Myofibrillar myopathies are neuromuscular disorders with disorganized myofibril structures at the Z-disk and accumulation of protein aggregates. BAG3-related myopathy represents a subgroup of myopathies caused by a mutation in the Bcl-2-associated athanogene 3 (BAG3), a co-chaperone with no direct role in muscle function. In order to investigate the possible involvement of other genes in BAG3 myopathy, we performed whole exome sequencing in an Italian family: a BAG3 myopathy proband affected by muscle weakness, respiratory insufficiency, cardiac arrhythmia, rigid spine, her unaffected parents and brother. Genomic DNAs from peripheral blood were exome enriched using Agilent SureSelectXT Human All Exon 50Mb kit. All samples were sequenced in paired-end with 72 bp length reads on Illumina Genome Analyser IIX. In accordance to a compound heterozygous model of inheritance, we identified in the proband three non-synonymous heterozygous variants in N-RAP gene: one predicted extremely damaging was inherited from her father and the other two less damaging from her mother. The mutation inherited from her father is very rare (MAF=0.0005) and causes an aminoacidic substitution in a domain essential for organizing actin filaments during myofibrillar assembly. The mutations from her mother cause aminoacidic substitutions in a domain critical for the Z-line assembly. Immunohistochemistry showed reduced N-RAP expression in the proband's muscle biopsy compared to a control. The muscle specific N-RAP protein scaffolds I-Z-I assembly during myofibrillogenesis and has a LIM-domain. This is the first exome approach to a BAG3 myopathy and suggests a contribution of a LIM-domain protein to the complex phenotype of the proband.

In myopathic patients molecular diagnosis is hampered by the genetic heterogeneity and the clinical interpretation of molecular findings are further hindered by the presence of low penetrant variations and by the effect of modifier genes. To gain a comprehensive view of all sequence variants in patients, we developed a broad core panel of 93 genes involved in myopathies. To analyze their 2,544 exons, we have developed a Next Generation Sequencing-based workflow, based on a Haloplex custom enrichment strategy (Motorplex). We studied 200 samples from myopathic patients with prevalent limb-girdle muscle involvement and 150 samples with congenital myopathies. In about 20% of patients we found typical causative mutations, while in an additional 30% other putative pathogenic variations were detected. In addition to the causes of monogenic disorders, we also discovered more than 35% of patients showing damaging variations in other disease genes. These variants, if they had been detected alone in the context of a single gene testing, would have been considered as causative. The high number of damaging mutations identified in each sample support the hypothesis of "multiple troubles" leading to a such complex phenotype. In conclusion, in a large cohort of patients with non-specific symptoms, our reliable, sensitive and specific method has been able to identify pathogenic mutations, despite of the heterogeneous conditions, improving significantly the diagnostic yield. Finally, intrafamilial and interfamilial phenotypic variability of patients sharing the same pathogenic mutations must be reevaluated considering the comprehensive view of all sequence variants.

P10.20-M

Childhood onset tubular aggregate myopathy associated with *de novo STIM1* mutations.

M. Niceta[1,2], *C. Hedberg*[3], *F. Fattori*[1], *B. Lindvall*[4], *A. Ciolfi*[2], *A. D'Amico*[1], *G. Tasca*[1], *S. Petrini*[1], *M. Tulinius*[5], *M. Tartaglia*[2], *A. Oldfors*[3], *E. Bertini*[1];

We investigated on three unrelated patients with tubular-aggregate myopathy and slowly progressive muscle weakness manifesting in the first years of life. All patients showed type 1 muscle fiber predominance and hypotrophy of type 2 fibers. Tubular aggregates of the sarcoplasmatic reticulum were abundant. In all three patients, *de novo* heterozygous mutations were identified in the Stromal Interaction Molecule 1 gene, *STIM1.* In one of the patients, the mutation was identified by exome analysis, coupled to a hypothesis-driven filtering strategy. Two patients harbored the previously described c.326A>G p.His109Arg change while the third patient carried a previously unreported mutation (c.343A>T, p.Ile115Phe). All mutations affected the EF-hand motif, which is required for Ca2+ ions binding. Besides, the tubular aggregates, autophagic debris and myophosphorylase deficiency were documented in patients' muscle cells. Consistent with previous findings, the c.326A>G change represent a recurrent mutation specifically related to early onset muscle weakness.

P10.21-S

Myotonia congenital type Becker in an endemic Bulgarian region

S. Tincheva[1,2], *A. Todorova*[1,2], *T. Todorov*[2], *I. Litvinenko*[3], *V. Gergelcheva*[4], *I. Tournev*[4], *V. Mitev*[1];
[1]*Department of Medical Chemistry and Biochemistry, Sofia Medical University, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [3]*Department of Neurology, University Pediatric Hospital, Medical University, Sofia, Bulgaria,* [4]*Department of Neurology, University Hospital "Alexandrovska", Sofia, Bulgaria.*

Myotonia congenita type Becker is an autosomal recessive nondystrophic skeletal muscle disorder primarily affecting lower limb muscles and later progressing to the arms, neck, and facial muscles. The disease is characterized by muscle stiffness and an inability of the muscle to relax after voluntary contraction. Sometimes muscle weakness may be transient. The autosomal recessive Becker type is caused by mutations in the CLCN1 gene, localized on chromosome 7q34 and encoding skeletal muscle chloride channel-1.
Here we report 5 Bulgarian families genetically proved to carry mutations in the CLCN1 gene. The following mutations were detected: nonsense (p.Arg894*), splice-site (c.1471+1G>A), missense (p.Val273Met; p.Tyr524Cys). Two additional nucleotide changes were detected in an asymptomatic individual (c.2284+5C>T possible splice-site change and p.Phe167Leu). It was not possible to clarify, whether these changes are located on a single allele or affect both alleles. Two of the detected mutations are interesting from population point of view. The missense substitution p.Val273Met was detected in a large Roma family with a high proportion of endogamous marriages. Secondly, the novel missense substitution p.Tyr524Cys was detected in a large Bulgarian family with a number of affected individuals both in vertical and horizontal pedigree direction. The later family originates from a small Bulgarian village and the citizens traditionally marry within the village, which is very surprising for the Bulgarian habits. Most probably there is an endemic region for myotonia congenital type Becker in Bulgaria, caused by the missense mutation p.Tyr524Cys.

P10.22-M

Targeted second generation resequencing reveals a homozygous CLCN1 mutation in a patient with an ambiguous myotonic dystrophy type 2 grey zone allele

J. Radvanszky[1,2], *E. Nagyova*[3], *T. Szemes*[3,2], *L. Kadasi*[1,3], *G. Minarik*[3,2,4];
[1]*Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia,* [2]*Geneton s.r.o., Bratislava, Slovakia,* [3]*Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia,* [4]*Institute of Molecular BioMedicine, Faculty of Medicine, Comenius University, Bratislava, Slovakia.*

In our previous study focused on the analysis of variability of the repetitive CCTG tract in the *CNBP* gene in patients with myotonic dystrophy symptoms and healthy population, we reported a patient harbouring an uninterrupted allele containing 34 CCTG repeats. Although there are several indications that it is not a causative allele in that patient, it was not possible to exclude its causality, until other candidate genes were screened for causative mutations. Therefore the patient's DNA was sequenced by targeted resequencing approach using a custom panel and Ion Torrent PGM. After alignment to the GRCh37/hg19 reference sequence three homozygous single nucleotide variations (SNVs) were identified. A missense variation p.S524G in the *SCN4A* gene (mutations of the gene are associated with paramyotonia congenita) and a missense variation p.G118W in the *CLCN1* gene (mutations of the gene are associated with myotonia congenita) were found to be mistakenly identified as variations, since according to the HapMap and 1000 Genomes Project data, the alleles harboured by our patient are in both cases the most common alleles and the reference sequence contains the rare variants (MAF=0,059 and MAF=0,009, respectively). The third SNV was a homozygous nonsense mutation p.P894* which is a known pathogenic mutation leading to myotonia congenita (Thomsen's disease). Identification of a known homozygous *CLCN1* mutation found by targeted resequencing led to conclusion that the previously identified possible DM2 grey zone allele is not a disease causing allele in the case of the reported patient with consequence in the genetic testing in this family.

