes are organised by a panel of experts and DNA samples are sent to participating laboratories once a year. Participating laboratories are asked to perform their routine analysis and interpret the results. The reports are marked by a group of experts. The participants receive a report on their performance.

400 laboratories from 42 countries around the world participated in the EQA schemes in 2007 and over 900 reports were evaluated from laboratories. The standards of genotyping accuracy were high but significant error rates were found and methods of reporting and interpreting data were varied. The error rate indicates a clear need for EQA to measure current standards of proficiency and encourage laboratories to raise their technical and reporting performance.

Outcome of neonatal screening in Leningrad province in 2007

I. A. Ivanov¹, M. O. Mkhaidze², O. P. Romanenko³;

¹District Children Hospital, St. Petersburg, Russian Federation, ²Medical Academy for postgraduate study, St. Petersburg, Russian Federation, ³Municipal Centre of Medical Genetics, St. Petersburg, Russian Federation.

Medical genetics service of Leningrad province is stationed at District Children Hospital being carried out in cooperation with the Department of Medical Genetics at MAPS and St. Petersburg Centre of Medical Genetics. Last year the genetic service was expanded with a neonatal screening for phenylketonuria, congenital hypothyroidism, congenital adrenal hyperplasia, galactosemia and cystic fibrosis. One infant with a high level of Phe and three infants with an increase in TSH were found among 10226 newborn babies. Three cases of congenital adrenal hyperplasia and none of cystic fibrosis risk were revealed among 4736 infants. Two babies (a girl and a boy) with galactosemia were found among 4942 infants screened. The girl had a GALT deficiency and presented a compound heterozygote Q188R/K285N; a molecular diagnostics was performed in Moscow Centre of Medical Genetics. Medical genetics service of Leningrad province comprises a confirmation of a hereditary diagnosis, medical care, long term inpatient and

outpatient care, dietary management and genetic counseling.

Effectiveness of a program aimed to prevent Nonketotic Hyperglycinemia in a highly inbred community in Northern Israel

Y. M. Hujeirat¹, H. Mandel², M. Nasar¹, V. Sabenco¹, A. Tsbaï¹, S. A. Shalev¹;

¹Genetic, Afula, Israel, ²Metabolic Unit, Rambam Medical Center, Haifa, Israel.

Introduction: Nonketotic Hyperglycinemia (NKH) is an autosomal recessive metabolic disease characterized by the accumulation of large amounts of glycine in body fluids. Patients with NKH have severe neurological symptoms such as seizures. Most patients die within a few weeks, whereas survivors show severe psychomotor retardation and do not achieve any developmental milestone. NKH is caused by a mutation in the genes encoding the components of the glycine cleavage multi-enzyme system. More than 80% of the patients have defects in the gene encoding P-protein, whereas the rest of the patients have defects in the gene encoding T-protein. In recent years, prevention programs for the detection of heterozygotes of relatively prevalent autosomal recessive diseases (with a frequency of about 1:1000), is available in Israel. **Aim:** to study the carrier frequency of NKH in a village in Northern Israel where 20 patients, homozygous for the H42R mutation in the T-protein gene, were diagnosed over the last decade.

Methods: 405 healthy individuals in their reproductive period, residing in this village, were screened for the H42R mutation using PCR-RFLP method. **Results and conclusions:** A high carrier frequency of 1/16 (25 out of 405) was found. Since no effective treatment is available for NKH, prenatal diagnosis was requested in four pregnancies, which led to the diagnosis of three unaffected fetuses. One couple decided not to perform prenatal diagnosis. An affected baby was born and died at age 3 months. The availability of DNA testing enabled genetic screening and counseling in this small village.

P09.47

Genetic care of families affected by albinism in an African cultural context

P. M. Lund;

Coventry University, Coventry, United Kingdom.

The birth of a baby with the autosomal recessive condition oculocutaneous albinism (OCA) in a black African population is often traumatic for the mother as the phenotype, with hypopigmentation of the hair, skin and eyes, differs so visibly from the normal level of pigmentation in this group. The incidence of OCA among the Venda of northern South Africa is relatively high, with 1 in 1970 affected, giving a carrier rate of 1 in 23. Myth and superstition surround OCA, with affected families believing they have been bewitched. The experiences of genetic nurses at the large regional hospitals in Venda and of families who have benefited from their genetic counselling services are explored via semi structured interviews. The genetic nurses, based in the midwifery section, identify affected babies as part of the National Birth Surveillance Programme and intervene immediately to inform the mother of the special health care needs of her baby. They explain the genetic causes of OCA and aim to empower her to counter negative attitudes she is likely to encounter from her family, who may accuse her of infidelity, and the wider community when returning to her rural home. Barriers to the provision of genetic care in this remote, rural region and strategies adopted by health care professionals to overcome these difficulties are explored. This genetic practice is a model for providing care to those affected by genetic conditions in rural, low resources regions of the world.

Orphanet: What's in it for you? UK case studies

E. E. Gillaspay¹, S. Aymé², D. Donnaï¹;

¹Nowgen, University of Manchester, Manchester, United Kingdom, ²ORPHANET-INSERM SC11, Paris, France.

Orphanet (www.orpha.net) is the largest international online resource for genetic and rare diseases. The recently improved website features a rare diseases listing and a directory of services alongside other specialised products which have been developed to better serve the rare disease community. This presentation uses case studies from the UK to highlight the information and services available to patients, health professionals and researchers.

Case study 1: Jane had a baby Jason who, at the age of 6 weeks, pre-

sented with nystagmus and photodysphoria. A few months later, Jason also suffered congestive heart failure due to dilated cardiomyopathy. Following visits to her local hospital, and a referral to Birmingham Children's Hospital, Jason was diagnosed with Alström syndrome. Jane had never heard of this condition before and uses Orphanet to find out more about it, and how to meet other parents with affected children.

Case study 2: Paul is a consultant clinical geneticist specialising in skeletal malformations. Paul has a patient with Schinzel Phocomelia and has learned, through the OrphaNews Europe newsletter, that a UK study is ongoing to discover genotype-phenotype correlations for this condition. He also uses Orphanet to find out that a laboratory in Berlin offers mutation analysis for the WNT7A gene, which causes Schinzel Phocomelia.

Case study 3: Samantha is a researcher who recently gained her PhD and then took a postdoctoral position working on Batten disease. Samantha uses Orphanet to discover what other research is ongoing for Batten disease and also to find contact details of potential collaborators.

P09.49

Protecting patient's confidentiality: opinions of russian medical geneticists

V. L. Izhevskaya, V. I. Ivanov;

Research centre for medical genetics, Moscow, Russian Federation.

The views of medical geneticists, working in Russian genetic consultations, on protecting the confidentiality of a patient and the availability of genetic information to his/her relatives, spouses and third parties were estimated. From 9 to 26 % of geneticists (depending on disease in question) considered it permitted to inform the relatives on the results of genetic testing without the consent of the patient. The significant part of geneticist (61.8%) considered, that samples of stored DNA, should be available to blood relatives of a patient without his consent. About a half of doctors considered, that the employer and the insurance companies could have access to the results of genetic testing with the consent of the patient, from 30 to 50 % - that such information can be given to schools with the consent of parents of the child. From 10 to 25 % of geneticists considered, that such information should be accessible to third parties without the consent of a patient. Thus, we could show, that Russian medical geneticists began to concern more respect to the right of a patient for confidentiality of genetic information then ten years ago.

P09.50

The role of Patient's Organizations in establishing some strategies in the healthcare system concerning rare diseases

M. Puiu¹, A. Tarniceru¹, D. Dan²;

¹University of Medicine and Pharmacy, Timisoara, Romania, ²Romanian Prader Willi Association, RONARD, Zalau, Romania.

In Romania rare diseases are really orpheline. The project started by Romanian Prader Willi Association in 2007 (a project realized with the financial support of Trust for Civil Society in Central and Eastern Europe) induced multiple changes and it has a real chance that it's main objective to be accomplished. This objective is to develop the awareness of the community regarding patients affected by rare diseases by involving the social actors from this domain: patients, families and specialists. In the same project it was founded Romanian National Alliance for Rare Diseases (RONARD) whose objectives are: to organize informational campaigns concerning rare diseases, to adopt a national strategy in approaching rare diseases, lobby and advocacy activities to transform these strategies in a National Plan for Rare Diseases approved by the Ministry of Health. Today Romania is much closer to the European system in approaching patients with rare diseases with the support and guidance of EURORDIS (European Organization for Rare Diseases), Orphanet (a database with information about rare diseases and orphan drugs) and the involvement of the Ministry of Health, Labor Ministry and Ministry of Education. The activities sustained by RONARD (courses, conferences, media messages) in the relationship with authorities, specialists, patients and their families, but also the civil society in general, will guarantee the necessary environment to create a social and medical system in which Romanian patients with rare diseases will benefit from diagnosis, treatment and care conditions similarly as patients from other European countries.

P09.51

Policy harmonization and population biobanks

S. Wallace, S. Lazor, B. Knoppers;

Université de Montréal, Montreal, QC, Canada.

Policymaking in an international context is often delegated to recognized international organizations (e.g. WHO, UNESCO, OECD). Similarly, international societies of concerned individuals and experts contribute to the elaboration of guidance, within the context of their cultural and national setting. Many of these groups have contributed policy recommendations that relate to the field of population genomics. But are the ethical, economic, environmental, legal and societal issues simply being multiplied and blurred by the sheer number of participants? At the Centre de recherche en droit public (CRDP) of the Université de Montréal, in Montréal, Canada, a Policymaking Core has been established to work with and inform the international community of the possibility and importance of prospective approaches to traditional issues such as consent, access, governance and commercialization, as they relate to population biobanks. If these issues are not discussed and some level of harmonization and clarity achieved, the population health goal of these ambitious projects will be hindered, due to the absence of policy interoperability. To this end, the Core collaborates with the Public Population Project in Genomics (P³G) member biobanks to create tools that will aid the harmonization of various aspects of biobank policy. Generic consent materials have been created and are publically available from the P³G Observatory; future work will focus on governance and access issues.

P09.52

Burden of Genetic Disease in Colombia, 1996-2025

J. Bernal, F. Suarez;

Instituto de Genética Humana, Bogota, D.C., Colombia.

Objective. To establish the load of genetic diseases in Colombia, according to population growth parameters until the year 2025. Methods. The frequency of new cases of genetic diseases and congenital malformations was calculated, establishing the potentially lost years of life, cause of incapacity and cause of death by these pathologies, weighing the data according to the growth and life expectancy of the Colombian population from 1996 until 2025. Results. Genetic diseases have a frequency that oscillates between 37.3 and 52.8 by each 1,000 inhabitants. Congenital malformation and birth defect frequencies are included, with a proportion of ≈ 50% of the studied genetic pathologies. Conclusions. There is a potential load of genetic disease that raises the need to implement more centers for the training of geneticists and auxiliary personnel who can in the future, provide suitable services, of diagnosis and genetic assessment.

P09.53

A retrospective analysis of clinical prenatal counselling activity performed by two clinical medical genetics centers in Emilia Romagna region, Italy (2000-2006)

F. Rivieri¹, S. Rosato¹, G. Astolfi¹, A. Baroncini², S. Bigoni¹, G. San², A. Sensi¹,

F. Sol², E. Calzolari¹, O. Calabrese¹;

¹U. O. di Genetica Medica, Ferrara, Italy, ²U. O. di Genetica Medica, Imola, Italy.

A retrospective analysis of clinical counselling records in two clinical genetics services in Emilia Romagna Region (Ferrara and Imola) is presented. A shared specific software (GCS) allows a systematic and homogenous collection of data. Diagnostic data were checked for correctness by medical geneticists. The study is focused on prenatal counselling in the period 2000-2006 (more than 9100 consultations) which represents >70% of the activity for both Medical Genetics Centres. The National Health System offers prenatal counselling for increased chromosomal anomalies linked to advanced maternal age (=>35 years). These referrals represent 45% of prenatal counselling. In 2.9% of these prenatal settings, unexpected additional relevant reproductive risks have been discovered (1.7% mental retardation and 1.2% mendelian diseases) requiring an urgent and appropriate activation of clinical and laboratory diagnostic pathways. The referrals for the other prenatal consultations were heterogeneous mendelian diseases (29.2%) followed by chromosomal conditions (16.6%). Different proportions were seen in the two medical genetics services, reflecting the specialised activities as regional hub centres: hemoglobinopathies in Ferrara and cytogenetics in Imola. These specialised centres attract

women from other health districts for prenatal referrals, (40.7% from outside the provinces and 19.5% from outside the Emilia Romagna Region).

Data of the primary care and specialists access to genetic services, accuracy of prenatal diagnosis and time to diagnosis were analyzed to provide information for the analysis of the committence, appropriateness of referrals and to improve the organization of clinical genetics services of in the Emilia Romagna region.

P09.54

Knowledge and understanding of prenatal screening and testing before and after the introduction of information booklet

V. Stefansdottir¹, H. Skirtort², J. J. Jonsson¹, H. Hardardottir¹;

¹Landsspítali University Hospital, Reykjavik, Iceland, ²School of Nursing and Community Studies, University of Plymouth, Taunton, United Kingdom.

Pregnant women considering prenatal screening need to have access to accurate information, facilitating informed choice. Uniform information about prenatal screening and testing was not available in Iceland prior to this study.

The study aim was to assess general knowledge about prenatal screening and diagnosis among pregnant women attending their first antenatal visit. An information booklet was produced as a part of this study. We compared the difference in knowledge and understanding between pregnant women in the intervention group (having access to the information booklet and normal care) (n=142) and women in the control group (normal care) (n= 237).

Women were recruited from five antenatal clinics in Iceland. The age distribution, experience and education of participants were in accordance with the general population. Overall 63% wanted information from their midwives and 31.7% from a doctor. Most had however, received information from their gynaecologist (53%) and friends (40%). The majority (60%) wanted both verbal and written information. The intervention group showed better knowledge when asked to explain the tests in their own words (p<.001), but no significant difference was detected between groups in description of methods used in prenatal screening in multiple choice questions. When asked about specific disorders (Trisomies 13 and 18) women in the intervention group were more knowledgeable (p=.001). We conclude that Icelandic women have a good basic knowledge of prenatal screening but want more information. There is a need for a better education on specific aspects of prenatal screening and diagnosis for women attending their first antenatal visit.

P09.55

Development of molecular biology laboratory training courses for health care professionals at Nowgen, a centre for genetics in healthcare

M. J. Leech^{1,2}, F. Salway³, F. Jun³, P. Day³, D. Carthy³, L. Gaunt⁴, S. Hamilton⁴, A. Wallace⁵, R. Elles⁵, A. Devereau⁵, M. Bottomley², K. Mathieson^{1,2}, P. Finegold^{1,2}, D. Donnai^{1,2}, H. R. Middleton-Price^{1,2};

¹Nowgen - A Centre for Genetics in Healthcare, Manchester, United Kingdom,

²Regional Genetics Service and Medical Genetics Research Group, CMMC NHS Trust & University of Manchester, Manchester, United Kingdom, ³Centre for Integrated Genomic Medical Research, University of Manchester, Manchester, United Kingdom, ⁴Regional Cytogenetics Unit, St Mary's Hospital, Manchester, United Kingdom, ⁵National Genetics Reference Laboratory and Regional Genetics Service, St Mary's Hospital, Manchester, United Kingdom.

Techniques for analysing genetic variants related to disease and treatment are constantly advancing, and allow ever more sophisticated and rapid analysis of patient samples. The consequence of greater access to these techniques is that many clinical and laboratory disciplines have to embrace the new technology.

Nowgen, a Centre for Genetics in Healthcare, in collaboration with research and clinical scientists in Central Manchester and Manchester Children's University Hospitals NHS Trust and the University of Manchester, has developed a portfolio of training courses for health professionals in response to expressed needs for training in practical molecular genetics laboratory techniques.

The first of these training courses - a national, two-day course for clinical cytogeneticists, accredited by The Royal College of Pathologists - was delivered in January 2007, with good training outcomes. Owing to high demand, the course was run a further three times in 2007 and 2008, reaching over 80 clinical cytogeneticists to date. Further training

courses have been developed and run with good outcomes, including a course tailored to the training needs of genetic counsellors and nurses. New courses have been launched in 2008, covering bioinformatics, quantitative & real-time PCR and biobanking.

All courses have been developed following initial consultation with the relevant professional groups' senior representatives. Following this, to determine specific training needs, questionnaires are sent to heads of individual units, asking about the optimum length of courses and which key laboratory techniques should be included.

P09.56

Genetic Counselling in pulmonary arterial hypertension: experience from the French Reference Centre

B. Giererd, A. Yaici;

hopital Antoine Bécélère, Clamart, France.

Pulmonary Arterial Hypertension (PAH) is a rare condition (prevalence from 15 to 50 cases per million) characterized by an increase in pulmonary vascular resistance leading to right-heart failure and death. This condition has a poor prognosis, although novel treatment options allow better quality of life and survival. Recent data indicate that early diagnosis and treatment should translate into better outcome and survival. PAH can be sporadic, associated with other conditions such as systemic sclerosis, or clustered in families.

Familial PAH currently represents at least 10% of so-called idiopathic cases. It segregates as an autosomal dominant trait with reduced penetrance (10-20%). Mutations of the gene encoding bone morphogenetic protein receptor type II (*BMPR2*) which belongs to the TGF β super family have been first described in 2000. 20% of so-called sporadic idiopathic cases and more than 70% of familial cases are characterised by germline *BMPR2* mutations, emphasising the relevance of genetic counselling in these families, in order to promote early diagnosis and treatment in at-risk subjects. We thus set up a genetic counselling clinic in our department. In the last 5 years, we screened 375 PAH patients (310 sporadic, 65 familial), and 125 first-degree relatives of patients harbouring a *BMPR2* germline mutation. 45 sporadic, 37 familial and 45 first-degree relatives have been showed to harbour a *BMPR2* mutation. First-degree relatives carriers received detailed information on the characteristic symptoms of the disease (mostly dyspnea, chest pain and syncope) and screening tools such as Doppler echocardiography (which should be repeated every year).

P09.57

Quality management and accreditation of genetic testing services

E. Dequeker^{1,2}, D. E. Barton^{3,2}, S. Berwouts^{1,2}, C. Brady^{3,2}, J. Camajova^{4,2}, P. Corbisier^{6,2}, A. Corveleyn^{1,2}, L. Desmet^{1,2}, R. Elles^{6,2}, B. Fowler^{7,2}, D. Gancberg^{6,2}, O. Kamarainen^{6,2}, M. Macek Jr.^{4,2}, G. Matthijs^{1,2}, M. A. Morris^{8,2}, C. R. Müller^{9,2}, N. Nagels^{1,2}, B. Quellhorst-Pawley^{10,2}, A. Stambergova^{4,2}, E. Swinnen^{1,2}, R. Hastings^{10,2};

¹University of Leuven, Leuven, Belgium, ²EuroGentest Network of Excellence, Leuven, Belgium, ³Our Lady's Children's Hospital, Dublin, Ireland, ⁴Charles University, Prague, Czech Republic, ⁵Institute for Reference Materials and Measurements, Geel, Belgium, ⁶St. Mary's Hospital, Manchester, United Kingdom, ⁷University Children's Hospital, Basel, Switzerland, ⁸University Hospital Geneva, Geneva, Switzerland, ⁹University of Würzburg, Würzburg, Germany, ¹⁰Oxford Radcliffe Hospital NHS Trust, Oxford, United Kingdom.

Governments, regulators and professional bodies have a responsibility to ensure that all genetic testing services are offered within a quality assurance framework that retains the confidence of the public. The recently published OECD guidelines for Quality Assurance in Molecular Genetic Testing are equally applicable to Cytogenetics & Biochemical Genetics. Agreement on appropriate standards in genetics, and how to measure them, will assist in harmonizing the quality of service across the European Union. External Quality Assessment (EQA) is an important instrument to reach the harmonization and quality improvement aimed for by the EuroGentest Network. The introduction of reference materials into the diagnostic service and the validation of new technology, as it moves from research to the diagnostic arena, are essential and agreement on best practice for standards and strategies can be achieved by consensus. In addition, Best Practice Guidelines for Cytogenetics (ECA), Molecular Genetics and Biochemical Genetics have been supported through the EuroGentest Network and published.

EQA and accreditation are recognized by international standards (ISO)

bodies as a tangible measure of the quality of a laboratory's performance as it provides a consistent standard to which services should aspire. Accreditation of laboratories will be valuable in the harmonization of standards and strategies, in the assessment of emerging technologies, as well as in the provision of training and education.

The Quality Management Unit of the EuroGentest Network is involved improving the quality of diagnostic services in all these areas, through training, education, reference materials, new EQAs, best practice guidelines, SOPs and validation documents.

P09.58

Quality and risk management for molecular genetic testing in the laboratory and clinical settings: A perspective from the United States

I. M. Lubin¹, A. E. Pollock¹, M. E. Romano², S. Snyder¹;

¹Centers for Disease Control and Prevention, Atlanta, GA, United States, ²Boston University, Boston, MA, United States.

A Quality / Risk Management Model is proposed for the provision of molecular genetic testing services. This Model emphasizes critical junctures in the testing process where the assembly and communication of clinically relevant information is necessary for appropriate patient management. The evidence-base for this model is derived from earlier studies and particularly those addressing the provision of DNA-based testing for cystic fibrosis in the United States. The Model emphasizes the pre- and post-analytic components of the testing process. Critical components include, among others, initial decision to order the test, efforts taken to collect and communicate patient/family information prior to testing (i.e., relevant clinical information, family history, race/ethnicity), specimen type, handling, and transport, laboratory evaluation of the test request, specimen adequacy, selection of methodology, development of the test report, communication of the result to the clinical setting, and evaluation of the report toward informing appropriate clinical decision making. The role of personnel competency, integration of professional guidelines into practice, costs, and variation in practice settings are commented upon. It is envisioned that such a Model may be useful as a tool for identifying and developing interventions to reduce risk and improve performance to promote high quality testing services in the United States and may have elements applicable elsewhere.

P09.59

The role of volunteers in activities supporting Rare Diseases Alliance

M. Gafencu¹, G. Doros¹, M. Puiu¹, D. Dar², A. Balint³;

¹University of Medicine and Pharmacy, Timisoara, Romania, ²APWR, Zalau, Romania, ³Save of Children, Timisoara, Romania.

The problematic of Rare Diseases in Romania was a true Cinderella until 2000. In the latest years due to the initiative of NGO is this pathology caught the attention of medical people by the means of the model that was offered in Europe, where the role of volunteers derived from families, universities and NGO is become essential.

In the activity of NGO Save the Children, Timis branch in partnership with pediatricians and the University of Medicine and Pharmacy Timisoara was initially penciled with two Associations of Patients suffering of genetic diseases (Down syndrome and Prader Willi Syndrome). Using the young group of volunteers that have worked with patients suffering of Down syndrome and using the expertise of Genetic Chair, was initiated collaboration by many specialists and NGOs resulting the National Alliance of Rare Diseases in Romania. Now we have more than 15 Associations I the Alliance.

The Volunteers of Save the Children, Timis branch participated at the first National Conference of Rare Diseases (2007 Zalau, Romania). In collaboration with specialists we have trained a number of 20 young volunteers from Save the Children Timis. Now they are preparing the activities for a week dedicated for Rare Diseases in each February (mass media campaign, street campaign about this theme, round table with specialists, patients, volunteers and family patients).

Conclusions

The role of young volunteers within this Association was essential. The volunteers of Prader Willi Romanian Association and Save the Children Timis have coordinated the first activities for those pathologies patients.

P09.60

Genetic counseling in familial autosomal reciprocal translocations

F. I. Sahin¹, Z. Yilmaz¹, T. Cok², O. Ozer¹, H. B. Zeyneloglu²;

¹Baskent University Faculty of Medicine Department of Medical Genetics, Ankara, Turkey, ²Baskent University Faculty of Medicine Department of Obstetrics and Gynecology, Ankara, Turkey.

Reciprocal translocations are common chromosomal rearrangements resulting in an increased risk of a segmental aneusomy in children of a carrier. The reciprocal translocation carrier families are interested in their risks of having an unbalanced offspring. Segregation analyses of pedigrees are important in such families before genetic counselling is given. In the current study, we examined the three generation pedigree analyses of 17 cases with autosomal reciprocal translocations with different indications for chromosome analyses. Karyotype analyses of Giemsa-trypsin banded chromosomes were made after the first genetic counselling session during which a three generation pedigree was drawn. Of all the patients, 7 cases were consulted because of recurrent abortuses, 3 cases of infertility. 1 case had a previous child with congenital abnormalities and 1 case had a known familial reciprocal translocation. 5 cases were detected prenatally. Of these, 2 had increased Down syndrome risk in an ongoing pregnancy. Amniocentesis was performed in 2 cases because of advanced maternal age and in 1 case because of a known reciprocal translocation in mother. We detected reciprocal translocation in all cases. During the second genetic counselling session, the patients were informed about their magnitude of calculated risks of having an abnormal child, about the possible abnormalities of the offspring and risks of pregnancy losses. As for the infertile couples, the possibility of preimplantation genetic diagnosis was also discussed as well as the impact of the translocation on gametogenesis.

P09.61

Certified Reference Materials for genetic testing

D. M. Gancberg, P. Corbisier, H. Schimmel, H. Emons;

European Commission, Joint Research Centre, Institute for Reference Materials and Measurements (IRMM), Geel, Belgium.

The lack of tailored reference materials (RMs) and reference measurement procedures for genetic testing slow down the validation and development of new assays and question the reliability of results as tests might potentially be performed in absence of adequate quality controls. The IRMM, as accredited reference material producer (ISO Guide 34), has released in 2006 a set of three certified RMs to be used for the detection of the G20210A mutation in the human prothrombin gene. The materials consist of a 609 bp fragment of the gene (wildtype or mutant sequence) inserted into a pUC18 plasmid. The certification procedure, including the methods used, is described in detail in the certification report and discussed in a recent publication (Clin Chem Lab Med, in press). These activities support the efforts of the genetic community to improve the quality assurance and the harmonisation of genetic testing in Europe and beyond. In addition, IRMM has issued, in the frame of the European Network of Excellence EuroGentest, a guidance document on the use of RMs in genetic testing. This document tackles, with internationally recognised definitions, the state-of-the-art in the field, the selection criteria for RMs according to their use and provides examples for better understanding of the requirements in the field. This presentation will provide an overview on both developments and an outlook to further needs.

P09.62

The Genetic Testing Reference Materials Coordination Program (GeT-RM)- A sustainable community process to improve availability of appropriate reference materials for genetic testing

L. V. Kalman, S. Barker;

Centers for Disease Control and Prevention, Atlanta, GA, United States.

BACKGROUND: The expansion of clinical molecular genetic testing has increased the need for appropriate and characterized cell line/genomic DNA reference materials for quality control, test validation, proficiency testing, and development of new genetic tests. However, despite the growing test volume and the rapidly increasing number of tests offered, the necessary reference materials are not available for the vast majority of tests. METHOD: The U.S. Centers for Disease Control and Prevention (CDC), in collaboration with the genetic testing

community, has established the Genetic Testing Reference Materials Coordination Program (GeT-RM) to improve public availability of reference materials and facilitate information exchange and communication on reference materials development, contribution, characterization, distribution, and needs assessment. **RESULTS:** The GeT-RM has characterized reference materials for Huntington disease, Fragile X, cystic fibrosis, Bloom syndrome, familial dysautonomia, Canavan disease, Niemann-Pick disease, Tay-Sachs disease, Gaucher disease, glycogen storage disease type 1a, Fanconi anemia, and mucopolidiosis type IV. The GeT-RM program also collects information from other sources about publicly available cell lines/DNA with clinically important mutations that may be useful as reference materials. This information is posted on the program website. To date, the GeT-RM has focused its efforts on DNA based testing for inherited genetic disorders. However, we hope to expand our efforts into other areas of genetics, including molecular oncology and biochemical genetic testing. **CONCLUSIONS:** The increased availability of characterized reference materials for quality assurance, proficiency testing, test development and research, will help to improve the quality and accuracy of genetic testing. GeT-RM website: <http://wwwn.cdc.gov/dls/genetics/rmmaterials/default.aspx>

P09.63

The role of AZFc region microdeletion in repeated pregnancy loss

S. M. Kalantar¹, M. H. Sheikhha¹, H. Fazli¹, M. Solimani¹, F. Pakravesh²;
¹Research & Clinical Centre for Infertility, Yazd, Islamic Republic of Iran, ²Aban Hospital, Tehran, Islamic Republic of Iran.

Objective: To evaluate the role of Y chromosome microdeletion in the case of couples had problem with repeated pregnancy loss (RPL) in group of unknown cause compared with couples with male factor infertility.

Materials & Methods: A controlled clinical study was designed in our centre. In total, 100 men from male factor infertility and 25 men with RPL were recruited in the study.

DNA was extracted from Peripheral blood sample. In each sample, six sequence-tagged-sites (STS) according to the european protocol and four other STSs in the proximal AZFc region namely; DYS262, DYS220, DYF8551, and DYF8651 were studied by polymerase chain reaction (PCR).

Results: Eight men tested evaluated had Y microdeletion in at least one of the six segments from European protocol (8%) VS non in RPL group. Five men with history of at least 3 PL in their wife tested for 4 STS in AZFc region had microdeletion (20%) but non of those other STS. In the infertile group had not any microdeletion related to the 4 STS from AZFc region.

Conclusion: From our results it could concluded that in case of couples with un explained PRL it may help to test these four STSs on Y chromosome to recognize the cause of PL.

P09.64

Mutational homogeneity of severe autosomal recessive retinal degeneration in endogamous Romany (Gypsy) communities in Slovakia

A. Ficek^{1,2}, E. Feráková¹, L. Kádaš^{1,2}, G. Minárik¹, H. Poláková², V. Ferák¹;
¹Comenius University, Faculty of Natural Sciences, Bratislava, Slovakia, ²Slovak Academy of Sciences, Institute of Molecular Physiology and Genetics, Bratislava, Slovakia.

Hereditary retinal degenerations comprise clinically and genetically wide group of mostly progressive ocular disorders and are one of the most frequent causes of vision impairment in developed countries. So far uncovered tremendous genetic heterogeneity underlying majority of these disorders however markedly impedes ongoing attempts on DNA diagnostics and therapy in most of populations. Contrary to panmictic populations, genetic heterogeneity in isolated populations is often reduced to high degree due to founder effect and inbreeding. Severe childhood autosomal recessive rod-cone progressive retinal degeneration with feature of retinitis pigmentosa (nyctalopia, dark pigment formations, attenuated retinal vessels) and nystagmus characteristic for LCA phenotype occurs in higher frequency in to the high degree isolated Romany communities in Slovakia. Whole genome autozygosity mapping and linkage analysis accomplished on analysis of two large pedigrees facilitated localization and identification of underlying mutation to which bidirectional allele specific amplification method

was designed for routine mutation detection. Geographically delimited occurrence of the disease confirmed community structure of Romany population with existence of small, endogamic founder settlements. Growing of such small communities, characterized by high consanguinity rate, results in markedly increased incidence of this autosomal recessive disorder in some regions leading to significant genetic burden to the population. While no effective therapy exists for the disorder at the moment, cascade carrier screening and genetic counseling proffered to the families is currently the only possible approach to the management of the disease.

P09.65

Governing the balance between 'duty to protect' and 'right to test' II: New forms of protection in genetic screening

M. C. Cornel, T. Pieters, C. G. van El;

VU University Medical Centre, Amsterdam, The Netherlands.

While in the previous century the availability of genetic testing and screening was governed by public health authorities and medical professionals, increasingly direct-to-consumer tests become available. While on the one hand people have become more free to decide for themselves whether they want to order their genetic risk test, on the other hand, lack of counselling, personalized advice resembling general lifestyle advice or incorrect results may lead to disappointment or may prove harmful. Quality of genetic services is no longer guaranteed by existing regulations.

In the United Kingdom the Human Genetics Commission has updated its recommendations concerning direct-to-consumer testing, calling for stricter control, without precluding commercial testing, for instance by recommending that the test be offered by a qualified health professional. To guarantee informed decision making, the public needs to have access to high quality information (trusted websites). Education and communication are needed to inform the public at large on pros and cons of genetic screening. Policy makers should engage with patient and consumer organisations. Especially for complex diseases translational research is needed. Possibilities to regulate marketing of commercial test offers after adequate pre-market evaluation need to be debated and implemented. The European certificate CE marking should guarantee analytical validity and clinical validity. Assessment of clinical utility, relating to the availability of effective interventions, should be performed for new forms of testing and screening for low-risk populations and high as well as low-risk gene variants.

P09.66

Governing the balance between 'duty to protect' and 'right to test' I: Challenges to the focus on protection in genetic screening

C. G. van El, T. Pieters, M. C. Cornel;

VU University Medical Centre, Amsterdam, The Netherlands.

For genetic screening, criteria have been developed based on the WHO Wilson and Jungner criteria (1968), in which the notion of protection of citizens against unwarranted screening was important. In some countries, such as the Netherlands, 'protection' even became cornerstone of legislation concerning population screening. Protection relates to notions of having a suitable test with good sensitivity and few false positives, the availability of treatment and follow-up after diagnosis, so that benefits of screening outweigh potential harm, for instance of stress caused by uncertainty, the knowledge of having a fatal disorder or unnecessary interventions.

In screening policy safeguards are needed because of the shared responsibilities of government and health care taking the initiative to offer screening to - in principle - healthy people.

We argue that recent developments challenge this protective stance. Firstly, on the basis of developments in genomics, among other association studies, labs and companies increasingly offer direct-to-consumer tests on the internet. Secondly, there is increasing awareness about and demand for testing and screening, sometimes stimulated by patient organisations. For instance, in the Netherlands, parents of children with Duchenne Muscular Dystrophy argue that people might want a newborn screening test for DMD to be able to prepare or make reproductive decisions.

The emphasis on protection ignores increasing demands for testing. Citizens want to be more autonomous. "Informed decision making" is not taken seriously when many genetic screening tests are simply not

made available. New ways to involve the public in policy decisions on screening and testing are necessary.

P09.67

The importance of genetic counselling for parents with normal constitutional karyotypes having multiple spontaneous abortions with aneuploidy

V. Culic¹, J. Pavelic²;

¹Pediatrics Clinic, Department for Medical Genetics, Split, Croatia, ²Institute Rudjer Boskovic, Molecular Genetics, Zagreb, Croatia.

The purpose of this research is to establish the hypothesis that two hits are responsible for aneuploidy which results in spontaneous abortion. The first hit could have been triggered by patient's former diseases of urinary and/or genital system. The number of spontaneous abortions recorded in their siblings of second generations creates predisposition that may end with termination of pregnancy. The second hit is usually triggered by chronic presence of EBV virus in male or/and female partner. It has been demonstrated that there is no significant relation between the age of male or female partners and the number of spontaneous abortions. Both males and females had former urinary or/and genital infections and the number of spontaneous abortions among the siblings of second generation is twice as high in relation to average population. Variations in constitutional karyotypes (per inv 9, 9qh+) are also evident as well as presence of antibodies for EBV, CMV, or HSV2 viruses. Reactivation of latent EBV infection provides possibility for second hit. Aneuploidy or tetraploidy is found at 23% of samples. Therefore we think that the presumed hypothesis of two hits is clearly established. Partners with spontaneous abortion with and without chromosomal abnormalities must undergo genetic counselling process for preventing trigger/s or to repeat the proces, because spontaneous abrotion is an multifactorial disease.

P09.68

Milestone in teaching genetics

R. Dragotoiu;

Medical and Pharmacy University "Carol Davila", Bucuresti, Romania.

On the verge of a new legislation in the educational system, when one of the main goals is the alignment to the international standards, it is suggested that student's evaluation has to become mandatory and its results should be made public by the university. More than a decade ago I evaluated my teaching methods and presented the results at the ESHG meetings. Three years ago I decided to change the way I taught the practicals.

Questionnaires were answered by 76 first year students of the Medical and Pharmacy University "Carol Davila" to evaluate the quality of the practicals they attended during the first term in the Department of Genetics. They were questioned about the quantity of information versus amount of time, the quality of information and presentation and if they enjoyed the practicals.

Answers to the question: Have you been satisfied with the way the practicals unfolded?

very much	7%
a lot	42%
enough	50%
satisfactory	1%
almost not at all	none
not at all	none

For several years I have stopped asking students for an evaluation, because the results were the same: almost half in favor of frontal teaching and the other half preferring the interactive method. Since I have modified my teaching method, the speed and the amount of information also changed, but only 7% of students considered it was too much data.

Adapting the teaching method to the students' present needs makes them more prone to enjoy the practicals. The study did not focus on achieving genetic knowledge, but apparently this did not improve.

P09.69

Thrombophilic gene mutations: two different approaches to the validation of commercial and "in-house" DNA diagnostic assays

A. Stambergova, J. Camajova, M. Macek Jr.;

Department of Biology and Medical Genetics, Prague 5, Czech Republic.