P10.23-S

Rapid High-Sensitivity Single-Step Screen for CTG Repeat Expansion Mutations in Myotonic Dystrophy Type I

S. S. Chong[1,2], *M. Mulias*[1], *K. Singh*[1,3], *I. Rajan-Babu*[1], *H. Law*[4,5], *C. G. Lee*[1,6,5];
[1]*National University of Singapore, Singapore, Singapore,* [2]*National University Hospital, Singapore, Singapore,* [3]*Manipal University, Manipal, India,* [4]*KK Women's and Children's Hospital, Singapore, Singapore,* [5]*Duke-NUS Graduate Medical School, Singapore, Singapore,* [6]*National Cancer Centre, Singapore, Singapore.*

Myotonic dystrophy type 1 (DM1), the most common adult muscular dystrophy, is caused by expansion of a CTG repeat in the 3'UTR of the *DMPK* gene. Repeat size is correlated positively with phenotypic severity and negatively with age-of-onset, with affected individuals classified as mild (50-150 CTGs), classic (100-1000 CTGs), or congenital (>1000 CTGs) DM1. Southern analysis reliably detects all expansions, but requires micrograms of DNA, yields approximate allele sizing, and is labor-intensive, time-consuming, and costly. PCR across the repeat accurately sizes all normal and also expanded alleles, although the upper limit of detection is unknown. Newer triplet-primed PCR (TP-PCR) assays will detect all normal and expanded alleles, but product analysis by capillary electrophoresis (CE) is still costly when applied in high throughput screening situations where a majority of tested samples may be screen-negative. We have now adapted the 5' and 3' TP-PCR assays for single-step detection of DM1 expansions by melting curve analysis (MCA), wherein melt peak profiles from normal samples were distinctly different from samples carrying an expansion. In a blinded validation of 60 clinical samples enriched for affected individuals, a 48-repeat plasmid clone was used to establish a cut-off temperature separating normal from affected samples, and 100% concordance with their known genotypes was achieved. We conclude that TP-PCR MCA is an accurate yet simple, rapid and inexpensive screen useful for identifying DM1 expansion mutations. Follow-up confirmation and sizing can be accomplished by capillary electrophoresis following a quick 5-cycle extension-labeling of the positive TP-PCR product.

P10.24-M

Elevated miRNA levels in serum of myotonic dystrophy patients relate to disease progress

A. Koutsoulidou[1], *T. Kyriakides*[2], *Y. Christou*[1], *E. Zamba Papanicolaou*[1], *L. Phylactou*[1];
[1]*The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus,* [2]*Yale Center for Analytical Sciences at Yale School of Public Health, University of Yale, New Haven, CT, United States.*

Myotonic Dystrophy type 1 (DM1) is the most common form of adult-onset muscular dystrophy. Clinically, DM1 is a highly variable multisystemic disorder that primarily affects skeletal muscle and is characterized by progressive skeletal muscle weakness, wasting and myotonia. DM1 patients are diagnosed using genetic tests and their muscle wasting progression is currently monitored through electromyography and regular physical examinations. Many scientific reports emphasize the importance for the discovery of non-invasive serum-based biomarkers for the diagnosis and therapy of diseases, since they are easily accessible and convenient. The identification of blood-based biomarkers for DM1 would provide added value for the monitoring of the progressive muscle wasting. Scientific reports showed that circulating miRNAs are stably present within blood circulation and have the potential to be used as clinical biomarkers for many diseases. The aim of this pilot study was to detect and evaluate the usefulness of miRNAs as biomarkers for DM1. DM1 patients and healthy participants were recruited and miRNA analysis was performed on RNA isolated from serum samples. Results show that the levels of particular miRNAs are elevated in the serum from DM1 patients compared to controls, presumably, as a consequence of the degradation of muscle tissue during muscle wasting. Moreover, the miRNA serum levels correlate with the progression of muscle wasting observed in the patients. Based on these results, we propose that miRNAs can be used as potential serum-based molecular biomarkers for monitoring the progress of muscle wasting in DM1 patients.

P10.25-S
Large copy number variations in *NEB* are frequent in nemaline myopathy patients

K. Kiiski[1], *V. Lehtokari*[1], *L. Laari*[1], *C. Wallgren-Pettersson*[1], *K. Pelin*[2];
[1]*The Folkhälsan Institute of Genetics and the Department of Medical Genetics, Haartman Institute, University of Helsinki, Helsinki, Finland,* [2]*Department of Biosciences, Division of Genetics, University of Helsinki, Helsinki, Finland.*

Recently, new large mutations have been identified in the nebulin gene (*NEB*) causing nemaline myopathy (NM). NM constitutes a heterogeneous group of disorders among the congenital myopathies, and mutations in *NEB* are a main cause of the recessively inherited form. *NEB* consists of 183 exons and it includes a 32 kb triplicate region (TRI) where eight exons are repeated three times. We have designed a custom NM-CGH microarray to detect copy number variations in the currently known nine NM genes and one unpublished gene. To date, 230 samples from 170 families have been run with the NM-CGH microarray and we have identified *NEB* TRI variation in approximately 14% of the NM families in this study cohort. The results suggest that the adjacent intronic repeat elements may predispose to the recurrent TRI variations. The possible pathogenicity of the TRI variations warrants further studies and elucidation of the exact breakpoints in each family. Moreover, we have identified seven different, novel, large disease-causing aberrations in *NEB* in seven different families. The size of the aberrations varies greatly, covering from only a part of one exon (0.9 kb) to more than half of the gene (133 kb). The NM-CGH microarray method is currently available for mutation analysis in our laboratory. Additionally we have analyzed ten samples with exome sequencing and identified causative mutations for half of the families. We believe that the combination of the NM-CGH microarray followed by exome sequencing will accelerate mutation detection and improve the diagnostics of NM and related disorders.

P10.26-M
A novel homozygous deletion in SGCB identified by a targeted next generation sequencing approach and the Motor Chip

T. Giugliano[1,2], *M. Savarese*[1,2], *G. Di Fruscio*[1,2], *A. Garofalo*[1], *M. Fanin*[3], *C. Angelini*[3], *G. Piluso*[1], *V. Nigro*[1,2];
[1]*Seconda Univerisità degli Studi di Napoli, Napoli, Italy,* [2]*Telethon Institute of Genetics and Medicine, Napoli, Italy,* [3]*Azienda Ospedaliera Universitaria di Padova, Padova, Italy.*

Different forms of muscular dystrophy are caused by mutation in genes coding for proteins of sarcoglycan complex, resulting in severe childhood autosomal recessive muscular dystrophies (SCARMD). Point mutations but also copy number variations (CNVs) have been found in sarcoglycan genes. Here we report one patient with SCARMD phenotype resulting from a new homozygous deletion of the last 12 codons in the exon 6 and 3'UTR of beta-sarcoglycan gene (SGCB). For the genetic diagnosis of this heterogeneous condition, we have performed the next generation sequencing. In particular, we have used the Motor Haloplex, a customized target enrichment of regions related to muscular disease, recently developed by our group. We targeted all the exons and the ten flanking bases of 89 genes involved in muscular dystrophies. At first, no point mutations or ins/del have been reported by bioinformatics analysis of the data, but a homozygous deletion in the exon 6 of SGCB has been identified by IGV analysis of sarcoglycan genes. To confirm the result and map the breakpoint, we have used the Motor Chip (Clinical Chemistry, 2011 Nov;57(11):1584-96), a customized aCGH developed by our group, which is able to investigate CNVs in 425 muscular genes. This data suggests that Motor Haloplex may be appropriate for routine diagnoses. It is able to investigate point mutations but also deletions and duplications so that is easier, less time-consuming than traditional gene by gene approach. Finally, the combination between Motor Haloplex and Motor Chip is a strong strategy for the diagnosis of muscular dystrophies.

P10.27-S
Trio-based study of neuromuscular dysfunction using next-generation sequencing under a diagnostic setting

A. M. Nissen, *A. Benet-Pages, C. Rapp, T. Neuhann, E. Holinski-Feder;*
Medical Genetics Center - MGZ, Munich, Germany.

We evaluated the use of next-generation sequencing to provide genetic diagnoses using a family trio consisting of healthy parents and an affected fetus which died intrauterine. The phenotype of the fetus was consistent with early onset neuromuscular disease. Suspected seizures, arthrogryposis multiplex congenita and suspected intrauterine epilepsy were detected in a sonography. We compared clinical gene panel analysis vs. whole exome sequencing (WES) for the family trio in order to identify candidate variants that account for the disease phenotype of the fetus. We used the TruSight™ One Sequencing Panel, which targets 4813 genes associated with known clinical phenotypes, and the Nextera Exome Enrichment Kit (62Mb). Data was analyzed using an in-house bioinformatics pipeline. We analyzed the 4813 disease-associated genes in both sequencing approaches and found two compound heterozygous non-synonymous substitutions in a gene that is involved in neuromuscular functioning. Extending the analysis to the whole exome did not provide any new candidate variants. Gene panel sequencing yielded higher quality and coverage results compared to the WES, which showed a higher number of uncovered nucleotides within the clinical genes. In addition, WES revealed many variants in genes which cannot be directed towards answering questions related to the medical conditions. As a diagnostic test, clinical gene panel sequencing including all relevant disease-associated genes was more efficient than WES by means of quality, costs, time and reporting. Although WES might not always lead to a direct diagnosis test, it is relevant for research to uncover new gene-disease associations.

P10.28-M
A pilot study using a targeted next-generation sequencing panel for diagnostic use in primary myopathies

A. Evilä[1], *P. Hackman*[1], *B. Udd*[1,2,3];
[1]*Folkhälsan Institute of Genetics, Helsinki, Finland,* [2]*Neuromuscular Research Center, University of Tampere and Tampere University Hospital, Tampere, Finland,* [3]*Neurology Department, Vaasa Central Hospital, Vaasa, Finland.*

Myopathies are a clinically and genetically heterogeneous group of disorders, most of which are genetic and many cause progressive weakness and atrophy of muscles. Mutations in more than 200 different genes are known to cause the disorders and several genes may have to be sequenced in order to identify the molecular defect in a patient. The large number of possible candidate genes, overlapping phenotypes as well as an enormous size of some of the genes e.g. *DMD, TTN* and *NEB* bring difficult challenges to diagnostics. Molecular characterization is nevertheless important for an accurate diagnosis and management of the diseases. Targeted next-generation sequencing (NGS) is an efficient and cost-effective method to sequence several genes simultaneously. Our first targeted NGS custom panel was designed for the coding exons and UTRs of 180 myopathy related genes with a total size of 1.3 Mb. For DNA capture a custom NimbleGen SeqCap EZ Choice Library was designed. Sequencing was performed at Institute for Molecular Medicine Finland (FIMM) using Illumina MiSeq with sequencing depth of 100X, and files were processed with their Variant Calling Pipeline. In the pilot study DNA samples of 20 patients were sequenced, of which four served as mutation controls with previously reported mutations. We were able to detect all the mutations in the control samples, except for one heterozygous 11-bp insertion/deletion mutation which was missed in the variant calling. Disease-causing mutations were detected in seven of the 16 patients, with three of them having previously reported mutations and four showing novel mutations.

P10.29-S
Highly efficient genetic diagnostic testing in patients with neuromuscular disorders using Panel-based Next Generation Sequencing

J. Mohr, *N. Gloeckle, T. Grau, F. Battke, S. Biskup, K. Hoertnagel;*
CeGaT GmbH, Tübingen, Germany.

Neuromuscular disorders (NMD) represent a genetically heterogeneous group of diseases. Deciphering the causative molecular defect can be valuable for diagnosis and in consequence for estimation of prognosis and recurrence risk. Towards this aim we have developed a comprehensive diagnostic panel comprising genes known to cause spinal muscular atrophies, neuropathies, muscular dystrophies, myopathies, myasthenia and myotonia to study their underlying genetic heterogeneity. 187 relevant genes associated with NMDs were subdivided according to their clinical phenotypes. MLPA was performed where appropriate, following customized target enrichment and NGS. Identified mutations were validated using Sanger sequencing. All genes associated with the primary diagnosis were analyzed first. In unsolved cases our approach allows to expand the analysis to all remaining genes of the panel. In our study over 200 patients with NMD were analyzed. In 29% the underlying cause could be identified and in 20% likely pathogenic but unclear variants were detected. 52% of the cases remained unsolved. We observed clearly pathogenic mutations in 34 different genes, with *CAPN3, MFN2* and *TTN* being the most frequently mutated genes, and unclear variants in additional 27 genes. Interestingly, in 7% of solved cases we could identify pathogenic mutations in genes not associated with the original diagnosis. We have developed a comprehensive diagnostic NGS panel to analyze the genetic basis of NMDs. As suspected, high genetic heterogeneity among patients could be shown in our cohort. Additionally, in a significant amount of cases we found evidence for new genotype-phenotype correlations, emphasizing the usefulness of NGS panels for diagnostic purposes.

P10.30-M
Genetic testing of inherited muscular dystrophies and myopathies using Sequence capture and targeted resequencing

D. Skalova, *K. Stehlikova, L. Fajkusova;*
Centre of Molecular Biology and Gene Therapy, University Hospital Brno, Brno, Czech Republic.

The inherited muscular dystrophies and myopathies comprise a heterogeneous group of muscle diseases that share similar clinical features as progressive skeletal muscle weakness and wasting. Mutations in several genes that encode proteins of extracellular matrix, endoplasmic reticulum, nuclear envelope, sarcolemmal proteins and glycosyltransferases are known to be responsible for muscular dystrophies and myopathies. The large overlap of phenotypic manifestations resulting from different gene mutations poses a challenge for determination exact type muscular disease. Targeted resequencing using next-generation sequencing technology is a cost-effective strategy to accelerate patient diagnosis. We designed capture library to target the coding and all flanking intron regions of 42 genes associated with group of disease as muscular dystrophies, congenital muscular dystrophies, congenital myopathies, distal myopathies and other myopathies. We performed targeted capture combined with next-generation sequencing using NimbleGen SeqCap EZ Choice library and Roche 454 sequencing platform in 33 Czech probands. Mutations associated with muscular dystrophies or myopathies were identified in 16 of them. Mutations were detected in *ACTA1, CAPN3, COL6A1, COL6A3, DNM2, DYSF, LAMA2, RYR1, SGCB* and *SEPN1* gene. This work was supported by grants IGA MZ CR NT14574-3.

P10.31-S
Swiss Cheese localization and function in the nervous system of Drosophila melanogaster third instar larvae

O. I. Trush[1], G. Kislik[2], **N. Matiytsiv**[1]*, S. Sarantseva[2];*
[1]Ivan Franko National University of Lviv, Lviv, Ukraine, [2]National Research Centre „Kurchatov Institute" B.P. Konstantinov St. Petersburg Nuclear Physics Institute, Gatchina, Russian Federation.

Neuropathy target esterase (NTE) is the 6th member of 9-proteins of patatin-like phospholipase domain-containing proteins, PNPLA1-9. Mutation in the catalytic domen of NTE (PNPLA6) can lead to the slowly developed diseases, known as organophosphorus compound-induced delayed neuropathy (OPIDN) and hereditary spastic paraplegia called NTE-related motor neuron disorder (NTE-MND). The Swiss Cheese (SWS) protein is an ortholog of NTE in *Drosophila* and shares 39% sequence identify with human NTE. The *Drosophila sws* mutants are characterized by progressive degeneration of adult nervous system, glial hyperwrapping, and neuronal apoptosis. *Drosophila sws* mutant thus provides an experimental model for functional studies of the SWS/NTE role in maintaining neural integrity. There is an evidence of SWS role in the age-dependent brain changes. However, possible disturbance caused by point mutations in *sws* gene in *Drosophila* larvae remained unknown.
The *sws*-point mutants were used to investigate SWS localization and function in the nervous system of *D.melanogaster* larvae. We were shown SWS localization mainly in glial tissue of larvae brain as well as in glial cells, wrapped axons in all investigated lines. Presence of SWS was also observed in the postsynaptic membranes of the larval NMJ. SWS protein in small amount was also detected in larvae neurons. Quantitative and qualitative parameters of NMJ in all investigated *sws*-mutants also were changed comparing with wild type flies.
Thus, SWS dysfunction in earlier stages of *Drosophila* ontogenesis can be important for nervous system development and aging in *D.melanogaster* adults.

P10.32-M
Central bradypnoe and hypotonia as diagnostic feature for male Rett syndrome

A. Baumer[1]*, E. Wey[1], D. Gubler[2], A. Rauch[1];*
[1]Institute of Medical Genetics, Schlieren, Switzerland, [2]Children's Hospital, Zurich, Switzerland.

Mutations in the MECP2 gene causing the X-linked dominant Rett syndrome are a relatively common cause of intellectual disability in girls. Although MECP2 mutations in males are usually considered lethal, leading to the prenatal loss of the fetuses, few observations of boys with severe congenital encephalopathy were reported. We present here a novel case of a newborn boy with Rett syndrome caused by the de novo MECP2 frameshift mutation c.806delG. The clinical suspicion of male Rett syndrome was triggered by the rare combination of neonatal hypotonia and central bradypnoe.
At the age of four days the newborn was transferred to the neonatal unit of a tertiary children's hospital because of poor suck, dysregulation of muscle tone and a pathological breathing pattern. On admission, the neonate was lethargic and the clinical examination showed multiple abnormalities, such as a severe brady-/hypopnea with apneas of up to 30 seconds, followed by an arousal reaction, frequent yawning, axial hypotonia and hypertonia of the extremities. The cerebral magnetic resonance (MR) image revealed bilateral T2 signal hyper intensities of the white matter, especially in the temporal and parietal areas, which raised the question of perinatal asphyxia. In the spectroscopy the lactate was elevated and the n-acetylaspartate level was low. The electroencephalogram (EEG) showed an immature activity with too many multifocal sharp transients. At discharge from the hospital, at the age of 1.5 months, the patient was more alert and was no longer dependent on nasogastric feeding.