Validation of molecular genetic analytical methods is the basic tool for quality assurance and has to be part of routine practice in clinical-diag-

nostic laboratories that are working in compliance with the ISO15189 guidelines (www.iso.org). Moreover, OECD has issued "Guidelines for Quality Assurance in Molecular Genetic Testing (www.oecd.org/st/bio-technology)" which stipulate that laboratories providing clinical services should be working within a "Quality Assurance System". Via method validation laboratories assess assay performance and demonstrate their suitability for the intended purpose. It is up to individual laboratories to establish an acceptable validation protocol in order to comply with general ISO principles. Here we report practical examples of validation procedures utilized for an „in-house" test that we developed for the detection of thrombophilic mutation PAI-1, versus approaches applied to a commercially produced RHA Kit Thrombo (Labo Bio:Medical Products; CE/IVD marked). For examination of the thrombophilic mutation PAI-1 our laboratory uses an "in-house" method based on fragment analysis of restriction endonuclease- digested amplicons, while the commercial assay is based on reverse slot hybridization (RHA) for simultaneous detection and identification of mutations in the genes coding for FII G20210A, FV-Leiden, including the MTHFR 677C/T variant. In both instances we assessed basic validation parameters including specificity, sensitivity, repeatability, reproducibility and robustness. Differences between both validation protocols are within the scope of validation parameters being tested. These procedures enabled us to confirm diagnostic reliability of both techniques and provide practical examples for other laboratories validating their genetic tests. Supported by VZFN00064203(6112) and EuroGentest.

P09.70

Genotyping of MTHFR 677C>T and 1298A>C variants by high resolution melting of small amplicons: an example of method validation.

P. Norambuena, J. Copeland, P. Krenkova, M. Macek Jr., A. Stambergova;

Department of Biology and Medical Genetics, Prague 5, Czech Republic.

High Resolution Melting (HRM) is a simple, cost-effective and rapid mutation scanning method. By reducing the respective amplicon size, it is possible to increase the resolution for reliable discrimination between homozygous wild-type and homozygous mutant samples. We introduced HRM close-tube method in our laboratory for genotyping of the most common variants in the MTHFR gene: 677C>T (rs1801133: C>T) and 1298A>C (rs1801131: A>C). PCR amplification and HRM was performed on the LightCycler® 480 Real-Time PCR System (Roche). For validation purposes we evaluated specificity, sensitivity, repeatability, reproducibility and the ability of the method to perform reliable calls. We were able to perform unambiguous calls in 98.4% (n=381) of the cases for rs1801133: C>T and in 98.1% (n=104) of the cases for rs1801131: A>C. For the 6 (1.6%) and 2 (1.9%) unknown samples for rs1801133: C>T and rs1801131: A>C respectively, by repeating the analysis we reached 100% of calls. Since in the end all calls were reliably detected by the LightCycler software we reached 100% specificity and sensitivity. Repeatability and reproducibility were also consistent. In conclusion, after optimization and diagnostic validation HRM of small amplicons is a reliable and precise method that can be broadly applied in DNA diagnostics of other genes.

Supported by VZFN00064203(6112) and EuroGentest.

P09.71

Training on quality management to support genetic testing laboratories in continuous improvement and progress towards accreditation

M. A. Morris^{1,2}, S. Berwouts^{3,2}, A. Wynants^{4,2}, E. Dequeker^{3,2};

¹Laboratoire de Diagnostic moléculaire, Service de Médecine Génétique, University Hospital, Geneva, Switzerland, ²EuroGentest Network of Excellence, Leuven, Belgium, ³Centre of Human Genetics, University of Leuven, Leuven, Belgium, ⁴Management Consulting & Research, Heverlee, Belgium.

ISO 15189:2007, the international standard developed specifically for medical laboratories, requires that staff receives relevant training in quality assurance and quality management (5.6.1). In response to the growing interest in accreditation and quality improvement, a series of interactive two-day training workshops were organized for genetics laboratories, within the framework of the European project EuroGentest.

The subjects of these workshops varied from living with quality systems and comparing the different standards for accreditation, to specific topics such as internal audit, managing the human side of change

processes and IT support for quality management.

Since 2005, 156 different participants, from 85 institutes and 27 countries worldwide, have participated in the 8 workshops organized to date.

In addition to the training sessions, an electronic survey was sent to all participating institutes in order to get a more detailed view on the progress laboratories make towards accreditation and the implementation of different quality aspects such as document control, performing internal audits and tracking non-conformities. Furthermore, the value of training in the improvement of a quality system was surveyed. The answers received from more than 50 institutes have been analysed. This survey gives us insight into the reaction of laboratories to the increasing pressure to develop their investment in continuous improvement and accreditation. Moreover, we will anticipate and address topics on quality in future workshops, particularly adapted to the needs of the genetic testing laboratories.

P09.72

Genetic counseling of families when one of the members is the carrier of balanced translocation

R. Sereikiene, V. Abraitis, D. Strazdienė;

KAUNAS MEDICAL UNIVERSITY HOSPITAL, KAUNAS, Lithuania.

Infertility in the family is one of most common courses of genetic consulting. Between 266 consulted families we found 4 families with carrier of balanced translocation. By the example of these families we'll try show the specific features of their genealogies and ethical aspects of genetic consulting. Translocation examples in the families:

1. Male/Female: 46 XY, t (1;4) (p36.2; q32)/ 46 XX.
2. Male/Female: 46 XY/ 46 XX, t (4;9) (p15.3; q12).
3. Male/Female: 45 XY; -13; -14; +t (13;14)/ 46 XX.
4. Male/Female: 46 XY/ 46 XX, t (6;10) (q23; p13).

Genealogies of these families had some characteristic features:

1. Sterility.
2. Spontaneous abortions and miscarriages.
3. Stillborns.
4. Different anomalies of fetus.
5. The cases of mental retardation of unclear etiology between relatives.

Some ethical problems rise during genetic counseling of these families:

1. Who must say the results of chromosomal examination for healthy spouse - doctor or translocation suffering husband or wife?
2. What tactic should keep the doctor in cases when translocation carriers don't agree inform other member of family?
3. The examination of first line relatives (parents, brothers, sisters and children) and other relatives sometimes needs to avoid more fetal anomalies. What tactic must be of the doctor in case when couple doesn't want informing others? Is it ethical to hide information which knows the doctor from relatives who might be interested in?
4. How explain family the results of examination in correct way to avoid conflicts and sometimes divorces of the families?

P09.73

Towards practical guidelines for the validation of genetic diagnostic tests

E. Swinnen^{1,2}, E. Bakker³, D. E. Barton⁴, S. Berwouts^{1,2}, P. Bossuyt⁵, J. Camajova^{6,1}, A. Corveleyn^{1,2}, E. Dequeker^{1,2}, T. Janssens^{1,2}, M. Macek Jr.^{6,1}, I. Mann⁷, C. Mattocks⁹, M. Morris⁹, C. Müller¹⁰, V. Pratt¹¹, I. Salden², H. Scheffer¹², A. Stambergova^{6,1}, A. Wallace¹³, J. A. Wilson¹⁴, M. Zoccolli¹⁵, G. Matthijs^{1,2};

¹Eurogentest Network of Excellence, Leuven, Belgium, ²KUL, UZ Leuven, Leuven, Belgium, ³Leiden University Medical Center, Leiden, The Netherlands,

⁴Our Lady's Children's Hospital, Dublin, Ireland, ⁵University of Amsterdam, Amsterdam, The Netherlands, ⁶Charles University, Prague, Czech Republic,

⁷Swiss Accreditation Service, Lausanne, Switzerland, ⁸Salisbury District Hospital, Salisbury, United Kingdom, ⁹University Hospital Geneva, Geneva, Switzerland,

¹⁰University of Würzburg, Würzburg, Germany, ¹¹Nichols Institute, Chantilly, VA, United States, ¹²University Medical Centre Nijmegen, Nijmegen, The Netherlands, ¹³St Mary's Hospital, Manchester, United Kingdom, ¹⁴Sequenom, San Diego, CA, United States, ¹⁵Celera Diagnostics, Alameda, CA, United States.

Continuous advances in human genetics and biotechnological developments have led to a rapid growth of nucleic acid-based diagnostic testing in medical laboratories. To further improve the quality of genetic testing, it is necessary to support the implementation of reliable tests.

Several quality assurance measures are demanded by regulatory organizations and accreditation bodies as outlined in published standards and guidelines (e.g. ISO 15189 standard, the IVD Directive 98/79/EC, the OECD Quality Assurance Guideline).

However, proper instructions or the know-how to fulfil these requirements, especially for the validation of genetic tests, are lacking.

A working group was created within EuroGentest, that aims to develop practical guidelines for - to begin with - the analytical validation of molecular genetic tests.

Through brainstorming meetings in Leuven (2007) and Prague (2008), literature studies and with the help of external experts, a background document was generated. It includes a consensus glossary of terms (applicable to molecular genetic testing), a categorization of the variable array of genetic test methods, discussions on the meaning of critical performance characteristics for genetic tests and several generic aids, such as a flowchart to guide the user to appropriate instructions, a generic validation SOP and a template file for the validation report. Future plans include the experimental design of test validations, a statistical evaluation of 'numbers' in validation experiments, interlaboratory (collaborative) trials and clinical validation.

The document will be posted and submitted to a public and expert consultation during the summer of 2008.

Comparative sequence analysis, structure prediction, primer design of ApolipoproteinE protein in Alzheimer's disease

K. Mahdiah¹, K. R. Rupesh²;

¹Special Medical Center, Tehran, Islamic Republic of Iran, ²IFREMER, Plouzane, France.

Alzheimer's disease (AD), neurodegenerative disease, is common cause of dementia, characterized clinically by progressive intellectual deterioration together with declining activities of daily living and neuropsychiatric symptoms or behavioral changes. Researchers have identified increased risk of developing late-onset AD to the apolipoprotein E (apoE) gene found on chromosome 19. In this study we have compared the ApoE gene and its protein in different organisms to understand the mechanism of expression of ApoE. Multiple sequence alignment (MSA) of the apoE gene revealed that it is analogous to all the other 16 organisms whereas the apoE protein is found to be 66% homologous. On analysis of apoE (NM_000041), it was found that ORF region was between 84-1034 position. Specific primers for the apoE coding region were designed which resulted in product size 1109 bp. The apoE protein analysis showed that it was hydrophilic. 13 antigenic determinants were found when the apoE protein was analysed for Antigenic prediction sites which could be used as potential targets. The positions of alpha helix and b-sheets in the secondary structure of the proteins were predicted along with 3D structure prediction of apoE. The degenerate primers designed could be used as a diagnostic tool for identifying apoE protein expression in AD patients. The predicted antigenic sites on the apoE proteins could be used as an effective target for interaction with candidate drugs for the control of the expression of the apoE in AD patients, this has to be further evaluated using in vitro and in vivo methods.

P10.02

Anthracyclines, an antibiotic family with anti-proliferating activity, can elevate γ -globin expression *in vitro* and increase HbF production in human erythroid cells

P. N. Spyrou¹, L. Kythreotis², A. Kirr², S. Christou², M. Kleanthous¹;

¹The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ²Makarios Hospital, Nicosia, Cyprus.

Anthracyclines are a family of natural products produced by microorganisms of the actinomycetes group. Some members of the anthracycline group of antibiotics show pharmacological and mostly anticancer activities. Their biological activities are proposed to be the result of drug-induced damage or structural alterations to DNA due to inhibition of enzymes that are involved in the DNA synthesis like topoisomerase II.

In this study we investigate whether some anthracyclines could be HbF inducers due to their DNA binding properties and the formation of stable complexes with it. A group of other DNA binding agents were

found to be strong HbF inducers. This group includes compounds like cisplatin analogs, Chromomycin-Mithramycin, Tallimustine and Angelicin. Some Ribonucleotide reductase inhibitors like Hydroxyurea, Didox and Trimidox were also found to be strong HbF inducers. Ribonucleotide reductase is an enzyme that plays an important role to DNA replication and repair. These properties therefore amplify our speculation that Anthracyclines might be inducers of HbF. We examined the following compounds: Doxorubicin, Aclarubicin, Idarubicin, Bleomycin and Daunorubicin on γ - and β - globin gene promoter activity in a dual luciferase assay in the GM979 cells. All of them increased the γ -globin promoter activity over 2 fold and were then tested in erythroid liquid cultures derived from normal donors. Doxorubicin, Idarubicin and Daunorubicin showed increasing levels of HbF and were then tested to thalassemic patients (preliminary results). The findings so far from all the measurements clearly show that the family of Anthracyclines could be a possible target for finding new HbF inducers.

P10.03

Medical rehabilitation for life quality improvement in a case with arthrogryposis

M. Cevei¹, D. Stoicanescu², C. Avram¹;

¹Faculty of Medicine and Pharmacy, Oradea, Romania, ²University of Medicine and Pharmacy, Timisoara, Romania.

Arthrogryposis is a congenital disorder characterized by multiple joint contractures found throughout the body at birth. We present the case of a girl of 3.5 year-old with multiple congenital defects: arthrogryposis involving bilateral hip, knee and ankle joints, together with sacral agenesis with lobar dysmorphism, anorectal agenesis, hydronephrosis of the left kidney as the result from reflux, right kidney hypoplasia, renal fusion and heart anomalies: tetralogy of Fallot. Immediately after birth, in several steps, colostomy, left ureterocystostomy and suprapubic cystostomy were performed. Later in infancy corrective surgery for the heart defect was required. At the age of 2 years, surgery for the equinovarus deformities and for left genu flexum was performed. Medical rehabilitation tries to maximize independent function. The main goals were increasing the muscle tonus of upper-limbs, increase the rate of motion of the joints, establishment of stability for ambulation, learning different schemes of movement according to her needs, obtaining of a functional independence. The patient followed a complex rehabilitation program with hydrokinetotherapy, electrotherapy, massage, occupational therapy, psychological counseling. The therapies were successful, after 10 weeks an improvement of the moving capacity and of the transfer in orthostatism with minimal external assistance, with the obvious increasing of the patient's satisfaction, were noticed. In order to fulfill our objectives the child will be hospitalized every two months for functional evaluation and for continuing the physical therapies.

P10.04

Delineation of the 5-Azacytidine pathway by use of siRNAs

J. Ghahesouran¹, A. Asgharian², Z. Deilami Khiabani², A. Aghajani¹, H. Khorram Khorshid¹, H. Najmabadi¹, M. Banan¹;

¹Genetics Research Center, Tehran, Islamic Republic of Iran, ²Cell and molecular biology, Islamic Azad University, Tehran, Islamic Republic of Iran.

Induction of γ -globin may become a useful means for treatment of β -thalassemia. 5-Azacytidine (5-Aza) is a chemical compound that leads to the induction of γ -globin, at least in part through blocking the function of methyl transferases. In addition, it is known that the Methyl Domain Binding Protein 2 (MBD2) binds to methylated DNA and may be involved in repressing γ -globin expression. Therefore the function of 5-Aza may in part be mediated through blocking MBD2 binding to DNA. Here we have looked at whether the K562 erythroleukemia cell line is an appropriate model system for studying this pathway. We have used non-radioactive northern blot analysis and real time PCR to show that γ -globin can be induced in K562 cells. In addition, we have validated the function of a published MBD2 siRNA sequence by showing that it can knock down MBD2-specific mRNAs in HeLa cells. We are in the process of testing these siRNAs in K562 cells for 1) MBD2 knockdown and 2) γ -globin induction. Upon validation, K562 cells will be used further to delineate this pathway.

P10.05

Studying the γ -globin induction pathway by hydroxyurea in K562 cell lines

Z. Deilami Khiabani¹, J. Ghahesouran², A. Asgharian¹, H. Najmabadi², M. Banan²;

¹Cell and molecular biology, Islamic Azad University, Tehran, Islamic Republic of Iran, ²Genetics Research Center, University of Social Welfare & Rehabilitation Sciences, Tehran, Islamic Republic of Iran.

β -thalassemia is a genetic disorder which may be ameliorated by induction of the fetal γ -globin gene. Several chemical agents can lead to the induction of γ -globin. One such chemical is hydroxyurea. This chemical is the only drug approved by the Federal Drug Administration (FDA) for treatment of β -thalassemia. Despite its use in β -thalassemia treatment, the mode of action hydroxyurea is poorly understood. Here, we have examined the effect of different hydroxyurea concentrations (50, 100, 200 μ M) on γ -globin induction in the K562 erythroleukemia cell line. We have used non-radioactive Northern blot analysis and RT-Real time PCR to measure γ -globin levels. We have determined that there is a 3-4 fold induction of γ -globin using 100 μ M and 200 μ M hydroxyurea concentrations. We have also optimized transfection conditions of K562 cells to show the effect of positive and negative control siRNAs. We are currently in the process of testing siRNAs against candidate gene(s) involved in this pathway.

P10.06

Congenital Disorder of Glycosylation type Ia: antisense therapeutics for an intronic variation causing exonization of an intronic sequence

A. I. Vega^{1,2}, C. Pérez-Cerdá^{1,2}, G. Matthijs³, M. Adamowicz⁴, M. Ugarte^{1,2}, B. Pérez^{1,2};

¹Centro de Biología Molecular Severo Ochoa. Dpto Biología Molecular. UAM, Madrid, Spain, ²CIBERER, Madrid, Spain, ³Center of Human Genetics, University of Leuven, Leuven, Belgium, ⁴The Children's Memorial Health Institute, Warsaw, Poland.

Congenital disorders of glycosylation (CDG) are a group of genetic diseases resulting from defects in N-glycosylation of glycoconjugates. The most common form of the disease is the CDG-Ia caused by a deficiency in the cytosolic enzyme phosphomannomutase (PMM). PMM converts mannose-6-phosphate to mannose 1-phosphate and is a key enzyme in the generation of N-linked glycans. The clinical presentation of PMM deficiency ranges from very severe to milder phenotype. In this work we report the functional analysis of a nucleotide change identified in the deep intronic region of intron 7 (c.639-15479C>T) of PMM2 gene and the use of antisense morpholino oligonucleotides (AMOs) to restore normal splicing. First, we have confirmed using splicing assay that this change provokes the exonization of 123bp between exon 7 and 8 in patient's cDNA. Using modified morpholinos to block access of the spliceosome to 3' and/or 5' cryptic splice site we have demonstrated that this insertion is a disease-causing mutation. After transfection of a fibroblast cell line from the patient, the analysis of the effect of the AMO was done by conventional RT-PCR, determination of PMM activity and western blot using polyclonal antibodies. The results obtained shown that a correctly spliced mRNA was rescued and efficiently translated in a functional protein detected by western blot. PMM activity was rescued close to the value of control cell line. Our results offer a novel promise mutation-specific therapeutic approach in this genetic disease where is not possible other effective treatment.

P10.07

Treating congenital defects: a purposal of algorithm for nutritional intervention in individuals with cleft lip/palate

R. J. Nogueira¹, A. E. S. Lima¹, L. G. Almstaden-Mendes², V. L. Gil-da-Silva-Lopes²;

¹Multiprofessional Nutritional Team-Clinical Hospital/UNICAMP, Campinas, Brazil, ²Department of Medical Genetics/UNICAMP, Campinas, Brazil.

Cleft lip and palate (CL/P) is one of the most common birth congenital defects, occurring in approximately 1/600- 1000 newborns babies worldwide. In view of the feeding difficulties presented by children with a cleft lip and/or palate and the importance of food in their growth and development, they should receive early and systematic healthcare, by a specialized team besides of regular pediatric care. Therefore, the search for strategies of low-cost and good effectiveness and improve of health care are recommended by the World Health Organization (WHO).

The diet of a child with a CL/P is critical for growth and development besides adequate gain in weight, which is important to corrective surgery at the right time. Despite of the high prevalence and the importance of nutritional intake, there are around 50 articles involving nutritional approaches over 50 years. We present a proposal of an algorithm for multiprofessional intervention for nutrition of CL/P babies before surgery.

P10.08

Mechanism of CMT1A phenotypic correction by high dose of ascorbic acid

S. Belin¹, F. Kaya¹, G. Diamantidis², M. Fontes¹;

¹INSERM, Marseille, France, ²University, Thessaloniki, Greece.

Charcot-Marie-Tooth [CMT] syndrome is the most common hereditary peripheral neuropathy usually results from triploidy of the PMP22 gene. Preclinical trials using an animal model show that disabled mice force-fed with high doses of ascorbic acid partially recover muscular strength after a few months of treatment, and suggest that high doses of ascorbic acid repress PMP22 expression (Passage et al, Nature medicine, 2004).

PMP22 gene expression was under the control of cAMP stimulation (Saberan et al, Gene, 2000). Recently we demonstrated that ascorbic acid represses PMP22 gene expression by acting on intracellular cAMP levels and adenylate cyclase activity. This action is dose-dependent and specific to ascorbic acid, since repression is not observed after treatment with other antioxidants (Kaya et al, Neuromuscular Disord, 2007). Indeed we showed that ascorbic acid is a competitive inhibitor of cyclase adenylate enzyme. This work enabled us to propose an unsuspected mechanism of action explaining the phenotype correction, and to identify two new potential therapeutic targets: the ascorbic acid would act directly on the PMP22 gene expression by decreasing intracellular cAMP concentration via the inhibition of the adenylate cyclase activity.

P10.09

U1snRNA-mediated rescue of mRNA processing in severe factor VII deficiency

F. Pagan¹, M. Pinotti², F. Bernard²;

¹ICGEB, Trieste, Italy, ²Department of Biochemistry and Molecular Biology, University of Ferrara, Ferrara, Italy.

Small nuclear U1-RNAs (snRNAs), the spliceosome components selectively recognizing donor splice sites (5'ss), were engineered to restore correct mRNA processing in a cellular model of severe coagulation factor VII (FVII) deficiency, caused by the IVS7 9726+5g/a change. Three U1-snRNAs, complementary to the mutated 5'ss (U1+5a) or to neighbouring sequences, were expressed with FVII minigenes in a hepatoma cell line.

The U1-snRNAs reduced from 80% to 40% the exon 7 skipping, thus increasing exon definition. The U1+5a construct also dramatically increased recognition of the correct 5'ss over the 37bp-downstream cryptic site preferentially activated by the mutation, thus inducing appreciable synthesis of normal transcripts (from barely detectable to 50%). This effect, which was dose-dependent, clearly demonstrated that impaired recognition by the U1-snRNA was the mechanism responsible for FVII deficiency. These findings suggest compensatory U1-snRNAs as therapeutic tools in coagulation factor deficiencies caused by mutations at 5'ss, a frequent cause of severe defects.

P10.10

Influence of proprioceptive training program in children with Down syndrome

E. Sirbu¹, B. Almajan-Guta², V. Almajan-Guta³, D. Stoicanescu⁴;

¹West University of Timișoara, Timișoara, Romania, ²University Politehnica Timișoara, Timișoara, Romania, ³Speranta Special Care Center, Timișoara, Romania, ⁴University of Medicine & Pharmacy, Timișoara, Romania.

Background: In these days, Down syndrome comes again in the concern of medical researchers because early intervention treatment can improve the quality of life of these children. The goal of our study was to prove the efficiency of a proprioceptive training program on the motor development stages of children with Down syndrome.

Methods: The study was performed between September 2006 - September 2007. The study was performed on 30 children from the "Speranta" Special Care Center Timișoara (16 girls and 14 boys) with the

age range between 2 months and 5 years. The lot was divided in two groups: control group (15 subjects) and experiment group (15 subjects). The study subjects underwent physiotherapy and physical exercise and the experimental group followed a proprioceptive training program. The intervention consisted of three sessions of 45 minutes each, per week. The children were assessed before, during and after this physical intervention using Bayley Motor Scales of Infant Development.

Results: As the results indicated, the experimental group showed a statistically significant improvement in all measured values when compared with the control group.

Conclusion: The proprioceptive training was superior in the improvement of the posture, of the transfers and of the balance, compared to classical physical therapy. The delays in motor development milestones were more severe in the study group compared to experimental group.

P10.11

Antisense Oligomer (AO) induced exon skipping in the mdx^{4cv} mouse model

C. Mitrpant, S. Fletcher, S. D. Wilton;

Australian Neuromuscular Research Institute (ANRI), Perth, Australia.

Duchenne muscular dystrophy (DMD), a relentless progressive muscular dystrophy is caused by protein truncating mutations in the dystrophin gene that result in the absence of functional dystrophin. Loss of dystrophin leads to irreparable membrane damage, thus promoting calcium ion influx and cell death.

Antisense Oligomer (AO) induced exon skipping is a molecular intervention whereby AOs are targeted to motifs involving in pre-mRNA splicing. This has been used to induce specific exon removal and by-pass the disease-causing gene lesion in the mdx mouse model of muscular dystrophy. We are investigating exon skipping in the B6Ros. Cg-Dmd^{mdx4cv}/J (mdx^{4cv}) muscular dystrophy mouse, which carries a nonsense mutation in exon 53 of the dystrophin gene. To restore the reading frame, both exons 52 and 53 must be excised from the mature dystrophin gene transcript to by-pass the primary gene lesion and maintain the reading frame. 2'-O-Methyl AOs, on a phosphorothioate backbone have been designed to mask these exons from the splicing machinery and lead to their excision. Initial AO combinations induced skipping of exons 52/53 and restored some protein expression. However the predominant transcript was missing only exon 53 as determined by RNA studies. We designed additional AOs to enhance exon skipping of both exons 52 and 53.

We highlight the importance of AO design to enhance efficiency of single and multi-exon removal.

P10.12

Study on the chaperone effect of several iminosugars and aminocyclitols on mutated glucocerebrosidases as a treatment for Gaucher disease

G. Sanchez-Olle^{1,2,3}, M. Egido-Gabas⁴, J. Duque⁵, A. Yudego⁵, J. Casas⁴, A. Chabas^{5,3}, D. Grinberg^{1,2,3}, L. Vilageliu^{1,2,3};

¹Universitat de Barcelona, Barcelona, Spain, ²IBUB, Barcelona, Spain, ³CIBER-ER, Barcelona, Spain, ⁴RUBAM, Departament de Química Orgànica Biològica, IQAB-CSIC, Barcelona, Spain, ⁵Institut de Bioquímica Clínica, Barcelona, Spain.

Gaucher disease is an autosomal recessive disorder, characterized by the accumulation of glucosylceramide in lysosomes, because of acid β -glucosidase deficiency. Some competitive inhibitors, at subinhibitory concentrations, can work as chemical chaperones. We have tested the effect of two iminosugars, *N*-(*n*-nonyl)-deoxynojirimycin (NN-DNJ) and *N*-(*n*-butyl)-deoxynojirimycin (NB-DNJ), and four aminocyclitols on stable transfected COS-7 cells and patient fibroblasts.

In stable cell lines, NN-DNJ led to a 1.2 to 1.4-fold increase in the activity of G377S, N188S and wild-type GBAs at different concentrations. A slight increase was noticed in the activity of the N188S;E326K GBA at 2.5 μ M. NB-DNJ at 5 μ M induced a 1.2-fold increase in the GBA activity of COS-7 cells transfected with the N188S and N188S;E326K cDNAs. A slight increase was also observed in cells transfected with the wild-type cDNA. The aminocyclitol C4 Ph showed a 1.2 to 1.4-fold increase on wild-type and N188S GBAs, at different concentrations. At 15 μ M, 1.2-fold increase for N188S;E326K GBA was also observed.

In fibroblasts, treatment with NN-DNJ produced an increase of activity

in cells bearing the following genotypes: L444P;E326K/G202R (1.3-fold at 2.5 μ M), D409H/N188S;E326K (1.4-fold at 5 μ M and 10 μ M, and 1.2-fold at 20 μ M), and N370S/N370S (1.7-fold at 5 μ M and 10 μ M, and 1.5-fold at 20 μ M). Treatment with the aminocyclitol C10 at different concentrations increased 1.5-fold the GBA activity in L444P/G202R fibroblasts, and from 1.2 to 1.7-fold in L444P;E326K/G202R patient cells.

P10.13

Hematopoietic stem cells therapy and risk of graft versus host disease: A report from Iran

M. Ebrahimi¹, M. Houshmand^{2,1};

¹Special Medical Center, Tehran, Islamic Republic of Iran, ²National Institute of Genetic Engineering & Biotechnology, Tehran, Islamic Republic of Iran.

Transplanted hematopoietic stem cells (HSC) and progenitor's cells can treat malignant and nonmalignant disorders, including immunological, gynecological, neurological, endocrinological and others pathologies and disorders. The transplantation of HSC that was not genetically identical (allogeneic) to that of the recipient resulted in an immunologic reaction by the donor lymphocytes against the recipient, causing inflammation of the target tissues, termed graft-versus-host disease (GVHD). GVHD is one of the major limiting factors in successful HSC transplantation. A wide range of host antigens can initiate graft-versus-host-disease, among them the human leukocyte antigens (HLAs). HLA-identical siblings or HLA-identical unrelated donors often have genetically different proteins that can be presented by MHC molecules to the recipient's T-cells, which see these antigens as foreign and so mount an immune response.

We enrolled 18 patients with one form of neuromuscular disorders at Genetics Department of Medical Special Center in Tehran. The all patients received transplants of HSC of the human embryonic liver. All patients were treated on clinical protocols, which were reviewed and approved by the Embryotech and Special Medical Centers. All patients provided written informed consent before being enrolled in the protocols.

The diagnosis of acute GVHD was initially based on clinical signs must be confirm by positive biopsy results from at least one involved organ. In period of observation GVHD is developed in nobody. The lowest risk of GVHD is associated with that the HSC derived from liver do not contain the antigens of major histocompatibility complex on their surface what makes them tolerant towards recipients.

P10.14

Effects of silibinin on cell growth and invasive properties of a human hepatocellular carcinoma cell line, HepG-2, through inhibition of extracellular signal-regulated kinase 1/2 phosphorylation

M. Noori-Daloi¹, M. Momeny, M. Khorramizadeh, M. Yousefi, M. Yekaninejad, R. Esmaili, Z. Jahanshiri, A. Noori-Daloi, S. H. Ghaffari;

Tehran Univ. of Medical Sciences, Tehran, Islamic Republic of Iran.

The purpose of the current study is to evaluate the effect of silibinin on human hepatocellular carcinoma HepG-2 cells. MTT assay, LDH release, Gelatin zymography, Griess reaction, Cell-based ERK 1/2 phosphorylation assay and quantitative real-time RT-PCR were employed to appraise the effect of silibinin on cell proliferation, cytotoxicity, metastatic potential, nitric oxide (NO) production, ERK 1/2 phosphorylation and activation in HepG-2 cells. Silibinin inhibited cell proliferation, matrix metalloproteinase 2 enzymatic activity, NO production and ERK 1/2 phosphorylation in a dose-dependent manner without exerting any cytotoxicity effect. In addition, an expressive increase in mRNA levels of Raf kinase inhibitor protein (RKIP), sprouty-related protein 1 with EVH-1 domain (Spred-1), sprouty-related protein with EVH-1 domain 2 (Spred-2) and tissue inhibitor of matrix metalloproteinase 2 (TIMP-2) coupled with a significant reduction in transcriptional levels of highly expressed in cancer (Hec1) and MMP-2 were observed. Altogether, these issues show for the first time that silibinin treatment could inhibit cell proliferation and invasive potential of HepG-2 cells through inhibition of ERK 1/2 cascade both directly (through suppression of ERK 1/2 phosphorylation) and indirectly (through up-regulation of RKIP, Spred-1 and Spred-2). In addition, cell growth and proliferation may be inhibited by silibinin through down-regulation of Hec1.

P10.15

Evaluation of transient transfection methods in Hu11 hybrid cells

A. Asgharian¹, J. Ghahesouran², Z. Deilami Khiabani¹, H. Najmabad², M. Banar²;

¹Cell and molecular biology, Islamic Azad University, Tehran, Islamic Republic of Iran, ²Genetics Research Center, University of Social Welfare & Rehabilitation Sciences, Tehran, Islamic Republic of Iran.

One important step in expression of exogenous genes in cells is transfection. The Hu11 cell line is a mouse erythroleukemia (MEL) cell line containing the human chromosome 11 (and thus the β -locus). Hu11 cells express the human globin genes and thus should be useful for studying the basis of globin gene regulation. In this study, we tested several transient transfection methods in Hu11 hybrid cells. The PSV- β -Galactosidase vector was used as a control to monitor transfection efficiency. We tested commercially available reagents such as lipofectamin™ 2000 (Invitrogen), FuGENE® HD transfection Reagent (Roche), X-tremeGENE siRNA transfection Reagent (Roche), HiPerfect Transfection Reagent (Qiagen) and DEAE-Dextran (Sigma). Also Hu11 cells were electroporated under different conditions. We have shown that different cationic lipid transfection reagents do not provide a reliable and effective method of transfecting Hu11 cells. Also electroporation did not work well for this cell line. Therefore we suggest that the best method for efficient transfection of Hu11 cells can be accomplished via a viral vector-based transfection procedure.

P10.16

Characteristics of patients with Hunter syndrome in Spain and Portugal compared with those in the rest of the world: analysis of data from HOS - the Hunter Outcome Survey

G. Pintos-Morell¹, E. Leão Teles², M. del Toro Riera³, M. Beck⁴, R. Giugliani⁵, R. Martin⁶, J. Muenzer⁷, E. Wraith⁸;

¹University Hospital 'Germans Trias i Pujol', Badalona, Spain, ²Sao Joao Hospital, Porto, Portugal, ³Hospital Vall d'Hebron, Barcelona, Spain, ⁴University of Mainz, Mainz, Germany, ⁵Medical Genetics Service, HCPA/UFRRGS, Porto Alegre, Brazil, ⁶Saint Louis University, St Louis, MO, United States, ⁷University of North Carolina, Chapel Hill, NC, United States, ⁸Royal Manchester Children's Hospital, Manchester, United Kingdom.

Aims: To compare the characteristics of patients with Hunter syndrome (mucopolysaccharidosis type II) in Spain and Portugal with patients in the rest of the world (ROW).

Methods: Analysis of data from HOS - the Hunter Outcome Survey - was conducted in January 2008. HOS is a global outcome survey established to assess the natural history of Hunter syndrome and the safety and effectiveness of enzyme replacement therapy with idursulfase (Elaprase®; Shire HGT, Danderyd, Sweden). As of January 2008, there were 367 'prospective' patients included in HOS, 33 of whom were from Spain and Portugal.

Results: Mean age (\pm SD) at onset of symptoms in patients from Spain/Portugal was 1.7 \pm 1.1 years and from the ROW 2.1 \pm 1.8 years. Delay in diagnosis after symptom onset in Spain/Portugal was markedly less than that for the ROW (1.1 \pm 1.4 vs 2.2 \pm 2.9, respectively). The occurrence of any neurological signs/symptoms was similar (84%) in patients from Spain/Portugal and the ROW. Respiratory symptoms were reported in 75% of patients in Spain/Portugal and in 84% of patients from the ROW. Cardiovascular signs/symptoms were reported in 69% and 85% of patients from Spain/Portugal and the ROW, respectively. Characteristic facial features were the most commonly reported manifestation of Hunter syndrome, occurring in over 90% of patients in Spain/Portugal and the ROW.

Conclusions: This analysis of HOS data indicates no substantial difference between patients with Hunter syndrome in Spain/Portugal and the ROW. However, it highlights the delay between the occurrence of signs/symptoms and diagnosis, and the need for increased awareness of this rare disease.

P10.17

Optimization of transient transfection of K562 in order to siRNA transfection

A. Asgharian¹, J. Ghahesouran², Z. Deilami Khiabani¹, H. Najmabad², M. Banar²;

¹Cell and molecular biology, Islamic Azad University, Tehran, Islamic Republic of Iran, ²Genetics Research Center, University of Social Welfare & Rehabilitation

Sciences, Tehran, Islamic Republic of Iran.

The K562 cell line is an erythroleukemia cell line that is widely used for studies of globin gene regulation. In this study, we have tested several transient transfection methods in K562 cells. The PSV- β -Galactosidase vector was used as a control to monitor transfection efficiency. We tested commercially available reagents such as Lipofectamin™ 2000 (Invitrogen), FuGENE® HD transfection Reagent (Roche), X-tremeGENE siRNA transfection Reagent (Roche), HiPerfect Transfection Reagent (Qiagen) and DEAE-Dextran (Sigma). Also K562 cells were electroporated under different conditions. Our Result demonstrated that Lipofectamin™ 2000 provide a reliable, effective and reproducible method for transfecting K562 cells. We have also used Lipofectamin™ 2000 to successfully transfect positive and negative control siRNAs into K562 cells. We are now in the process of using this system to study the effect of siRNAs against potential γ -globin repressors (in the hope of inducing the γ -globin gene).

P10.18

Loeys-Dietz syndrome: *In-vitro* restoration of fibrillin and elastin production after treatment with losartan and dexamethasone

C. P. Barnett, A. Hinek, T. J. Bradley, D. Chitayat;
Hospital for Sick Children, Toronto, ON, Canada.

A 2-year-old boy born to non-consanguineous parents was seen by us following his fourth inguinal hernia repair. He was noted to have facial dysmorphism including brachycephaly, high forehead, hypoplastic supraorbital ridges and malar areas, proptosis with ptosis, posteriorly rotated ears, high arched palate with a normal uvula, arachnodactyly and camptodactyly. Echocardiography demonstrated a dilated aortic root and tortuous aortic arch and branches. X-rays revealed craniocervical instability, craniosynostosis and generalized osteopenia. Loeys-Dietz syndrome (LDS) was suspected clinically and DNA analysis of the *TGFBR1* gene revealed a missense mutation in codon 4 (c.722C>T) leading to substitution p.S241L. No mutations in the *TGFBR2* or *FBN1* genes were detected.

In vitro studies of skin fibroblasts derived from this patient indicated that they were significantly deficient in elastin and fibrillin gene expression (RT-PCR technique). Consistently, immunohistochemistry confirmed a lack of adequate production of elastin and fibrillin. Production of fibulins 1, 2 and 5, auxiliary components of elastic fibers shown to be important in normal elastogenesis, was not affected. Treatment of the cultured fibroblasts with losartan (angiotensin II receptor blocker) or dexamethasone restored normal production of elastic and fibrillin fibers. *In vitro* treatment of fibroblasts derived from other LDS patients is underway to assess the reproducibility of these findings and may provide more information on the potential for future clinical use.

Our findings further highlight the overall role of imbalanced signal transduction through TGF receptors that lead to impaired elastogenesis in LDS and similar diseases.

Towards a pharmacological therapy for Mandibuloacral Dysplasia syndrome

A. Vielle-Canonge¹, F. Gullotta², S. Salvator², P. Molinaro², F. Lombardi¹, S. Acci¹, M. D'Adamo³, P. Sbraccia³, A. M. Nardone², M. R. D'Apice¹, G. Lattanzi⁴, N. M. Maraldi⁴, G. Novelli^{1,5};

¹Departments of Biopathology and Diagnostic Imaging, Rome, Italy, ²Departments of medical genetics, A.O.U. Policlinico Tor Vergata, Rome, Italy, ³Department of Internal Medicine, University of Rome Tor Vergata, Rome, Italy, ⁴IGM-CNR, Unit of Bologna, c/o Istituti Ortopedici Rizzoli, Bologna, Italy, ⁵University of Arkansas for Medical Sciences, Little Rock, AR, United States.

Recently, different groups have demonstrated that the farnesyl transferase inhibitors (FTIs) were able to reverse *in-vitro* and *in-vivo* some phenotypic manifestations of progeroid syndromes secondary to *LMNA* and/or *ZMPSTE24* mutations (Hutchinson-Gilford progeria syndrome and restrictive dermopathy). The rationale of this treatment is based on blockage of the toxic effect of the farnesylated forms of prelamin A which in turn is responsible of cellular morphology alterations and genomic instability. In order to verify if this treatment is reproducible also in the mandibuloacral dysplasia (MADA), we studied the cellular effects of FTIs treatment on primary fibroblasts cell lines after 72 hrs at different concentrations (10 - 500 nM) of the drug. We observed that this treatment induces in MADA's cells, an increase of abnormal nuclei in a dose-manner dependent effect. On the basis of these results, we

decided to test the effect of two different drugs (bisphosphonates and statins) known to act on the same biochemical pathway at different levels. We treated MAD fibroblasts in a two steps model (24 hrs statins treatment and then 12hrs bisphosphonate in a single dose). This treatment, showed an improvement of the cellular phenotype (reduction of the number of misshapen nuclei and a partial rescue of the heterochromatin organization). Singularly, these drugs were ineffective. All together these results, suggest that FTI treatment is ineffectiveness versus MADA patients, while inhibitors of prenylation pathways could be considered as potential.

This work was supported by the AIFA (Italy) and EURO-Laminopathies (Contract LSHM-CT-2005-018690).

P10.20

A tendency in the treatment of mitochondrial complex I deficiency

B. Radeva¹, M. Stancheva¹, E. Naumova²;

¹University Children Hospital, Sofia, Bulgaria, ²Central laboratory of Clinical Immunology, UMBAL "Alexandrovska", Sofia, Bulgaria.

The treatment of the mitochondrial disorders is difficult and not well known. With an integral clinical-laboratory method we were diagnosed 5 children with mitochondrial complex I deficiency: 2 patients with mutation of ND5 gene and 3 - with ND3, ND2, ND1. Their mutations were confirmed by PCR SBT method of mitochondrial regions in peripheral intravenous blood. The clinical symptoms were various. The child with ND5 mutation - T 12880 C (with aminoacid change phenylalanine with leucine) had hemiparesis, weakness, muscle hypotonia, decreased sensitivity, the other boy (synonym basal changes), T 11311 C and polymorphisms - convulsions, ophthalmoplegia, ataxia, decreased hearing and vision, weakness and fatiguit. The patient with ND3 mutation had the same symptoms, but more severe: atrophy of n. opticus, deafness due to neuritis nervi acustici and severe ataxia. The child with ND2 mutation C 5472 G and multiple polymorphisms had muscle hypotonia, hyporeflexia, myoclonic convulsions. After treatment with high doses vitamins B1, B2, B6, B12, Q10, L-carnitine the general condition and neurologic status improved. The children with ND5 mutation recovered at all, as the patients with ND 3 and other mutations who showed an improval too. The treatment of the children proceeds.

P10.21

Indicating FTA Elute: for the collection, processing, and elution of DNA from biologically clear samples for use in downstream amplification technologies

J. Dinan¹, S. Judice², N. Nelson³, L. Battalagine², M. Green¹, B. Moran⁴, M. Harvey², B. Parker³;

¹Whatman International, Maidstone, Kent, United Kingdom, ²Whatman Inc, sanford, ME, United States, ³Whatman Inc, Sanford, ME, United States, ⁴Whatman Inc, New Jersey, NJ, United States.

Collecting samples using an oral swab and Indicating FTA Elute is a non-invasive procedure that can be carried out easily and safely by the layperson, thus providing an ideal format for collecting human genetic material from virtually anywhere in the world.

To visualize sample collection and placement, Indicating FTA Elute has been developed for use with clear biological samples by the incorporation of a colour indicating dye that distinguishes the clear sample once it is applied to the matrix. It is functionally equivalent to traditional FTA Elute in that it protects DNA samples from degradation and provides a source of amplifiable DNA which is eluted from its matrix with a simple heat and water elution step. We ran a number of tests on various biological samples to show that DNA eluted from Indicating FTA Elute is functionally identical to that eluted from traditional FTA Elute. The aim was to demonstrate that Indicating FTA Elute provides a template for amplification dependent assays such as STR and allelic discrimination analysis but greatly simplified and optimized sample extraction from the matrix.

In summary, Indicating FTA Elute in combination with an oral swab represents a revolutionary, non-invasive method for simplified genetic sample collection, sample transport in the mail, simplified DNA extraction requiring nothing more than water and heat, plus the added benefit of storing the samples at room temperature for literally years if this is a requirement. Indicating FTA Elute is therefore perfectly positioned to support the emerging discipline of pharmacogenomics or personalized medicine.

P10.22**Oxidative stress in nonsyndromic sensorineural hearing loss**H. T. El-Bassyouni¹, A. M. Ashour¹, M. Afiif², A. Ezzat¹;¹National Research Center, Guiza, Egypt, ²Hearing and speech Institute, Guiza, Egypt.

Introduction: Ototoxicity seems to result from the inhibition of cochlear antioxidant defenses, causing an increase in the amount of reactive oxygen species. These findings suggest a causal relationship between the formation of reactive oxygen species, oxidative stress and functional/morphological ear damage.

Aim: to shed more light on the link between oxidative stress and non-syndromic sensorineural hearing loss.

Methods: auditory function was monitored along with plasma concentrations of copper, zinc, calcium, phosphorus, magnesium and iron. Further more, lipid peroxidation, β carotene, vitamin A, E and C activities and immunoglobulin G, M and A levels were estimated.

Results: Significant decrease in calcium, phosphorus, β carotene, and vitamin E activities were found, as well as low levels of immunoglobulin G and M. Increase in lipid peroxidation was observed indicating oxidative stress which suggests a putative role of antioxidants in the pathogenesis of sensorineural hearing loss.

Conclusion: The results support the hypothesis that dietary and immune factors influence individual susceptibility to hearing loss. Further studies are needed to verify whether antioxidants, correction of deficient nutrients and/or immune modulation would improve sensorineural hearing loss.

P10.23**Role of amniotic fluid mesenchymal stem cells in gene and cell therapy**F. Boldà¹, A. Bos², R. Baffell², G. Porta³, W. Quasim⁴, B. Gaspar⁴, F. Porta², A. Lanfranchi²;

¹Stem Cell Lab, Oncohaematology and BMT Units, Ospedale dei Bambini, brescia, Italy, ²Stem Cell Lab, Oncohaematology and BMT Units, Ospedale dei Bambini, Brescia, Italy, ³Università dell'Insubria, Varese, Italy, ⁴Department of Clinical Immunology, Great Ormond Street Hospital NHS Trust, London, United Kingdom.

Mesenchymal stem cells (MSCs) are multipotent cells capable of differentiating into diverse lineages: osteocytes, chondrocytes, adipocytes, neuronal cells and cardiomyocytes. MSCs were initially identified in adult bone marrow (BM), but cells resembling BM-MSCs have also been found in many other tissues: adult and foetal peripheral blood, foetal liver, foetal spleen, placenta, umbilical cord, amniotic membrane and synovial fluid.

Human amniotic fluid (HAF) obtained during the process of amniocentesis is a valid source of MSCs and they could be a valid vehicles for gene therapy.

The aim of this study was to isolate MSCs from amniotic fluid and to test their transduction efficiency.

HAF specimens were obtained between 15 and 18 weeks' gestation by amniocentesis, previous written consent.

Amniotic-fluid MSCs (AFMSCs) were cultured under specific conditions for 7 weeks and analysed by flow cytometry and quantitative real time PCR to assess the presence and the expression levels of specific markers. Mesenchymal markers (CD73, CD106, CD54, CD90, CD29, CD44, CD105) present a peak of expression between 3rd and 4th week of culture.

To assess the transducibility of AFMSC we used a SIN HIV-1-based lentiviral vector. This vector encloses SFFV-U3 promoter and eGFP. It also encodes a mutant WPRE and cPPT.

Transduction efficiency was 60%. We demonstrate with the immunocytochemistry and molecular techniques the presence of human multipotent MSCs in the second-trimester amniotic fluid. We suggest that AFMSCs may be good target for prenatal gene therapy. The model under investigation is severe combined immunodeficiency (SCID) due to adenosine deaminase deficiency (ADA).

P10.24**BNP is a transcriptional target of the short stature homeobox gene SHOX**A. Marchini¹, B. Häcker¹, T. Martila¹, V. Hesse², J. Emons³, B. Weiß¹, M. Karperien³, G. A. Rappold¹;¹Institute of Human Genetics, Heidelberg, Germany, ²Dept. of Pediat-rics, Sana Klinikum Lichtenberg, Berlin, Germany, ³Dept. of Pediatrics & Endocrinol.&Metab. Diseases, Leiden Univ. Med. Center, Leiden, The Netherlands.

Short stature due to SHOX deficiency represents a common congenital form of growth failure and is involved in the etiology of "idiopathic" short stature and the growth deficits and skeletal anomalies in Léri-Weill, Langer and Turner syndrome. While much is known on the clinical and molecular aspects of SHOX haploinsufficiency, the integration of SHOX in the signalling pathways regulating bone growth is currently not defined. Here we identify *NPPB* encoding the natriuretic peptide BNP, a well known approved cardiac and natriuretic peptide hormone (drug), as a transcriptional target of SHOX. The ability of SHOX to transactivate the *NPPB* endogenous promoter was demonstrated in luciferase reporter assays using serial deletions of the *NPPB* promoter region. Binding of SHOX to the *NPPB* promoter was also demonstrated *in vivo* by chromatin fixation and immunoprecipitation. We also demonstrate the lack of promoter activation in two SHOX mutants from patients with Léri-Weill syndrome. In addition, immunohistochemical analysis of human growth plate sections showed for the first time a co-expression of BNP and SHOX in late proliferative and hypertrophic chondrocytes. Together these data strongly suggest that BNP represents a direct target of SHOX.

One may speculate that BNP as a downstream effector of SHOX may also open up new potential avenues for the treatment of short stature. BNP in the systemic circulation is likely to reach growth plate chondrocytes. It may either directly influence NPR-B signaling or indirectly increase local CNP levels by saturating the competing receptor NPR-C.

P10.25**Designing and constructing a new package for further suicide gene therapy**S. Hajizadeh-Sikaroodi¹, S. Zeinali², A. Kayhan³, M. Jafarpour², L. Teimoori-Toolab²;¹Research and Science Azad University, Tehran, Islamic Republic of Iran,²Department of molecular medicine, Pasteur Institute of Iran, Tehran, IslamicRepublic of Iran, ³Department of Hepatitis and AIDS, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran.

A commonly used strategy for gene therapy of solid tumors is suicide gene therapy. In order to decrease the side-effects of suicide gene therapy it would be better to express the suicide genes selectively in cancerous tissues. Using cancer specific promoters is the most applicable strategy to reach this aim. CD (Cytosine Deaminase) and TK (Thymidine Kinase) are used as suicide genes, but a suitable vector is needed for inserting any promoters upstream of them.

Firstly, the new MCS was designed by studying the sequence of our own pUCLacZ (engineered pUC which can express LacZ in eukaryotic cells because of its BGH-polyA downstream of LacZ). Two partial complementary 37 base long oligonucleotides were designed.

Cytosine deaminase and thymidine kinase genes were amplified by PCR on *saccharomyces cerevisiae* and herpes simplex virus DNA, and then were inserted downstream of MCS instead of lacZ.

Insertion of the MCS bidirectionally into pUCLacZ was proved by PCR and digestion analysis. In fact we made six constructs which are capable of adopting suitable and specific promoters upstream of these two suicide genes and LacZ reporter gene.

pUC-RMCS-TK

pUC-RMCS-CD

pUC-FMCS-TK

pUC-FMCS-CD

pUC-LacZ-CD

pUC-LacZ-TK

These constructs are compatible plasmids for further tumor specific suicide gene therapy as the availability of suitable restriction sites in MCS enables us to clone any promoter directionally upstream of reporter and suicide genes. These reporter and suicide constructs can be used in gene therapy of any types of cancer by the potential of accepting any tumor specific promoter upstream of their genes.

P10.26**Treatment of SMA fibroblasts and lymphoblasts with drugs that increase SMN expression reveals no responders and no additive effects**

E. Also-Rallo, L. Alias, L. Caselles, S. Bernal, R. Martínez, C. Soler-Botija, P. Gallano, M. Baiget, E. F. Tizzano;
Hospital Sant Pau, Barcelona, Spain.

Spinal muscular atrophy (SMA) is a neuromuscular genetic disorder caused by mutations in the SMN1 gene. The homologous copy (SMN2) is always present in SMA patients. Exon 7 is spliced out of most SMN2 transcripts (delta7) whereas SMN1 gene transcripts contain mainly exon 7 (full-length). Recent advances in SMA treatment with pharmacologic agents have resulted in an increase in SMN mRNA and protein levels *in vitro*. We performed a systematic analysis of SMN expression in primary fibroblasts and lymphoblasts from 7 SMA patients with varying clinical severity and different SMN1 genotypes to determine expression differences in two accessible tissues (skin and blood). The basal expression of SMN mRNA full-length and delta7 in fibroblasts and lymphoblasts at 24 and 48 hours was performed by quantitative real time PCR. The ratio SMNFL/SMNΔ7 was significantly higher in control cells than in patients ($p < 0.001$). The FL/Δ7 ratios ranged between 0.8-1.53 in SMA fibroblasts whereas they were between 1.18-2.82 in lymphoblasts. Furthermore, we investigated the response of these cell lines to different drugs such as valproic acid, phenylbutyrate and hydroxyurea. We classified the samples according to the increase in SMN expression as responders or non responders (to one or more of the drugs). Moreover, the combination of two of the drugs showed no synergistic effect in the responder cases. Despite the similarity of the basal SMN expression in our cells, the results of treatments that increase SMN expression was very variable, suggesting individual response factors. Supported by FIS05-2416, CIBERER and Project GENOME.

P10.27**Oxidative stress damage as early event in the pathogenesis of X-Adrenoleukodystrophy: therapeutic implications**

A. Pujol^{1,2}, S. Fourcade^{3,2}, J. Lopez-Erauskín^{3,2}, J. Galino^{3,2}, C. Duval³, F. Villarroya^{4,5}, I. Ferrer^{6,7}, R. Pamplona⁸, M. Portero-Otín⁸;

¹Catalan Institution of Research and Advanced Studies (ICREA), Barcelona, Spain, ²CIBERER, ISCIII, Barcelona, Spain, ³Institut d'Investigació Biomèdica de Bellvitge (IDIBELL), L'Hospitalet de Llobregat-Barcelona, Spain, ⁴Bioquímica i Biologia Molecular, and Institut de Biomedicina IBUB, Universitat de Barcelona, Barcelona, Spain, ⁵CIBER Fisiopatologia de la Obesidad y Nutrición, ISCIII, Barcelona, Spain, ⁶Institut de Neuropatologia de Bellvitge, Universitat de Barcelona, L'Hospitalet de Llobregat-Barcelona, Spain, ⁷CIBERNED, ISCIII, Barcelona, Spain, ⁸Departament de Medicina Experimental, Universitat de Lleida-IRBLLEIDA, Lleida, Spain.

X-linked adrenoleukodystrophy (X-ALD) is a fatal neurodegenerative disorder, characterized by progressive cerebral demyelination (CCALD) or spinal cord neurodegeneration (adrenomyeloneuropathy, AMN), adrenal insufficiency and accumulation of very long-chain fatty acids (VLCFA) in tissues. The disease is caused by mutations in the ABCD1 gene, which encodes a peroxisomal transporter that plays

a role in the beta-oxidation of VLCFA into peroxisomes. The *Abcd1* knock-out mice develop a spinal cord disease that mimicks AMN in adult patients, with late onset at 20 months of age. The mechanisms underlying cerebral demyelination or axonal degeneration in spinal cord are unknown. Here, we present evidence by GC/MS that MDAL (malonaldehyde-lysine), a consequence of lipoxidative damage to proteins, accumulates in the spinal cord of *Abcd1* knockout mice as early as 3.5 months of age. At 12 months, *Abcd1*- mice accumulate additional proteins modified by oxidative damage arising from metal-catalyzed oxidation and glycooxidation/lipoxidation. While we show that VLCFA excess activate enzymatic antioxidant defences at the protein expression levels, both in neural tissue, in *ex-vivo* organotypic spinal cord slices from *Abcd1*- mice and in human ALD fibroblasts, we also demonstrate that the loss of *Abcd1* gene function hampers oxidative stress homeostasis. We find that the α -tocopherol analog Trolox is able to reverse oxidative lesions *in vitro*, thus providing therapeutic hope. These results pave the way for the identification of therapeutic targets that could reverse the deregulated response to oxidative stress in X-ALD.

P10.28**Recombinant lentiviral particles for gene therapy of β -thalassemia**

M. Bikhof Torbati¹, F. Jamshidi A.², H. Khanahmad², M. Karimipor², F. Maryami², A. Amanzadeh², M. Sadeghizadeh³, M. Shokrgoza², S. Zeinali²;

¹Islamic Azad University-Shahre Rey Branch and Science and Research Campus., Tehran, Islamic Republic of Iran, ²Pasteur Institute of Iran, Molecular Medicine Department, Tehran, Islamic Republic of Iran, ³Tarbiat Modarres University, Tehran, Islamic Republic of Iran.

β -thalassemia disease is caused by absence or reduction of β -globin chain synthesis. The β -globin gene is controlled by LCR. Gene therapy using homologous recombination is method of choice for replacing the defective beta-globin gene with the normal one. One of the effective therapeutic methods for this disease is gene therapy by lentiviral vectors.

The capacity of lentiviral vectors is approximately 9 kb. The transgene was designed as a 6 kb construct containing mini LCR and β -globin gene. HS2, HS3, HS4 segments (mini LCR) and β -globin gene with 5' and 3' UTR amplified from the genomic DNA from a normal individual by PCR. Each of segment was cloned into pTZ57R/T vector and then sub cloned in pBGGT vector. Finally this construct was subcloned into a lenti transfer vector and confirmed by restriction digestion and sequencing. Transfer vector and three packaging plasmids (P1p1, P1p2, P1p/VSVG) were cotransfected into 293T packaging cell line by the use of lipofectamine 2000. Presence of transgene was confirmed in the harvested viruses by RT PCR on extracted RNA from these recombinant lentiviruses and also by p24 ELISA test. The titer of lentiviral stock was determined in a HT1080, K562 cell lines and compared with COS-7 cell line. This titer, in HT1080 cell line, was higher than COS-7 and K562. The remained transduced COS-7 colonies were expanded and DNA was extracted. PCR was used to evaluate random integration of construct in the genome and compared with homologous recombination in this gene transfer technique.

Recall and interpretation in genetic counselling, after intake and non-informative DNA-test results in BRCA1/2: discrepancies, explanations and consequences

J. Vos¹, C. J. Van Asperen¹, J. C. Oosterwijk², E. B. Gomez Garcia³, F. H. Menko⁴, J. M. Collee⁵, A. M. Stiggelbout⁶, A. Tibben¹;

¹Leiden University Medical Center, Center of Human and Clinical Genetics, dep. of Clinical Genetics, Leiden, The Netherlands, ²University Hospital Groningen, dep. of clinical genetics, Groningen, The Netherlands, ³Maastricht University Medical Center, dep. of clinical genetics, Maastricht, The Netherlands, ⁴VU University Medical Center, dep. of clinical genetics, Amsterdam, The Netherlands, ⁵Erasmus Medical Center Rotterdam, dep. of clinical genetics, Rotterdam, The Netherlands, ⁶Leiden University Medical Center, dep. of Medical Decision Making, Leiden, The Netherlands.

Background The patients' subjective interpretation of genetic counselling may be as important as correct understanding.

Methods In study I, 166 cancer patients filled-in a questionnaire after intake for hereditary breast/ovarian cancer. To date, 31 of them received an inconclusive (no-mutation) DNA-test result and filled-in a second questionnaire. In study II, 24 cancer patients were interviewed 1-3 years after receiving an Unclassified Variant-result (i.e. variant-of-uncertain-clinical-significance).

Results In study I, although most counselees correctly recalled the communicated medium heredity and intermediate/high cancer risks, they interpreted this like pathogenic information. After inconclusive-results, counselees correctly recalled the counsellor communicating a non-informative DNA-result with unchanged cancer risks. However, heredity was recalled as low and interpreted as medium.

In study II, sixty-seven percent recalled having received a non-informative DNA-result, but 80% interpreted this as pathogenic.

In both studies, discrepancy between interpretation and recall were explained by previous interpretations, health history, genetic uncertainty, denial coping style, autonomy, self-acceptance, low need for certainty.

In both studies, interpretation explained changes in intended and actual cancer screening and surgery; in study I, recall explained some of these changes.

Discussion Counselees subjectively interpreted intake information and non-informative DNA-results as being more pathogenic than how they factually recalled counselling sessions.

Interpretation explained more than recall. Previous interpretations, health, and personality explained recall-interpretation discrepancies. The decrease in recalled/interpreted heredity after inconclusive results is probably due to correction of pathogenic interpretation at intake, and need for certainty. Counsellors and researchers should address discrepancies between the counselees' recall and interpretation of genetic information.

EPL1.2

Is enhanced information at genetic counselling necessary? A randomised study

A. Roshanaei¹, R. Rosenquist², K. Nordin¹;

¹Department of Public Health and Caring Sciences, Uppsala, Sweden, ²Department of Genetics and Pathology, Uppsala, Sweden.

Purpose: The aim of this randomized study was to explore the effect of receiving enhanced onco-genetic information on probands' knowledge, risk perception, distress and communicating information to at-risk relatives.

Patient and methods: A total of 148 subjects (134 female and 14 male) who attended genetic counselling at the onco-genetic clinic of Uppsala University Hospital, Sweden (2003-2006) were randomised to information (n=85) or control (n=78) groups. The intervention group received the videotaped session, a copy of medical records, pedigree and a pamphlet about basic genetic concepts. Additionally, they had contact with a specialist nurse for more discussion and further questions. The control group received the standard information and the video in association with last follow-up eight months later. The knowledge about hereditary cancer, levels of emotional distress and personal risk estimations were measured at the base line, two weeks and eight months later.

Results: The majority had a high level of knowledge about hereditary

cancer, although a significant improvement was observed in breast cancer group after counselling. The levels of anxiety and depression indicated a significant reduction at follow-ups. At two-weeks follow-up, the correct estimation of personal risk for developing hereditary cancer, compared to initial estimation pre-counselling, had changed from 47% to 90% in the intervention and from 45% to 85% in control group. The majority (86% in control and 95% in intervention group) intended to communicate the genetic information to their relatives.

Conclusion: Enhanced information did not improve the participants risk perception. However the intention of informing relatives was elevated.

EPL1.3

Determining the genetic status of women newly diagnosed with breast cancer prior to treatment decisions: An ethical challenge

E. A. Lobb^{1,2}, N. Hallowell³, K. Barlow-Stewart⁴, G. Suthers⁵;

¹Medical Psychology Research Unit, University of Sydney, Camperdown, Australia, ²WA Centre for Cancer & Palliative Care, Curtin University of Technology, Perth, Australia, ³Public Health Sciences, The University of Edinburgh, Edinburgh, United Kingdom, ⁴Centre for Genetics Education, Royal North Shore Hospital, St Leonards, Australia, ⁵Familial Cancer Unit, Department of Genetic Medicine, Children's Youth & Women's Health Service, Adelaide, Australia.

Background: Ethical issues raised in genetic consultations for common diseases, for example, confidentiality and the disclosure of genetic information from bioethical, legal and user perspectives have been documented. However, less is known about cancer genetics service providers' experience of ethical issues that arise in their practice. **Aims:** This study aimed to document the types of issues practitioners define as ethically contentious in their practice, with what frequency they occur, or how they attempt to resolve them. **Method:** We undertook semi-structured telephone interviews with 21 genetic counsellors and 13 clinicians. All interviews were tape-recorded, transcribed verbatim and a thematic analysis was undertaken. **Results:** BRCA1/2 mutation testing to tailor the management of newly diagnosed high risk women was identified as a future ethical challenge for cancer genetics services. Themes identified included balancing the ethical concept of "do no harm" with the rights of women to be fully informed prior to making treatment decisions; questioning the ability of a woman to fully comprehend the implications of a positive mutation test on herself and other family members and managing the increasing client load on limited clinic resources. The importance of involving genetic counsellors in the multi-disciplinary team was emphasised. Clinicians identified fewer barriers to fast tracking BRCA1/2 testing than did genetic counsellors. **Conclusion:** Further understanding of the barriers to the management of BRCA1/2 testing in newly diagnosed breast cancer patients is needed to guide future cancer genetics practice as clinical testing is likely to transform the direction, priorities and processes of cancer genetic services.

EPL1.4

Impact of using family history on motivation to prevent type 2 diabetes: an RCT

M. Pijl^{1,2}, D. R. M. Timmermans^{1,2}, L. Claassen^{1,2}, A. C. J. W. Janssens³, G. Nijpels^{1,4}, T. M. Marteau⁵, L. Henneman^{1,2};

¹Department of Public and Occupational Health, VU University Medical Center, Amsterdam, The Netherlands, ²EMGO-Institute, VU University Medical Center, Amsterdam, The Netherlands, ³Department of Public Health, Erasmus University Medical Center, Rotterdam, The Netherlands, ⁴Department of General Practice, VU University Medical Center, Amsterdam, The Netherlands, ⁵Psychology & Genetics Research group, King's College, London, United Kingdom.

Genetic susceptibility testing for many multifactorial diseases is not yet warranted. Family history is an important risk factor for many common chronic diseases that may be used as a surrogate marker for genetic susceptibility. The aim of this study was to assess the potential effectiveness of communicating familial risk of type 2 diabetes and emphasising preventive options, on intentions to change behaviour to reduce the risk.

Individuals with a positive family history of diabetes were randomised into two groups: risk information based on general risk factors and familial risk (n=54) (intervention group) or risk information based on general risk factors alone (n=54) (control group). The information was provided during a personal consultation. Intentions to change health behaviour, self-reported behaviours (healthy diet; physical activity), perceived causes and severity of diabetes, perceived controllability,

and perceived risk were assessed using questionnaires (at baseline, one-week, and three-months follow-up).

Compared with those receiving information based on general risk factors alone, those receiving information on familial risk perceived heredity to be a more important cause of diabetes ($p < 0.01$) and greater control over developing diabetes ($p = 0.001$). Although at one-week follow-up there were no differences in intentions to change behaviour between the two groups, at three-months follow-up the intervention group reported having eaten more healthily ($p = 0.01$).

Familial risk information given in a personal consultation did not result in fatalism. There was some evidence to suggest it increased healthy behaviour. More research is needed to confirm these findings in a larger sample, using objective measures of health-related behaviours.

EPL1.5

Illness risk representations and preventive behaviour in people diagnosed with Familial Hypercholesterolemia by DNA-testing

L. Claassen¹, L. Henneman¹, I. Kindt², T. M. Marteau³, D. R. M. Timmermans¹; ¹EMGO-Institute, Department of Public and Occupational Health, VU University Medical Center, Amsterdam, The Netherlands, ²Foundation for Tracing Hereditary Hypercholesterolemia (StOEH), Amsterdam, The Netherlands, ³Psychology & Genetics Research Group, King's College, London, United Kingdom.

The objective of the study was to explore illness risk representations and preventive behaviour of people diagnosed with Familial hypercholesterolemia by DNA-testing.

The study employed a cross-sectional design, using Leventhal's Common Sense Model of self-regulation of health and illness as a framework, and was carried out among people recently diagnosed with FH by DNA-testing. Illness risk representations and preventive behaviour of 81 participants were assessed by self-administered postal questionnaires.

A majority of participants (75%) perceived their risk of developing CVD as lower or equal to that of an average person their age. Although in general participants believed strongly in the efficacy of the recommended actions, medication was seen as being somewhat more effective than a healthy diet and physical activity in reducing the risk of CVD ($t(65) = 2.460, p = .017$). Of hypercholesterolemics, 88% reported using cholesterol-lowering drugs as prescribed, whereas only 50% of all participants reported following recommendations concerning diet and physical activity. 70% reported having one or more first-degree relatives with CVD. Participants with more affected family members had higher risk perceptions and were more likely to perceive CVD as a permanent condition, consider hereditary as a likely cause of CVD, and report following recommendations concerning diet and physical activity.

In conclusion: In general FH screened positives are optimistic about their risk of developing cardiovascular disease. Those with more first-degree family members affected with CVD are less optimistic about their risk and more likely to adopt a healthy diet or to be physically active.

EPL2.1

Genetic testing in asymptomatic minors: social and ethical issues

P. Borry, K. Dierckx;

Centre for Biomedical Ethics and Law, K.U.Leuven, Leuven, Belgium.

Background. Although various guidelines and position papers have discussed in the past the ethical aspects of genetic testing in asymptomatic minors, the European Society of Human Genetics had not endorsed any statement exclusively focused on this issue.

Objective. Within the project Eurogentest attention has been devoted to the provision of appropriate counselling to accompany genetic testing, the education of patients and professionals, and the ethical, legal and social issues surrounding testing. The focus of the ethics unit was oriented towards the study of the ethical issues related to genetic testing in minors.

Method. Firstly, research has been performed on the existing recommendations regarding predictive genetic testing in minors and carrier testing, with as main attention to identify areas of agreement and disagreement. Secondly, the medical-ethical and medical-legal literature regarding predictive genetic testing in minors, carrier testing, the position of minors and patient rights was studied. Thirdly, a systematic literature review has been realized to gather information regarding the

attitudes of different stakeholders (minors, healthcare professionals, parents and relatives of affected individuals) towards genetic testing in asymptomatic minors. Fourthly, the attitudes of European clinical geneticists were gathered with regard to genetic testing in asymptomatic minors.

Results. Based on this preparatory work a draft guideline and background paper were elaborated. These will be discussed with the Professional and Public Policy Committee of the European Society of Human Genetics. Afterwards, both documents will be sent out for public consultation.

EPL2.2

Public attitudes towards genetic testing for susceptibility to major depression

A. Wilde¹, B. Meiser¹, P. B. Mitchell¹, P. R. Schofield²;

¹University of New South Wales, Sydney, NSW, Australia, ²Prince of Wales Medical Research Institute, Sydney, NSW, Australia.

Introduction: Successful intervention in psychiatry based on genetic risk will depend on public understanding of and attitudes towards the complexity of risk prediction involving susceptibility genes and gene-environment interactions. This study aimed to qualitatively evaluate attitudes and beliefs regarding the psychosocial implications of genetic risk for major depression in an urbanised population.

Method: Participants (N=36) of focus groups discussed their understanding of the role of genes in psychiatric disorders and their beliefs and attitudes towards genetic testing for risk for major depression.

Results: More than half the participants reported personal or family history of psychiatric disorders. The majority (67%) of participants indicated interest in having a genetic test for susceptibility to major depression, if it was available. After discussion of perceived psychosocial implications, only 42% still favoured having the test. All participants still interested in genetic risk testing for major depression reported they would only do so through trusted medical professionals. Participants were unanimously against independent genetic testing via the internet.

Discussion: Having a family history of psychiatric disorders was a major reason for interest in having a genetic test to determine risk for depression, which participants reported would enable them to be better prepared. Psychosocial implications influencing change of attitude included privacy issues and fear of genetic discrimination by insurance companies and employers.

Conclusion: The study highlights the importance of public education about psychiatric genetics, potential risks and benefits of genetic testing and availability of appropriate support services in association with future genetic risk testing in psychiatry.

EPL2.3

Exploring Psychiatric Genetics through Interactive Drama

F. Ticehurst¹, B. Williams², L. Osborn³, P. Gibbins⁴, J. Davies⁴;

¹Wales Gene Park, Cardiff, United Kingdom, ²Genetic Interest Group, Cardiff, United Kingdom, ³Freelance Writer, Cardiff, United Kingdom, ⁴Gwent Theatre Company, Abergavenny, United Kingdom.

The Wales Gene Park recently collaborated with the Genetic Interest Group and Gwent Theatre to develop and produce an interactive theatre workshop exploring contemporary developments in human genetics for young people from schools and colleges across Wales. The collaboration combined expertise in scientific and social and ethical aspects of genetics, science communication and in developing drama techniques for education. The main aim of the project was to use an innovative and creative approach to engage young people and encourage understanding and appreciation of different aspects of a complex area of biomedical science and the associated social and ethical issues. The project was funded by a Wellcome Trust Public Engagement Society Award.

Working with a writer, the project team developed a challenging drama centred on a young man's experience of mental illness. The performance explored questions and issues related to genetics and mental health including those surrounding family relationships, expectations of 'normality' and social responsibility. The young people's participation was task driven and structured to facilitate an intellectually and emotionally stimulating learning experience, requiring them to take an investigatory and mediatory role in the drama. Additional educational resources for use in school extended the learning experience beyond

the activity itself.

This presentation draws on material produced by participants during the development of the project and subsequent performances to illustrate how aspects of the methodology used within the project sought to engage participants and to facilitate their appreciation complexity of the issues raised.

EPL2.4

Professional ambivalence: accounts of ethical practice in childhood genetic testing

M. A. Arribas-Ayllon, S. Sarangi, A. Clarke;
Cardiff University, Cardiff, United Kingdom.

Childhood genetic testing raises complex ethical and moral dilemmas for both families and professionals. In the family sphere, the role of communication is a key aspect in the transmission of 'genetic responsibility' between adults and children. In the professional sphere, genetic responsibility is an interactional accomplishment emerging from competing views over what constitutes the 'best interests' of the child. In the present paper we extend our previous research into parental accounts of childhood genetic testing and explore the ethical explanations/descriptions of professionals in research interviews. Interviews (n=20) were conducted with professional practitioners involved in the genetic diagnosis and management of children and their families. We first identify four inter-related themes - juxtaposition of parental rights vis-à-vis child's autonomy, elicitation of the child's autonomy, avoidance of parental responsibility and acknowledgement of uncertainty - and then, using Rhetorical Discourse Analysis, examine the range of devices through which ethical explanations are situationally illustrated: contrast, reported speech, constructed dialogue, character and event work. An important device for facilitating ethical explanations is the use of *extreme case scenarios* which reconstructs dilemmas as justifications of professional conduct. Our analysis of professional accounts suggests that ethical practice is not a simple matter of implementing principles but managing the practical consequences of interactions with parents and children. We conclude that more attention is needed to understand the way professional practitioners construct and share cases as useful illustrations of evidence-based ethical practice.

EPL3.1

Patients' attitudes to the use of preimplantation genetic diagnosis for inherited predispositions to bowel cancer

A. A. D. Melville, H. E. Musgrave, T. Clancy;

Medical Genetics Research Group and Regional Genetics Service, University of Manchester and CMMC NHS Trust, Manchester, United Kingdom.

Familial Adenomatous Polyposis (FAP) and Hereditary Non-Polyposis Colorectal Cancer (HNPCC) are dominantly inherited cancer predisposition syndromes which confer a significantly increased risk of bowel and other cancers. The Human Fertilisation and Embryology Authority (HFEA) have approved preimplantation genetic diagnosis (PGD) for FAP and HNPCC in the UK. Semi-structured telephone interviews were used to explore the views of 6 FAP and 8 HNPCC mutation carriers (6 men and 8 women) regarding the use of PGD for their condition and other scenarios. The general acceptability of the use of PGD depended on the perceived severity of the condition in question and views about the moral status of the embryo/foetus during development. While both patient groups perceived FAP or HNPCC to have a low impact on quality of life, approximately half of the participants accepted the use of PGD for their condition in principle. Fewer participants however, from both the FAP and HNPCC groups, would consider personally using PGD for their condition. The importance of individual choice around reproductive decision-making was a central theme although there were concerns about the expansion of PGD into non-medical trait selection. The main advantage of PGD was seen to be avoiding termination of pregnancy. Disadvantages identified included the emotional and financial costs of undergoing the procedure, and the relatively low chance of a successful pregnancy.