P10.33-S
Evaluation of AR genetic polymorphisms influencing spinal and bulbar muscular atrophy phenotype

C. Bertolin[1]*, G. Querin[2], M. Pennuto[2], F. Zoccarato[1], E. Pegoraro[1], C. Gellera[3], G. Sorarù[1];*
[1]University of Padova, Department of Neurosciences, Padova, Italy, [2]2 Dulbecco Telethon Institute Laboratory of Neurodegenerative Diseases, Centre for Integrative Biology (CIBIO), University of Trento, Trento, Italy, [3]3 Unit of Genetics of Neurodegenerative and Metabolic Diseases, Fondazione IRCCS Istituto Neurologico ,Carlo Besta', Milan, Italy.

Spinal and bulbar muscular atrophy (SBMA) is caused by a pathological expansion over 38 of a CAG repeat in the first exon of the androgen receptor (*AR*) gene on chromosome X, coding for a polyQ tract (La Spada et al, 1991). SBMA is an androgen-dependent disorder, with males with full disease manifestations, and females showing only mild symptoms even if homozygous for the mutation. While a correlation between expansion size of polyQ tract and disease severity has been reported, patients with the same number of CAG repeats have different age at onset and disease progression even if relatives. Human *AR* exon 1 encodes further short aminoacidic stretches. The effect of these sequences on SBMA phenotype has not been studied yet. In order to further characterize the effect of *AR* coding repeated sequences on SBMA phenotype, we genotyped *AR* exon1 polymorphisms in 132 molecularly defined SBMA patients, referring to the Motor Neuron Clinic of the University of Padua and to Fondazione IRCCS Istituto Neurologico "Carlo Besta", Milan. Among AR exon-1 trinucleotide stretches, a polymorphic GGN sequence coding polyG showed a tendency to be higher in patients with an earlier onset. Our study confirms that the length of SBMA-causing polyQ tract does not fully explain the disease phenotype and point to a polyG strech within *AR* exon 1 that is a potential disease modifier in SBMA:

P10.34-M
Mutation analysis of SCN1A gene in Slovak patients with various types of childhood epilepsy

M. Surovy[1]*, A. Soltysova[1,2], M. Kolnikova[3], P. Sykora[3], D. Ilencikova[4], A. Ficek[1], L. Kadasi[1,2];*
[1]Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia, [2]Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia, [3]First Department of Pediatrics, Department of Child Neurology, Department of Clinical Biochemistry, Comenius University Children's Hospital, Bratislava, Slovakia, [4]2nd Pediatric Department of the Comenius University, Medical School and University Children's Hospital, Bratislava, Slovakia.

Mutations in SCN1A gene are by far the most frequent cause of Dravet syndrome (DS) worldwide, with mutation prevalence approximately between 70 and 80%. One of the main features of DS is the fact that many patients do not respond well to the treatment with anticonvulsive drugs. Furthermore, there have been observations that some drugs, which function as sodium channel blockers, may induce aggravation of seizures in patient, thus worsening their symptoms. As most of the DS SCN1A mutation result in truncation of the protein, the use of antiepileptic drugs would further decrease the inhibitory function in central nervous system. The aim of this study was to identify mutations in SCN1A gene in a broad testing group of patients with phenotypes raging from DS to milder phenotypes such as Genetic Epilepsy with Febrile Seizures Plus (GEFS+). Completing mutation screening in 37 unrelated patients, 4 causative mutations located in the coding region were identified. All mutations were found in DS patients and in accordance with previously identified disease variants, found mutations, of which three are novel, result in creation of a premature stop codon, either by substitution or an insertion and thus to a possible loss of function of the altered protein. In summary, our findings contribute to the broadening of the mutation spectrum of the SCN1A gene and enrich the clinical data of DS. Genetic testing may prevent the need for unnecessary clinical examinations and provide genetic counseling for families.

P10.35-S
De-novo deletion or uniparental disomy as SMA determining cause: a case report

G. Dubsky de Wittenau[1], *S. Radovic*[2], *R. Pascolo*[1], *F. Cesca*[1], *A. Cifù*[1], *F. Curcio*[1,3], *R. Lonigro*[1,3];
[1]*Department of Medical and Biological Sciences, University of Udine, Udine, Italy,* [2]*IGA Technology Services, Parco Tecnologico L. Danieli, Udine, Italy,* [3]*Dipartimento di Medicina di Laboratorio, SOC Istituto di Patologia Clinica, A.O.U. di Udine, P.le S.M. della Misericordia, Udine, Italy.*

We report a 3-months old female with type I spinal muscular atrophy (SMA) born to a young and non-consanguineous couple. Molecular analysis confirmed the diagnosis of SMA with an homozygous deletion of SMN1. Parents analysis revealed that only the mother was a carrier of the SMA causative deletion. It is important to find out if the father, that carries two SMN1 copies, has a CIS-duplication of the gene on one chromosome bearing to a 2/0 genotype or the deletion occurred de-novo during gametogenesis. Indeed, the risk for future pregnancies could be reduced from 25%, usually estimated for SMA couple, to residual risk arising from recurrent de-novo mutation (2% of the affected individual). Alternatively, the uniparental disomy (UPD) of the maternal-deleted-chromosome, with an estimated incidence of about 1:3500 live birth, must be taken into account. Gene dosage analysis of the father's relatives does not support a paternal 2/0 genotype. To discriminate between a paternal de-novo mutation and a maternal isodisomy we analyzed in the affected infant and parents a total of nine microsatellite markers in a region spanning 3.0 Mb at the SMN locus. Five microsatellites at 5'/3'-ends of that region demonstrate a maternal and paternal inheritance but could not definitively exclude the maternal segmental UPD. Finally, using a NGS approach we identify three paternal and one maternal-inherited variants in the SMN2 genes of the infant. All together our data support for a de-novo mutation of paternal chromosome 5 as could result by unequal crossing-over during gametogenesis.

P10.37-S
Prevalence of SMN1 gene duplication in different ethnic groups: implication for carrier testing

P. Rimessi, *C. Trabanelli, M. Fabris, A. Venturoli, B. Dolcini, M. Taddei Masieri, R. Selvatici, A. Balboni, L. Melchiorri, A. Ravani, F. Gualandi, A. Ferlini;*
U.O. Medical Genetics, Azienda Ospedaliero Universitaria, Ferrara, Italy.

Spinal muscular atrophy (SMA) is an autosomal recessive disorder, characterized by symmetrical muscular weakness and atrophy. The incidence is variable from 1 in 6000 to 1 in 10000 live births in different geographic areas. A homozygous deletion involving exon 7 in SMN1 gene is present in more than 95% of the cases. Carrier testing in parents and relatives of SMA patients is complicated by the occurrence of SMN1 gene duplication (4-5 %).
Here we report on the SMN1 genetic test results obtained in our lab in the last two years. The most frequent clinical indication is represented by positive family history for SMN1 gene deletion or SMA, partner heterozygous for the deletion and consanguinity with the partner.
We calculated the frequency of different SMN1 genotypes in 326 tested subjects. We found a percentage of SMN1 gene duplications (subjects with 3 copies of SMN1) a bit higher than expected, ranging from 6 to 6.5%. The 55% of the subjects with the duplication is represented by North and West Africans that have been tested because of consanguinity with the partner, the remaining are Italians, 25% with SMA positive family history and 20% with partners heterozygous for the deletion.
Our results highlight once again the importance of taking into account the occurrence of SMN1 gene duplication when performing carrier testing and suggest that the prevalence varies in different ethnic groups, therefore affecting the recurrence risk assessment .