EPL3.2

Pre-implantation genetic diagnosis (PGD) and prenatal diagnosis (PND) for cancer predisposition syndromes: reported practices and attitudes of French professionals

C. M. Julian-Reynier^{1,2}, F. Chabal³, F. Nowak⁴, T. Frebourg⁵, D. Lemeny⁶, C. Noguès⁷, F. Puech⁸, F. Thepot⁹, D. Stoppa-Lyonnet¹⁰;

¹INSERM (UMR912), Marseille, France, ²Institut Paoli-Calmettes, Marseille, France, ³UMR912 INSERM, Marseille, France, ⁴Institut National du Cancer, Paris, France, ⁵University Hospital, Rouen, France, ⁶University Hospital, Clermont-Ferrand, France, ⁷Regional Cancer Centre, Saint-Cloud, France, ⁸University Hospital (Jeanne de Flandre Hospital), Lille, France, ⁹Agence de Biomédecine, Paris, France, ¹⁰Institut Curie, Paris, France.

PGD and terminations of pregnancy for foetal indications are registered in France but the spontaneous demand experienced by medical professionals in their practice is unknown.

Objectives : to describe the reported demand and acceptability of PGD/PND for cancer predisposition syndromes such as observed by cancer geneticists and prenatal diagnosis centres.

Methods: Mail/postal survey (self-administered questionnaires) among all French cancer geneticists (N=123) and multi-disciplinary prenatal diagnosis (MPD) teams (N=47) registered by the French regulatory biomedicine agency.

Results: Cancer geneticists (47 y.o., SD=8) and MPD team coordinators (55 y.o., SD=7) answered in 62% and 64% of the cases, respectively. Half the cancer geneticists reported a spontaneous demand from their consultees during the preceding year (50% for PGD, 59% for PND). The issue of PGD, had been raised for the same pathologies as for PND but less frequently. PND was discussed for Familial Adenomatous Polyposis (n=57), Retinoblastoma (n=45), NEM1 (n=34), Breast-Ovarian Cancer (n=20) and Li-Fraumeni syndrome (n=8). MPD teams only reported 6 requests for PGD (5 for FAP; 1 for BRCA1). When cancers are likely to occur during early childhood with high penetrance, high severity and no effective prevention/treatment, the acceptability of PGD/PND was very high (>80%). When cancers are likely to occur before 50 y.o. but never in childhood and that an effective non deleterious prevention/treatment is available, the acceptability of both interventions was low but much higher for PGD (40%) than for PND (<27%).

Conclusion: Spontaneous demand for PGD/PND for cancer predisposing syndromes is already an issue in France.

EPL3.3

Motivations for genetic testing among individuals at risk of hereditary breast-ovarian cancer (HBOC) and Lynch syndromes

D. Fortuny¹, N. Gadea¹, B. Graña², T. Ramón y Caja³, A. Torres⁴, J. Brune⁵, A. Velasco⁶, E. Darder⁶, J. Sànz⁷, C. López⁸, J. Balmaña¹;

¹Hospital Universitari Vall d'Hebrón, Barcelona, Spain, ²Medical oncology department ICO, Hospital Josep Trueta, Girona, Spain, ³Medical oncology department. Hospital de Sant Pau, Barcelona, Spain, ⁴Medical oncology department, Hospital Sant Joan, Reus, Spain, ⁵Medical oncology department ICO, Hospital Josep Trueta, Barcelona, Spain.

Background: Knowing the motivations for genetic testing may help address pre-test genetic counselling sessions more individually.

Methods: Individuals (n=292) undergoing genetic testing for HBOC and Lynch syndrome who had received genetic counselling were included in a prospective multicenter study (IMASS). Individuals completed a self-reported questionnaire about demographic and clinical information, psychological well-being and motivations about genetic testing. Chi-square test was used to compare clinical and demographic variables with the main motivation for genetic testing.

Results: Overall, 240 individuals (82%) were women, median age= 44y (18-88). One hundred and eighty-one (62%) had been diagnosed with cancer, 236 (81%) were at risk of HBOC, 189 (62%) had children, 154 were probands (65%), and 125 (43%) had the perception of being a mutation carrier. The three main reasons to undergo genetic testing were: to know if their children were at risk in 134 (46%), to know their cancer risk in 90 (31%), and to know if they need more screening practices in 40 (14%).

A greater proportion of individuals >30 y, and those affected by cancer, or having children, or probands reported that knowing if their children were at risk was the main reason to undergo genetic testing (p > 0.001 in all cases), while individuals <30y, and those non-affected by cancer, not having children, and relatives undergoing testing of a

mutation identified in the family reported knowing their own risk as the main reason ($p < 0.001$).

Conclusions: The main motivation reported by individuals undergoing genetic testing is to know if their children are at risk. Pre-test genetic counselling sessions need to address specific motivations and concerns reported by individuals being tested.

EPL3.4

Exploring the influence of the family social network on the psychological well-being of individuals undergoing genetic counseling and testing for Lynch syndrome

D. W. Hadley, S. Ashida, N. R. Kuhn, J. F. Jenkins, C. M. McBride, L. M. Koe-hly;

National Institutes of Health, Bethesda, MD, United States.

Facilitating family communication is an important component of genetic counseling. However, little is known about how the information obtained through the genetic counseling process is translated and communicated to family members. Furthermore, we do not know the effect of family conversations on the cognitive and social outcomes of other family members.

The current study focuses on families (240 persons representing 35 unrelated families) known to carry a mutation in a mismatch repair gene associated with Lynch syndrome. We investigated whether previous family experiences with genetic services and communication within the family network, are associated with a decline or increase in psychological distress or cancer worry. Dependent variables examined included distress, depressive symptoms, and cancer worries. Independent variables included 1) time (days) between provision of genetic test results to the proband and the provision of genetic counseling to family members at risk to inherit the mutation and; 2) the generation of the family member relative to the proband (older, same, or younger). Results indicate an increase in depressive symptoms ($p = .06$) and cancer worry ($p = .01$) with increasing time from the probands' notification. Family members in the same generation ($p < .01$) as the proband or previous generation ($p < .01$) experienced a significant increase in distress with increasing time from the probands' notification; however, those in younger generations experienced a significant decrease in distress ($p = .03$).

Gaining insight about social influence processes will provide critical information for developing innovative genetic and genomic-based education & counseling programs that target families.

EPL3.5

Genetic counselling and testing for melanoma risk in Australia: A prospective study of uptake and psychological implications

N. A. Kasparian^{1,2}, B. Meiser^{3,2}, P. N. Butow⁴, J. M. Simpson⁵, G. J. Mann⁶;

¹School of Women's and Children's Health, University of New South Wales, Kensington, Australia, ²Department of Medical Oncology, Prince of Wales Hospital, Randwick, Australia, ³Prince of Wales Clinical School, University of New South Wales, Kensington, Australia, ⁴Medical Psychology Research Unit, School of Psychology, University of Sydney, Sydney, Australia, ⁵School of Public Health, University of Sydney, Sydney, Australia, ⁶Westmead Institute for Cancer Research, University of Sydney at Westmead Millennium Institute, Westmead, Australia.

This prospective study is one of the first worldwide to examine uptake and implications of genetic testing for melanoma risk amongst individuals with a strong family history of melanoma. Families comprising three or more relatives with a confirmed melanoma diagnosis were ascertained via the Westmead Institute for Cancer Research/University of Sydney centre of the Genetic Epidemiology of Melanoma Study. Eligibility criteria included identification of a family-specific mutation in the *CDKN2A* gene via the research protocol, and no previous genetic testing for clinical purposes. A series of mailed, self-report questionnaires were used to collect data at: notification of genetic test availability (January 2005), and two weeks and 12 months after receipt of genetic test results (for 'test takers'), or 12 months after notification (for 'test decliners'). One-hundred twenty-one eligible individuals (48% male) returned baseline questionnaires (response rate of 72%). At baseline, mean psychological distress scores were relatively low. Factors associated with distress included: personal history of melanoma ($OR = 3.37$, $p = 0.03$), perceiving greater family-related consequences of melanoma ($OR = 2.52$, $p < 0.0001$), and displaying a tendency to monitor for risk-relevant information ($OR = 3.12$, $p = 0.01$). So far, 25 participants

have undergone genetic testing, with 75% of those who have received results identified as mutation carriers. At baseline, test takers reported significantly higher levels of distress compared to decliners ($Z = -2.27$, $p = 0.02$). Carriers reported significantly reduced depression scores two weeks after receipt of a positive result ($Z = -2.25$, $p = 0.02$). Distress was relatively uncommon in this familial melanoma cohort, even after receipt of positive genetic test results.

EPL4.1

Antenatal screening for fetal abnormality - ensuring informed choice for parents

H. Skirton¹, O. Barr², J. Frost³, T. Wells¹;

¹University of Plymouth, Taunton, United Kingdom, ²University of Ulster, Belfast, United Kingdom, ³University of Plymouth, Plymouth, United Kingdom.

Antenatal screening for fetal abnormalities is available in many European countries. Previous research has identified that parental choice regarding whether to accept screening is limited by lack of information and the attitude of health professionals that the screening is 'routine'. The aim of this study was to identify the ways in which prospective parents can be supported to make informed decisions about antenatal screening.

In Phase 1, focus groups were held in 5 UK regions with prospective parents (pregnant women and partners) and professionals offering screening. Transcribed data were analysed using a grounded theory approach. In Phase 2, the focus group data were used to develop questionnaires. These were completed by prospective parents and relevant health professionals. Data were analysed using descriptive statistics and cross tabulations.

Findings indicate that parents feel overloaded with information at the start of the pregnancy about a range of topics; this restricts the attention paid to the screening decision. Some midwives were anxious when parents declined screening, due to fear of litigation. Appropriate information is frequently unavailable to those whose first language is not English or who are illiterate. Experience of the personal lives of people with disabilities influenced parents and midwives in their attitudes to screening. Parents were keen to have additional resources in this area. Resources focussed on the lives of affected persons and a decision-making tool for parents may help to ensure informed choice in antenatal screening. This information needs to be available in a comprehensible form for all parents.

EPL4.2

The role of attitudinal ambivalence towards Down's syndrome in prenatal testing decisions

L. D. Bryant¹, J. M. Green², J. Hewison¹;

¹Leeds Institute of Health Sciences, University of Leeds, Leeds, United Kingdom, ²Department of Health Sciences, University of York, York, United Kingdom.

There is a growing consensus that decisions about prenatal testing should reflect the individual's attitudes and values: but what if the individual's attitudes are ambivalent? This study investigated the potential relationships between attitudinal ambivalence towards Down's syndrome and testing and termination decisions.

Data was collected from women attending an antenatal clinic in the UK. Using a questionnaire distributed at the booking appointment, attitudes towards using testing and termination for Down's syndrome were collected along with attitudes and attitudinal ambivalence towards Down's syndrome itself. Screening uptake was obtained from patient records. Overall, attitudes and attitudinal ambivalence towards Down's syndrome were not good predictors of screening behaviour and women with high levels of ambivalence were not less likely to use prenatal screening. However, women who were unsure about amniocentesis and termination were more likely to hold ambivalent attitudes towards Down's syndrome than were women who gave a definite yes/no response. In particular, a higher level of ambivalence about the effect of a child with Down's syndrome on parental quality of life predicted a 'don't know' response. Ambivalence correlated positively with higher levels of religiosity and was associated with a desire to make decisions in partnership with a significant other.

Psychological research shows that ambivalent individuals are more likely to be influenced by factors external to their own attitudes, such as the perceived opinions of others. The findings from this study suggest that holding ambivalent attitudes towards Down's syndrome may

have implications for the facilitation of 'autonomous' informed choice in the testing context.

EPL4.3

'Balance' is in the eye of the beholder: perceptions of balanced information to support informed choices via AnSWeR (Antenatal Screening Web Resource)

S. Ahmed, L. D. Bryant, J. Hewison;

University of Leeds, LEEDS, United Kingdom.

Objectives: AnSWeR (Antenatal Screening Web Resource), designed to support informed choices in prenatal testing, aims to provide balanced information about disability from the perspective of disabled people and their families. Following our independent evaluation of AnSWeR, this paper presents participants' evaluation of AnSWeR in terms of providing balanced information. Setting: U.K. Method: Eight focus groups with health professionals, participants from the general population, and parents with personal experience of the conditions. Questionnaires were completed by parents of newborns, people with spina-bifida or cystic fibrosis, and fifteen professionals with special expertise in this area. Findings: Information about experiences of living with the tested-for conditions and terminating affected pregnancies was considered important to support informed decisions. However, participants differed in their perceptions of whether the information about the tested-for conditions was balanced. For example, participants believed that photographs of people with the tested-for conditions introduced biases - both positive and negative. Within the context of supporting informed choice, participants also talked about the significance of providing information about women's experiences of terminating affected pregnancies. Conclusion: This study highlights the difficulty of designing 'balanced' information about tested-for conditions and a lack of methodology for doing so. We conclude that AnSWeR provides a counterbalance to other websites that focus on more medical aspects of disability. Its aim to provide 'balanced' information would be aided by increasing the number and range of case studies available on the website, for both family members and individuals living with the tested-for conditions, and women terminating affected pregnancies.

EPL4.4

Testing times, challenging choices; women, prenatal testing and genetic counselling

J. M. Hodgson¹, M. A. R. Sahhar^{1,2}, L. H. Gillam^{1,3}, S. A. Metcalfe^{1,3};

¹Murdoch Childrens Research Institute, Melbourne, Australia, ²Genetic Health Services Victoria, Melbourne, Australia, ³University of Melbourne, Melbourne, Australia.

Although prenatal testing is increasingly considered to be a 'routine' part of many women's pregnancy experience it is unclear how women experience this process or whether they are making informed decisions to participate. Genetic counselling exists to support women at this time but there is a dearth of research exploring either prenatal genetic counselling process or women's experiences. This research aimed to:-

- explore the experiences of women who received an increased result from a prenatal screening test, attended genetic counselling and made a decision about diagnostic prenatal testing
- examine, in detail, the process of prenatal genetic counselling

Women attending genetic counselling following an increased risk result from a screening test were invited to participate. Two data sets were obtained:-

1. 21 genetic counselling sessions were audiotaped, transcribed and analysed using content and discourse analysis (Data set 1)
 2. 15 semi-structured follow up interviews with women from Data set 1 were audiotaped, transcribed and analysed thematically (Data set 2)
- Rigorous qualitative research methodologies produced rich insights into counselling process and evocative accounts of women's experiences. Most women reported high levels of distress and decisional conflict and many women did not make an informed choice to participate in either screening or diagnostic testing. Research findings and theoretical literature are used to demonstrate that facilitating informed choices is an ethically appropriate model for prenatal genetic counselling practice. A contemporary model for practice, specifically addressing women's distress and actively encouraging clients to deliberate fully, is proposed and critiqued.

EPL4.5

„It's something I need to consider“: women's decisions about population carrier screening for fragile X syndrome

A. D. Archibald^{1,2}, A. M. Jaques¹, S. Wake³, S. A. Metcalfe^{1,2};

¹Murdoch Childrens Research Institute, Melbourne, Australia, ²University of Melbourne, Melbourne, Australia, ³Genetic Health Services Victoria, Melbourne, Australia.

Population carrier screening for fragile X syndrome (FXS) identifies carriers, and provides information for reproductive decision making. Few studies have explored women's decisions when offered carrier testing for FXS through a population screening program. This study is an in-depth exploration of factors that influenced women's choice regarding the carrier test.

In Victoria, Australia a pilot study was conducted offering carrier screening for FXS to women in a pre-conception setting. Women completed a questionnaire, were offered screening, and completed a second questionnaire one month later or after receiving their result. A selection of women then participated in follow-up interviews.

318 women participated in the study and 20% of women chose testing revealing one pre-mutation carrier and three grey zone results. 31 women were interviewed: 13 who chose to be tested, including three with positive results (two grey-zones, one pre-mutation); and 18 who chose not to be tested.

Factors that influenced test choice included: the woman's perception of the benefits of screening, her life stage and whether she had prior experience with health related issues. No women who were tested regretted their decision and it was clear that providing women with time aided the decision making process. Overall women were supportive of population carrier screening for FXS in a pre-conception setting.

This is the first attitudinal study to include women who declined screening as well as those who accepted. These results provide valuable insight into factors that influenced women's decisions regarding testing and will help inform future development of carrier screening programs.

EPL5.1

Verification of consumers' experiences and perceptions of genetic discrimination and its impact on utilisation of genetic testing

K. K. Barlow-Stewart¹, S. Taylor², S. Treloar³, M. Stranger^{4,5}, M. Otlowski^{4,5};

¹The Centre for Genetics Education, Sydney, Australia, ²Department of Social Work and Human Services, Central Queensland University, Rockhampton, Australia, ³Centre for Military and Veterans' Health, The University of Queensland, Brisbane, Australia, ⁴Centre for Law and Genetics, University of Tasmania, Hobart, Australia, ⁵School of Law, University of Tasmania, Hobart, Australia.

A major component of the Australian Genetic Discrimination Project 2002-5 was to undertake a systematic process of verification of consumer accounts of alleged genetic discrimination, defined as the differential treatment of an asymptomatic person on the basis of their real or assumed genotype or genetic characteristics. Asymptomatic individuals reporting incidents in a survey conducted through Australian clinical genetics services 1998-2003 were recruited for the subsequent verification process. Others were recruited through genetics support groups and referrals from clinical genetics professionals. Verification of alleged incidents of genetic discrimination was determined, with consent, through interview, document analysis and, where appropriate, direct contact with the third party involved. Reported incidents of negative treatment in life insurance, employment, and health service domains met criteria for verification in 27/99 instances. Verification was possible in 14 cases (7 breast and ovarian cancer; 3 HNPCC; 3 Huntington disease and one each of hereditary haemochromatosis and polycystic kidney disease). All involved life insurance products. Issues included fear of genetic discrimination that impacted upon uptake and access to genetic testing for relatives; overly broad exclusion clauses; inability to increase policy amount; denial of insurance; coercion to access genetic test results and lack of recognition of prophylactic and screening strategies in underwriting decisions. In the course of verification, the decision-making process underpinning the life insurance underwriting was elucidated and reversal of adverse decisions following challenges to the company or provision of expert clinical genetics advice was confirmed. Verification is a potentially fruitful but a complex and challenging process.

EPL5.2

The Multiplex Initiative: a study to determine who seeks free multiplex genetic susceptibility testing among a healthy population of American adults

C. M. McBride¹, S. Hensley-Alford², R. Reid³, E. Larson³, A. D. Baxevanis¹, L. C. Brody¹;

¹National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, United States, ²Henry Ford Health System, Detroit, MI, United States, ³Group Health Cooperative, Seattle, WA, United States.

Genetic tests designed to provide individuals estimates of their disease risk are now commercially available. In theory, this information can be used to guide risk reduction behaviors. Currently, little is known about who might avail themselves of such testing and how they would interpret their test results. To understand the impact of such testing, we developed a prototype genetic test including 15 polymorphisms associated with increased risk for eight common conditions. Healthy adults ages 24-40 receiving care at a large managed-care organization are offered testing via Web-based information modules (<http://multiplex.nih.gov>). Individuals opting for testing receive test results by mail, with telephone follow-up from a research educator; they are contacted three months after receiving test results for a final telephone survey. Our study design enables us to evaluate approaches that facilitate decision making about genetic tests, assess methods for communicating test results, and explore whether health system factors influence health outcomes. Baseline surveys have been completed on ~1600 individuals. For most, this is their first experience with clinical research. The majority of those completing the baseline survey are high school graduates, married, self-report being in excellent or good health, and are relatively familiar with their family's health history. So far, 472 individuals visited the Web site to consider testing; 272 have decided to undergo testing. Factors regarding reviewing information about testing on the Web and ultimate uptake of testing will be presented. Early results are already providing insight regarding how healthy individuals might respond to genetic susceptibility testing.

EPL5.3

Willingness for blood donation for genomic studies: a comparative study between scientists and the public

K. Muto¹, A. Naga², A. Tamakoshi³, I. Ishiyama², K. Kato⁴, Z. Yamagata²;

¹The University of Tokyo, Tokyo, Japan, ²Yamanashi University, Yamanashi, Japan, ³Aichi Medical University, Aichi, Japan, ⁴Kyoto University, Kyoto, Japan. Objectives: To compare attitudes between scientists and the public in Japan towards human genomic research and to seek new approaches for better science communication, we conducted questionnaire surveys and focused group interviews.

Methods: Self-reporting questionnaires were sent by post to 4,257 scientists regarding molecular biology and human genetics/genomics via two academic societies in Japan. They were asked about their value and risk cognition towards genome sciences, social norms for accountability and responsibility. We compared these results with the data we obtained from 2,171 citizens in 2005.

Results: A total of 1,494 completed our questionnaire (586 men and 157 women). The total response rate was 35.1%. Both groups support genome sciences very positively. The main difference was observed on willingness of blood donation for genomic research. 74.8 % of the scientist group responded that they were willing to donate for genomic research regarding healthcare, while 39.3% of the citizen group did. Regarding the conditions for donation, the scientist group responded that they would donate their blood when they could agree the research purpose and significance (87.3%). On the other hands, most of the citizen group responded that they would donate if researchers disclosed personal results (78.5%). From the FGI data to students, their understandings of "breach of personal information" and "disclosure of personal analyzed data" were obscure and were influenced by the media which criticized science. Discussion: We need to start discussions on the process of disclosure of personal analyzed data to each research participant for future human genomic research.

EPL5.4

Privatising susceptibility to disease: the need for regulation?

A. J. Clarke¹, I. Frayling², M. Arribas-Ayllon¹, S. Sarangi¹;

¹Cardiff University, Cardiff, United Kingdom, ²University Hospital of Wales, Cardiff, United Kingdom.

As genetic technologies continue to reach new areas of healthcare, there are concerns whether genetic services might be compromised by consumer-oriented practices, especially promoted via TV or the internet. The marketing of genetic testing as capable of shaping lifestyles through the forecasting of future health may promise consumers more than the science can deliver, emphasising the supposed 'benefits of knowing' while downplaying the potential hazards. From the professionals' point of view, the marketing of commercial genetic services may misrepresent the complexity and uncertainty of genetic risk, obscuring reality with the fog of marketing. To illustrate our point, we consider a recent reality-based TV programme, broadcast in the UK, that documented the experiences of four 'celebrities' who consented to testing in a private London-based practice. Our analysis of the programme's transcript will show how interactions with the clients departed from established protocols of professional practice in several ways: overestimating clinical validity, underestimating the clinical uncertainty and the possibility of problems from test results, and practicing inappropriately directive ('promotional') counselling. How should the genetics services community in Europe respond to such developments? Our findings emphasise the already well recognised need for the development of regulatory and legislative approaches to monitor and/or prevent such practices. We consider several strategies for establishing standards of professional practice. One important concern is to ensure that too heavy-handed an approach does not inhibit the appropriate development of genetic services offered in good faith by non-specialist health professionals.

EPL5.5

Gene patents and diagnostics: numbers don't count

N. Berthels^{1,2}, B. Verbeure¹, E. van Zimmeren¹, G. Van Overwalle¹, G. Matthijs²;

¹Centre for Intellectual Property Rights, KULeuven, Leuven, Belgium, ²Center for Human Genetics, KULeuven, Leuven, Belgium.

Gene patenting is allegedly abundant and hampering access to genetic testing. This was given proof when Myriad Genetics exerted its exclusive rights to BRCA1/2. The case highlighted problems of patenting and licensing of genes and methods for genetic diagnosis, and laboratories' ignorance to patents, infringement, and risk for being litigated. In practice, laboratories usually lack legal expertise to engage in patent analysis and licensing negotiations. Patent abundance could create 'patent thickets', e.g. when many patents owned by several patent owners relate to a single test, and complicate licensing.

We aim at elucidating the patent situation in genetic diagnostics. Detailed patent landscape analyses of triplet repeat expansion diseases - Fragile X, Huntington disease, spinocerebellar ataxia, Friedreich ataxia, myotonic dystrophy, Kennedy disease - show patents' validity in time and territory, scope of protection, and, where possible, licensing mode. Both in Europe and US, disease-specific patents are granted, and applications under examination. Moreover, the patent situation of these diseases is complicated by 'generic' patents relating to their shared etiology. Broad in scope, these patents could also be overlooked in disease-specific patent searches because of their non-disease-specific nature.

In Europe gene patenting seems less abundant than proclaimed, in contrast to the US where patent thickets, and overlapping patent scope, are observed. Gene patent families not always have a European equivalent, or the European patent has lapsed in most, or all, countries. Despite low gene patent numbers in Europe as observed in this study, caution should remain towards broad patents and potential restrictive licensing conditions.

EPL6.1

Psychosocial Impact of X-linked Carrier Status: Experiences of Female Adrenoleukodystrophy Carriers

J. Bowen¹, R. Mountford², L. Kerzin-Storarr³;

¹Sheffield Clinical Genetics Service, Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom, ²Department of Medical Genetics, Liverpool Women's NHS Foundation Trust, Liverpool, United Kingdom, ³Regional Genetic

Service and Medical Genetics Research Group, CMMC NHS Trust and University of Manchester, Manchester, United Kingdom.

We report the results of a qualitative study of the psychosocial impact of adrenoleukodystrophy (ALD) on female carriers. ALD is an X-linked metabolic disorder with extreme variability in phenotype, including the risk of symptoms in female heterozygotes. Carrier testing based on biochemical assay is unreliable, but accurate mutation based testing has been available in the UK since 1999.

Eighteen women with a confirmed ALD gene mutation were interviewed, and the transcripts analysed using the constant comparison method. The impact of the test result often correlated with the timing of the test, with less impact described by those who had requested testing in the mid teens, before reproduction, and more traumatic responses recalled by women who had testing at the same time as other emotional events, such as pregnancy. For the majority of women, carrier status had an ongoing impact, including feeling different and frequent intrusive thoughts. Women who had female relatives with symptoms, but were asymptomatic themselves, expressed anxiety about the risk of symptoms developing, against a perceived lack of medical understanding and treatment options.

These findings add to the broader literature on psychosocial impact of X-linked carrier status, and contribute new evidence that the implications for female carriers extend beyond reproduction. Genetic counselling should include discussion of the potential impact on self-image as well as living with the uncertainty of late onset manifestations in an increasing number of X-linked conditions where this is an issue.

EPL6.2

The marital relationship and psychological wellbeing in patients with Myotonic Dystrophy

R. Timman¹, A. Rotteveel¹, A. Wintzen¹, A. Tibben²;

¹Neurology, Leiden, The Netherlands, ²Human and Clinical Genetics, Leiden, The Netherlands.

Introduction: Myotonic dystrophy (MD) is characterised by progressive muscular weakness and myotonia. Other organs are involved as well, including the brain, implying, among others, mental slowness and lack of initiative, and causing problems in daily life both for patients and their spouses. Some couples seem to deal with these problems satisfactorily while others experience great trouble.

Objectives: to describe the relationship of severity of MD, marital satisfaction and psychological well-being in MD-patients and their partners.

Methods: 69 MD-couples were interviewed regarding the influence of MD on their marital relationship, and they filled out questionnaires on severity of MD, anxiety and depression (HADS), hopelessness (BHS), and general psychological health (GHQ-12).

Results: For patients, the need for help was associated with a worse view on the future, a worse general well-being, more anxiety and more depression. For their partners, a lack of initiative was associated with a worse general well-being and more anxiety. Marital satisfaction was associated with a better view on the future for patients, and a better general well being, less anxiety and less depression in partners. It is remarkable that no less than 40 % of the patients and, particularly, female partners had BHS scores suggestive of clinically relevant depression.

Conclusion: Severity of MD places a heavy burden on patients and, especially, on female partners. Marital satisfaction is a strong predictor of a better well-being, both for patients and partners, but more so for the latter.

EPL6.3

Living with NF1: The perspectives of young people

K. F. May¹, R. A. Collier², L. Kerzin-Storarr³;

¹West Midlands Regional Clinical Genetics Service, Birmingham, United Kingdom, ²Nottingham Regional Clinical Genetics Service, Nottingham, United Kingdom, ³North West Regional Genetics Service, Manchester, United Kingdom.

Neurofibromatosis type 1 (NF1) is a genetic condition of variable phenotype and progression, with several features (including learning difficulties and cosmetic effects) which may occur during childhood and adolescence. Previous psychosocial research on the effects on young people has largely been based on reports from parents or retrospective reports of affected adults on their childhoods.

This qualitative, exploratory study was conducted by two research-

ers and involved semi-structured interviews with fourteen adolescents (eight males and six females) aged 16-20 years. Analysis of the interview transcripts was performed using the constant comparative methodology.

Overall, both male and female participants reported that they had coped well with being affected by NF1, and although some identified that they felt 'isolated' or 'different' to others, this had usually not prevented them from 'getting on' with life. Some of the older participants felt they had learned to cope with NF1 better over time, although male participants frequently commented upon uncertainties regarding future progression.

The main areas of importance to both male and female participants were the challenges of talking to others about NF1, impact on education, developing friendships, relationships with parents, reproductive issues and concerns about the future. Cosmetic aspects of NF1 and employment concerns appeared more important to female participants.

While further studies are required to confirm and expand these initial findings, this study adds insight into the experiences and views of affected young people.

EPL6.4

Quality of life in hypertrophic cardiomyopathy mutation carriers

I. Christiaans¹, I. M. van Langen¹, E. Birnie², G. J. Bonse¹, A. A. M. Wilde³, E. M. A. Smets^{1,4};

¹Department of Clinical Genetics, Academic Medical Centre, Amsterdam, The Netherlands, ²Institute of Health Policy and Management, Erasmus Medical Centre, Rotterdam, The Netherlands, ³Department of Cardiology, Academic Medical Centre, Amsterdam, The Netherlands, ⁴Department of Medical Psychology, Academic Medical Centre, Amsterdam, The Netherlands.

Background: Hypertrophic cardiomyopathy (HCM) is a common autosomal dominant heart disease associated with heart failure and sudden cardiac death (SCD). Quality of life (QoL) was found to be impaired in symptomatic HCM patients but has never been assessed in mutation carriers, with or without manifest HCM.

Methods: From approached HCM mutation carriers, 89% (n=212) completed a questionnaire. QoL was assessed using the Short Form 36 Health Survey (SF-36) and the Hospital Anxiety and Depression Scale (HADS) and compared with reported QoL-data of HCM patients and the general Dutch population. Demographic, clinical and illness perception related variables were evaluated as predictors of QoL.

Results: HCM carriers' QoL did not differ from the Dutch population. Carriers with HCM had lower QoL scores than carriers without HCM, but higher scores than previously reported in HCM patients. Surprisingly, carriers without HCM scored significantly better than the general population on several QoL subscales. Best predictors of impaired physical QoL were: having symptoms ($\beta=5.4$, $p=0.001$) and stronger belief in serious consequences ($\beta=4.2$, $p<0.001$); predictors of impaired mental QoL were: stronger emotional reactions ($\beta=2.0$, $p=0.032$) and higher perceived risk of symptoms ($\beta=0.7$, $p=0.034$). Important predictors of anxiety were: female gender ($\beta=1.3$, $p=0.008$) and stronger emotional reactions ($\beta=1.2$, $p=0.002$). Stronger belief in serious consequences ($\beta=0.9$, $p=0.004$) and perceived risk of SCD ($\beta=0.3$, $p=0.002$) predicted depression.

Conclusions: HCM carriers' QoL is comparable to QoL reported in the Dutch population. Presence of manifest HCM influences QoL in carriers, but other variables, mainly illness perception related, are stronger predictors of QoL.

EPL6.5

Developing a cancer genetic-specific measure of coping

C. Phelps¹, P. Bennett², H. Jones¹, K. Brain¹, K. Hood³, A. Murray⁴;

¹Institute of Medical Genetics, School of Medicine, Cardiff University, Cardiff, United Kingdom, ²Nursing, Health and Social Care Research Centre; Cardiff University, Cardiff, United Kingdom, ³Centre for Health Sciences Research; Cardiff University, Cardiff, United Kingdom, ⁴Institute of Medical Genetics, University Hospital of Wales, Cardiff, Cardiff, United Kingdom.

Background Generic measures of coping fail to capture the process of undergoing a specific health process such as cancer genetic risk assessment. A coping matrix has been developed to provide greater specificity of measurement, by breaking the risk assessment process into a number of specific stressors, and identifying the coping efforts used in response to each stressor.

Methods The matrix measures 11 recognised stressors and 8 specific coping strategies for individuals undergoing cancer genetic risk assessment, identified through previous research. The matrix was piloted within a psychological questionnaire as part of a randomised trial of a coping intervention (CARIAD).

Findings Preliminary analyses revealed that 134 of the 139 respondents completed the matrix, with the current data reported from the first 50 participants. Of the three most frequently endorsed stressors, 60% of respondents were quite a bit/very worried about how family members would react if found to be at increased risk, and primarily made use of social support; 54% were quite a bit/very worried about how they would cope if found to be at increased risk and primarily coped through positive appraisal; and 48% were quite a bit/very worried about having to wait to find out their own risk and coped mainly through acceptance.

Discussion Participants reacted in different ways to different stressors, although emotion-focused strategies were the most common overall. The completion rates for the matrix and specificity of responses provided suggests this coping matrix may be an acceptable measurement tool. Further data collection and validation is ongoing.

EW1.1

Talking about disability in prenatal genetic counselling sessions: identifying tensions and developing strategies

J. M. Hodgson¹, J. Wei²;

¹Murdoch Childrens Research Institute, Melbourne, Australia, ²University of California, San Francisco, CA, United States.

To facilitate informed decision-making in prenatal genetic counselling it is essential that counselees and counsellors engage in a process that provides:

- relevant information concerning the nature of genetic conditions
- an opportunity for counselees to consider parenting a child with a disability

This workshop will provide an opportunity for participants to reflect on the sensitivities inherent in such discussions and participate in developing strategies for best practice in addressing these complex issues. Academic literature and an ethical analysis of the goals of prenatal genetic counselling will be presented to demonstrate that facilitation of informed decision-making is an ethically appropriate goal of prenatal genetic counselling. Data from an Australian research project and the results of an interactive workshop at the 2007 NSGC Convention will provide further evidence of the need for more effective communication about disability in prenatal genetic counselling and identify complexities and impediments involved in doing so. Preliminary suggestions for addressing these issues will be presented.

A small group format will then be used in which participants will discuss and reflect on their experiences of communicating about disability, identify specific tensions and concerns associated with such dialogue, and develop strategies to promote effective and ethically appropriate discourse between counselees and counsellors. Written outlines from the groups will be used to develop a preliminary summary and synthesis, with further participant discussion. It is anticipated that this workshop will provide valuable information that can be complemented by input from consumer groups and other stakeholders.

EW2.1

Assessing Quality of Counselling in the Context of Genetic Testing Workshop

H. Skirton¹, H. Kaariainen², E. Rantanen³, M. Hietala³, J. Sequeiros⁴, U. Kristoffersson⁵, L. Kerzin-Storara⁶, A. Tibben⁷, G. Evers-Keibooms⁸, A. Faucet⁹, A. Clarke¹⁰;

¹Faculty of Health and Social Work, University of Plymouth, Taunton, United Kingdom, ²National Public Health Institute, Helsinki, Finland, ³Department of Medical Genetics, University of Turku, Turku, Finland, ⁴IBMC, University of Porto, Porto, Portugal, ⁵Department of Clinical Genetics, University Hospital, Lund, Sweden, ⁶Regional Genetics Service & Medical Genetics Research Group, CMMC & University of Manchester, Manchester, United Kingdom, ⁷Centre for Human and Clinical Genetics, Leiden University Medical Centre, Leiden, The Netherlands, ⁸Centre for Human Genetics, University of Leuven, Leuven, Belgium, ⁹Emory University School of Medicine, Atlanta, GA, United States,

¹⁰Institute of Medical Genetics, Cardiff University, Cardiff, United Kingdom.

The EuroGentest network is a 5 year collaboration between many European experts, the aim of which is to harmonise and standardise genetic testing in Europe. In Unit 3, counselling issues have been the focus. Recommendations have been made about the need for certain types of genetic testing (e.g. prenatal, predictive) to be accompanied by appropriate genetic counselling, as well as psychosocial support in some instances, to safeguard those being tested. However, if genetic healthcare is to be evaluated or audited, appropriate standards and measurable outcomes need to be defined.

Assessing the outcomes of genetic counselling has long been a challenge to those in the field. Many outcomes (e.g. altered sense of control, peace of mind, ability to plan for the future) are difficult to measure. In addition, the structure of health services differs greatly across European countries. The Expert Group of Unit 3 has devised an assessment tool, setting standards and potential measurable outcomes for genetic counselling. The standards address aspects of the service including access to peer support and continuing professional education, supervision of junior staff, waiting times, physical clinical environment and communication with counselees. A set of measures that can be applied across different systems of healthcare has been drafted.

In this workshop, we will present work already undertaken, but the main aim will be to engender discussion and to use the feedback and ideas generated to further develop a set of assessment tools that will be applicable to genetic counselling services in the European context.

EW3.1

Workshop: Genetic Counseling and predictive testing: A dynamic perspective

A. Tibben^{1,2}, L. Hoffman³;

¹Leiden University Medical Centre, Leiden, The Netherlands, ²Erasmus Medical Centre Rotterdam, Rotterdam, The Netherlands, ³Department of Oncology, Faculty of Medicine, McGill University, Montreal, QC, Canada.

Genetic counseling aims to allow counselees to make informed decisions and act accordingly. In this workshop we wish to explore how genetic counseling and the procedure of predictive testing can benefit from both psychodynamic and family therapy theory and practice. First, psychodynamic theory and its application in genetic counseling will be clarified using four models: the developmental, object-relationship, the self-psychology and the drive model. Second the relevance of and application of structural family therapy theory will be described. Third, elaboration of two clinical cases will show the usefulness of these theories. Finally, we will explore the requirements of training and education, in both psychodynamic and structural family theory and practice, in genetic counseling. Participants are invited to bring their own cases.

EW4.1

Analysing the social dimensions of coping in families: a workshop on presenting the results in clinical practice

H. G. Van Spijker, T. Brouwer;

Medical Genetics University Medical Centre, 3508 CA Utrecht, The Netherlands.

Coping is commonly viewed as an individual stress response, but it has also a social dimension. How do people experience stress in social groups, like families? How do they engage together in actions to deal with a stressor, like a genetic disease? In clinical practice, obtaining a family history is an essential skill for genetic counsellors. It provides a basis for making a diagnosis, determining risk, and assessing the needs for patient education and psychosocial support. Valuable psychosocial information can be obtained in parallel with medical-genetic information. The family pedigree however does not show data on social interactions within the family, although 'the process [of gathering family data] frequently induces a thoughtful frame of mind that is both inward- and outward-looking regarding family members and family dynamics'. (Weil, Psychosocial genetic counseling, 2000).

In this workshop, we start with an introduction of a conceptual model on social dimensions of coping, illustrated by data from a family questionnaire we used in a study on coping strategies. Next, we present some tools by which the information about social interactions within a family visually and conceptually can be organized. These tools can be helpful in analysing the dynamics of a family: kin and nonkin relationships, communication patterns, social roles and messages. In this way

insight is gained into the processes within the nuclear and blended family and the history of the extended family. This insight can be useful in getting a process of change going in the way counselees cope with the genetic information.

EP01. Reproductive issues in genetics

EP01.01

How can prenatal genetic counseling be conducted in a country where abortion is not considered as women's right?

C. Tamura;

Ochanomizu University, Tokyo, Japan.

Abortion in Japan is primarily illegal with the exception of special reasons, such as maternal health threats, financial difficulties, etc. Fetal problems are not included in these exceptions. If women want abortion, they have to ask permission from doctors and partners. When prenatal diagnosis revealed fetal problems, doctors use a financial reason as an excuse to allow abortion. In this way, prenatal diagnosis and selective abortion is available. About one percent of all pregnant women undergo amniocentesis. Professional societies established guidelines for prenatal diagnosis, and state that it can be conducted only to test childhood-onset severe conditions. If women want prenatal diagnosis, doctors, often clinical geneticists, have to make ethically sound judgment, and will tell women whether or not they can undergo testing.

Although genetics societies have certified some non-MD genetic counselors recently, genetic counseling in Japan is supposed to be provided by clinical geneticists, as they have done for over thirty years. And, clinical geneticists are regarded as authorities who make ethical judgment on prenatal diagnosis and selective abortion. Thus, genetic counseling in Japan seems to be a place where clients need to make an inquiry to ask permission to undergo prenatal diagnosis, and geneticists sometimes try to convince women not to undergo testing, or sometimes give clients permission to do it.

Appropriate prenatal genetic counseling approach in Japan should be considered, but, it is difficult because those who are regarded as genetic counseling providers believe that their current practice is an appropriate way of genetic counseling in Japan.

Hadassah University Medical Center, Jerusalem, Israel.

The option of offering PGD for BRCA1/2 to carriers who are of reproductive age was recently discussed in the literature. This raises medical, psychological and ethical dilemmas. Our cancer-genetic counseling team started recently to discuss this option with young carriers. Six women, 4 of them carrying a mutation in BRCA1 and 2 in BRCA2, applied for further genetic and reproductive counseling in our PGD clinic. Four of these carriers were healthy but had at least one 1st degree relative with breast cancer (BC), and 2 were 4 years post BC diagnosis. All women needed IVF because of coexisting infertility. After counseling, 4 women declined the option (including the two BC survivors who eventually conceived naturally) and 2 underwent the PGD procedure. One of them conceived in her first treatment attempt. In this case, 8 embryos with 7 or more cells were biopsied. The blastomeres were analysed, using PCR for the BRCA2-6174delT mutation together with linked polymorphic microsatellites. Four embryos were conclusively diagnosed as BRCA2 wt, 2 of these were transferred, leading to a twin pregnancy. Because the woman would not have terminated a pregnancy in case of misdiagnosis, amniocentesis was not performed. Her request to confirm the PGD in her newborns after birth raises additional legal and ethical dilemma of testing minors for adult onset disease.

EP01.03

Hereditary breast/ovarian cancer predisposition and reproductive decision-making

L. Ormondroyd¹, C. Moynihan¹, R. Eeles², G. Evans³, S. Lavery⁴, M. Watson¹;

¹Psychology Research Group, Institute of Cancer Research/Royal Marsden NHS Foundation Trust, Sutton, United Kingdom, ²Translational Cancer Genet-

ics Team & Cancer Genetics Unit, Institute of Cancer Research/Royal Marsden NHS Foundation Trust, London/Sutton, United Kingdom, ³Medical Genetics Research Group and Regional Genetics Service, University of Manchester and Central Manchester and Manchester Children's University Hospitals NHS Trust, St. Mary's Hospital, Manchester, United Kingdom, ⁴IVF Hammersmith, Queen Charlotte's and Hammersmith Hospital, London, United Kingdom.

Purpose: Mutations in the *BRCA1* and *BRCA2* genes predispose individuals to breast, ovarian, prostate and other cancers, generally from the mid-third decade onwards. Penetrance is not complete, and options for substantial risk reduction are available. A subset of people cite reproductive decision-making as a motivation for undergoing predictive testing, but very little is known about how *BRCA* status impacts on these decisions. With the recent (2006) decision by the HFEA to grant licences for pre-implantation genetic diagnosis for late onset cancer predisposition, this ongoing study exploring reproductive behaviour and attitudes to prenatal testing and PGD is timely.

Method: A qualitative approach using semi-structured, in depth interviews, analysed using interpretative phenomenological analysis. We aim to recruit up to 40 women and men who have had a positive *BRCA1/2* predictive genetic test during the preceding 5 years, between the ages of 18 and 45, who did not have children at the time they were tested.

Results: Data will be presented from analysis of interviews completed to date. Preliminary analysis indicates that *BRCA* status does affect reproductive decision making in a variety of ways, including timing of having children and number of children planned. *BRCA* status is also taken into account in partner-relationship building. Prenatal testing, either pre- or post- implantation would not be considered by interviewees personally, although they would not object to use by other *BRCA* carriers.

EP01.04

Attitudes of young women with cystic fibrosis to pregnancy and motherhood

S. J. Kenwick¹, E. Chapman²;

¹Addenbrooke's Hospital, Cambridge, United Kingdom, ²Papworth Hospital, Cambridge, United Kingdom.

Over the past two decades, improvements in treatment have resulted in most patients with cystic fibrosis (CF) reaching adulthood. Consequently, more affected individuals are becoming parents. Pregnancy is not considered dangerous for women with mild disease and good lung function, but health and survival may be compromised by pancreatic insufficiency and poor lung function. Clearly, careful counselling is required to discuss the risks of having an affected child, health risks of pregnancy as well as how to cope with illness while raising a family. The purpose of this pilot study was to explore psychosocial issues concerning pregnancy and motherhood among young women with cystic fibrosis, in order to inform reproductive counselling. Semi-structured interviews were conducted for five women with CF, aged between 20 and 25, and transcripts subjected to qualitative, thematic analysis. Emergent themes highlight a wide variety of issues for these women centred around; desire for a family, health risks, relationships and communication with others, difficulties in motherhood and the prospect of a child with CF. The results show that young women with CF may have varying attitudes towards pregnancy and motherhood, depending in part on their current health, their upbringing, professional opinion and social support available. Participants with a strong desire to have children viewed this as a natural progression and described strategies to cope with potential health problems. The study also highlights a number of measures that may help in counselling these women, including access to the experience of mothers with CF.

EP01.05

Reproductive decision making in CF carrier couples; an explorative study in couples with an affected child

R. Jassi, W. H. Beckett, T. Roberts, M. McAllister, D. Scotcher;

Regional Genetics Service and Medical Genetics Research Group, CMMC NHS Trust and University of Manchester, Manchester, United Kingdom.

This study is part of wider qualitative research project exploring reproductive decision making in cystic fibrosis (CF) carrier couples. Here we describe the personal experience of 19 participants living with the condition because they had a child affected by CF. Men and women in each couple were interviewed separately by different researchers in

their own home.

It emerged from the analysis that different approaches were taken by participating parents before they reached a reproductive decision, and while several factors influenced this, the first diagnosis of CF in the family had a particularly significant influence. Parents in this study appeared to have undergone an adaptation process during which they overcame the initial shock of a CF diagnosis in their child, developed a more positive outlook based largely on their own experiences of CF, and then felt able to address further reproductive decisions. However, following adaptation, some differences between the sexes emerged. Women frequently acknowledged that the decisions remained fluid and dynamic, whereas men tended to portray a more rigid standpoint once a particular decision had been reached. Furthermore, men and women often felt that they had inherently different roles in reproductive decision making, with the ultimate decision resting with the woman. In most cases, couples felt that the decision was made together, without significant external influence.

EP01.06

Uptake of genetic counselling and prenatal diagnostic services for CF in Ireland

D. M. Lambert^{1,2}, M. Morgan¹, S. Lynch²;

¹Children's University Hospital, Dublin, Ireland, ²National Centre for Medical Genetics, Dublin, Ireland.

Cystic fibrosis (CF) is a common recessive condition in Ireland with 1 in 19 carriers and 1 in 1440 affected. From January 2004 to July 2007, 76 patients were sent appointments for genetic counseling for CF: 23 (30%) were routine referrals from the CF clinic for a new CF family; and 53 (70%) were GP referrals for positive family history.

For GP referrals the risk of being a CF carrier was: CF affected (3.7%), known carrier (20.7%), 2/3 risk (22.6%), 1/2 risk (41.5%), 1/4 risk (7.5%), population risk (1.9%). 66% had a partner while 34% wanted to discuss carrier status before finding a partner. Those at higher risk of being a carrier were more likely to wait until they had a partner before being referred. Five of 53 (9%) were found to be at a 1 in 4 risk of CF. Of 25 families with a child with CF, 21 of the 23 referred attended the genetics appointment. Of the 30 families at 1 in 4 risk of CF, 15 (50%) remained childless since. For 26 of 30 couples a molecular prenatal diagnosis was available, with 12 having a pregnancy and 5 (42%) a prenatal test. 4 indicated interest in pre-implantation genetic diagnosis (PGD). 6 families (20%) had members seen for cascade screening although the offer was made to all. The uptake for prenatal diagnosis and screening of family members is lower than other European countries, perhaps reflecting the illegality of termination and PGD in Ireland.

EP01.07

Reproductive decision making in CF carrier couples; an explorative study in couples without an affected child

J. Myring¹, R. Sayers², T. Roberts³, D. Scotcher³, M. McAllister^{4,3};

¹Clinical Genetics, NHS Tayside, Dundee, United Kingdom, ²Sheffield Clinical Genetics Service, Sheffield Children's NHS Foundation Trust, Sheffield, United Kingdom, ³Regional Genetics Service and Medical Genetics Research Group, CMMC NHS Trust and University of Manchester, Manchester, United Kingdom, ⁴Nowgen (A Centre for Genetic Healthcare), Manchester, United Kingdom.

We report on part of a larger research project which uses qualitative methodology to explore the reproductive decision making process in CF carrier couples. 5 males and 7 females from CF carrier couples without an affected child were interviewed individually in their home, to explore both male and female perspectives of the reproductive decision making process.

Data analysis revealed that while couples may consider different scenarios, the decision making process remains largely unstructured. Personal experiences of CF were an important factor: Individuals had to weigh up their perception of the physical difficulties of CF, the fact that CF is not an intellectually disabling condition, and their attachment to someone with CF. Individuals may not fully engage with their risk of having a child with CF during the decision making process, which may lead them to be unprepared for bad news.

Men and women may play different roles within the reproductive decision making process. Men appeared to take on a supportive role, tending to agree with their partner. Women felt that the decision was mutual and intuitive, possibly due to this support from their partner. Both partners felt that ultimately, the decision was primarily the woman's;

influenced by the physical attachment to pregnancy and possibly their role as primary carer.

CF carrier couples who have a healthy child in their first at-risk pregnancy may feel that they have "used up their luck", which may lead to a decision to limit family size.

EP01.08

Ancestry-based preconceptional CF and HbPs carrier screening in a multi-ethnic population: attitude and participation, psychological outcomes, reproductive intentions and satisfaction

P. Lakeman, A. M. C. Plass, L. Henneman, P. D. Bezemer, M. C. Cornel, L. P. ten Kate;

VU University Medical Center, Amsterdam, The Netherlands.

Objective: to investigate attitude and participation, psychological outcomes, reproductive intentions and satisfaction in ancestry-based preconceptional carrier screening for cystic fibrosis (CF) and hemoglobinopathies (HbPs).

Methods: 9,453 individuals were offered carrier-testing, which was conditional on survey-participation. Eligible for test-participation were invitees who were planning a pregnancy with their partner. Both partners' ancestry determined eligibility for the CF and/or HbP-test(s). Data were gathered with structured questionnaires, one of which was based on the Theory of Planned Behaviour, among 418 invitees of whom 247 refrained from testing and 171 intended to participate in the testing, but of whom 143 actually did. Non-Western participants (n= 46) were under-represented.

Results: All survey-participants, Western and non-Western, had a positive attitude towards test-participation. Among those who refrained from test-participation, 68% would participate in this kind of screening in the future if it became possible. Time and effort needed for participation were important declining factors. The majority reported no predominant feelings of stigmatization. More non-Western (23%) than Western participants (10%) thought that there would be discrimination against carriers. In general, the test-participants reported low levels of anxiety, intended to draw reproductive decisions from test-results, were satisfied and none of them regretted participation.

Conclusion: Ancestry-based preconceptional CF and HbPs carrier screening was evaluated as positive and desirable among Western and non-Western participants. No major adverse psychological outcomes were reported. The effort and time needed for participation was an important reason for declining participation, which might be overcome by facilitating access to the screening.

EP01.09

Recruiting for reproductive choices

S. Karner¹, B. Wieser¹, W. Berger²;

¹IFZ, Graz, Austria, ²IFF, Klagenfurt, Austria.

Prenatal testing has become a routine practice of antenatal care. According to international standards informed consent is a requirement prior to testing. However, due to the introduction of non-invasive screening (nuchal translucency measurement and the combined maternal blood test), this arrangement is undermined in some important ways. There is a tendency that counselling starts not before the first screening, but only if the results are conspicuous.

In Austria antenatal care is organised in a comprehensive programme that is mandatory for all pregnant women. The aim of this programme is to secure the wellbeing of both the mother and her child. We argue that because of the contextualisation of non-invasive screening into the routine antenatal care it is difficult for pregnant women to distinguish between mandatory and elective examinations of antenatal care. This is especially relevant for the quality of informed consent that can be achieved in prenatal screening and subsequent diagnostic testing of the foetus.

The presented case addresses recruiting processes for prenatal testing and subsequent reproductive choices. We will present data which show how non-invasive screening has significantly changed prenatal testing in Austria. From 2002 on there is a sharp increase in diagnosed cases per tested pregnant woman. The current abortion rate of Down's syndrome fetuses is about 94%. The remaining 6% include those who screened false-negative, decided against screening or testing, and those who decided not to terminate the pregnancy.

EP01.10**Association of CoL1A1 Gene alleles with the development of symphysis joints pathology in pregnant women in the Kazakh population****S. K. Kyzdarbaeva L.L.;***NCAGP, Almaty, Kazakhstan.*

Pregnancy has a negative influence on the skeleton and the development of osteoporosis. Patients with symptoms of symphysiolysis are seen in the symphysiopatias clinic.

Objective To investigate the distribution of TG polymorphisms in the CoLI A1 gene with development symphysis joints pathology of Kazakh population.

Subjects DNK 42 healthy pregnant females (the control group) and 30 pregnant with symphysopathias (patient group).

Results. The GG genotype was present in 64,2% of Healthy pregnant women and in 36,6%, of the patient group ($p < 0,05$). The TT genotype was 3 times more prevalent in controls than in patients (16,6 % and 4,7 % respectively). Prevalence of the T allele in the control group was 20,2 %, but it was only - 40,0 \pm 4,8 % in the patient group ($p < 0,05$).

Conclusion. This study demonstrated that the T- allele of the CoL1A1 gene may be a predictor of susceptibility for symphysiopatias.

EP01.11**The study of reproductive behavior in exposed populations****P. W. Izhevskij;***State Research Center - Institute of Biophysics, Moscow, Russian Federation.*

The aim of this research was the study of possible unfavorable influence the radiation factor on the populations by means:

- analysis of the radiation doses absorbed by population;
- determination of pre- and post-accidental rate of unfavorable pregnancy outcomes (UPO) in exposed populations.

The materials were collected in 226 populations of Belorussia and Russia. The given districts have different levels of ^{137}Cs surface contamination: up to $111 \cdot 10^4$ - to $148 \cdot 10^4 \text{ Bk/m}^2$. Doses accumulated since 1986 to 1992 was rated for a person who was continuously resident in studied populated areas.

The materials were collected retrospectively by interview by specially form. Women (2233) from a random sample, who were continuously resident, both 1208 of them lived in town and 1025 lived in the country. All the pregnancy outcomes of questioned women at reproductive age in the two temporary intervals: preaccidental (1980 - 85) and postaccidental (1986 - 92).

In the postaccidental period UPO rate reliably increased and the increase rate was much more in the united population. The data obtained don't allow us to isolate reliably the radiation-induced component in postaccidental reproductive behavior of the studied populations.

In populations which were exposed to ionizing radiation, in postaccidental period were noted the decrease of the live-birth rate and increase of the medical abortion's rate, that can be caused the stress situation and the decrease of standard of living.

EP02. Genetic risk and testing: impact on men**EP02.1****PSA Screening: A comparison of attitudes and behaviour in US and UK men with a family history of prostate cancer****M. Watson¹, R. McCurdy², J. Bloom³, C. Moynihan⁴, S. Stewart⁵;**

¹Royal Marsden Hospital, Sutton, United Kingdom, ²University of California Berkeley, San Francisco, CA, United States, ³University of California Berkeley, San Francisco, CA, United States, ⁴Institute of Cancer Research, Sutton, United Kingdom, ⁵University of California, San Francisco, CA, United States.

Purpose: This study compared PSA screening, attitudes and risk perceptions of US and UK men with a family history of prostate cancer.

Methods: 272 healthy white males [150 US/122 UK], aged 35 - 74 with a family history of prostate cancer. Multivariate logistic regression tested associations between screening behaviour and components of the health belief model, adjusted for socio-demographic and family history variables.

Results: College educated men and those with more cases of prostate cancer in the family were more likely to rate their prostate cancer risk as "greater than average". Having a family member with prostate can-

cer significantly affected PSA uptake [$p < .01$] and perceived benefits to PSA screening [$p < .01$]. Health anxiety was associated with prostate cancer worry and perceived risk [$p < .05$]. Men were more likely to have a PSA test if older, married, reporting perceived benefits to PSA screening, and rating personal risk as greater. US men were more likely to have a PSA test and reported higher perceived risk of prostate cancer and perceived benefit of testing. The cost of PSA testing was a barrier [$p < .05$](US only).

Conclusions: Findings support the view that family history is a determinant both of PSA uptake and perceptions of prostate cancer risk. This study found some differences between US and UK men. Variations are most likely associated with health system differences.

EP03. Genetic risk and testing: carriers of x-linked conditions**EP03.1****Cardiac screening in Becker and Duchenne Muscular Dystrophy carriers known to the North West Genetic Family Register in Manchester, UK****P. D. Greene, G. Hall, H. Kingston, L. Kerzin-Storarr;***Regional Genetics Service and Medical Genetics Research Group, CMMC NHS Trust and University of Manc, Manchester, United Kingdom.*

We report patient responses and cardiac outcomes of 122 Duchene and 43 Becker Muscular Dystrophy carriers (aged between 20-77years) who were offered cardiology screening as part of their annual register contact. The Becker (BMD) and Duchenne Muscular Dystrophy (DMD) Register was set up in 1980 to foster long term contact with families and to offer genetic counselling, carrier testing and discussions around reproduction for women in families with muscular dystrophy.

The evidence of cardiac complications in dystrophinopathy carriers has been widely reported resulting in guidelines for cardiology screening from the 107th ENMC (European Neuromuscular Centre) International Workshop. In the light of these we wrote to confirmed / obligate carrier women informing them of their cardiomyopathy risk. So far, 95 DMD and 33 BMD carriers have requested referral for cardiac screening, the majority of whom were happy to be referred directly and only a few described shock or anxiety upon receiving their letter.

Dystrophinopathy is one of several X-linked conditions in which symptoms amongst carrier women are increasingly recognised. We will explore the role and responsibility of genetic registers in re-contacting women about unforeseen complications and the acceptability of this from the patient's perspective.

Cardiac screening amongst this cohort showed a much lower incidence of clinical problems than had been anticipated from previous studies.

EP04. Genetic conditions: impact on significant others**EP04.1****Legacy for the living - A collaborative model of referral between state coroner's office and a clinical genetic service****R. M. Forbes¹, R. Savarirayan¹, M. Lynch², N. Morgan³;**

¹Genetic Health Services Victoria, Parkville, Victoria, Australia, ²Victorian Institute of Forensic Medicine, Southbank, Victoria, Australia, ³Victorian Institute of Forensic Medicine, Southbank, Victoria, Australia.

The Coronial Service Centre receives approximately 4000 reports of deaths each year. The majority of these reports are referred to the VIFM for autopsy to establish cause of death. During the course of a forensic investigation into the cause of death the pathologist may discover information of direct relevance to the health of first-degree family members. Traditionally exchange of information between forensic pathologist and families has been limited due to emphasis placed on the legal nature of the investigation.

We present a program that has been successfully established between the Family Liaison Coordinators at VIFM and GHSV. Families identified as being "at risk" of a genetic condition are given the opportunity to discuss findings of the autopsy. Implications for surviving family members is discussed and the availability of referral to GHSV, with family consent, is provided. Due to the complexity and specialised nature of the conditions, benefits of collaboration have been two-way

with resultant specialist care for the families.

An audit of conditions referred to GHSV, uptake by families, role of genetic counsellor at coronial and clinical service and outcomes over a 2 year period is discussed and presented as a model for future and extended collaboration between forensic and clinical medical genetics unit.

EP05. Access to genetic services

(challenges in Europe)

EP05.1

Why don't Deaf People come for Genetic Counselling?

A. Middleton¹, S. Emery², G. Turner², A. Clarke¹, S. Sarang³;

¹Institute of Medical Genetics, School of Medicine, Cardiff University, Cardiff, United Kingdom, ²Department of Languages & Intercultural Studies, School of Management & Languages, Heriot-Watt University, Edinburgh, United Kingdom, ³Health Communication Research Centre, School of English, Communication and Philosophy, Cardiff University, Cardiff, United Kingdom.

Despite genetic deafness being one of the most common genetic conditions, deaf adults very rarely access genetic counselling, neither to discuss deafness nor other conditions that may be running through their family, e.g. cancer. Each genetics centre in the UK will have several thousand deaf sign language users within their catchment area; however, referrals are likely to be received for less than 5 deaf adults per year. There may be many complex reasons behind this - e.g. lack of information, assumptions about inheritance, mistaken beliefs of a link between present-day genetics services and eugenic practices of the past or fears about being told not to have children. This project aims to gather the views of various different groups of people with deafness, looking specifically at the above issues. 30 interviews have been conducted in sign language and qualitative analysis performed. Video clips of deaf people signing their views about genetics will be shared as well as results from a large (n = 1000) quantitative study gathering attitudes. The research findings offer suggestions as to why currently genetics services are very rarely used by deaf patients in the UK. Once more is understood about this then steps can be taken to address access issues.

EP05.2

Genetic Led Multidisciplinary Clinics As Communities of Practice

S. A. Watts;

Guy's Hospital, London, United Kingdom.

Care for patients and their families with genetic disease has become increasingly complex in recent years due to a rapid rise in scientific knowledge, expanding technological innovation and demand for services, resulting in a need for multidisciplinary working. Although such working is well documented in general healthcare there is sparse literature within the specialty of clinical genetics. The results of an ethnographic study, which sought to examine the way in which patient care was organised and delivered in three multidisciplinary clinics in a Regional Genetic Centre in the UK, will be presented. Different models of healthcare were identified. However, data analysis using the theoretical framework of Communities of Practice (Wenger 1998), a theory of social learning and participation, suggests that functioning of the clinics is more closely related to the way in which clinicians establish a specific pattern of working together. The principal factor that contributes to the success of the clinics is that of coherence. The Genetic Counsellors play a crucial role to this coherence by acting as maintainers of the clinic. The results of this study contribute to our understanding of multidisciplinary working within clinical genetics and are important for the future planning and implementation of healthcare for patients with genetic disease.

EP05.3

European Network of Genetic Nurses and Counsellors

C. Patch¹, H. Skirton²;

¹Guys and St Thomas' NHS Foundation Trust, London, United Kingdom, ²University of Plymouth, Taunton, United Kingdom.

While there are a growing number of non-medical genetic practitioners in clinical practice in Europe, there is no European-wide organisation dedicated to the needs of those professionals. In an environment

where the numbers of genetic tests are growing, the need to educate and develop non-medical practitioners who are competent in genetics is essential. Importantly, nurses and counsellors may also be working in situations with few colleagues, where peer support is hard to access. To address these needs, late in 2007, with the support of the ESHG, a new European Network of Genetic Nurses and Counsellors was initiated.

An invitation to join the network was sent to EuroGentest and ESHG members, requesting that they pass it on to any genetic nurses or counsellors known to them in their countries. Language is a difficulty and colleagues from several countries have offered to translate the information for colleagues who do not speak English. It is clear from the responses that professionals in many countries are trying to develop this new profession and are keen to use the network for support during this important period.

A questionnaire has been sent to establish the aims and focus of this network and the findings will be presented at an initial meeting of the network at the EMPAG/ESHG conference in Barcelona

As of February 2008, the network has 72 registered members from Netherlands, France, Spain, Portugal, Denmark, Sweden, Finland, Italy, Croatia, Bulgaria, UK, Czech Republic, Greece, Belgium, Cyprus, Ireland, Turkey, Israel, Switzerland, Poland and Iceland.

EP05.4

The value of personal interaction: can a family history questionnaire replace a face-to-face family history gathering appointment with the genetic counsellor for parents of children with an undiagnosed genetic syndrome?

B. J. Dell¹, G. Westwood², C. Phelps³;

¹School of Medicine, Cardiff, United Kingdom, ²Wessex Clinical Genetics Service, Southampton, United Kingdom, ³Institute of Medical Genetics, Cardiff, United Kingdom.

Evidence suggests that parents often feel unprepared for their contact with Genetic Services (Skirton, 2006). Whilst family history questionnaires (FHQ) are increasingly used to gather data prior to attending a genetics clinic, such questionnaires have been found to raise anxiety (Phelps et al, 2006) and can act as a barrier to accessing services (Geer et al, 2001). This pilot study explored the impact of completing a specially developed FHQ upon subsequent perceptions of providing a family history face-to-face.

Seven parents completed the FHQ and an evaluation questionnaire. Results revealed that whilst the completion of the FHQ did not have any overall negative impact, it did have the potential to raise distress when asking for sensitive details such as miscarriages.

Four parents also completed telephone interviews to explore their perceptions of the FHQ and their appointment with the Genetic Counsellor. Thematic analysis revealed that parents encountered obstacles to the completion of the FHQ and that they appreciated their personal interaction with the Genetic Counsellor, which provided an opportunity for them to gain reassurance, to ask questions about the referral process and to clarify the relevance of the family history details.

The combination of both the FHQ and the Genetic Counsellor clinic was the preferred option, permitting the parents to be better prepared to utilise their contact with the genetic services.

EP06. Lay beliefs and public understanding of genetics

EP06.1

Using ethnography to optimise clinical practice in cancer genetics services

M. T. Saleh^{1,2}, B. Meiser², K. Tucker³, J. Kirk⁴, M. Eisenbruch⁵, K. Barlow-Stewart¹;

¹Centre for Genetics Education, St Leonards, NSW, Australia, ²The University of NSW, Sydney, Australia, ³Hereditary Cancer Clinic, Prince of Wales Hospital, Sydney, Australia, ⁴Familial Cancer Service, Westmead Hospital, Sydney, Australia, ⁵Monash University, Melbourne, VIC, Australia.

This project explores, using ethnography, the cultural beliefs about inherited susceptibility to cancer amongst the Arabic-Australian Community.

A group of 15 individuals who identify themselves as Arabic-Australian were recruited through two Sydney familial cancer services. Ethnographic interviews explored themes such as beliefs about inherited illnesses including inherited susceptibility to cancer, cultural beliefs and practices when communicating within families about inherited cancers and the impact, if any, of attending a cancer genetics service on these beliefs and practices. Thematic analysis of interview summaries identified common outcomes, informing the development of an explanatory model for inherited susceptibility to cancer in this sample.

The cultural backgrounds of the 7 males and 8 females interviewed were Egyptian, Iraqi, Lebanese and Turkish, and ages ranged from 29 to 82 years (median age 54). Participants generally were highly acculturated as measured by their English language proficiency and had a good understanding of the genetic basis of the cancer in their family. There was little or no discrepancy between the individuals' beliefs about inherited cancer and the model of clinical practice utilised in the clinics attended.

People of an Arabic-Australian background are one of the fastest growing ethnic groups in Australia. It is therefore important to document their beliefs to ensure they are compatible with the current models of practice in cancer genetics clinics.

A better understanding and awareness of cultural beliefs and potential areas of disparity will guide optimal cancer genetics service provision. More research is needed to confirm reported beliefs of non-attending family members.

EP06.2

The public understanding of newborn screening

B. Wieser;

IFZ, Graz, Austria.

Neonatal screening for genetic disorders is a routine practice for many decades. In particular, screening for PKU has become a standard procedure. However, internationally the way by which neonatal screening is carried out varies notably. Especially for disorders where treatment options are not as straightforward as they are for PKU, screening may be offered, but only on voluntary basis. Austria has decided to expand its programme significantly in 2002. The introduction of tandem-mass-spectrometry plays a crucial role in this regard. With this technology it became possible to screen for 30 inherited disorders. All together the Austrian neonatal screening programme comprises as many as 23 conditions.

In this paper I will especially address the issue of the public understanding of newborn screening. I will do so by drawing on the Wilson and Jungner guidelines as developed for the WHO. Specifically I will address the 6th principle: "The test should be acceptable to the population" (cf. Dhondt 2007). Taking this requirement seriously this raises important issues of lay understanding of genetic disorders and the way in which an expansion of newborn screening can be perceived. The issue will be contextualised into the historical context in which the Austrian newborn screening programme has been initiated. I will also contrast the Austrian case from other European countries in order to point out differences of the way in which a public understanding of newborn screening can be facilitated.

EP06.3

Why do intenders not behave: exploring the gap between the intention to take part in preconception carrierscreening for cystic fibrosis and/or haemoglobinopathies and not doing so

A. C. Plass^{1,2}, P. Lakeman¹, J. Wenink^{1,2}, M. C. Cornel^{1,2};

¹VU University medical center, Amsterdam, The Netherlands, ²EMGO-institute, Amsterdam, The Netherlands.

The aim of this study was to explore why couples who intended to participate in a preconceptional carrierscreening for cystic fibrosis and/or haemoglobinopathies (N=142), did not take part in the test after all (N=66), particularly beyond reasons like of lack of time.

All 66 couples were called up and asked whether they were willing to answer a few questions directly or some time later at their home about their non-participation in the test. All phone calls and face-to-face interviews were recorded and analyzed using the IPA-method.

41 couples were contactable. 13 couples no longer belonged to the research target group of couples that were planning a pregnancy in the future, and were excluded. 20 couples agreed to a telephone-interview and 5 others were interviewed at their home. The reason most

frequently mentioned for not taking part in the test after all was 'lack of time'. But, in asking about social influence it appeared that sometimes parents, other family members, friends or GPs had expressed their doubts about the couple's intention to take part in such a test.

Even though lack of time was the most frequently mentioned reason for not taking part in a preconception carrier-screening test after clearly having expressed the intention to do so, the negative input of the social environment might have played a major role in not carrying out one's intentions. Most couples were surprised by the negative reactions of their social environment and reevaluated test participation as being less important.

EP06.4

Attitudes towards thalassaemia carrier testing in saudi arabis

H. Y. Alabdulwahed;

Dhahran Health Center, Saudi Aramco, Dammam, Saudi Arabia.

Thalassaemia is a life limiting condition, characterised by severe anaemia which requires frequent blood transfusions. It is a global health problem, and is prevalent in countries with a history of malaria outbreak. Thalassaemia is a recessively inherited condition, i.e. both parents have to carry the thalassaemia gene in order to have affected children. Carriers do not show any symptoms of thalassaemia, and a blood test is necessary to identify carrier status. There are many mass public screening programmes throughout the world which aim to control and prevent this condition. In 2004, Saudi Arabia started a compulsory premarital screening programme to identify thalassaemia carriers, along with carriers of another haemoglobinopathy (sickle cell anaemia). To date no attempt has been made to investigate the Saudi people's thoughts and feelings towards the screening. This qualitative study used a semi-structured interview guide and was designed to explore the attitude of Saudis who have undergone mandatory screening for thalassaemia. Sixteen individuals participated in the study. The primary findings were that: participants accepted and supported the premarital screening programme; their motivations to undergo testing included: having healthy children, reducing the incidence of hereditary diseases in the country, and removing any risk in entering an arranged (usually consanguineous) marriage; the majority of participants lacked knowledge about screening; and many misconceptions and negative feelings towards screening emerged. The main conclusion is that there is a pressing need to increase public awareness about screening advantages and, more importantly, to educate individuals undergoing carrier testing.

EP07. Disclosure of test results

(professionals/patients/families/third parties)

EP07.1

Communicating genetics research results to families: problems arising when the patient participant is deceased

L. Ormondroyd¹, C. Moynihan¹, A. Ardern-Jones², R. Eeles³, C. Foster⁴, S. Davolls¹, M. Watson¹;

¹Psychology Research Group, Institute of Cancer Research, Sutton, United Kingdom, ²Cancer Genetics Unit, Royal Marsden NHS Foundation Trust, London/Sutton, United Kingdom, ³Translational Cancer Genetics Team and Cancer Genetics Unit, Royal Marsden NHS Foundation Trust, London/Sutton, United Kingdom, ⁴Macmillan Research Unit, School of Nursing and Midwifery, University of Southampton, Southampton, United Kingdom.

Purpose: This study explores communication within families of clinically significant genetics research results, after the death of the patient participant. *BRCA2* mutations were found in several men after their death from prostate cancer. Spouses were given the results in a genetic counselling session and asked to inform relatives.

Method: Cross sectional, qualitative exploratory study. Interviews with 13 relatives, including informers and recipients of the information, were analysed using interpretative phenomenological analysis.

Results: Dissemination was hampered when communication channels between relatives were limited, because of family rifts or socially distant or problematic relationships. When informing other branches of

the family, relatives approached individuals in the generation of the deceased man, regardless of their risk status, who were then responsible for informing younger relatives. Most people informed by a relative did not seek genetic counselling. The informing relative may not have sufficient authority for the information either to be taken seriously, or to challenge individual constructions about the aetiology of cancer. This impeded information transmission to further at risk relatives. Most participants knew of relatives who had not been told about their cancer risk.

Research Implications: When recruiting participants to genetics research studies, consideration should be given to requesting contact details of specific relatives, in the event of clinically significant results becoming available *post mortem*.

Clinical Implications: The limited efficiency of information transfer among relatives is discussed in the context of a potential role for genetics services in contacting at risk relatives directly.

EP07.2

Exploring family communication after receipt of BRCA1/2 results: Early data from family cases

C. Jacobs¹, M. Wallace², J. Smith³, S. Michie²;

¹Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, ²University College London, Department of Psychology, London, United Kingdom,

³Birkbeck College, Department of Psychology, London, United Kingdom.

Research investigating family communication about test results for the BRCA1/2 genes has largely been quantitative or limited to investigation with individuals undergoing testing. Little is known about how test information is communicated to other family members or received by them. This study examines how results of BRCA1/2 gene mutations are received by affected index patients and communicated through the family. The study examines the flow of information from clinician to patient and on to relatives; factors influencing communication; the impact of communication on cognition, emotion, behaviour and family relationships; and decision-making regarding risk management. Results consultations with participants are audio-recorded. One month later, interviews with participants explore their understanding of, and response to, the test result, and the experience of communicating this to first-degree relatives. Similar interviews are then conducted with relatives recruited by the index patients, with whom results have been shared. All interviews are recorded, transcribed and analysed.

Early data from family cases will be presented to illustrate the factors influencing family communication, and the impact of communication on risk perception, emotional state, behaviour and family relationships. The value of these findings both clinically and scientifically will be discussed.