P10.38-M
Methylation level of SLC23A2, NCOR2 and CDK2AP1 genes' regulatory regions correlates with spinal muscular atrophy severity

G. Y. Zheleznyakova[1,2,3], *M. A. Maretina*[1,4], *A. V. Kiselev*[3], *E. Nilsson*[2], *V. S. Baranov*[3], *H. B. Schiöth*[2];
[1]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation,* [2]*Uppsala University, Uppsala, Sweden,* [3]*D.O. Ott Research Institute of Obstetrics and Gynecology, Saint-Petersburg, Russian Federation,* [4]*D.O. Ott Research Institute of Obstetrics and Gynecology, Saint-Petersburg, Austria.*

Spinal muscular atrophy (SMA) is a monogenic neurogenerative disorder that is subdivided into four different types and caused by SMN1 gene deletion. Whole genome methylation analysis revealed about 40 CpG sites associated with genes which were significantly different methylated between SMA patients and healthy individuals of the same age. To investigate the relevance of discovered methylation changes for SMA severity, we compared the methylation level of target and nearest CpG sites in a larger group of SMA patients. The methylation level of CpG sites situated in regulatory regions of ARHGAP22, CDK2AP1, CHML, NCOR2, SLC23A2, RPL9 genes were analyzed in 24 I type, 43 II type and 29 III-IV SMA patients using bisulfite sequencing. The methylation level of target CpG site and one nearby CpG site belonged to 5'UTR of SLC23A2 was significantly lower by 11-15% in III-IV type comparing to I type SMA patients. Moreover, a significantly increased allele A frequency of polymorphism rs1279683 (g.G>A) situated in target CpG site was found in III-IV type SMA patients. III-IV type comparing to I type SMA patients demonstrated decreased methylation level by 9-16% of target CpG site and nearest CpG site belonged to 5'UTR of NCOR2. Significant difference in the methylation level between different types SMA patients was revealed for three CpG sites located in the region 1735-1398 bp of TSS of CDK2AP1. Thus this study confirms that DNA methylation changes of SLC23A2, NCOR2, and CDK2AP1 might be associated with spinal muscular atrophy severity.

Molecular analysis of common mutation associated with SMA în Romanian population

M. L. Toma[1], *M. Stavarachi*[1], *S. Spandole*[1], *N. Butoianu*[2], *M. Budisteanu*[2], *C. Iliescu*[2], *D. Iancu*[3], *L. Barbarii*[3], *L. Barbarii*[3], *A. Alexiu*[1], *I. Radu*[1], *D. Cimponeriu*[1];
[1]*Department of Genetics, Bucharest, Romania,* [2]*Clinical Psychiatric Hospital „Prof. Dr. Alexandru Obregia", Bucharest, Romania,* [3]*Institute of Forensic Medicine „Prof. Dr. Mina Minovici", Bucharest, Romania.*

Spinal muscular atrophy (SMA) is characterized by degeneration of motor neurons that cause progressive muscle weakness and muscle atrophy. SMN1 homogizot gene deletion is present in most patients with SMA (~95%). The objective of this study was to evaluate the SMN1, SMN2 and NAIP gene mutational status in SMA Romanian patients. In this study, we analyzed by PCR-RFLP 90 patients with suspected SMA and 52 relatives. We also performed three prenatal test fetal with DNA obtained by amniocentesis from mother, who had prior history of another child diagnosed with SMA. We identified homozygous deletion of exons 7 and 8 of SMN1 and SMN2 genes in 35 patients, and only deletion of exon 7 at 2 patients. Homozygous deletion of exon 7 and 8 of SMN2 gene was identified in 2 patients and one relative of a patient. NAIP gene deletion was identified in 8 patients and 3 relatives. For prenatal testing, we identified homozygous deletion of exon 7 and 8 of SMN1 gene. Molecular diagnosis of SMA by identifying of SMN1 gene deletion is a useful tool for the diagnosis of SMA in Romania, being necessary deermination of SMN copies for a better matching phenotype - genotype.
This work was supported by CNCSIS - UEFISCDI, project number PN II - IDEI 2152/2008 and Program 8, the project „Intervention for diagnosis and management of spinal amiotrophy and muscular dystrophy type Duchenne and Baker, and the prevention of their hereditary transmission" 2011.

P10.40-M
Exon skipping mutation in collagen VI detected in a patient from Lithuania

E. Preikšaitienė, *A. Utkus, V. Kučinskas;*
Dept. Human and Medical Genetics, Vilnius University, Vilnius, Lithuania.

We report on a patient who presented with clinical features of Ullrich congenital muscular dystrophy. The patient is a girl, four years of age, the first child of healthy non-consanguineous Lithuanian parents. The proband was born at 40 weeks gestation in normal delivery. Hip dysplasia was noted from birth. The girl has chronic constipation from 2 months of age. Her intelligence is in normal range, but motor development is delayed. She could sit at age of 6 months, stand up with support at age of 2 years, can walk only with support. Clinical examination at the age of 4 years revealed the contractures in elbows and knees but striking distal phalanx hyperlaxity. The consentration of CK was mildly elevated (315 U/L). Spine CT and MRT investigations, cardioechoskopy were normal. The clinical diagnosis of Ullrich congenital muscular dystrophy was suspected and molecular genetic testing of *COL6A1*, *COL6A2* and *COL6A3* genes was performed. The mutation c.6210+5G>A, IVS16+5G>A, in intron 16 of the *COL6A3* gene in a heterozygous state was detected. The analysis of parents confirmed *de novo* origin of the mutation. The protein immunohistochemistry analysis of the muscular biopsy concluded that the finding is compatible with dominant in frame deletion in exon 16.
The mutation c.6210+5G>A, IVS16+5G>A, has already been described as causative for a dominant form of Ulrich congenital muscular dystrophy. The molecular and clinical characterization of our patient provides additional information for genotype-phenotype correlation and confirms dominant acting mutation in collagen VI gene as a course of Ullrich disease.

P10.41-S
Paternal germline mosaicism in COLVI related myopathies: a case report

C. Trabanelli[1], A. Armaroli[1], A. Venturoli[1], C. Scotton[1], **A. Ravani**[1]*, L. Merlini[2], C. Bruno[3], A. Ferlini[1], F. Gualandi[1];*
[1]U.O.Genetica Medica - Laboratory of Molecular Genetics, Ferrara, Italy, [2]Laboratory of Musculoskeletal Cell Biology, Istituto Ortopedico Rizzoli, Bologna, Italy, [3]Muscular and Neurodegenerative Diseases, G. Gaslini Institute, Università degli Studi, Genova, Italy.

Mutations in the COL6A1, COL6A2 and COL6A3 genes cause collagen VI related disorders, characterized by muscle wasting, weakness, joint contractures, distal laxity, serious respiratory dysfunction and cutaneous alterations. The severe Ullrich congenital muscular dystrophy (UCMD) can be due to autosomal recessive mutations in one of the three genes of collagen VI with a related 25% recurrence risk. In the majority of UCMD cases nevertheless, the underlying mutation is thought to arise *de novo* and the recurrence risk is considered as low.
Here we report a family with recurrence of UCMD in two sibs only by father's site. In both, the molecular analysis revealed heterozygosity for the c.896G>A mutation in COL6A1 exon 10 (Gly299Glu) and for the COL6A1 c.1823-8G>A variation within COL6A1 intron 29. The Gly299Glu mutation, despite not previously reported, is likely to be pathogenic, leading to the disruption of the Gly-Xaa-Yaa motif in the triple-helix domain of collagen VI alfa(1)-chain. The intronic variation was inherited from the father and RNA analysis in skin fibroblasts allowed to exclude its role in affecting COL6A1 transcript processing. The Gly299Glu mutation occurred apparently *de novo* in the two sibs.
The described mutational segregation strongly suggests the occurrence of paternal germline mosaicism , to be confirmed by mutational analysis of the sperm. The reported family represents the first observation of gonadal mosaicism in collagen-VI related myopathies and, similarly to other collagen related diseases as osteogenesis imperfecta, this possibility deserve to be considered in genetic counseling and recurrence risk estimation.

P10.42-M
Diagnosis of spinal muscular atrophy in Algeria

B. Imessaoudene, *S. Hallal, M. Ghouali - z. Chami - m. Djeddou- benchaib- a. Berhoune; Laboratory Of Biochemistry Chu Mustappha, Algiers, Algeria.*

The spinal muscular atrophy is neuromuscular diseases characterized by degeneration of motor neurons and paralysis associated with muscular atrophy.
Depending on the age of onset and progression of the disease , there are 3 types of spinal muscular atrophy : the severe form or type 1 (Werdnig - Hoffman disease), intermediate or standard form II, and the least severe form or type III (Kugelberg - Welander disease of) . The frequency of these ASI is 1/10000 new borns.
Infantile spinal amyotrophy resulting in over 95 % of cases , a homozygous deletion of exon 7 of SMN1 gene located in 5q13 .
This deletion can be detected by a PCR - Digestion, by creating an artificial restriction site for the enzyme Dra I (ACRS : artificial created restriction site). This technique is now validated in our laboratory , which allowed us to analyze 150 patients (128 childrens and 22 adults).
The deletion was found in the homozygous state in 95 of them , representing a value of 53%.
While our series of patients tested from specialized services but it does not explain all the high rate of positive cases, this shows that the disease is not as rare in our population.
Our vision for the future is to establish a genetic counseling for families.

P11.001-S
14q32.2 Microdeletion and Thyroid carcinoma

S. Briuglia[1]*, I. Loddo[1], A. Capalbo[2], L. Bernardini[2], M. C. Cutrupi[1], E. Moschella[1], A. Novelli[2], T. Arrigo[1], D. C. Salpietro[1];*
[1]Dipartiment of Paediatric Science Messina, Messina, Italy, [2]CSS-Mendel Institute, Roma, Italy.