EP07.3

Active Non-Disclosure in the Familial Cancer Setting: A Case Report

M. K. Kentwell, M. Harris, G. Lindemann;

Familial Cancer Centre, Royal Melbourne Hospital, Parkville, Australia.

A 77 year old woman unaffected by cancer was shown to carry the family specific BRCA2 mutation identified in her sister. At the results disclosure appointment, the client stated she would not inform her four daughters, aged in their 30s and 40s of her positive result.

This presentation will analyse the client and genetic counsellor's perspective, and the interaction between the two. Firstly, the reasons why the client elected not to share her results with her daughters will be explored. These include perception about effectiveness of risk management, family relationships and communication, perceived receptivity of the daughters regarding genetic information, judgement of how the daughters would cope with the knowledge of their mother's BRCA2 mutation carrier status, the perceived harm which may arise from disclosure and personal belief in the daughters' right not to know. Secondly, from the Genetic Counsellor's perspective, the counselling strategies utilised during and following the disclosure appointment will be outlined. In addition, the discussion will reflect on the challenges encountered in counselling the client, and the impact of a consultation involving non-disclosure on the Genetic Counsellor. The presentation will also describe the self-reflection which occurred in attempting to define the Genetic Counsellor's role in this case, and the ethical questions the Genetic Counsellor asked herself around the issue of non-disclosure.

EP07.4

The psychological impact of genetic testing of symptomatic patients - A literature review

F. Vansenne, P. M. M. Bossuyt, C. A. J. M. de Borgie;

Academic Medical Centre, Amsterdam, The Netherlands.

At present more and more genetic risk factors are identified to explain the development of common disease. As a consequence an increasing number of genetic tests are becoming available to clinicians. To guide the appropriate use and clinical utility of genetic tests it is important to consider the psychological impact of testing. In this study we performed a literature review to evaluate the psychological impact of genetic testing and its measurement in symptomatic patients.

We completed a systematic literature search from 1966 to april 2007. Relevant studies were identified from searches of Medline, Embase and Psychinfo databases. Additionally we searched for recent overview articles and relevant reports and in the Health Technology Assessment and Dare database. Prospective studies, evaluating genetic testing in symptomatic patients (n≥20) and using at least one standardized psychological outcome were included and evaluated.

In total 1233 studies were identified. After abstraction of information 17 studies were eligible and independently assessed. In half of the studies all participants were female, diagnosed with breast and/or ovarian cancer. Socio-demographics were comparable between the studies. Methodology used to measure the impact of genetic testing, protocols, and psychological outcome definitions differed substantially among the reviewed studies.

Little research has been conducted to support the feasibility on when and how to evaluate the psychosocial impact of genetic testing in symptomatic patients. Because of discordant results and short-term follow-up it is uncertain whether patients experience long-term negative psychosocial consequences of genetic testing. This important clinical evaluation question should be addressed in future research.

EP08. Predictive testing: process and impact

EP08.1

Decision making for young adults in predictive genetic testing

K. M. Mattingley¹, G. Betts², M. Freckmann¹, R. Sachdev¹;

¹Clinical Genetics, St George Hospital, Sydney, Australia, ²Sydney Children's Hospital, Sydney, Australia.

In recent years a number of articles have discussed the predictive testing process in minors and young adults. A young individual's ability to make an informed and responsible decision regarding predictive testing and the potential harm this may cause has been a contentious issue. A more recent view (1) argues that assessment of the individual's maturity of judgement in the decision making process, should be a consideration in predictive genetic testing protocols for minors. Should this not also be applied to young adults? Not all adults by the nature of their age are 'mature' in their decision making ability. Cognitive but also psychosocial factors influence decision making whether in adolescence or adulthood. Legally 'mature' by age may not mean cognitive or psychosocial maturity and can result in immature decision making. Should we then deny young adults who don't have a mature outlook access to testing? The case of three sisters, 18 to 22 years of age, at 50% risk for Huntington disease and their journey through the predictive testing process is presented and discussed.

1. Richards, FH. (2006) Maturity of judgement in decision making for predictive testing for nontreatable adult-onset neurogenetic conditions: a case against predictive testing of minors. *Clinical Genetics* 70: 396-401.

EP08.2

Accurately assessing uptake of predictive testing for Huntington disease.

R. J. Tassicker;

Genetic Health Services Victoria, Parkville, Australia.

The current literature fails to provide an accurate calculation for the uptake of predictive testing for Huntington disease. Uptake figures are reported from several centres based on the total number of people who have undertaken predictive testing as a percentage of those estimated to be at 50% risk in their catchment area. This method produced

a figure of 35% from this state's service, much higher than observation of the local pedigrees indicated. Reworking uptake as an annual figure partly corrects for the length of time a program has been operating. Other identified errors include the use of the cumulative total of those who have tested, with a static denominator of those at 50% risk; and the failure to exclude from the at-risk group those who are too young (ineligible) to test.

Most studies have used population prevalence of Huntington disease to calculate the total of those at 50% risk. We report new data for this state, Victoria, estimating the prevalence to be 8 per 100,000 in 1999. Additional information collated from the Huntington Disease Register of Victoria indicated that for every diagnosed person, there were 4.2 individuals at 50% risk (1:4.2), a lower ratio than the 1:5 hypothesized in the literature. We are currently developing an uptake formula which more accurately incorporates the variables. Our calculation gives an uptake of approximately 13% for this region. An accurate uptake is necessary to assess and interpret testing behavior.

EP08.3

Psychosocial genetics: psychological long term family impact (5 years) of the predictive test for Machado-Joseph disease on Azores

C. D. Gonzalez¹, E. M. Gomes², M. Lima³, C. Bettencourt³, T. Kay⁴, J. Santos⁵, J. Vasconcelos⁵;

¹Serviço de Psiquiatria do Hospital do Divino Espírito Santo, Ponta Delgada, Portugal, ²Grupo Açoriano de Investigação Neurogenética, Ponta Delgada, Portugal, ³Centro de Investigação em Recursos Naturais (CIRN) e Departamento de Biologia, Universidade dos Açores, Ponta Delgada, Portugal, ⁴Serviço de Medicina Genética, Hospital D. Estefânia, Lisboa, Portugal, ⁵Serviço de Neurologia do Hospital Divino Espírito Santo, Ponta Delgada, Portugal.

Objective: Evaluate the long term(5 years) psychological impact in the pre-symptomatic genetic testing(PT) for the Machado-Joseph disease (MJD) in Azores, the motivations for the test and the disease representations.

Methods: Scales to measure the individual well-being;family satisfaction, semi-structured interviews of psychosocial assessment and family dynamics.

Results: Of the 53 individuals revalued, 92.45% say that would take again the PT, presenting as the main motivation planning their future based on the test results.

In terms of geographic distribution of individuals, its to highlight that in Flores island, all individuals reassessed said that they would do again the PT,maintaining the motivation initially submitted.

Regarding family dynamics, 58.49% of those claim not notice any change, however this information is opposed by the results of the interviews conducted, in which it is noted that 24.53% of these individuals describes changes in dynamics either by approximation or by distancing family.

Conclusions: The study shows that most of the individuals who made the PT for MJD would repeat it, considering that knowing the test result contributed to "plan their future."

In terms of family dynamics, it is apparent that changes were focusing on these two opposing poles: the remote and closer family.

Levels of moderate and severe stress in subjects reflect the influence of the results of PT in the psychological well-being of individuals.

It's clear that the results of PT, influence the psychosocial situation of the individuals and their family dynamics, justifying the need for a psychosocial monitoring of individuals and families during the program.

EP08.4

Psychosocial evaluation for the predictive test of the Machado-Joseph disease

C. D. Gonzalez¹, E. M. Gomes², M. Lima³, C. Bettencourt³, T. Kay⁴, J. Santos⁵, J. Vasconcelos⁵;

¹Serviço de Psiquiatria do Hospital do Divino Espírito Santo, Ponta Delgada, Portugal, ²GAIN - Hospital do Divino Espírito Santo, Ponta Delgada, Portugal, ³Centro de Investigação em Recursos Naturais (CIRN) e Departamento de Biologia, Universidade dos Açores, Ponta Delgada, Portugal, ⁴Serviço de Medicina Genética, Hospital D. Estefânia, Lisboa, Portugal, ⁵Serviço de Neurologia do Hospital do Divino Espírito Santo, Ponta Delgada, Portugal.

Objective: To publicise the methodology used in the psychosocial evaluation process prior to the test for Machado-Joseph disease of the Azores.

Methods: Semi- structured interview, family genogram and psychomet-

ric scales measuring the individual and systemic resilience of those who wish to carry out the Predictive Test (PT).

Content: According to one of the objectives of GAIN (Azorean Group of Neurogenetics Research), the continued improvement of the protocol of the Genetic Counseling for the PT, and after the completion of a detailed study of revaluations of PT's until 2006, which led us to consider the importance of the first interview in psychosocial adjustment to the test result, we started a new methodology in psychosocial assessment of the candidates for the PT.

This approach seeks to identify the different types of these individuals, taking into account the influence of risk factors increased or decreased as the interaction with the individual protective factors and its relational system, making prognosis of a better or worse adapt to the results of PT. In this sense, we've followed a set of criteria which take into account the evaluation of the self, the kind of argument used by individuals and the systemic factors within and outside the family.

This assessment allows the scheduling of sessions of psychosocial counseling, aimed enhance the protective factors and minimize the risk factors prior to the predictive test, for a better psychological adjustment after the predictive genetic information.

EP08.5

Psychology of predictive medicine: Acceptance of testing for genetic predisposition to breast cancer

A. V. Shopova, S. Shopova, E. Simeonov;
Medical Faculty, Sofia, Bulgaria.

This presentation is the closing part of longitudinal study over attitude of Bulgarian people towards the possibilities and achievements of genetic science. The first part that included women, health-care workers(non-genetics) was "Acceptance of testing for genetic predisposition to breast cancer: The attitude of medical professionals."

The second part covered the acknowledgments of medical or biological students and was titled "Acceptance of testing for genetic predisposition of academic youth to PS DNA t for autosomal dominant inherited late onset diseases".

At this third level we expanded our study in the opinion of non-medical healthy people.

In conclusion this study compares the three groups- MD specialists, students and non-medical healthy people mainly towards:

1. Information sources.
2. Attitude of the possibilities of "predictive medicine".
3. Personal choice in genetic case situation.

EP08.6

Lessons of uncertainty from a rare inherited neurodegenerative disease: may it be a model?

E. Di Maria^{1,2}, S. Gattone², V. Viassolo², F. Forzano², F. Faravelli²;

¹University of Genova, Genova, Italy, ²Laboratory of Genetics, Galliera Hospital, Genova, Italy.

The acronym IBMPFD designates inclusion body myopathy with Paget's disease of the bone and frontotemporal dementia, a rare autosomal dominant disorder caused by missense mutations in the VCP gene. The disease usually presents in adult life; no effective treatment is available.

When we encountered the questions and the needs of an at-risk family member, we dealt with a disease characterised by: i) variable involvement of multiple systems; ii) age-dependent, yet unpredictable, penetrance of each of the cardinal signs; iii) possible occurrence of progressive cognitive decline. The co-presence of these features makes IBMPFD a compelling model for genetic counselling, as it resembles a complex disorder despite the Mendelian mode of inheritance.

The recommendations for predictive testing published for familial dementias state that the protocol developed for Huntington's disease (HD) should be followed. However, the deterministic scenario prompted by the HD mutation may appear simplistic when we face a number of additional uncertainties, including: i) the inability to predict the clinical presentation, i.e. the involvement of either muscles, bones, brain, or all; ii) the low predictive value of a negative test result, due to the high prevalence of cognitive decline among aged individuals. Nevertheless, it can be inferred from literature that predictive testing was performed in families included in research protocols, although the genetic counselling procedures were not mentioned. We will address some of these issues, by comparing the theme of multiple uncertain-

ties raised by IBMPFD with the evidence from the genetic counselling protocols available for other neurodegenerative and neuromuscular disorders.

EP08.7

The role of the disease in the psychological impact of presymptomatic testing for SCA2 and FAP ATTRV30M: knowledge of the disease in the family, degree of kinship and gender of the transmitting parent

M. Paneque Herrera^{1,2}, C. Lemos¹, L. Velázquez Pérez², J. Sequeiros¹, M. Fleming¹;

¹IBMC, Porto, Portugal, ²CIRAH, Holguín, Cuba.

To study factors of psychological impact of presymptomatic testing (PST) of spinocerebellar ataxia type 2 (SCA2) and familial amyloid polyneuropathy (FAP ATTRV30M), we analyzed (i) the effect of previous experience with the disease in the family, kinship with closest affected relative and gender of transmitting parent, when adapting to test results; and (ii) differences in the course of psychological wellbeing in 63 subjects, 28 offspring at risk for FAP, Portugal, and 35 at risk for SCA2, Cuba (who up-took testing May 2004 to April 2006).

Persons with less previous knowledge of the disease in the family referred more anxiety; lower levels of anxiety and depression were seen when the disease was present in first-degree relatives; having an affected mother was associated with lower levels of depression, both immediately and one year after results. Offspring at-risk for FAP had less anxiety than those at-risk for SCA2, during the whole follow-up (1 year), though differences were not significant.

A longer period of contact with the disease, closer kinship and an affected mother all lessen the impact of PST, as expressed in levels of anxiety and depression.

EP08.8

Is emotional impact of genetic testing related to the subjective risk to be a mutation carrier? The example of neuroendocrine tumors

K. Lahlou-Laforet¹, S. M. Consoli¹, X. Jeunemaitre², A. Gimenez-Roqueplo²;

¹C-L Psychiatry Department, Paris 5 University of Medicine, Georges Pompidou European Hospital, Paris, France, ²Department of genetics, Georges Pompidou European Hospital, Paris, France.

Paranglioma and pheochromocytoma are generally benign neuroendocrine tumors, inherited in about 25% of cases (autosomal dominant model), causing by germline mutations in SDHD, SDHB, SDHC, VHL, RET or NF1 genes. The hereditary form of the disease is characterized by an early onset with a higher risk of recurrency and/or malignancy. Genetic testing of patients and their families opens to earlier diagnosis and treatment of asymptomatic tumors in mutation carriers.

Objective: To evaluate emotional impact of genetic testing in consecutive patients met during oncogenetic multidisciplinary consultation dedicated to pheochromocytomas and paragangliomas.

Methods: Baseline state and trait-anxiety (STAI), depression (BDI-13) and subjective risk to be carrier of the mutation were assessed before the blood sample. A second assessment of state-anxiety, depression and traumatic impact of the announcement (IES-R) was performed after the definitive test result.

Results: 29 subjects were tested and 22 received the definitive result (12 positive, 10 negative). Baseline depression was correlated with the number of children ($\rho=0.40$; $p=0.03$). There was no change in state anxiety and depression after the test result. Psychological scores were not associated with subject's status (index case or relative). State-anxiety, depression and impact of event scores did not differ according to the test result. A higher impact of the result was found when subjects expected to be carriers whereas they actually were not ($p<0.05$).

Conclusion: Our data encourage to evaluate the subjective risk to be a mutation carrier before the test and to be particularly careful when the result is opposite to the subjective risk.

EP09. Predisposition to common diseases: genetic testing and preventive behaviour

EP09.1

Women's attitudes towards genetic susceptibility screening for breast cancer to target disease prevention

L. Henneman^{1,2}, C. M. Bouwman^{1,2}, D. R. M. Timmermans^{1,2}, C. G. Van El^{1,3}, H. Meijers-Heijboer^{1,3};

¹VU University Medical Center, Amsterdam, The Netherlands, ²EMGO Institute, Amsterdam, The Netherlands, ³Dept. of Clinical Genetics, Amsterdam, The Netherlands.

Currently, breast cancer screening is offered to all women based on age, usually beginning at age 50. It has been suggested that susceptibility testing for breast cancer genes may be used for risk profiling to target interventions (i.e. mammography screening) only to those at higher risk. The aim of the study was to explore women's attitudes towards population genetic susceptibility screening to target breast cancer prevention.

Four focus groups were conducted with 26 women aged 40-73 years. Women were selected irrespective of personal or family history of breast cancer.

The results show that in general women are positive towards genetic risk profiling for breast cancer, provided that in the lower risk group, though maybe less frequent, women are still offered mammography screening. Women reported that they would expect that some women would find it difficult to cope with knowing to be at higher risk. Others believed that in this way women would be able to change their lifestyle or start screening at earlier age. Bottlenecks mentioned by the women were potential problems with insurance, expected high costs of testing, putting too much emphasis on genetics. Women recognized that this risk profiling was just for one disease, but were ambiguous whether or not it should be extended to other diseases.

In conclusion, these results suggest that women currently offered breast cancer screening based on age, accept a possible future susceptibility screening for breast cancer, but also identified issues that need to be discussed and studied further.

EP09.2

Health behaviour after genetic counseling: A population-based study

E. M. Mikkelsen¹, L. Sunde², C. Johansen³, S. P. Johnsen¹;

¹Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, ²Department of Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark, ³Department of Psychosocial Cancer Research, The Danish Cancer Society, Copenhagen, Denmark.

Background: Alcohol consumption and obesity are known risk factors for breast cancer. Together with other health behaviours, such as physical exercise and smoking, they may also influence the risk of hereditary breast cancer. To date, however, very few studies have addressed the impact of genetic counseling on any of these health behaviours.

Purpose: To assess the impact of genetic counseling on health behaviours, in terms of smoking, physical exercise, alcohol intake and diet habits.

Method: A population-based prospective cohort study including women (N=319) who received their first genetic counselling for hereditary breast and ovarian cancer risk, and two reference groups. Reference Group I consists of women (N = 417) who received mammography. Reference Group II consists of women (N = 1,271) randomly selected from the Danish population.

Data were collected by standardized, questionnaires mailed prior to counseling or mammography and 12 months post-counseling.

Results: Findings on smoking, physical exercise, alcohol intake and diet habits will be presented and discussed.

EP10. Genetic counselling: communicating genetic information

EP10.01

Pitfalls in communicating 5-Probe FISH results- Lessons learned in genetic counselling

M. I. Ross¹, G. McGillivray²;

¹Victorian Clinical Genetics Services, Clayton, Victoria, Australia, ²Murdoch Childrens Research Institute, Melbourne Victoria, Australia.

In Victoria Australia, all pregnant women are offered serum screening to identify those fetuses which are considered to be at an increased risk for Trisomy 21, Trisomy 18 and Neural Tube defects. Women returning an increased risk may be counselled by their general practitioner, obstetrician, midwife or genetic counsellor, and are offered diagnostic testing. Many choose to have a FISH analysis as part of the diagnostic testing.

I present a number of women who experienced a normal FISH result from diagnostic testing, many believing that this was the complete result. They were later found to have a (different) abnormal karyotype-an event that caused distress and confusion.

I discuss their varied reactions and emotions in response to this "changed" result, and how they addressed the unexpected and difficult decision-making that followed.

Examination of these cases highlights the need to exercise great care when giving and discussing prenatal FISH results in the setting of increased risk for aneuploidy via serum screening. Clearer information given when the test is offered may alleviate these situations, but does little to reduce anxiety. The cases also demonstrate a need to provide ongoing education for health professionals who offer these tests to their clients, often also believing that the normal FISH result is an accurate description of the final result.

EP10.02

Family Perspectives on Inherited Arrhythmia Services

C. R. Honeywell^{1,2}, B. Wilson², R. Gow¹;

¹Children's Hospital of Eastern Ontario, Ottawa, ON, Canada, ²University of Ottawa, Ottawa, ON, Canada.

Assessing the interests and experiences of individuals affected by genetic conditions is an important component of service development. In the genetic arrhythmia literature, there is a paucity of information about what both affected and at-risk family members feel are the important elements of their care. We present the results of an anonymised survey administered to patients and their relatives who have been assessed for genetic arrhythmia through the CHEO Inherited Arrhythmia Clinic. A response rate of 52% was achieved with online and postal surveys. The respondents were 55 individuals (45% male) from 25 families, aged 14 to 70+ years who attended the clinic because of diagnosed or suspected long QT syndrome, arrhythmogenic right ventricular cardiomyopathy, or catecholaminergic polymorphic ventricular tachycardia. Results: Respondents perceive education and protective follow-up care to be the most important roles of an inherited arrhythmia service. Healthcare decision-making and support also emerged as important roles. At the first appointment, primary information needs concern the heart condition itself, long-term outcomes, and restriction of activities. Support group information is a low priority initially, but emerges later as an important requirement. With respect to timing of genetic counselling, respondents indicated no strong preference for counselling in advance, same-day or after heart investigations. However, 70% of respondents expressed that the location of counselling matters; the majority expect face-to-face counselling in a private location. These findings provide insight into families' preferences for inherited arrhythmia services, and how such services might be most optimally configured to meet their needs within inevitable resource constraints.

EP10.03

What physicians tell to individuals at risk of breast and ovarian cancer syndrome (HBOS) referred for genetic counselling. IMASS Spanish cohort

E. Darder, B. Graña, A. Velasco, D. Fortuny, T. Ramón y Cajal, A. Torres, J. Sanz, C. López, N. Gadea, I. Mensa, C. Saura, J. Brunet, J. Balmaña; IMASS, Barcelona, Spain.

Background: Individuals at risk of HBOS are referred to genetic counselling units for genetic testing. It is unknown how much information these individuals get by their reference physicians before counselling. Materials and Methods: Spanish individuals at risk of HBOCS referred to genetic counselling were asked to participate in a multicenter study by fulfilling a self-completed questionnaire before *BRCA1/2* testing. Variables were analysed using descriptive statistics and Fisher Exact test with SPSS.

Results: Overall, 243 individuals were enrolled. Median age was 44 years (range 19-88), 88% were women and 67% had a previous diagnosis of cancer. Most participants (65%) were referred by a physician, 30% by a relative and 5% were self-referred. The reference physician did not inform 48% of individuals about their risk of developing cancer, of those informed 70% were told to have a higher cancer risk than the average population. Physician informed 46% of total individuals about the possibility of genetic testing recommending it to 37%. Seventy-five individuals (31%) did not received any information about genetic counselling/testing before their risk assessment visit, while the main information source for 74 (30%) was the media. A similar proportion of cancer patients and healthy individuals at risk of HBOS received previous information by the reference physician (53% vs. 49%, p=0.58).

Conclusions: A low percentage of individuals at risk of HBOS are informed by their reference physician about their cancer risk and genetic predisposition before genetic counselling. Further efforts have to be done to improve medical awareness about hereditary cancer syndromes.

EP10.04

Cancer Knowledge, Risk Perception, and Cancer Worry after Genetic Counselling for Hereditary Breast Cancer in Spain.

E. Cabrera¹, A. Zabalegui¹, M. Peris², I. Blanco²;

¹Universitat Internacional de Catalunya, Barcelona, Spain, ²Genetic Counselling Unit. Prevention and Cancer Control Department. Catalan Institute of Oncology, L'Hospitalet, Spain.

Identification of a genetic basis underlying breast cancer has led to an increase in demand for genetic counselling about individual risks of the disease. Genetic Counselling Units are becoming an integral part of cancer services. It is, therefore, important to assess how attendance at these clinics impacts on cancer knowledge, cancer-related concerns, and risk perceptions. Previously, we have reported a validation of a Spanish Translation of the Cancer Worry Scale, *Escala de Preocupación por Cáncer*, which can be used to assess cancer worry in the setting of genetic counselling. A total of 212 Spanish patients were consecutively recruited, and 152 completed all questionnaires before and one and 6 months after genetic counselling. Cancer knowledge, including breast cancer prevention measures, significantly increases after genetic counselling. Patients' risk perception did not correlate with the actual breast cancer risk calculated by the counsellors. Patients' perceived risk did not modify after genetic counselling. Patients were significantly less worried after counselling. Higher levels of worry were predicted by high degree of perceived risk of developing cancer, higher levels of anxiety and low level of education. In conclusion, counsellors met the patients' psychological needs to a satisfactory degree during counselling. However, patients did not fully understand their risk of developing cancer.

EP10.05

Breast Cancer Genetic Counselling in Cyprus: First epidemiological data

V. C. Anastasiadou^{1,2}, E. S Aristidou¹, A. Hadjisavvas³, Y. Marcou¹, E. Kakouri¹, T. Delikurt¹, K. Kyriacou³;

¹Clinical Genetics Service, Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, ²Makarios Medical Centre, Nicosia, Cyprus, ³Department of Electron Microscopy and Molecular Pathology, Cyprus Institute of Neurology and Genet-

ics, Nicosia, Cyprus, ⁴Bank of Cyprus Oncology Center, Nicosia, Cyprus. Cancer Genetic Counselling in Cyprus was established recently. Breast cancer patients, account for the majority of referrals at present. They are referred to the Cancer Genetics Clinic based on age of diagnosis, type of cancer and family history. Referred patients are offered two counselling appointments to be appropriately informed of the risks, benefits, and limitations prior to decision making for testing. Results are communicated through a further appointment which is followed by other counselling appointments according to the needs of the patients and their family.

In 2007, 103 breast cancer patients and healthy relatives at risk were seen at the CGCC. We analyzed the variability within this patient group in terms of demographic information.

The 101 female and 2 male patients were mainly referred by their oncologists. In terms of age, 4 were < 30, 42 were 30-39, 29 were 40-49 and 28 were > 50 yrs. 97 were Greek Cypriot, 1 was Turkish Cypriot and 5 were of other ethnic backgrounds. Genetic counselling for cancer predisposition genes was in general well appreciated. Uptake of genetic testing by patients and their family members were diverse. These and other data are being analyzed currently and will be reported in this poster.

EP10.06

The increased incidence of breast cancer makes obligatory the genetic counseling

H. Vaida¹, I. Tomulescu², L. Filimon¹, G. Roseanu¹, M. Marian¹;

¹Faculty of Socio-Human Sciences, Oradea, Romania, ²Faculty of Sciences, Oradea, Romania.

In our days there are more and more cases of different cancer types. We can mention many causes responsible for the appearance of cancer: environmental, chemical, physical and biological factors. Of course, in many cases the inheritance has an important role in appearance of different types of cancer. Our study is about the dynamics of cancer in our county during the 1990-1999 period and the necessity of genetic counseling of the persons who have cancer affected relatives. We analysed the data from Medical Direction of Bihor county in mentioned period. We made a statistical study about the incidence of breast cancer in our county. Also we show the stages for genetic counseling in two types of groups (one already breast cancer affected and one with relatives affected).

We studied the incidence of breast cancer in feminine population. Also, we studied the area of proceeding and type of cancer. The stages in genetic counseling in breast cancer must include: family and medical history, hereditary vs. sporadic cancer, genes associated with cancer, risk assessment, testing options, test results, screening options, possible prevention options and psychosocial assessment.

The breast cancer has an increased incidence in Bihor county. The incidence depends in some types of cancer on patient sort (masculine or feminine), age and proceeding area. Because of these, genetic counseling is very important in prevention of this type of cancer.

EP10.07

Communicating genetic information: learning from patient experiences and preferences

C. L. Bennett¹, S. Burke^{2,1}, J. Bedward², P. Farndon¹;

¹NHS National Genetics Education and Development Centre, Birmingham, United Kingdom, ²Centre for Research in Medical and Dental Education, Birmingham, United Kingdom.

Where do patients get information about the genetic basis of their condition? What healthcare professional groups outside specialist genetics services provide genetic information and what kinds of information are given? How would patients prefer to receive such information? A qualitative study was conducted in the UK in 2006 to explore these issues, through telephone interviews with 27 people with or at risk of genetic conditions and parents of children affected by a genetic condition.

The results highlight the range of healthcare professionals who may be approached by patients seeking information and indicate a perceived need for greater awareness of genetic aspects of conditions amongst healthcare professionals. Patients acknowledged that healthcare professionals cannot be familiar with all genetic conditions in detail, but felt that identifying and referring patients appropriately, and acknowledging professional limitations of expertise, were important.

Patients gave us their views on the knowledge, skills and attitudes

which they believed would enhance care by non-genetics professionals. They valued certain attitudes: providing genetic information without judgement; being mindful of the use of terminology; and being aware of the emotional impact of genetic information on individuals and the wider family. Tailoring the information provided to individual preferences and informing people where they can access further information were also considered important.

These results have implications for the education and practice of all health professionals involved in providing genetic information. They are being used in the UK to raise health professionals' awareness of genetics and to inform the integration of genetics into professional training.

EP10.08

Evaluating Service Development: a community based genetic service for consanguineous families of South Asian origin

N. Khan¹, R. Macleod¹, J. Benson², V. Hollings³, H. Kingston¹;

¹Regional Genetics Service and Medical Genetics research Group, Manchester, United Kingdom, ²East Lancashire Teaching Hospital, Blackburn, United Kingdom, ³Blackburn with Darwen Primary Care Trust, Blackburn, United Kingdom.

A UK Department of Health service development project developed community based, hospital linked genetic services for Asian families affected by autosomal recessive conditions. The 2 year pilot project (2005-2007) took place in Blackburn a town in the North of England where 20.4% of the population are of Asian Origin, 50-60% marriages are consanguineous and there is a high incidence of autosomal recessive disorders. The aim was to provide a culturally sensitive service by an Asian speaking genetic counsellor. An evaluation determined how genetic information was understood, received and transmitted within these families and factors that affected decisions about genetic testing and sharing of information.

A total of 42 families affected by a range of autosomal recessive disorders were included. On average 5 extended family members were seen from each index family referred. Uptake of the service was 95% with positive feedback from families.

Evaluation Key points:

- 97% of families found the service useful and informative.
- The number of requests for prenatal diagnosis and carrier testing demonstrates utility.
- Families identified language and a lack of understanding about Genetic services as previous barriers to accessing services.

Key outputs:

- development of protocols/care pathways to access appropriate family members.
 - establishment of a community based hospital linked genetic service.
 - contact with families previously unknown to clinical genetics service.
- The paper will highlight families' views and feedback on the service and make recommendations for future practice.

EP10.09

Attributions as predictors for level of functioning and depression in cancer patients

M. Marian¹, G. Roseanu¹, I. Tomulescu²;

¹Faculty of Socio-Human Sciences, Oradea, Romania, ²Faculty of Sciences, Oradea, Romania.

In this study we aimed at analyzing whether a negative attributional style is an efficient predictor, for both the male and female patient's future evolution, depending on their stage of illness and type of diagnosis. Our main objective was to uncover changes and reactions at the psychological level of the patients during their stay at the oncology ward or during medical interventions. By interviewing the patients (before we administered specific instruments based on the learned helplessness theory, such as the Attributional Style Questionnaire) we gathered information regarding their level of functioning which led to the formation of three independent groups.

Patients diagnosed with cancer (overall 120 subjects) who did not show any symptoms of mental disturbance, 67 females and 53 males who were diagnosed with cancer, classified as having stage one and two, and 36 stage three and four 84. A total of 79 patients suffering from depression were included in the study, 34 males and 45 females. Regression analysis showed that the negative attributional style is an efficient predictor for depression in the case of patients suffering from cancer of the digestive tube. The negative attributional style is a very

efficient predictor for the level of functioning and perceived pain in the case of patients suffering from pulmonary cancer and digestive tube. Overall, the results show that the negative attributional mechanisms coupled with other socio-cognitive variables can increase the level of depression for patients diagnosed with cancer, on the background of lack of control and / or deficient functioning.

EP10.10

An international online survey of genetic health professionals' practice involving family communication

L. E. Forrest^{1,2}, M. B. Delatycki^{1,3}, L. Curnow³, L. Skene⁴, M. Aitken¹;

¹Murdoch Childrens Research Institute, Parkville, Australia, ²The University of Melbourne, Parkville, Australia, ³Genetic Health Services Victoria, Parkville, Australia, ⁴The University of Melbourne Law School, Parkville, Australia.

Communication of genetic information in families is becoming increasingly important due to the low numbers of at-risk family members that contact genetic services for counselling. Genetic counsellors and clinical geneticists (genetic health professionals) are responsible for educating and discussing the familial implications of a genetic diagnosis with probands and consultands. However, genetic health professionals' practice in family communication is largely unexplored.

This is the first international survey to be developed and validated which aims to explore genetic health professionals' current practice involving family communication. The survey was administered online and participants were recruited through the membership email lists of organisations with clinical geneticists and genetic counsellors as professional members.

The survey was completed by 628 genetic health professionals. The results demonstrate that the majority of genetic health professionals always identify which relatives are at-risk (95.6%) and encourage communication about the genetic condition to these family members (95.4%). There were generally no differences between clinical geneticists and genetic counsellors practice ($p>0.05$) when counselling probands about at-risk relatives, except when discussing which relatives are at-risk of developing Huntington disease ($p=0.02$). Genetic health professionals' practice did not vary greatly when compared across four scenarios which each involved a genetic diagnosis of haemochromatosis, familial adenomatous polyposis, Huntington disease or a balanced reciprocal chromosomal translocation.

The results of this survey provide an insight into genetic health professionals' practice internationally and provide information for the development of evidence-based practice for genetic and non-genetic health professionals in the area of family communication.

EP10.11

Genetic Counseling in the Muslim World : The Challenges

A. I. Al-Aqeel;

Riyadh Military Hospital/ King Faisal Specialist Hospital, Riyadh, Saudi Arabia.

Genetic counseling is the process in which an individual or a family obtains information and advice about a genetic condition that may affect the individual, his progeny, his relatives, or the family as a whole. Based on this knowledge he can take the pertinent decision regarding marriage, reproduction, abortion and health management.

Genetic counseling includes five themes, medical management, risk determination, risk options, reproductive decision making, and support services. It involves a partnership of physicians, genetic counselors, and genetics support groups. The majority of clinical geneticists subscribe to the principle of non-directive ness: information about risks, natural history, treatment, and outcome are presented in a balanced and neutral manner, but decisions about reproduction are left to the family.

Public health authorities are increasingly concerned by the high rate of births with genetic disorders especially in developing countries where Muslims are a majority. Therefore it is imperative to scrutinize the available methods of prevention and management of genetic disorders. In the Muslim World and in the Kingdom of Saudi Arabia (KSA), genetic counselling involves many challenges, as it has to be carried within the context of religion and culture, according to Islamic ethical and cultural background of the individual, with community-based genetic counselling in one's own language, in the presence of paucity of expertise, resources and technology.

EP10.12

„Do you know why the doctor sent you?“ - Characteristics of the genetic counselling process in a multicultural antenatal context in Johannesburg South Africa

T. Wessels¹, C. Penn²;

¹Division Human Genetics, Johannesburg, South Africa, ²University of the Witwatersrand, Johannesburg, South Africa.

Few genetic counselling (GC) research studies have examined the GC process itself, particularly within multicultural settings. State-funded antenatal GC clinics in South Africa service culturally diverse populations and this research study aims to investigate the nature of these encounters. Using qualitative methodology, the required data is obtained from GC sessions and post-session interviews with genetic counsellors and the women using the service. GC sessions are video recorded, transcribed and analysed using thematic content analysis. The results of three sessions from two counsellors will be presented. Initial findings suggest that there is an almost standard structured GC format used by counsellors which includes: establishing patient's expectations, explaining GC role, obtaining information, providing information, facilitating decision-making and making referrals. Time spent on each aspect varies according to the women's understanding of language and content (as assessed by the counsellor), depth of emotional engagement and counsellor's skills of communication and relationship building. Analysis of the nature of the sessions shows some themes emerging and these include: encouraging discussions, attempts to connect, clarifying techniques, simple language and patient beliefs. This initial analysis showed heightened counsellor awareness of the need to use comprehensible language to convey concepts and counsellor willingness, but difficulty in eliciting and responding to emotional content in the face of language and cultural differences.

EP10.13

Evaluation of genetic counselling in a hospital-based clinical service

C. Serra-Juhé^{1,2}, I. Valenzuela-Palafox^{1,2}, M. Del Campo^{1,2}, S. García-Miñaur², T. Vendrell¹, L. A. Pérez-Jurado^{1,2};

¹Unitat de Genètica, Universitat Pompeu Fabra, U-735 CIBERER, Barcelona, Barcelona, Spain, ²Programa de Medicina Molecular i Genètica, Hospital Vall d'Hebron, Barcelona, Spain.

In order to ascertain the effectiveness of genetic counselling it is necessary first to evaluate how it is carried out and identify aspects that need to be improved. There are few published studies on this topic. Our aim was to evaluate the genetic counselling provided by the Genetics Service of the Vall d'Hebron Hospital in Barcelona. Seventy-four out of 108 cases/families (68%) seen in clinic from February to December 2007 were eligible and agreed to participate in this study. Each participant answered a questionnaire before and after the consultation. The whole survey was developed taking into account previous work and publications on the evaluation of genetic counselling. We were particularly interested to study the patient's prior expectations and whether they had been met during the consultation, patient's satisfaction (instrumental, affective and procedural aspects), and the level of comprehension of genetic and medical information given during the consultation. Other epidemiological data, such as gender or age, were also collected. Subsequently, a statistical analysis was performed. Participants were satisfied with the genetic counselling received (mean score of 3.42 / 4, equivalent to 85.5% maximum satisfaction), and their expectations were met in 79%. They answered correctly 84% of the questions about medical and genetic information given to them by the geneticist during the consultation. In summary, the evaluation of the genetic counselling service was globally quite positive and allowed to identify some aspects that could be improved.

EP10.14

Clinician-patient interaction during genetic consultation and counselling - Case study in five genetic clinics in Colombia

M. C. Rodas Perez¹, J. Powell¹, M. Thorogood¹, J. C. Prieto^{2,3}, I. Zaranté²;

¹Health Sciences Research Institute, University of Warwick, Coventry, United Kingdom, ²Human Genetics Institute, Javeriana University, Bogota, Colombia, ³Bogota Health Service, Bogota, Colombia.

In Colombia and Latin America, genetics services are relatively new, and little attention has been paid to the critical process of communication during genetic consultation and counselling.

In collaboration with the Bogota Health Service (Ministry of Health and Social Protection of Colombia), the Medical Genetics group of the Colombian Association of Human Genetics, and the University of Warwick (UK), we observed 25 genetic consultations in Colombian genetic clinics and undertook semi-structured interviews with the participants before and after the consultation. Thematic analysis of the interview transcripts demonstrated widespread mismatches between practitioner perception and patient comprehension. Effective communication was inhibited by patient, family, practitioner and environmental factors. Principal among these were excessive administrative procedures, interruptions during the consultation, patients' lack of attention to medical terminology, excessive information given in one session, beliefs and education level of the patient and/or relatives, patient distress caused by bad news, unfulfilled expectations and no availability of treatment. We also interviewed 20 medical consultants working in genetics services. There was general agreement that genetic counselling in Colombia was problematic, and that more training in communication skills was required at Medical schools. Many physicians did not believe that other health professionals should work as genetic counsellors. There was a widespread recognition of limited genetic knowledge in most medical specialities.

These findings will inform the future development of an effective and robust genetic counselling service in Colombia. They will also be used in the development of the academic curriculum related to basic and clinical genetics at Colombian Universities.

EP10.15

Communication of genetic information in families: Funding for a randomised controlled trial of a genetic counselling intervention.

M. Aitken¹, M. Delatycki^{1,2}, L. Skene³, I. Winship⁴, S. Donath¹, V. Collins¹, J. Hodgson¹, S. Metcalfe¹, C. Gaff¹, J. Halliday¹;

¹Murdoch Childrens Research Institute, Parkville, Australia, ²Bruce Lefroy Centre for Genetic Health Research, Parkville, Australia, ³Law School University of Melbourne, Parkville, Australia, ⁴Royal Melbourne Hospital, Parkville, Australia, ⁵Genetic Health Services Victoria, Parkville, Australia.

When a person receives a diagnosis of a genetic condition for themselves or for their child, many of their at-risk relatives remain unaware of this information. This has important health implications, at present usually in families with single gene disorders, but in future for complex disorders and pharmacogenomics, toxicogenomics and nutrigenomics. How should important information that will reduce morbidity and mortality be communicated?

The aim of this study is to investigate whether a genetic counselling intervention will result in increased access to genetic services by family members at risk of serious genetic conditions. We have been funded to conduct, a randomised controlled trial to assess the effectiveness of intense genetic counselling follow-up on the numbers of at-risk relatives utilising genetics services. The intervention will be developed using appropriate theoretical approaches such as family communication and family systems theory. Clients presenting to a clinical genetic service for diagnosis or genetic testing will have the number of at-risk relatives recorded. Following randomisation into an intervention or control arm, the number of those at-risk relatives who utilise genetics services will be compared.

This multi-disciplinary study will determine whether a genetic counselling intervention improves information exchange in families while also exploring the issues that arise. The ultimate aim of this study is to provide evidence to enable best practice both nationally and internationally for the accurate and efficient communication of genetic information in families for the promotion of their health and well being.

EP10.16

Mutations of self-other relations in genetic counseling discourse

S. Sarangi, A. Clarke;

Cardiff University, Cardiff, United Kingdom.

Drawing upon the seminal work of George Herbert Mead which underscores how the 'self' is conceptualised as a socially situated reflexive process made possible through the perception of alterity, we propose that the notions of self and other can be understood at a relational level along three possible configurations - 'self-as-other', 'self-and-other' and 'self-vs-other'. The counselling and therapeutic settings, with their narrative and reflection orientation, give primacy to the 'presentation' and 'performance' of the 'self', as can be argued from a Goffmanian

dramaturgical perspective.

Based on a theme-oriented discourse analysis of over 50 audio-recordings of genetic counselling sessions covering a range of conditions, we suggest that different familial lines are mutated along self-other categorisations, reflecting not only the genetic status of the individual concerned but also the trajectories of past and present familial relations. This means that decisions to test and decisions to disclose test procedures/results have to be other-oriented. As far as an individual's genetic status is concerned, the 'carrier' status of a family member may necessitate a different self-other orientation when compared with someone's 'affected' and 'at-risk' status.

In conclusion, we argue that in genetic counselling, both counsellors and clients have to be other-oriented by 'decentering the self' while balancing self-other relations by warranting, explicitly, situated differences and contingencies. The counsellor by seeking 'other' perspectives becomes other-oriented, which simultaneously makes the client other-oriented. Such a stance conflates, following Mead, the 'self-as-other' and 'self-and-other' positions.

EP10.17

To develop and translate a set of leaflets for patients and families across Europe, that provide information on issues related to genetics and genetic testing

C. Lewis¹, A. Kent¹, H. Skirton², D. Coviello³;

¹Genetic Interest Group, Islington, United Kingdom, ²Faculty of Health and Social Work, Plymouth University, United Kingdom, ³Fondazione IRCCS, Ospedale Maggiore Policlinico, Milan, Italy.

Aim: To develop and translate a set of leaflets for patients and families across Europe, that provide information on issues related to genetics and genetic testing (part of the EuroGentest project).

Leaflet development: A set of 11 patient information leaflets were developed on topics related to inheritance patterns and genetic testing. The themes of the leaflets were decided by a panel of professionals and patient group representatives. The content of the leaflets was developed with input from patients as well as by building on existing written patient information. After the first draft the content and layout was tested out with patients to ensure readability and ensure key topics were covered. When the content was finalised it was checked by professionals to ensure accuracy of the text and images.

Leaflet translation (currently underway): First, the content is checked with genetic healthcare professionals in each country through a specifically designed questionnaire. Adaptations are then made to the text to ensure it is 'country specific'. Translators are all bilingual genetic professionals or PHD students who are recruited through universities and genetic departments. Translations are cross checked by a second bilingual genetic professional to ensure their accuracy. Leaflets are then uploaded onto the EuroGentest website www.eurogentest.org/patients to be freely downloaded by professionals and patients. Leaflets are currently available in 8 languages, with 12 more to follow. A new set of leaflets which will focus specifically on the psychosocial aspects of genetic testing are currently underway.

EP10.18

I say, you hear: What do Interpreters say when there are no words.

M. I. Ross;

Victorian Clinical Genetics Services, Clayton, Victoria, Australia.

Monash Medical Centre is a busy hospital serving a multicultural population in excess of one million people. Many clients are young refugees and couples keen to have children now they have reached Australian "safety".

All pregnant women are offered serum screening for Down syndrome, Trisomy 18 and neural tube defects. Women receiving an increased risk for any of these conditions are referred for genetic counselling to discuss their risk, the condition in question, and their choices.

Interpreters greatly assist our efforts to provide genetic counselling and choices to these migrant couples, but it has become clear that there are times when the clients simply do not understand what the central issues under discussion are. This raises concerns that the decisions made may not have a sound base. Terms such as risk, chance, chromosomes, Down syndrome and spina bifida are a mystery to some.

In order to improve genetic counselling practise, interviews were conducted with hospital interpreters to elicit what is said, especially when

there is not a corresponding word in their given language. Interviews consisted of standard questions as well as an exploration of generally held beliefs about inheritance, and how decisions are made in the family culture.

A review of the questionnaire and the outcomes of these interviews will be discussed.

EP10.19

The genealogical tree is a very important stage in genetic counseling of the families with mentally retarded children

I. Tomulescu¹, H. Vaida², M. Marian², G. Roseanu²;

¹Faculty of Sciences, Oradea, Romania, ²Faculty of Socio-Human Sciences, Oradea, Romania.

In humans, some traits are abnormal and they have diverse etiologies. Certain traits appear isolated in a person and others appear associated in a diseases called syndromes.

To make a pedigree of an individual or a family, it's a necessity to gather data about the family or individual. We investigated 600 children hospitalized on period of 2000-2002 in Neuropsychiatric Infantile Section of Neurology and Psychiatry Clinical Hospital from Oradea.

Results and discussions

In 600 children that were examined, 397 presented different levels of mental deficiency. We made family investigations and genealogical tree.

More than 65% of children with mental deficiency have one or more affected relatives in family. The relatives may be affected by congenital abnormalities and/ or mental diseases. The incidences of affected relatives are important in groups with mild and moderate mental deficiency. In the group with severe mental deficiency, the incidence of affected relatives is lower.

This result may be an argument for the hypothesis that genetic factors are very important in the inheritance of mental deficiency. It seems that, elementary, severe mental deficiency appears because of genes and chromosomes disorders, and secondary because of dominant or recessive inheritance. The data about family are systematized in pedigree or genealogical tree of the family. Analysing the pedigree of a family, we can say that some traits are inherited or not. Also, we can anticipate some normal or abnormal traits of individuals of the next generation.

EP10.20

Psychological and familiar impact of genetic diagnosis in oculopharyngeal muscular dystrophy

M. Fernández-Prieto¹, M. J. Sobrido^{1,2}, B. Quintáns^{3,2}, F. Barros^{1,2}, J. L. Castro¹, J. Pardo⁴, A. Carracedo^{1,2,5};

¹Fundación Pública Galega de Medicina Xenómica, Santiago de Compostela, Spain, ²Centro de Investigación en Red de Enfermedades Raras (CIBERER), ISCIII, Santiago de Compostela, Spain, ³Hospital Clínico de Santiago-SER-GAS, Santiago de Compostela, Spain, ⁴Servicio de Neurología-Hospital Clínico de Santiago de Compostela, Santiago de Compostela, Spain, ⁵Grupo de Medicina Xenómica-USC, Santiago de Compostela, Spain.

Oculopharyngeal muscular dystrophy (OPMD) is a late-onset, slowly progressive muscular disease. Inheritance is autosomal dominant; penetrance is full, age-dependent. Symptoms are paresis of extraocular eye muscles, dysphagia and limb weakness. Because it is not considered a very disabling disorder and molecular diagnosis is simple - making it easily accessible to almost any laboratory- testing may be requested without much concern about psychological and social aspects. Psychological and familiar impact of this diagnosis has not been tackled. Out of 76 patients with suspected OPMD seen in our unit, 45 (29 families) were positive. In families referred for genetic counselling we carried out a psychological evaluation with a semi-structured in-depth interview analyzing motivations, attitude and anxiety. We found an average of 1.8 secondary cases (symptomatic or asymptomatic) per index case. 82 % of predictive analyses were positive. We received no requests for antenatal diagnosis. Twelve months after genetic testing another psychological exam was done using HAD and a semi-structured in-depth interview to assess personal and familiar impact of the diagnosis. Although molecular confirmation of OPMD did generally not cause serious distortion in psychological aspects or in the familiar core, some aspects of family life were indeed modified. Even if not perceived as a severe disease in their relatives, for many individuals the possibility of a predictive diagnosis caused significant stress. A protocol for

genetic counselling and psychological assessment are fundamental in this disease. Reasons for the low proportion of secondary cases may be multiple and should be further investigated in the future.

EP10.21

Sense Making in Predictive Genetic Testing of Hereditary Cancer. An Interview Study

E. Sumalla^{1,2}, C. Ochoa¹, R. Martínez¹, C. Yague¹, M. Salinas¹, I. Blanco¹;

¹Genetic Counseling Unit, L'Hospitalet, Spain, ²Fundació P Gastroenterologia Dr. Vilardell, Barcelona, Spain.

Purpose: Mankind involves an active effort to find a purpose in the events that surround us. This construction of meaning is a process that is reinforced with stressful events that may be inconsistent with our beliefs about when and why things happen. The aim of this study was to evaluate, from a narrative perspective, how biographical factors may contribute to the formation of different meanings of the genetic diagnosis .

Methods: Three pairs of siblings (n = 6) identified as carriers of a genetic defect were evaluated using semi-structured interview designed to identify vital changes associated with the process of genetic counseling. Three independent researchers conducted content analysis and identified significant differences between each pair of interviews by consensus.

Results: In pair of siblings A, the presence of other stressful events minimize the potential harmful of the genetic diagnosis experienced by one of the brothers; in pair B, the relationship with a very affected close relative encourages active coping problem with one of the members; and in C, the concept of brotherhood and sacrifice allow one of the sisters assume their genetic alteration as an opportunity to increase their family privacy.

Conclusions: Despite sharing diagnosis, family history of cancer and genetic counseling process, the narratives of the siblings presented significant differences between them. The use of different frameworks of interpretation according to the biography of each subject provides the genetic diagnosis of sense and different consequences.

EP10.22

Delivering genetic counselling via telehealth: practitioner's experience of a virtual consultation

E. M. Ziliacus^{1,2}, B. Meiser^{1,3}, E. A. Lobb^{4,5}, J. Kirk⁶, A. Spigelman⁷, K. Barlow-Stewart⁸, L. Warwick⁹, K. Tucker¹⁰;

¹Psychosocial Research Group, Randwick, Australia, ²School of Psychiatry, University of New South Wales, Randwick, Australia, ³Prince of Wales Clinical School, University of New South Wales, Randwick, Australia, ⁴Medical Psychology Research Unit, Sydney, Australia, ⁵WA Centre for Cancer & Palliative Care, Perth, Australia, ⁶Familial Cancer Service, Westmead, Australia, ⁷Hunter Family Cancer Service, Newcastle, Australia, ⁸Centre for Genetic Education, Royal North Shore Hospital, St Leonards, Australia, ⁹ACT Genetic Service, Woden, Australia, ¹⁰Department of Medical Oncology, Randwick, Australia.

Telehealth, or videoconferencing, is an evolving field in general and cancer genetics. The aim of this study was to qualitatively explore clinicians' perspectives and experiences of delivering telehealth genetic counselling. Semi-structured interviews were conducted with geneticists and genetic counsellors. The interviews explored experience, satisfaction, aims of the service, advantages and disadvantages of the technology, and roles within the consultation. RESULTS: Fifteen practitioners participated. They reported that telegenetics increased staff efficiency and accessibility to outreach clinics. The geneticists presented as the consulting specialist, delivering medical information and screening advice and depended more on the genetic counsellor to assess non-verbal behaviour and subtle emotional cues from the client. Consultations were described as being more formal, and possibly less open to emotional expression than face-to-face consultations. Interactions on-screen were moderated by the physical positioning of the genetic counsellor and client. When the counsellor was positioned "off screen", a medically modelled dyadic interaction occurred and non-verbal cues between the counsellor, the geneticist and the client were obscured. When positioned "on screen", counsellors reported they offered a higher level of psychosocial support before, during and after the telehealth session.

Practitioners were highly satisfied with telegenetics but acknowledged the trade off involved in the geneticist not being physically present. The technology is efficient and offers sufficient resolution to attend to

most patients' psychosocial needs. Findings highlight the benefits of co-facilitation between geneticists and genetic counsellor when each has clearly defined complementary roles.

EP10.23

Explaining X-linked inheritance: the importance of the personal drawing

T. Gale¹, S. Pasalodos-Sanchez², L. Kerzin-Storarr¹, R. Macleod¹;

¹Regional Genetics Service and Medical Genetics Research Group, CMMC NHS Trust and University of Manchester, Manchester, United Kingdom, ²Nottingham Regional Clinical Genetics Service, NUH NHS Trust, Nottingham, United Kingdom.

An explanation of the mechanism of inheritance is a key component of many genetic consultations. However, no evidence base exists for this significant area of practice.

We present the results of a process study, involving twenty-one individuals with a family history of an X-linked condition. Their genetic counselling consultations were videotaped and participants were then visited at home by the researcher. Adapting techniques of Interpersonal Process Recall, the section of videotape featuring the explanation of inheritance was played back to participants. Their responses and reflections were elicited and recorded on audiotape. In a separate arm of the study, the counsellors were shown the videotape and were similarly interviewed by a second researcher about their experience.

The patients felt that a personalised diagram, drawn by the counsellor during the consultation, conveyed X-linked inheritance in a visual and engaging way, allowing them to conceptualise risk figures. Its step-wise construction facilitated slower assimilation of information, allowed room for questions and assisted with retention of the information. The diagram's individualised nature allowed patients to contextualise their family history such that personally relevant questions could be answered. Importantly, this did *not* appear to require patients to first understand complicated genetic concepts such as the biological basis of genes or chromosomes.

Counsellors too reflected on the construction of a drawing during the consultation; which they felt helped them to both pace and individualise the explanation.

This presentation will elaborate on patient and counsellor reflections on this key aspect of the genetic counselling consultation.

EP10.24

Explaining X-linked inheritance: the importance of the counsellor-counselee relationship

S. Pasalodos-Sanchez¹, T. Gale², G. Half², L. Kerzin-Storarr², R. Macleod²;

¹Nottingham Regional Clinical Genetic Service, NUH NHS Trust, City Campus, Nottingham, United Kingdom, ²Regional Genetics Service and Medical Genetics Research Group, CMMC NHS Trust and University of Manchester, Manchester, United Kingdom.

Previous research has highlighted that the quality of the relationship between genetic counsellor and counselee can impact on a successful outcome of genetic counselling. Many studies have focused on the counselee's perspective. We report on a process study involving 2 experienced genetic counsellors, as part of a triangulated study looking at how X-linked inheritance is explained in the genetic clinic. Following 10 clinic consultations, the genetic counsellors and the researcher (SP-S) watched the relevant sections of the video together, and counsellor comments were audiotaped and transcribed.

The counsellors recognised a favoured sequence for explaining X-linked inheritance, whilst holding a goal of tailoring the explanation. This was made difficult where rapport was less well established because of lack of verbal/non-verbal cues from the patient or whether it was the first contact. Where the counsellors felt a good rapport had been achieved, they felt better able to take account of age/educational background/need for information in order to personalise the explanation more effectively.

In a separate arm of the study, counselees also expressed the importance of the relationship in giving them confidence- both in themselves to ask questions for clarification- and in the counsellor's ability to help them achieve an understanding.

It is noteworthy that both counsellors and counselees reflected on counselling dynamics during the part of the consultation, which would be thought of as primarily educative. This paper will present further evidence that a division between education and counselling goals in

genetic counselling consultations may be unhelpful.

EP11. Strategies to facilitate decision making in genetics

EP11.1

The impact of a BRCA support-information group on the choice for a preventive mastectomy is limited

K. M. Landsbergen;

Department of Human Genetics. From the Hereditary Cancer Clinic, Nijmegen, The Netherlands.

Introduction: Important aims of a BRCA group are assimilation of being BRCA1/2 carrier, and professional guidance in choosing prophylactic mastectomy or breast cancer surveillance.

Aim: To determine whether attending a BRCA group influences the choice for surveillance or prophylactic mastectomy.

Patients and methods: 196 BRCA1/2 mutation carriers were included of whom 89 participated in a BRCA group. Preference for prophylactic mastectomy was registered after mutation carriership was revealed, thus before first attendance of the group.

Results: Characteristics of patients, who did or did not participate in a BRCA group, did not show any difference in demographic variables, age at breast cancer diagnosis, menopausal status or family cancer history. Preference for preventive mastectomy or surveillance was not significantly different in participants and non participants, being 31/89 (35%) and 27/107 (25%) respectively ($p=0.13$).

After a median observation period of 2 years (range 1-9 years) the percentage of women actually performing preventive mastectomy was significantly higher in participants than in non-participants of a BRCA group, 45% and 29% respectively ($p=0.02$). However, in the group with prior preference for mastectomy who did and did not participate in a BRCA group, prophylactic mastectomy was performed in 90% and 55%, respectively ($p=0.003$), in the group with prior preference for surveillance these percentages were 19% and 20% respectively ($p=0.09$).

Conclusion: The impact of a BRCA support group on the choice for prophylactic mastectomy is limited, and is determined by the woman's preference prior to the establishment of a BRCA mutation.

EP11.2

Development of a tailored, online decision aid on screening options for unaffected men with a family history of prostate cancer

C. Wakefield^{1,2}, B. Meiser^{1,2}, K. Watts¹, A. Barratt³, M. Patel³, G. Mann⁴, E. Lobb^{5,6}, K. Howard³, C. Gaff⁷, J. Ramsay⁸;

¹Prince of Wales Hospital, Randwick, Australia, ²University of New South Wales, Sydney, Australia, ³University of Sydney, Sydney, Australia, ⁴University of Sydney, Westmead, Australia, ⁵Curtin University of Technology, Perth, Australia, ⁶Edith Cowan University, Perth, Australia, ⁷Genetic Health Services of Victoria, Parkville, Australia, ⁸Liverpool Hospital, Liverpool, Australia.

PURPOSE: Men at increased risk for prostate cancer on the basis of family history are confronted with difficult decisions regarding the management of that risk. The information that needs to be conveyed is complex, and men often have difficulty accurately weighing up the costs and benefits of screening tests such as prostate specific antigen (PSA) screening.

METHODS: This study has two stages: (i) to develop and pilot-test an online, tailored decision aid for unaffected men with a family history of prostate cancer to inform them about their risk management options; and (ii) to compare in a randomised trial the efficacy of the decision aid to that of a comparison website amongst men at increased risk of developing prostate cancer on the basis of family history.

RESULTS: The early prototypes of the online decision aid were developed using an iterative process involving a working party comprised of experts and a consumer representative. It provides information on the genetics of hereditary prostate cancer, personal and family risk of developing prostate cancer; putative protective factors; screening tests and efficacy and side-effects of treatment options. Pilot-testing with approximately 20 unaffected relatives of men diagnosed with prostate cancer is currently underway, and results will be reported from the pilot testing phase.

CONCLUSION: A decision aid seems particularly suitable to provide

this group of men with decision support, and we anticipate that men will report better understanding of different risk management strategies and increased consumer satisfaction and will be more involved in decision-making.

EP12. Family dynamics and genetic

conditions

EP12.1

Perceived impact of BRCA1/2 testing on familial relationships and association with psychological distress

M. Dorval, K. Bouchard, E. Maunsell, S. Camden, J. Simard;
Université Laval, Québec, QC, Canada.

Objectives: This study describes the perceived impact of BRCA1/2 testing on relationships with first degree relatives. It also assesses whether experiencing a negative impact on relationships is associated with psychological distress and whether a positive impact is protective against distress.

Methods: A total of 636 French-Canadian women from 236 families, who underwent BRCA1/2 testing in the context of the INHERIT BRCA program between August 1998 and July 2004, were enrolled. Among them, 44% had already had cancer; 131 women were found to be mutation carriers, 172 non-carriers, and 333 had an inconclusive result. Questionnaires completed at pre-test and then at 1, 12, and 36 months post-disclosure were used to assess the perceived impact of testing on family relationships and psychological distress.

Results: Three years post-disclosure, 11% of women perceived that testing has a positive impact on their familial relationship compared to only 3% who perceived that the impact was negative. Among mutation carriers, these proportions reach 16% and 7%, respectively. After controlling for a range of socio-demographic, medical, and psychosocial factors, experiencing a negative impact on relationships with a first-degree relative was significantly associated with long-term distress ($p=0.04$). However, the perception that genetic testing had a positive impact on relationships was not protective against distress.

Conclusions: Although the perception that genetic testing had a negative impact on family relationships is associated with long-term distress, this is quite infrequent. More research is needed to better understand how the impact of BRCA1/2 testing on family dynamics may affect individuals' quality of life.

EP12.2

Social Intervention in the context of presymptomatic testing for late-onset neurological disorders

N. Oliveira, J. Pinto-Basto, J. Sequeiros;
IBMC, Porto, Portugal.

These diseases have several social and psychological implications (structural, processing, cognitive, emotional changes). Social intervention should be based in the systemic concept: good balance between psychodynamics demands of illness and family dynamics and their resources is determinant for the adaptation process and confrontation with the illness.

In our protocol of presymptomatic testing, the social worker assesses two groups of risk factors: (1) vulnerability centred on the subject (the genetic risk, personality resources, cognitive resources, etc.); and (2) vulnerability connected with inadequacy of the environment (familial structure, separation or death of a parent, chronic disease, economical fragility/poverty, social isolation, etc.).

Social Intervention is carried out through (1) exchanges holding emotional positive attitudes; (2) (formal or informal) counselling, allowing the establishment of interactions that have the aim of sharing information on the disease; (3) material or instrumental support; (4) technical support or of services; and (5) access to new contacts. In terms of social intervention, several people have also been helped with waivers for fees in health care (exemption from fees, medication, technical aids) (23); in the process of their incapacity retirement (10), professional conversion or changes (5), in the process for fiscal (IRS) benefits (3), and help finding a nursing home, continued care unit or care at home (6).

Social intervention, in presymptomatic testing for late-onset, so far incurable, neurological diseases, has the aim to help the persons at-risk and their family to keep balance and functioning, when confronted with

crises, such as test results or beginning of symptoms.

EP12.3

Susceptibility to type 2 diabetes: perceptions and family communication regarding inheritance and primary prevention

S. C. M. van Esch^{1,2}, F. J. Snoek^{1,2}, M. C. Corne^{1,2};

¹VU University medical center, dept. of Medical Psychology, Amsterdam, The Netherlands, ²VU University medical center, EMGO Institute, Amsterdam, The Netherlands, ³VU University medical center, dept. of Clinical Genetics, Amsterdam, The Netherlands.

Type 2 diabetes is a multi factorial disease, which means diabetes onset is triggered by interaction of (multiple) genes and environmental factors. Family history may serve as a good predictor of diabetes risk. People at risk can delay or possibly prevent diabetes by following a healthy lifestyle. We wonder whether this information is known by patients and whether they (are able or willing to) share it with their relatives.

544 People diagnosed with type 2 diabetes filled in a questionnaire. It appears in most families talking about diabetes is not taboo. Most respondents indicate that 'sometimes' diabetes is discussed; mostly initiated by the patients themselves. Subjects include mainly diabetes related problems; less developing or preventing diabetes onset.

Approximately half of the respondents knew about the inheritable character of diabetes; half of the group prefers more information provided by professionals. A majority agrees on the potential role of patients informing their family; half of the group actually intends to do so. They indicated they knew what, how, and whom to tell. Approximately half of the respondents believes patients should be coached by health professionals. In the presentation, relations between demographic variables (including ethnicity), diabetes related factors (including illness perceptions and family history), knowledge on inheritance and primary prevention, and family communication will be outlined.

In our opinion, the results may contribute to more targeted and effective health promotion strategies in diabetes prevention programs. However, we experienced quite different reactions, mostly in non-responders, discussing health issues in relation to family matters.

EP13. Living with genetic disease

EP13.1

The long-term information and support needs of BRCA1/2 mutation carriers

V. L. Hunt¹, R. Iredale²;

¹Peninsula Clinical Genetics Service, Exeter, United Kingdom, ²Institute of Medical Genetics, Cardiff, United Kingdom.

Genetic testing for inherited breast/ovarian cancer can have far reaching implications, both for the individual and their family. Research to date has mainly focused on the short-term impact of testing. The aims of this study were to explore the long-term impact of being identified as a BRCA1/2 mutation carrier, investigate the information and support needs of this group and explore best how cancer genetics services can meet these needs.

Data was gathered using semi-structured interviews with women who had undergone genetic testing in Wales and had received a mutation positive result. The interview transcripts were thematically analysed to gain insight into participant's thoughts and experiences.

For these women their 'genetic journey' did not end upon receipt of their test results. The findings suggest that BRCA mutation carriers may have specific needs for information and support that extend beyond the genetic testing process and that these needs may vary over time. A number of real or perceived barriers were identified which prevented participants from accessing support and information. Participants made valuable suggestions as to how cancer genetics services could address these issues.

It is likely that no single intervention will be effective in addressing the needs of this heterogeneous group. Further large scale research is needed to investigate how best to target resources to meet client needs. This study explores the views of this group, highlighting issues that are important to them. The findings emphasise the fact that long-term user involvement is essential in the planning and optimising of service provision.

EP13.2**Decision making dilemmas for E-cadherin mutation carriers: A family case study****S. C. Downing;***Department of Medical Genetics, Addenbrookes Hospital, Cambridge, United Kingdom.*

This case study presents two siblings, whose health beliefs, career and family responsibility had a strong influence on how they perceived their risk, management choices and decisions. Both were carriers of an E-cadherin (CDH1) mutation and chose to manage their risks differently. Gastric cancer affects 15 per 100,000 people in the UK and around 3% arise from a clearly identified inherited gastric cancer predisposition. One third of families with a strong history of diffuse gastric cancer have germ line mutations in the E-cadherin gene. Mutation carriers have a 70-80% life time risk of developing gastric cancer with associated poor outcome, they also have an increased risk of lobular breast cancer and colon cancer. Predictive testing is available for individuals where a familial mutation has been identified. A positive result provides challenging decisions regarding personal risk management with the option of endoscopic screening or prophylactic gastrectomy. Screening is unproven and there is concern that early cancer may be missed since it is submucosal. The alternative option of surgery carries a high morbidity with life long adaptations required; limited data exists on the outcome for prophylactic gastrectomy. One sibling opted for preventative surgery, the other endoscopy screening. Counselling issues included: career changes, family dynamics, psychosocial aspects, coping with major surgery, and quality of life. Management of cancer risk is a personal issue, risk management options should be explored in depth to enable the individual to make fully informed decisions.

EP13.3**Quality of life in adults with familial adenomatous polyposis (FAP)****K. Fritzell¹, J. Björk¹, M. Arman², R. Hultcrantz¹, L. Wettergren²;***¹The Swedish Polyposis Registry, Stockholm, Sweden, ²Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden.*

Background: FAP is a disease which among other symptoms is manifested as multiple polyposis with adenomas in the large intestine, rectum and duodenum. These adenomas are very likely to turn cancerous over time. The disease is inherited autosomal dominant. Surgery is the only treatment that can prevent colorectal cancer and prophylactic surgery is performed on all patients. Preoperative symptoms are rare, but a large number of patients report functional impairments after surgery.

Aim: The aim of the study was to describe how adult patients with FAP perceive that the disease has affected their life.

Method: Adult patients (≥20 years) attending the outpatient clinic at The Swedish Polyposis Registry were invited to participate in focus group interviews (n=43). Three focus group interviews were conducted. Data was analysed by means of content analysis.

Results: The content analysis revealed nine themes: Worries and concerns, Social life, Choice of career and education, Risk of giving the disease to the children, Changed food and toilet habits, Experiences of endoscopic examinations, Relationships to health care providers, Stories about hospital stay at their first surgery, Knowledge of FAP.

Conclusion: The study has highlighted several issues of concerns related to FAP. Worries about getting worse due to the disease were expressed by many of the participants but not anyone mentioned cancer as a threat for future health. Due to the heredity of the disease, having own children or not was a deep and complex question and the discussion gave an impression of a need to defend one's standpoint.

EP13.4**Participation in Huntington's disease research: hoping, coping and a nice day out****J. Needs;***Cardiff University, Cardiff, United Kingdom.*

This poster is based on an ongoing PhD examining Huntington's disease (HD) as a case study of how the development of genetic technologies and identification of human genetic mutations, affect the work of the clinic and the lives of patients. Ethnographic data from neurological research clinics (n=11) will be used to explore the current nature and structure of clinical work itself, and will illustrate how different mean-

ings of the clinic are enacted by the participants, including patients, family members, carers, and researchers. This work will be used to inform later stages of the PhD, which will include interviews with patients and clinical teams and the examination of an archive of HD patient records from the 1970's to the present day.

Current clinical practice emphasises genetic, biological, cognitive and physical measurement. These are areas associated with neuroscientific research programmes, and patient recruitment is crucial in order to provide large data sets for possible future clinical trials. These data sets will be kept indefinitely and provide material for international collaborative research. However, for patients and families, research involvement is not always the focus. Rather, they view participation as a privileged medical appointment and a way of getting answers to their own situations. They hope for effective treatment via research (stem cells) and participation may provide one strategy for coping with the effects of the disease. The research environment and relationships with researchers at repeated clinic visits also provides familiarity and a social aspect to the whole process, in effect, a nice day out.

EP13.5**Consensus document on best care in HD: a training/educational program for Italian neurologists****G. Jacopini¹, P. Zinzi², A. R. Bentivoglio², M. Frontali³;***¹ISTC/National Research Council, Rome, Italy, ²Istituto di Neurologia Università Cattolica del Sacro Cuore, Policlinico "A.Gemelli", Rome, Italy, ³INMM/National Research Council, Rome, Italy.*

Huntington's disease is a rare, complex, hereditary disorder, characterized by motor as well as psychiatric symptoms; very often, neurologists are unable to handle these patients, lacking guidelines about the most appropriate way of care for them. In July 2007, upon request of the Italian Association for Huntington's Chorea (A.I.C.H-Rome and A.I.C.H-Milan), our research group organized a multidisciplinary panel of experts with the main task of providing recommendations for the best care in HD. The panel produced a "consensus document" with recommendations which address HD patients and families' main needs, combining together scientific information and long lasting clinical experience. The document covers multiple aspects: making the diagnosis and communicating it, therapeutic management and paramedical treatments, nutrition and dietary supplements, genetic risk and genetic testing protocol, co-morbidity, palliative and end-of-life care, non medical support, indications for referral.

The document, written in a synthetic style, contains practical recommendations aimed at minimize inappropriate care and introducing research findings into clinical practice of neurologists not familiar with HD issues. The document will be printed (10.000 copies) and, starting May 2008, first introduced in the course of three main educational events (in Northern, Central and Southern Italy) for neurologists. Then the document will be delivered to 3,500 neurologists working both in public health care settings and in the private field. In the future we plan to assess the impact of the document through meaningful and measurable outcomes.

EP13.6**Living with a person with Huntington's disease****A. J. A. G. Van Tongerloo, A. M. J. J. De Paepe;***University Hospital Gent, Gent, Belgium.*

Introduction: Huntington's disease, an autosomal dominant neurodegenerative disorder, is characterized by a triad of progressive motor, cognitive and emotional symptoms. In 1994, predictive testing through the direct DNA test became available. The psychological impact of carriership on the testee and his/her partner has been extensively evaluated and reviewed. Few studies however, have been conducted to explore how living with a person with the disease affects the healthy partner's daily life.

Materials and Methods: In January 2008, a qualitative study was set up, in which partners of persons with HD are questioned through a semi-structured interview. Topics that are questioned are: coping with the partner's symptoms, the symptoms that are the most difficult to deal with, the changes in personal life of the healthy partner, and the future perspectives for the healthy partners. Furthermore, participants are asked about their feelings towards their partner, and about communication on the disease with the affected partner, with their children and with significant others.

Results: Preliminary results of this study, which is still ongoing, will be presented. It is anticipated from our clinical experience that emotional/character changes of the partner are most difficult to cope with, since the partner often becomes a “different” person to live with. Changes in personal life include mainly changes in the role model in the partner relationship. Healthy partners often experience the daily care and the material consequences of Huntington’s disease as a major burden for the future.

EP13.7

Psychosocial aspects of living with Long QT Syndrome. A qualitative study

J. Andersen^{1,2}, N. Oyen^{1,3}, C. Bjorvatn^{1,3}, E. Gjengedal¹;

¹Department of Public Health and Primary Health Care, University of Bergen, Bergen, Norway, ²Norwegian Porphyria Center, Haukeland University Hospital, Bergen, Norway, ³Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway.

Background: Long QT syndrome (LQTS) is a genetic disorder characterized by prolongation of the QT interval on the electrocardiogram, potentially leading to life-threatening arrhythmias and increased risk of sudden death. In Norway LQTS patients and their families are offered diagnostic or predictive genetic testing. Norwegian legislation states that genetic counseling is mandatory in connection with genetic testing of healthy individuals.

Purpose: The purpose of this qualitative study was to

- Investigate the psychosocial aspects of living with LQTS
- Describe LQTS patients’ experiences with healthcare services.

Material and methods: In-depth interviews with seven Norwegian adults tested for long QT genetic mutations, was conducted. Four participants had an implantable cardiac defibrillator (ICD).

Results: Participants experienced worries and limitations in daily life and it was a general wish among them to be able to talk to someone with the same condition. Their main concern was not for their own health but for their children or grandchildren. Having an ICD was experienced as an additional safety but it could also cause social embarrassment and anxiety. Early and gradually acquired knowledge of the syndrome was reported as an advantage. Healthcare providers’ minimal knowledge of LQTS resulted in uncertainty, misinformation, and even wrong advice on treatment.

Conclusion: Knowledge of the challenges met by this patient group is important in order to provide adequate genetic counseling. Further investigations into the psychosocial aspects of LQTS are desirable.

EP13.8

Unmet information and support needs amongst individuals affected by one of two rare cancer syndromes: MEN2A and VHL

N. A. Kasparian^{1,2}, A. Rutstein^{3,2}, B. Meiser^{3,2}, J. Koehler⁴, J. Tyler⁴, K. Tucker⁴;

¹School of Women’s and Children’s Health, University of New South Wales, Kensington, NSW, Australia, ²Kensington, Australia, ³Department of Medical Oncology, Prince of Wales Hospital, Randwick, Australia, ⁴Prince of Wales Clinical School, University of New South Wales, Kensington, NSW, Australia, ⁵Kensington, Australia, ⁶Hereditary Cancer Clinic, Prince of Wales Hospital, Randwick, Australia.