We described a young man, the third son of healthy and non consanguineous parents. He was born small for gestational age. He had delayed height growth and psychomotor development. Karyotype was 46,XY. At the age of 6, he developed precocious puberty At the age of 9 years, brain MRI showed partially empty saddle. At the age of 15, we evaluated him for microsomia, delayed psycomotor development, dysmorphisms. On physical examination, height and weight were below 3° centile, there was microcephaly, triangular face, frizzy hair, laterally sparse eyebrows, strabismus, hypotelorims, hypoplasia of midface, wide nasal bridge, short broad nose, large and low set ears, pointed chin, micrognatia, arched palate, scoliosis, kyphosis, long hands with tapering fingers, hallux valgus bilaterally, clubfeet. An aCGH showed 14q32.2□14q32.31 de novo microdeletion of 1.106 Mbp. At the age of 20, he had enlargment of the thyroid gland, exophtalmos, weight loss, tachycardia and diarrhea. Blood test showed an hyperthyroidism An ultrasound scan of the thyroid showed the presence of a dishomogeneous pseudonodular area, bilateral laterocervical lymphnodes The patient underwent thyroid fine-needle aspiration. The histology was compatible with a papillary carcinoma. Thyroidectomy was performed. In 2013, Buldrini et al reported the first patient with 14q32.2 microdeletion and thyroid carcinoma. We suggest that these patients have an increased cancer risk. We hypothesize that it is caused by haplo-insufficiency for one or more imprinted or dosage sensitive genes. The DLK1 gene plays a critical role in tumorigenic growth in 14q32 deletions.

P11.002-M
15qter deletion/duplication and growth effects

A. Petracca[1]*, S. Romano[2], I. Sani[2], M. Pantaleo[2], G. Traficante[1], S. Bargiacchi[1], A. Gulino[1], S. Guarducci[2], E. Lapi[2], S. Stagi[3], S. Giglio[1,2];*
[1]Medical Genetics Unit, Department of Clinical and Experimental Biomedical Sciences, University of Florence, Florence, Italy, [2]Medical Genetics Unit, Meyer Children's University Hospital, Florence, Italy, [3]Department of Health's Sciences, Paediatric Endocrinology Unit, University of Florence, Florence, Italy.

We describe two cases with opposite rearrangements (deletion and duplication) in 15q region including Insulin-like Growth factor I receptor (IGF1R) gene. The IGF1R is involved in growth, insulin-related phenotypes, and longevity and is expressed equally from the maternal and paternal alleles.
Case 1: Girl of 11 years with unexplained intrauterine growth retardation (IUGR), birth weight <-1.5 SD and persistent short stature (<-2.0 SD). She displayed dysmorphic features suggestive of Silver-Russell Syndrome, with unspecific multiple hyperpigmented lesions on the body. She had a normal methylation study of the 11p15.5 region. Significant increases in IGF-I levels were observe during two IGF-I generation tests. SNP-array analysis identified a heterozygous de novo 4,92 Mb deletion in15q26.2 including IGF1R gene.
Case 2: proband was first evaluated at the age of 4 months for overgrowth, hypotonia and some dysmorphic features (a prominent nasal bridge, deep set eyes, epicanthic folds and micrognathia). He delivered by C-section at 39 weeks of gestation for breech presentation, with a birth weight of 3600 g (50th centile), a birth length of 53 cm (75th centile) and an OFC of 35 cm (+1.7 SD). He had presented craniosynostosis, corrected at 3 months of age. Array-CGH analysis showed a 17,3 Mb de novo duplication from 15q25.2 to 26.3 encompassing the IGF1R gene.
Our two cases again demonstrate that overgrowth, craniosynostosis, macrocephaly, and mild developmental delay in patients with trisomy 15q26.1 result from dosage increase of IGF1R, whereas gene dosage decrease of IGF1R can cause IGF1-resistance and underline IUGR with subsequent short stature.

P11.003-S
Two children with triplication of 16p11.2 associated with global developmental delay and dysmorphic features

G. A. M. Nimmo[1]*, A. Guerin[1], R. Badilla-Porras[1], D. J. Stavropolous[2], G. Yoon[1], M. Carter[1];*
[1]Division of Clinical and Metabolic Genetics, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [2]The Department of Pathology and Laboratory Medicine, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada.

We report two patients with de novo triplication of 16p11.2. This region is particularly prone to genomic disorders due to the large number of low copy repeats on the p-arm of chromosome 16. Patient 1. The proband is a 4 year old male and a product of an uncomplicated pregnancy delivered at 35+2 weeks to a non-consanguineous couple. A moderate ASD, peri-membranous defect of the tricuspid valve, and coarctation of the aorta was repaired at 6 weeks of age. He also had bilateral cryptorchidism, chronic constipation, and developmental delay. Patient 2. The proband is a 12 year old female delivered at 36 weeks gestational age to a non-consanguineous couple. Hydronephrosis was diagnosed antenatally with grade III reflux confirmed postnatally. Conjugated hyper-bilirubinaemia was found in early infancy and a liver biopsy demonstrated a paucity of bile ducts; genetic testing for Alagille syndrome was negative. There is a history of failure to thrive with delayed bone age and moderate developmental delay. Both children had microcephaly and dysmorphic facial features. Deletions and duplications of 16p11.2 are relatively well-characterized, and associated with global developmental delay, behavioural problems, dysmorphic facial features, seizures, abnormal head size, and variable congenital anomalies. This is the first report of 16p11.2 triplications and the associated phenotypes.

P11.004-M
Familial cases of 22q11.2 Deletion syndrome in Belarus: phenotype's variability, genetic counseling, prenatal diagnostics

N. Rumiantsava, *O. Khurs, N. Venchikova, V. Kulak, O. Zobikova, E. Trebka, L. Isakovich, L. Savenko, T. Plevako;*

Republican Medical Centre "Mother and Child", Minsk, Belarus.

The 22q11.2 Deletion syndrome (Del22S: #188400; #192430) manifested by distinct phenotype is characterized high (~10%) incidence of inherited cases (InhC). Disorder is displayed variability of phenotype's expression for heart defect (HD) and mental delay (MD). Adult's del22q11.2 carriers may demonstrate mild signs.We present InhC del22q11.2 (4 families, 9 patients) confirmed by FISH and the scheme of genetic counseling in Belarus. InhC incidence composes 10,5% (4/38). Two families (F1, F2) underwent through genetic counseling due to affected children aged 1,5 and 3,5 months with prenatal hypoplasia, dysmorphic signs, retardation, hypocalcemia, thymus agenesia, immunodeficiency, HD (F1: multiple VSD+ASD; F2: VSD+ASD+PDA). Birth weight was 1720g (F1) and 2100g (F2) at 36 and 37 week's gestation accordingly. Affected parents showed borderline intellect, facial dysmorphisms; HD: ASD (F1); hearing impairment, unilateral renal agenesis (F2). In F3, F4 Del22S was firstly revealed at pregnants counseled due to fetus's heart malformation. F3 presented 3 affected persons: pregnant with dysmorphisms, cleft palate, hypertension; fetus with HD (VSD+aortic coarctation) and normal thymus was born at 35 weeks gestation (weigh 2400g), died in 2 days; 11 years old child with MD, VSD. F4: pregnant operated for tetralogy Fallot (TF) with dysmorphisms, myopia, scoliosis, renal hypoplasia; fetus with TF. Both couples refused pregnancy's termination. Patient's management: cardiac surgery; follow-up for heart, mentality, immunological status, age-dependent assessment. Counseling del22q11.2 carriers: discussion for etiology, diagnostics, variability, impossibility to predict phenotype impairment→genetic risk (50%)→prenatal del22q11.2 testing (FISH)→discussion for pregnancy course. Our data illustrate wide phenotype's variability and importance of early Del22S carriers detection.

P11.005-S
Phenotypic characterization of a recurrent 22q11.2 deletion spanning low copy repeats (LCR)s C-E

M. A. Ramos-Arroyo, *A. Bengoa-Alonso, B. Hernandez-Charro, M. Moreno-Igoa, A. Valiente-Martin, C. Romero;*
Complejo Hospitalario de Navarra, Pamplona, Spain.