Multiple endocrine neoplasia type 2A (MEN2A) and von Hippel Lindau syndrome (VHL) are rare, inherited, early onset cancer syndromes characterised by the development of tumours in one or more parts of the body. Genetic testing is typically carried out in young children with a family history of either condition. Individuals identified as gene carriers undergo lifelong surveillance in order to detect tumours at an early stage. Little is known, however, about the psychosocial experiences of individuals affected by MEN2A or VHL. This study aims to identify the unmet information and support needs of individuals affected by these rare cancer syndromes. Patients with a confirmed diagnosis of MEN2A or VHL were ascertained via the Hereditary Cancer Clinic at Prince of Wales Hospital, NSW, Australia. A semi-structured individual interview was developed to assess five broad themes: impact of MEN2A/VHL on various life domains such as relationships, education and employment; attitudes towards childbearing; coping strategies; family communication about the disease; and unmet information and support needs. Interviews with approximately 20 patients and 16 caregivers are currently underway, with 16 completed patient interviews and 8 completed caregiver interviews. Data will be analysed separately for patients and caregivers, using qualitative data analysis software, QSR N6. Partic-

ular focus will be placed on potential thematic differences between cancer groups and genders. These data will inform the development of a survey instrument, which we aim to administer on an international scale through collaborations with the Association for Multiple Endocrine Neoplasia Disorders (AMEND) and the VHL Family Alliance.

EP13.9

Managing relationship needs while living with chronic genetic illness

F. Pearce;

Genetic Health, Parkville, Victoria, Australia.

The special care requirements of children, who progressively become physically and intellectually disabled due to metabolic illness, can be emotionally and physically overwhelming.

All family relationships are under pressure in these circumstances. At the same time, people discover capabilities and strengths that would rarely be known about or used, under more normal situations.

Often, the sick child’s primary care-giver (usually their mother) has to make choices from several competing needs at the one time. How are these choices made? On what basis are they prioritised? A great number of relationships fail in these circumstances, however others are awe inspiring.

This presentation will include case material that demonstrates how some couples cope and how others feel forced to ‘give up’.

EP14. Other relevant psychological and social topics in genetics

EP14.01

Mental representations of pregnant women with advanced maternal age (AMA) who undergo amniocentesis: a unique dynamic process

A. S. Leonardo¹, J. Justo², I. Cordeiro¹;

¹Hospital Santa Maria, Lisboa, Portugal, ²Faculdade Psicologia e Ciências de Educação, Universidade de Lisboa, Lisboa, Portugal.

Non routine medical procedures, such as amniocentesis, have been suggested to have an emotional impact on pregnant women. Anxiety is an obvious consequence, the psychological “suspension” of the pregnancy might be another one. We propose that the process of accepting the reality of gestation and the reality of the foetus, expected to occur respectively in the first and second trimester, is postponed in AMA women who undergo amniocentesis until after the result comes through.

Building mental representations about the foetus is an important part of the psychological process that takes place during pregnancy. In fact, some studies have questioned the importance of these representations for the quality of the mother-baby relationship/ interaction. Amniocentesis is thus performed during a crucial period of intense and dynamic internal activity. The purpose of this study was to understand how does this procedure influence the dynamic process by which AMA women build representations of the foetus as their “child-to-be”.

We applied an adaptation of Interview R to a group of 35 pregnant AMA women (A) and a control group (NA), before and after amniocentesis. Before amniocentesis, group A gave “less rich” and “less positive” descriptions of their future babies, and characterised them as “less active” and “quieter”. After the results were known, the only difference between the two groups was that NA women continued to describe their future children in a more positive way.

These findings suggest that the dynamic process of maternal mental representations is unique in AMA women who undergo amniocentesis.

EP14.02

GeneBanC. Studying the ethical, legal and social aspects of Biobanking

P. Borry, K. Dierickx;

Centre for Biomedical Ethics and Law, Leuven, Belgium.

Background. The last few years have witnessed an important expansion of collection and processing of human biological samples and of the related information data. Biobanks are huge repositories of human biological specimens and have a strategic importance for genetic research, clinical care and future treatments.

Objective. GeneBanC is an acronym for the research project *Genetic bio- and dataBanking: Confidentiality and protection of data. Towards a European harmonization and policy*. This E.U.-funded research project that has been funded by the European Commission and aims to investigate the ethical, legal and social issues of three types of biobanks: classical banking, population banking and forensic DNA databases.

Method. The workload has been split up in various workpackages, studying respectively (a) the issue of privacy and confidentiality in biobanking; (b) the existing regulatory framework of biobanks across the E.U. and the regulation regarding the establishment, management and functioning of biobanks; (c) forensic genetic databases; (d) governance aspects of biobanks.

Expected results. It is expected that the results obtained within the different objectives described above will be of great use for the development of policy oriented recommendations concerning the organisation and management of biobanks. Proposals will be elaborated in order to reach where appropriate a harmonized regulatory framework across the European Union.

EP14.03

Support groups for women carrying a BRCA1 or BRCA2 mutation : a first experience.

K. Baudry-Samb¹, P. Pujol¹, C. Laurent¹, I. Coupier^{1,2};

¹CHU Arnaud de Villeneuve, Montpellier, France, ²CRLC Val d'Aurelle, Montpellier, France.

During consultations we felt that women carrying a BRCA1 or BRCA2 mutation had a strong desire to share their experience. We decided to set up a support group for them.

The aim of this support group was to give the patients a place where each individual could be heard, and where experiences and information could be shared.

53 women patients were invited by mail, and 8 of them decided to participate. They all had a personal history of breast and/or ovarian cancer. Six had undergone preventive surgery.

We chose a non-directive method, allowing the patients to decide what topic was to be addressed at each meeting. We met every 1.5 month, during 1 hour, for 7 months (5 meetings). Meetings were led by a psychologist, a geneticist and a clinical research assistant. The themes addressed were: cancer (family history, isolation, relationships with closed ones, the body image, treatment, surgery, femininity), loss (of self, of a part of one-self, of a loved one), pre-symptom analysis, maternity, preventive surgery, and medical questions.

Our goal was met. Indeed, a positive dynamic was present throughout the meetings. Most of the themes of concern in this particular patient population were addressed. The patients' feedback was very positive. It allowed some of them who could not talk at home to share their difficulties, and others to begin a dialog with their closed ones.

This year, we started 3 new groups, involving 22 patients, based on Spiegel's supportive-expressive method.

EP14.04

Dying with a family history of cancer: A phenomenological study

A. K. Lillie;

University of Birmingham, Birmingham, United Kingdom.

There has been widespread media coverage about the potential for an inherited predisposition to cancer in Britain. This study aimed to describe how this was affecting care needs of palliative care patients. Data was collected through recorded, semi-structured interviews with twelve patients with advanced cancer. Purposive sampling ensured that participants had been predeceased by at least one first degree relative with cancer. Data was coded using an iterative approach into themes that arose from the participants experiences. Van Manen's (1990) schema of existential analysis was then used to identify the relationship between the themes under investigation.

This study showed that patients were dying with concerns about the implications of their disease for their families. Concerns for children were widespread and existed in patients who did not think that their own cancer was associated with an inherited susceptibility, patients who had been informed that they were not at high risk of familial disease and in patients who had not discussed their anxieties before.

The participants' experience of dying was affected by previous death within the family: especially by the deaths of relatives who had died at a younger age than normal. It changed the way the participants com-

municated about cancer and affected family cohesion and hence the support available to participants. It also increased their awareness of their dying trajectory, altering the way they coped with the disease.

This study shows that there are complex challenges for health care professionals when supporting dying patients worried about their family history of cancer.

EP14.05

Translating research into practice: Health care professionals' and researchers' understanding of cancer genetics activities in the UK

N. Hallowell¹, S. Cooke¹, G. Crawford², M. Parker³, A. Lucasser²;

¹University of Edinburgh, Edinburgh, United Kingdom, ²University of Southampton, Southampton, United Kingdom, ³University of Oxford, Oxford, United Kingdom.

DNA-testing for hereditary cancers and high risk cancer surveillance in the UK takes place either as part of research protocols (and thus, requires ethical approval) or is offered as an NHS clinical service. The route chosen may depend on a range of factors. This multidisciplinary project investigates healthcare professionals', patients' and regulators/ other stakeholders' understandings of cancer genetics activities within the UK. It looks at how these different groups conceive of research and clinical practice, and aims to identify any perceived ambiguities and practical and/or ethical problems that are generated by these activities for the different actors. Semi-structured interviews have been carried out with healthcare professionals and researchers (HCPs) (n= 40) who are involved in cancer genetics research and/or provide a clinical cancer genetics service. The interviews suggest that research and clinical practice are perceived as standing in a complex relationship with each other. In some cases our respondents made strenuous efforts to distinguish these activities, while at other points in their interview they struggled to identify differences between them. The boundary between research and clinical practice within cancer genetics, could thus, be characterised as ambiguous, flexible, permeable and a permanently shifting phenomenon. The strategies that healthcare professionals use to distinguish these activities are described.

EP14.06

Evaluating the impact of a self-help coping intervention: a study outline of the CARIAD Trial.

H. Jones¹, C. Phelps¹, P. Bennett², K. Brain¹, K. Hood³, J. Gray⁴, A. Murray⁵;

¹Institute of Medical Genetics, School of Medicine, Cardiff University, Cardiff, United Kingdom, ²Nursing, Health and Social Care Research Centre; Cardiff University, Cardiff, United Kingdom, ³Centre for Health Sciences, School of Medicine, Cardiff University, Cardiff, United Kingdom, ⁴Wales Centre for Health, Cardiff, United Kingdom, ⁵Institute of Medical Genetics, University Hospital of Wales, Cardiff, Cardiff, United Kingdom.

Background Around a third of individuals undergoing genetic risk assessment report high levels of distress and are likely to benefit from increased psychological support. A self-help leaflet has been developed, based upon coping theory, to help individuals cope with unwanted worries whilst waiting for genetic information. The intervention encourages individuals to restrict consideration of the issues related to their risk for a set time each day, and to actively distract from intrusive thoughts at all other times. The CARIAD trial is evaluating the psychological impact of this intervention.

Study aims 1) To evaluate the short- and longer-term impact of the intervention on levels of distress at key stages of the assessment process 2) To explore the impact of the intervention on emotional responses and coping.

Design Recruitment commenced in September 2007. Over a nine month period 1,000 male and female referrals into the Cancer Genetics Service for Wales will be pre-randomised to receive either the coping leaflet or standard care and asked to complete a postal questionnaire at 3 time points: upon referral, whilst waiting for genetic risk information (4 weeks post-referral) and one month post-risk.

Outcomes The primary outcome measure is the level of situation-specific distress over time, as measured by the Impact of Event Scale. Secondary outcomes and potential moderators include positive and negative affect, risk understanding, illness perceptions, and coping. The intervention may also be appropriate during other periods of waiting and uncertainty such as undergoing predictive or prenatal genetic testing or awaiting screening outcomes.

EP14.07**Psychosocial and demographic profile of a deaf community in the Altai Republic: a pilot study**

O. L. Posukh, O. V. Posukh;

Institute of Cytology and Genetics, Novosibirsk, Russian Federation.

The study is based on data obtained from self-completion questionnaires designed to evaluate marital status and marriage patterns of deaf persons, their communication mode, access to education, employment and information, and their living standard and social status. The participants belonged to the association of deaf and hard-of-hearing people in the Altai Republic (south Siberia, Russia).

In recent years total number of the association members varied from 150 to 160 people at the age of 18-85 years with approximately equal gender ratio. Most of them have congenital or early onset severe-profound deafness. About two thirds of adult members are married to deaf partner and almost all the young unmarried people with hearing loss tend to prefer deaf partner in future. Deaf participants indicated sign language as communication mode with other deaf persons, whereas in communication with hearing people they use lip-reading, writing, and oral language skills, if any. Their embarrassment in contacts with hearing people due to mutual misunderstanding leads to preferential contacts with deaf people. Most of participants consider their hearing loss as disability which limits access to education and employment, and decreases their social status and living standard.

Our molecular-genetic studies revealed deafness caused by Cx26-mutations in not less than 15% of examined members of this association, and several families with hereditary deafness of yet unknown etiology.

This study has implications for genetic counselling for families with hereditary deafness, and provides insight to deafness prevalence pattern in the Altai Republic.

Work is supported by Russian Foundation for Humanities (07-06-00765a).

EP14.08**Psychosocial impacts of the neonatal hearing screening**R. Heitor^{1,2}, H. Romano³, I. Rouillon¹, C. Pol⁴, N. Loundon¹, C. Rebichon¹, E. Garabédian¹, F. Denoyelle¹, S. Marlin^{1,2};

¹Hôpital Armand Trousseau, Paris, France, ²Centre de référence des Surdités Génétiques, Paris, France, ³Hôpital Henri Mondor, Créteil, France, ⁴Hôpital du Kremlin Bicêtre, APHP, Le Kremlin Bicêtre, France.

Since February 2005, an experimental program of neonatal screening of the congenital deafness is in process in France.

Our purpose is: - to estimate the psychological impacts of the screening; - to measure the risk of creating an anxiety in the parents and thus to hinder the development of the attachment mother / child links, which set up in the very early neonatal period; by the study of the false positive families (hearing children with pathologic automatic ABRs).

A questionnaire was realized, and sent by mail to families, accompanied with a letter explaining the reasons of our research. The first part of the questionnaire concerns the information which was given to the parents before the screening, the result obtained at the test and the information which followed this result. The second part of the questionnaire focuses in the way back at home looking forward to the consultation with the ENT, in which the hearing defect will be confirmed or not. The third part of the questionnaire concerns the feelings of the parents at the time of the ENT consultation, the information given to them, and the impact of the final diagnosis. Then the last part is about the general feelings of the parents as regards the neonatal screening of the deafness and finally the impact of this screening on their relations with their baby.

This work allows us to give some recommendations to improve this screening in the future.

EP14.09**Exploring the impact of genetic testing for Familial Hypercholesterolaemia: a family perspective.**M. S. Watson¹, D. Townsend², I. McDowell¹, K. Featherstone³;

¹Institute of Medical Genetics, Cardiff, United Kingdom, ²Department of Medical Biochemistry, Cardiff, United Kingdom, ³CESAGEN/ School of Nursing & Midwifery, Cardiff, United Kingdom.

Familial Hypercholesterolaemia (FH) is an autosomal dominant disorder with a prevalence of 1 in 500, approximately 110,000 people are

thought to be affected in the UK, but unfortunately the majority remain undiagnosed. Effective preventative treatment is available, if untreated it leads to premature Coronary Heart Disease (CHD) and death. Cascade testing using genotyping has recently become available in South Wales on a research basis.

The main aims of this study were to explore how patients and their family members receive, make sense of and transmit genetic information and the impact this dynamic process has on perceptions of risk.

Face to face semi structured interviews were conducted with seven patients in whom a clinical diagnosis of FH had been made and who had recently undergone genetic testing and received a mutation positive result. A further seven interviews were conducted with members of their families who had also undergone genetic testing to follow the flow of this genetic risk information. The interview transcripts were thematically analysed to gain insight into their experiences.

The findings suggest that this genetic information help the patients to make sense of their condition. Family members reported an open style of communication although this process and emotional responses to genetic risk information were complex. This research highlights some key issues for future research of this complex dynamic process.

EP14.10**Carriers of a cancer pre-disposition gene: Gaining an insight of their ongoing needs**M. K. Kentwell, R. D'Souza, M. Bogwitz, F. Macrae, G. Lindeman, L. Hodgkin; *Familial Cancer Centre, Royal Melbourne Hospital, Parkville, Australia.*

Research has shown that people who carry a cancer predisposition gene (gene carriers) value follow up from a Familial Cancer Centre (FCC) after learning of their results. Gene carriers may require ongoing support over time, as their needs in adjusting to their genetic status may change through the family life cycle. This ongoing support may include a discussion of issues around impact and adjustment to the genetic test result. From an FCC perspective, communication of genetic information to family members also needs to be explored.

The follow up practice at the Royal Melbourne Hospital Familial Cancer Centre has involved a yearly phone call from a Genetic Counsellor to a gene carrier. This format may not be optimal for many gene carriers. As the number of gene carriers increase, many FCCs may find their increased workload unsustainable.

This presentation will summarise a trial of an alternative strategy of supporting gene carriers over time. In addition, issues identified by the gene carriers themselves will be described.

EP14.11**Comparison of experiences between Italian and other European Genetic Nurses**M. Regele¹, M. Gabaldo², F. Benedicenti¹, F. Stanzial¹, C. Castellani¹;

¹Genetic Counseling Service of the Province of Bolzano/Bozen, Bolzano/Bozen, Italy, ²Section of Biology and Genetics, Dpt. of Mother and Child and of Biology-Genetics, University of Verona, Italy.

The professional figure of the Genetic Nurse (GN) is well defined in some European and extra-European Nations. In these countries there are formal courses of studies, which allow the students to graduate to GN.

In Italy there isn't either a formal acknowledgement of the figure of the GN, nor does exist a specific education for non-medical personal working in clinical genetic institutes.

Nevertheless we knew that some people, scattered among Italy and generally without knowing of the existence of other colleagues sharing the same mansions, were working in the field of clinical genetics.

With the aim of creating a national net of GNs and of promoting the official situation of this figure after specific learning programmes, we made the first census of the Italian GNs.

After phone contact with the directors of the centers for clinical genetics, we submitted a questionnaire to the people working as GNs and analyzed the results.

The activities of the GNs in other countries were taken from literature and through direct contact with Dr. Heather Skirton.

Our data showed marked heterogeneity of duties of the GNs in Italy but the majority of the mansions matches that of the foreign colleagues.

The Italian GNs feel in need of a specific course of studies to prepare them to a highly specialized work, which should be acknowledged by the national health system.

EP14.12

The role of the specialist midwife in Fetal Medicine Units.

F. Pancetti¹, S. Boxall², C. Bravi³, A. Kustermann³, P. Simi¹, I. Cetin³, D. A. Coviello³;

¹Dipartimento di Ostetricia e Ginecologia, AOU Pisana, Pisa, Italy, ²Fetal Medicine Unit, Princess Anne Hospital, Southampton, United Kingdom, ³Fondazione IRCCS, Ospedale Maggiore Policlinico, Mangiagalli e Regina Elena, Milan, Italy.

The role of the midwife in fetal medicine unit in UK is quite well defined. Some specific actions are: advocate and support for women; provision of information about the nature of the abnormality (both written and verbal) for women and other health professionals; counselling women about their choices regarding the pregnancy, and preparing women for either termination of pregnancy or continuing with a baby who has abnormalities; led clinics for antenatal counselling and follow up after TOP and bereavement care; communication with other health professionals to ensure continuity of care for women. In Italy the role of specialist midwife is still quite heterogeneous, depending on the presence or not of a well defined Fetal Medicine Units. We present a collaborative effort to share experience between UK and Italian midwife in defining the appropriate skill required as advanced communication skills; counselling training; specialist knowledge about prenatal diagnosis; highly developed analytic and judgemental skills; planning and organisational skills; technically adept; leadership skills; IT literate; support for self- emotional and psychological.

The aim of this collaborative work is to define a general framework that describe the role of the specialist midwife in fetal medicine in order to establish a model that can be applied internationally.

The work of the specialist midwife in Fetal Medicine is challenging and rewarding, and offers scope for providing excellence in clinical care for pregnant women and their families.

EP14.13

Collecting data of HD patients for the Euro-HD Registry: an uptodate from Rome sites

P. Zinzi¹, A. Fasano², A. Guidubaldi², T. Ialongo², G. Loria², F. Soletti², A. R. Bentivoglio², S. Romano^{1,3}, M. Spadaro^{1,4}, G. Jacopini¹, M. Frontali⁴;

¹Institute of Cognitive Science and Technologies, National Research Council, Rome, Italy, ²Institute of Neurology, UCSC, Rome, Italy, ³UOC Neurology Azienda Ospedaliera Sant'Andrea, Rome, Italy, ⁴Institute of Neurobiology and Molecular Medicine, CNR, Rome, Italy.

The Euro-HD Network is aimed at providing a platform for professionals and people affected by HD and their relatives in order to facilitate collaboration throughout Europe. The core of the study is the Registry, a systematic collection of clinical research data of HD patients, of mutation carriers and of individuals who are part of HD families.

Two study sites participate to Euro-HD network in Rome: one is at the Consiglio Nazionale Ricerche (C.N.R.) and is based on the long lasting cooperation between two main institutes of public research, the Institute of Cognitive Sciences and Technologies (I.S.T.C/CNR) and the Institute of Neurobiology and Molecular Medicine (I.N.M.M/CNR); the other one is at the Neurology Department of the Università Cattolica del Sacro Cuore (U.C.S.C.) Both sites are involved in running an outpatient clinic for HD patients started in 1989 as a common research project and which has assumed, since 1994, the characteristic of a multidisciplinary clinic. The individuals followed at the clinic are 312: 65% are symptomatic patients, 20% are subjects at risk (pre-test neurological examination), 15% are asymptomatic gene carriers (post-test follow-up).

For the Euro-HD project, from Sept 2004 to Dec. 2007 we have completed and entered into the Registry the data collection of 75 patients (37 Males and 38 Females): 69 symptomatic patients and 6 asymptomatic gene carriers. For further 15 patients we are now completing the last forms and their data will be entered quite soon.

Data analysis and comments on different aspects of data collection will be reported.

EP14.14

The risks & benefits of screening for Klinefelter syndrome: A critical analysis

A. S. Herlihy^{1,2,3}, J. Halliday^{1,4}, R. I. McLachlan^{2,3}, M. Cock³, L. Gillam^{1,5};

¹Murdoch Childrens Research Institute, Melbourne, Australia, ²Monash University, Melbourne, Australia, ³Andrology Australia, Melbourne, Australia,

⁴Melbourne University, Melbourne, Australia, ⁵Melbourne University, Melbourne, Austria.

Background: Klinefelter Syndrome (KS) is a genetic condition (47,XXY) affecting males and resulting in a spectrum of clinical features, ranging from infertility, androgen deficiency and breast development to varying levels of cognitive, social, behavioural and learning difficulties. The prevalence has been estimated to be 1:650, yet up to 70% of males remain undiagnosed. Early identification has been advocated for many years, but population-based genetic screening for KS has never been explored.

Aim: To identify the potential risks and benefits that could arise from implementing population-based genetic screening for KS at different ages and stages of development.

Method: A framework was developed to assess the medical (hormone, therapeutic interventions), psychological (self-esteem, relationships) and ethical (autonomy, associated stigma) implications of genetic screening for KS in four hypothetical age-dependent scenarios - newborn, infancy, primary school entry and high school entry - chosen as providing opportunistic circumstances in which an individual might be evaluated. The outcomes have been considered in relation to diagnosis in adulthood and the most common scenario of lifelong non-diagnosis. Evidence of potential risks and benefits associated with KS diagnosis was collected by analysis of the existing literature.

Results: Our analysis indicates that while there is information on available medical, educational and psychological interventions, there has been no consideration of the impact of age of diagnosis and the related timing of interventions on psychosocial and other quality of life outcomes.

Conclusion: More research is needed to fill these evidential gaps and inform decisions regarding population-based genetic screening for KS.

EP14.15

Genetic counselling training and supervision in a second language: is it different?

R. D. Vanneste, J. Fitzpatrick, L. Russell;

McGill University, Montreal, QC, Canada.

Purpose: Live supervision is a key component of the training of genetic counsellors. However, the ways in which training and supervision differ for students and supervisors when these activities occur in a second language have not yet been explored.

Method: A questionnaire was distributed to members of the CAGC and NSGC using the online survey provider, www.surveymonkey.com@. Data were analyzed using a consensual qualitative method modified from Hill et al. (1997).

Results: Supervisors find it difficult to assess students' psychosocial counselling skills in the second language, and feel personal discomfort in having an incomplete understanding of session content. Students, in turn, describe decreased competence when counselling in their second language, and a greater focus on the medical aspects than on the psychosocial dimensions. Interestingly, students whose second language is French (mainly Canadian) describe more negative experiences and more difficulties in certain areas, such as building rapport with patients, than do students who counsel in Spanish (mainly American). This may reflect differences in patient expectations for receiving service in their native tongue in Canada compared to the US. The language of training, whether it is the student's first or second, was described as having a major impact on counselling abilities and comfort level in the second language. Overall, however, the use of second languages in training seems to have a positive impact for both students and supervisors, leading to increased satisfaction in providing linguistically and culturally-centered patient care. The implications of these findings for genetic counselling training will be discussed.

EP14.16

"Asking for oncogenetic counseling": evaluation of psychological aspects, need for information and perceived risk

E. Razzaboni, D. Turchetti, D. Fabbro, E. Pompili, A. Petracca, C. Graziano, A. Wischmeijer, M. Seri, G. Romeo;

Operative Unit of Medical Genetic, Bologna, Italy.

The amount of clients seeking oncogenetic counselling (OGC) is rapidly growing up. Understanding communicational aspect and clients' styles of information seeking, together with personality, is fundamental

to optimize counseling service. We necessitate to analyze psychosocial features to fit counseling process to client personality and needs. To reach this goal, since 2004 we have evaluated needs for information, motivations and psychosocial characteristics of individuals asking for OGC because of their familial history of common cancers (breast, colon, thyroid, etc.). 110 counsees fulfilled a questionnaire before receiving OGC assessing: sociodemographic features, health locus of control, monitoring/blunting, general self efficacy, motivations, emotional state and perceived risk. 76 were affected by cancer and 34 were unaffected. Cancer risk was assessed either with genetic testing or with validated probabilistic models. Our results have showed that counsees have: no clinical psychological distress, high level of self efficacy but not a specific style of information seeking. They feel at high risk for cancer running in the family and they strongly want information about surveillance and prevention actions. Perceived risk is related to some psychological variables (coping and mood) and in unaffected people it is not related to cancer risk estimated. We can conclude that, individual seeking OGC have adaptive psychological resources that let them cope with familial cancer risk, and that evaluating psychological profile has several implications into clinical practice, because psychological variables significantly influence risk perception.

EP14.17

Triangulation of methods: a novel approach to investigating valued outcomes from using clinical genetics services

M. McAllister¹, K. Payne², R. MacLeod³, D. Donnai¹, L. Davies²;

¹Nowgen (A Centre for Genetics in Healthcare) & Medical Genetics Research Group, The University of Manchester, St Mary's Hospital, Manchester, United Kingdom, ²Nowgen (A Centre for Genetics in Healthcare) & Health Economics Research at Manchester, School of Community-based Medicine, The University of Manchester, Manchester, United Kingdom, ³Medical Genetics Research Group, The University of Manchester, St Mary's Hospital, Manchester, United Kingdom.

The patient benefits from using clinical genetics services are hard to measure, and there is little consensus about appropriate outcome measures. This paper describes a programme of research that aimed to work towards a core set of outcome measures suitable for evaluating clinical genetics services. The approach involved 4 types of triangulation (method, investigator, discipline and data). Three methods were used:

- (1) A systematic review of the literature identified the validated outcome measures (30 genetics-specific and 37 generic) used, or developed, to evaluate clinical genetics services.
- (2) A Delphi survey, aimed at identifying the degree of consensus about the relevance of existing outcome measures, was completed by a panel of 115 genetics clinicians and 72 patients of clinical genetics services. At least 75% of the panel agreed that the following outcome domains were useful: knowledge of the genetic condition, decision-making, perceived personal control, risk perception, satisfaction, meeting of expectations, coping, accuracy of diagnosis and quality of life.
- (3) Qualitative research (7 focus groups and 19 interviews) with patients of clinical genetics services, patient representatives and genetics health professionals explored the outcomes valued by those stakeholders, and resulted in construction of a model of empowerment. Data triangulation clarified that the qualitative findings support many of those from the Delphi, but identified some additional valued outcome domains that are not captured by available outcome measures, such as empowerment of other relatives and future generations. In conclusion, triangulation is a useful approach to investigate complex areas, such as outcome measurement.

EP14.18

Psychological evaluation of familial ovarian cancer screening (PsyFOCS): Study update and baseline psychological data

D. Lancaster¹, K. Brain¹, L. Fraser², U. Menon², A. Rosenthal³, I. Jacobs², J. Mackay², R. Iredale¹, C. Phelps¹, M. Rogers¹, J. Austoker³, C. Bankhead³, A. Clements³, E. Watson⁴;

¹School of Medicine, Cardiff, United Kingdom, ²Gynaecological Oncology, Institute for Women's Health, UCL, London, United Kingdom, ³Primary Care Research Education Group, Oxford, United Kingdom, ⁴School of Health and Social Care, Oxford Brookes University, Oxford, United Kingdom.

Purpose: The UK Familial Ovarian Cancer Screening Study (UK FO-CSS) aims to determine the effectiveness of ovarian cancer screen-

ing for women at significantly increased risk of familial ovarian cancer. Phase 2 of the study involves annual transvaginal ultrasound scan (TVS) of the ovaries and 4-monthly CA125 blood tests with further tests prompted by rising CA125 or abnormal TVS.

Method: PsyFOCS is a prospective cohort study which aims to determine the psychological effects of ovarian cancer screening. Around 66% of women invited to PsyFOCS returned pre-screening baseline questionnaires.

Results: Baseline analyses (N=991) showed that clinical levels of depression and anxiety were reported by 2.63% (n=26) and 14.63% (n=145) of women respectively. However, over a third (n=369, 37.24%) were moderately or highly distressed about their ovarian cancer risk according to the Impact of Event Scale (IES). There were no significant associations between IES distress and prior ovarian TVS (p=.50) or the number (p=.95) or reported stressfulness (p=.56) of repeat ovarian cancer screening in the past. However, highly distressed women were significantly younger than those reporting moderate or low distress (p<.001) and there was a significant association between distress and past ovarian cancer screening recall (p<.05).

Conclusion: The results suggest that although most women reported low levels of distress prior to UK FOCS screening, younger women and those recalled for repeat testing may experience greater distress.

EP14.19

Mental and psychomotor development of 2-year-old PGD/PGS twins compared to ICSI twins

J. Nekkebroeck¹, M. Bonduelle², S. Desmyttere², I. Ponjaert-Kristoffersen¹;

¹Vrije Universiteit Brussel, Brussels, Belgium, ²UZ Brussel, Brussels, Belgium.

Introduction: Embryo biopsy is a invasive procedure applied in ART for diagnostic reasons in Preimplantation Genetic Diagnosis (PGD) or to increase pregnancy rate in Preimplantation Genetic screening (PGS). The objective of this ongoing study is to investigate mental and psychomotor developmental outcomes in 2-year-old twins born after PGD/PGS and Intracytoplasmic Sperm Injection (ICSI).

Materials and Method: PGD/ PGS (n = 32) and ICSI (n = 32) children were recruited from the registry of the Centre for Medical Genetics (UZ Brussel). The obtained response rates were 97% and 94% respectively. All twins were assessed around age 2 and were matched for gender, educational level of the mother, birthorder and mothertongue. There were no significant differences between the 2 conception for these demographics.

Mental and Psychomotor development of the 2 groups of study participants was assessed using the Bayley Scales of Infant Development (BSID-II-NL). Data on interval level were analysed using ANOVA's and a significance level of 0.05 was accepted throughout.

Results: Scores on the Mental Scale revealed no differences between the 2 groups (F (2, 62) = 0.09, p = 0.764). Scores on the Motor Scale neither showed any differences between the PGD/PGS, ICSI and NC twins (F (2, 54) = 1.16, p = 0.286).

Conclusion: PGD/PGS twins show similar mental and psychomotor developmental outcomes at age 2, as measured with the BSID-II-NL, in comparison to twins conceived after ICSI. In order to provide more solid reassurance twin children should also be compared to their naturally conceived counterparts.

EP14.20

Should Skin Color Matter in the Decision to Offer Preconception Genetic Screening?

V. L. Bonham¹, S. Knerr¹, A. O. Odunlam²;

¹National Human Genome Research Institute, NIH, Bethesda, MD, United States, ²Harvard School of Public Health, Boston, MA, United States.

Objective: To investigate the influence of U.S. physicians' perceptions of patient race and ethnicity on their decisions to offer preconception genetic screening.

Methods: Primary care physicians (N=1,035) were surveyed to study, among other aims, their decisions to offer preconception screening for genetic conditions and the influence of patient skin color and other characteristics on these decisions. Physicians were randomly assigned to view a vignette with a picture of either a "Black" or "White" patient.

Results: 978 physicians answered questions on the vignette of a patient considering pregnancy; her race, ethnicity and ancestry were not described. Respondents who viewed the "Black" patient were more likely to offer any genetic screening than those who viewed the "White"

patient (35% vs. 26%, $p < .001$). Screening for sickle cell disease was offered more often by physicians presented with the "Black" patient (78% vs. 7%, $p < .0001$) and screening for cystic fibrosis was offered more often by physicians presented with the "White" patient (49% vs. 26%, $p < .0001$). Physicians who viewed the "Black" patient rated race as more important to their decision to offer screening than those who viewed the "White" patient (76% vs. 49%, $p < .0001$).

Conclusion: As we move beyond screening for single gene disorders to screening for multiple gene variants that predict risk for common complex diseases, a greater understanding of the appropriate use of phenotypic characteristics including skin color and the social constructs of race and ethnicity in decisions to offer genetic services, including preconception genetic carrier screening is needed.

EP14.21

The emotional experience of termination of pregnancy (TOP): differences between women and men

A. S. Leonardo, F. Sousa, I. Cordeiro;
Hospital Santa Maria, Lisboa, Portugal.

Looking at our experience of seven years supporting couples who go through TOP, we propose there is a difference in the way women and men go through the emotional process underlying this experience, from beginning to end.

Once the couple has made the decision to terminate the pregnancy, the medical procedure should take place within a short period, because the interval between the decision and TOP is of intense discomfort. We draw from these women and men own words. Some women said they could no longer stand at the mirror and see their growing belly. Men recalled no longer touching their spouse's belly. Other women said it was shocking to feel the foetus' movements while waiting for TOP.

At the time of TOP, women are confronted with a question: should I see the foetus? Men, on the other hand, know for sure they would choose not to see the foetus because, otherwise, its image would be recorded and they want to forget this experience as soon as possible.

After TOP, women and men usually have different timings when considering another pregnancy. Women take longer to mourn the foetus and men are faster to overcome the fear of another loss.

Understanding the emotional process of TOP makes professionals more able to demystify this painful experience at the eyes of the couples. Studying and accepting differences between women and men going through TOP, helps psychologists minimise the impact of these couples' loss and work with them to find a future project.

EP14.22

Can a family history questionnaire for children with an undiagnosed genetic syndrome replace a face-to-face appointment with a genetic counsellor?

B. J. Dell¹, G. Westwood², C. Phelps³;

¹School of Medicine, Cardiff, United Kingdom, ²Wessex Clinical Genetics Service, Southampton, United Kingdom, ³Institute of Medical Genetics, Cardiff, United Kingdom.

Increasing service demands mean that genetics services need to identify alternative ways of collecting family history information other than through face-to-face clinics. This study explored whether a family

history questionnaire developed by the author for parents of children with an undiagnosed genetic syndrome (Wessex Family History Questionnaire, WFHQ) can replace a family history gathering appointment with a Genetic Counsellor and reduce the number of appointments provided. Previous family history questionnaires were evaluated and the following criteria were utilised to evaluate the WFHQ: response rate, degree of omitted data and reliability.

The WFHQ was piloted in a multiphase approach. Seven parents completed the WFHQ and an evaluation questionnaire and the data assessed and compared to the data collected through the face-to-face clinic.

Telephone interviews revealed that the WFHQ was seen as a useful preparatory tool. However parents valued the personal interaction of the clinic appointment, during which Genetic Counsellors were able to clarify family history details and provide reassurance.

The WFHQ clearly enhanced the obtaining of a family history in clinic. However, the use of the WFHQ alone may fail to reduce service demands, as Genetic Counsellors are likely to have to clarify family history details or seek additional details. Further research is required to explore alternative methods of service delivery such as collecting family history data via telephone in order to accommodate rising referral rates.

EP14.23

What Increase the Vulnerability in Children and teenagers with Disability in Rio de Janeiro, Brazil

A. S. N. Marinho¹, F. G. Cavalcante^{2,3};

¹CIAD/FUNLAR-Rio, Rio de Janeiro, Brazil, ²Universidade Veiga de Almeida, Rio de Janeiro, Brazil, ³CLAVES/FIOCRUZ, Rio de Janeiro, Brazil.

This qualitative and quantitative research investigated the scenario of violence against children and teenagers with disability due to genetic conditions, congenital anomalies and related conditions assisted by Deinstitutionalization and Social Rehabilitation Based in Community Program and two Rehabilitation's institution from Francisco de Paula Municipal Foundation (2005-2007). It aimed to make a situational diagnosis of the problem, investigate the kind of violence disabled children and teenagers encounter and, discuss the prevention strategies. The study associated 84 case-studies, using a triangulation method of case-discussions with team work, reflexive groups with families, interview leaderships and participant-observation and, quasi-statistical approach (Becker, 2000). The sample of 33 cases was picked through analysis of the study's protocol considering the variables of most interests to the research. It was observed that family negligence is the most recurrent form of violence; there is a dominion of the male sex case in the minor age and female in the age of 24 years; 88% of the children and teenagers with disability in situations of violence investigated live in Favelas, in houses that lack basic infra-structure. Most families have income inferior to two Brazilian minimum wages; there are situations where the family is solely sustained by the governmental benefit received by the disabled child (50%). The social isolation of the families, the absence of the public power, the social impact of the drug traffic and the recurrent basic human rights violation are aggravating factors to the violence risk of those who already have vulnerability due to the disability condition.