The well characterized 22q11.2 deletion syndrome is associated with a wide range of clinical phenotypes including the velo-cardio-facial syndrome (MIM 1924300) or DiGeorge syndrome (MIM 188400). About 90% of patients have a common 3Mb deletion (typical deletion), between LCR22-A and LCR22-D, while a recurrent 2.1Mb deletion is found spanning LCR22-D and LCR22-H (distal deletion). We describe 2 patients (ages 4 and 2 years) with a 1,3Mb 22q11 deletion (19362239 bp-20788469 bp, Hg18) detected by a-CGH, that spans the distal end of the typical deletion and the proximal end of the distal deletion (between LCR22-C and LCR22-E).
We compare their clinical findings with those described in patients with similar deletions in an attempt to further delineate the associated phenotype. Patients present a quite homogeneous phenotype which seems to overlap with those described in Russel-Silver and Goldenhar syndromes. It is characterized by prematurity, pre and postnatal growth retardation, microcephaly, cranio-facial dysmorphic features, heart defects, ear and renal anomalies, and mild developmental delay. Cleft palate, skeletal defects and behavioural problems were also present. Genotype-phenotype correlation supports the hypothesis that haploinsufficiency of the *CRKL* (Crk-like) gene is the major candidate gene for the cardiac anomalies associated with the 22q11.2 deletion involving LCRs C-E.

P11.006-M
MLPA reveals broader spectrum of abnormalities in patients with 22q11.2DS phenotype

Y. Kozlova, *N. Shilova, M. Minzhenkova, V. Antonenko, V. Zabnenkova, T. Zolotukhina;*
Federal State Budgetary Institution "Research Centre for Medical Genetics" of the Russian Academy of, Moscow, Russian Federation.

MLPA analysis is considered to be a reliable, accurate and cost-effective method with high sensitivity and specificity for detecting 22q11.2 microdeletion, both typical and distal. MLPA analysis with SALSA MLPA P250-B1 DiGeorge (MRC-Holland) kit was performed on the group of 78 probands with phenotype suggestive of 22q11.2 deletion syndrome (22q11.2DS) (CHD, facial anomalies, cleft palate, hypocalcemia). Different-sized deletion 22q11.2 was revealed in 28 cases. Most patients had common recurrent 3 Mb 22q11.2 deletion (79%). In our study MLPA test didn't reveal deletions in 49 patients. One patient was found to have deletions of probes within 4q34.2 region included in the probe set. The phenotype of patient presented with double outlet right ventricle, hypotrophy, brachycephaly, narrow fontanelles, dysplastic ears, anteverted nares, broad face, small lower jaw, double-sided cryptorchidism, chiasm of hand digits, seizures, cleft of soft palate. The patient's karyotype showed derivate 4q terminal deletion of maternal origin (46,XY,der(4)t(4;8)(q35;q22)mat).

Previously we evaluated a group of 140 probands with phenotype typical for 22q11.2DS. Forty three patients were diagnosed with 22q11.2 deletion by FISH and MLPA techniques (31%). Three patients with highly suggestive 22q11.2DS phenotype were found to have chromosomal abnormalities and three patients in non-deleted group presented with other syndromes detected afterwards. Thus patients with negative 22q11.2 deletion test results showed quite a vast etiological heterogeneity and may have been underdiagnosed for some genomic disorders. Array CGH should be advised in cases where discernibly suggestive phenotypes aren't confirmed by FISH and MLPA methods.

P11.007-S
3p deletion syndrome: clinical presentation and molecular description of array CGH

A. A. Syrmou[1], *M. Tzetis*[1], *K. Kosma*[1], *V. Oikonomakis*[1], *P. Makrythanasis*[1,2], *H. Fryssira*[1], *S. Kitsiou-Tzeli*[1], *E. Kanavakis*[1];
[1]*Department of Medical Genetics, University of Athens, «Aghia Sophia» Childrens Hospital,Greece, Athens, Greece, Greece,* [2]*Service of Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland, Geneva, Switzerland.*

Deletion 3p syndrome is a rare contiguous-gene disorder involving the loss of 3p25-p26 delineated by array CGH and associated with characteristic dysmorphic features, microcephaly, developmental delay (DD) and growth retardation. It was suggested that a 1,5 Mb minimal terminal deletion causes the syndrome, but there is a strong connection between the severity of the disease and the size of the deletion (Gunnarsson and Foyn Brunn 2010, Peltekova et al 2012, Reiss et al 2012). We present three patients with normal karyotype and DD, various congenital anomalies and dysmorphic features. For array CGH analysis Agilent arrays 4x180k and 1x244k (>170.000 and > 236.000 probes respectively, average resolution 8.9kb) were used. An interstitial 3p25-p26 microdeletion was detected in all patients, ranging in size from 1.9Mb to 11.3Mb and comprising the genes *CRBN, CNTN4, CHL1, LRRN1 and SRGAP3* (Ellery PM et al 2014). Additional pathogenetic aberrations which were also observed in two of our patients (dup 8q24.23-q24.3, dup 22q11.21) might contribute to the severe phenotype, presumably acting as modifiers of their clinical manifestations. Further studies of patients with application of array-CGH, will probably expand our knowledge on the phenotypic and genotypic spectrum of 3p deletion syndrome.

P11.008-M
3q27.1-q27.3 microdeletion syndrome: description of a pediatric case with previously undescribed features

C. Catalli, *A. Bengoa Alonso, B. Hernández Charro, M. Moreno Igoa, L. M. Morales Garofalo, J. R. Vílchez Gutiérrez, M. A. Ramos Arroyo;*
U. O. Genética Medica - Complejo Hospitalario de Navarra, Pamplona, Spain.

Here we describe a case of a 5 year old boy who came to our genetic service due to small stature in association with hypospadias and psychomotor retardation. Convenctional karyotype was normal, while a microarray-CGH detected a 2.8Mb deletion spanning from 3q27.1 to 3q27.3: 46,XY.arr 3q27.1q27.3(185852379-188697676)x1[Hg18]. Recently a new 3q27.3 microdeletion syndrome has been described, overlapping molecular features with our case, but only partially concordant regarding clinical phenotype. Our patient exhibit a genitourinary malformation previously unreported and a borderline IQ, opposed to reported severe mental impairment. IUGR and subsequent small stature and peculiar dysmorphisms are also seen. It is remarkable that all cases described before are adults, and as we concern this is the first case described at young age. This case expands the phenotype and clinical features of the 3q27.3 microdeletion syndrome and offers new insights about genotype-phenotype correlation.

P11.009-S
A New Syndrome? Severe growth and develop mental delay associated with Bilateral Polycystic kidney Disease.

S. Sakazume[1], *Y. Kido*[1], *H. Numabe*[2];
[1]*Dokkyo Medical University Koshigaya Hospital, Koshigaya, Saitama, Japan,* [2]*Ochanomizu Women's University, Tokyo, Japan.*

In this report, we describe two girls with severe growth and developmental delay with polycystic kidney disease. Long arm of chromosome 4was consistently deleted in almost same posisions. The common locus in the chromosome is 4q21-22. One patient had a simple 4q contiguous gene deletion, whereas the other patient had a complicated chromosomal rearrangement. In the first patient, a smaller part of the 4q was inserted to 3p. In both patients, abdominal ultrasonography revealed renal cysts. In the deletions PKD2, which causes autosomal dominant polycystic kidney disease (MIM 613095) was mapped. , The common 52 genes deleted in both patients. Typical phenotypes, were severe growth and developmental retardations, and a characteristic facial appearance consisting of frontal bossing, thin broad

eyebrows, epicanthus fold, missing, missing teeth. And mild hand and foot anomalies. Although these patients carry different chromosomal aberration, the common deletion causes the quite similar phenotype, suggesting a new syndrome due to 4q21-q22 deletion.

P11.010-M
9p deletion syndrome-like in a girl with a 9p insertion on chromosome 2 without 9p deletion

D. Carli[1,2], *G. Mandrile*[1,2], *E. Savin*[3], *G. Rivalta*[4], *M. Rolando*[4], *D. F. Giachino*[1,2], *E. Di Gregorio*[3,5], *A. Brusco*[3,5];
[1]*University of Torino, Dept. Clinical & Biological Sciences, Torino, Italy,* [2]*Medical Genetics, San Luigi University Hospital, Orbassano (TO), Italy,* [3]*S.C.D.U. Medical Genetics, Città della Salute e della Scienza, Torino, Italy,* [4]*S.C. Neuropsichiatria Infantile ASLTO3, Collegno-Pinerolo (TO), Italy,* [5]*University of Torino, Department of Medical Sciences, Torino, Italy.*

Partial deletions of 9p have been reported as a clinically recognizable syndrome characterised by the variable association of intellectual disability, speech delay, hypotonia, cardiac anomalies and dysmorphisms.
We report a 3 years old girl with midface hypoplasia, downslanting palpebral fissures, teeth agenesis and teeth fusions. Language was not acquired. At birth, severe neonatal hypotonia and patent ductus arteriosus were present. Phenotype was consistent with the clinical diagnosis of "9p deletion syndrome" (OMIM#158170), with uncommon features such as bilateral cataract (diagnosed at 5 months), chronic constipation, high pain threshold and poor temperature control.
Karyotype analysis showed an apparent 9p deletion. Array-CGH (60K Agilent) demonstrated a 2q microdeletion (600 Kb, from 166,993,501 to 167,602,904, NCBI Build 37/hg19) with normal dosage of chromosome 9. Subsequent FISH analysis revealed a 9p22.1p24.3 insertion in chromosome 2q [46,XX,ins(2;9)(q24.3;p22.1p24.3)dn]. The 2q microdeletion involved only two genes: *SCN9A* and *SCN7A*.
SCN9A recessive mutations cause congenital insensitivity to pain. *SCN7A* is not associated with human disease, and in mouse is likely to be a sodium-level sensor of body fluids in the brain. *SCN9A* haploinsufficiency may support the clinical observation of the patient high pain threshold and the poor temperature control. We are verifying the presence of a second mutation on the remaining allele. Assuming that the 2q deletion cannot account for the whole phenotype, we speculate that a critical gene/regulatory region key for the "9p deletion syndrome" is located in the 9p breakpoint(s). This patient deserves future studies that may help to refine 9p critical region.

P11.011-S
Identification of de novo 2,62Mb deletion in chromosome 15q26.1 in a boy with stigmata dysplastica, developmental delay, short stature, microcrania, nasal polyposis, hypermetropia

S. Bertok[1], *U. Grošelj*[1], *M. Jekovec-Vrhovšek*[1], *L. Lovrečič*[2], *V. Marija*[2];
[1]*University Children's Hospital, 1000 Ljubljana, Slovenia,* [2]*Clinical Institute of Medical Genetics, 1000 Ljubljana, Slovenia.*

We report a 14 years old boy with developmental delay, stigmata dysplastica and multiple organ involvement. History: no familiar congenital anomalies or consanguinity; born on 38th gestational week. IUGR. Developmental delay: sitting at the age of 8 months, walking at 16 months; at the age of three years speech with only some words. Short stature, microcrania, stigmata dysplastica, nasal polyposis and hypermetropia. Head MR showed suspect hypophyseal calcinations. Normal feeding and voiding. Dry skin. Normal hearing. No cerebral paroxysms. Postnatal microarray analysis (Agilent, Human CGH Microarray Kit 8x60k): de novo interstitial microdeletion of 2620±70kb in chromosome 15, region 15q26.1 (arr[hg19] 15q26.1(90,971,047-93-,586,680)x1 dn)1. The deleted region contained 18 RefSeq genes, encompassing CHD2, ST8SIA2 and RGMA, among others. Background: So far, there has been no case with similar 15q26.1 deletion submitted to the publicly available databases1. CHD2 gene belongs to the CHD family of proteins, characterized by the presence of chromo (chromatin organization modifier) domains and SNF2-related helicase/ATPase domains. Moreover, ST8SIA2 and RGMA genes play an important role in developing and adult central nervous system. Conclusion: Taking into consideration the de novo origin of the 15q26.1 deletion, its size and functional characteristics of the encompassed genes, the deletion is most likely associated with the developmental delay, dysplastic signs and multiple organ involvement. We believe phenotype is predominantly the consequence of CHD2 haploinsufficiency. Further studies are required to determine the role of CHD2 gene in the characteristic phenotype. 1Data generated by the ECARUCA, DECIPHER, ISCA

P11.012-M
A novel mutation in the AAAS-gene in a Bulgarian patient with Triple-A syndrome

M. Lukova[1,2], *E. Stefanova*[3], *A. Todorova*[4,2], *T. Todorov*[2], *V. Mitev*[1];
[1]*Department of Medical Chemistry and Biochemistry, Sofia Medical Unversity, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [3]*University Hospital of Pediatrics, Medical University - Sofia, Sofia, Bulgaria,* [4]*Department of Medical Chemistry and Biochemitry, Medical University Sofia, Sofia, Bulgaria.*

Triple A (Achalasia-Addisonianism-Alacrima, Allgrove) syndrome is an inherited condition characterized by three specific features: achalasia, Addison disease, and alacrima. Allgrove syndrome is inherited in an autosomal recessive pattern and is caused by mutations in the AAAS gene localized at 12q13.13. The gene encodes a protein called ALADIN. It localizes to nuclear pore complexes, large multiprotein assemblies that are the sole sites of nucleocytoplasmic transport. Achalasia-Addisonianism-Alacrima syndrome is a rare condition, incidence is unknown, and only scattered family and case reports are noted in the literature. Here we report a female patient with Triple A syndrome born to non-consanguineous parents from Bulgarian origin. She was diagnosed as Triple A at the age of 17. The patient express a typical phenotype: achalasia, Addison disease, and alacrima. The affected patient also has muscle weakness, peripheral neuropathy, skin hyperpigmentation, optic atrophy and papillae atrophy. Many of the features of triple A syndrome are caused by dysfunction of the autonomic nervous system and the neurological symptoms have worsen over time. Molecular genetic testing of the patient showed 2 heterozygous mutations in the AAAS-gene: an already reported nonsense mutation c.1024C>T, p.(Arg342*) and a novel splice site mutation c.1331+2dupT. The one basepair duplication, located 2 basepairs upstream exon 14, disrupts the donor splice site of intron 14 of the AAAS-gene. Based on Alamut software prediction, it is very likely that the mutation leads to skipping of exon 14.

P11.013-S
Acrocallosal syndrome caused by novel mutations in the KIF7 gene_a report on a Polish family and review on KIF7 syndromology

M. Krajewska-Walasek[1], *M. Kugaudo*[1,2], *M. Jędrzejowska*[1,3], *T. Attié-Bitach*[4], *A. Jezela-Stanek*[1];
[1]*Department of Medical Genetics, The Children's Memorial Health Institute, Warsaw, Poland,* [2]*Department of Child and Adolescent Psychiatry, Medical University of Warsaw, Warsaw, Poland,* [3]*Neuromuscular Unit, Mossakowski Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland,* [4]*Département de Génétique et INSERM U781, IHU IMAGINE et Université Paris Descartes, Hôpital Necker-Enfants Malades, Paris, France.*

Acrocallosal syndrome (ALCS) is a multiple congenital anomaly disorder characterized by postaxial and/or preaxial polydactyly, cutaneous syndactyly, macrocephaly, widely spaced eyes, absence of the corpus callosum, and intellectual disability. It was first described by Albert Schinzel in 1979, but the diagnosis of this syndrome still remains challenging. This may be due to both non-specific clinical symptoms, as well as to a heterogeneous and difficult to clearly define molecular background. In 2011 mutations in the *KIF7* gene were identified for the first time in patients with acrocallosal syndrome. The *KIF7* gene encodes a cilia-associated protein belonging to the kinesin family that plays a role in the hedgehog signaling (SHH) pathway through the regulation of GLI transcription factors; it also regulates acetylation and stabilization of microtubules.
We report on a family with 2 children (a girl and a boy) affected with acrocallosal syndrome caused by novel mutations in *KIF7*. The presented sibs met the clinical criteria of acrocallosal syndrome, i.e.: polydactyly, corpus callosum anomalies, facial dysmorphism (frontal bossing and hypertelorism) and hypotonia/developmental delay. Despite the same spectrum of congenital malformations noted in the presented patients, their psychomotoric development is quite different. The boy is much more delayed, with poor contact, cannot sit unsupported. He has hyperventilation and, as his sister, sleep disorders (frequent awakening). On the basis of this family, we discuss the heterogeneity of *KIF7*-associated disorders.
The study was partially financed by NCN Project Harmonia 4 no. UMO-2013-/08/M/NZ5/00978.

P11.014-M
A new locus for syndromic acroosteolysis with intellectual disability, sensory neuropathy and enhanced osteoclast function

Gnocchi, Milan, Italy, [13]Department of Infectious Diseases, Catholic University, Rome, Italy, [14]Department of Plastic and reconstructive Surgery and Handsurgery, Erasmus University MC, Rotterdam, Netherlands, [15]Istituto di Chimica del Riconoscimento Molecolare, Consiglio Nazionale delle Ricerche, Rome, Italy.

We describe an inbred family with three individuals affected by syndromic acroosteolysis, inherited as an autosomal recessive trait. This condition is characterized by intellectual disability, hypogonadism, sensory neuropathy and recurrent infections. Furthermore, decreased bone mineral density and low levels of 25-hydroxyvitamin D_3 were detected. Mutations in genes previously associated to acroosteolysis (*NOTCH2*, *MMP2*, *WNK1*, *FAM134B*) were excluded by Whole Genome Sequencing. This same technique, in combination with SNP haplotyping of the pedigree, allowed the identification of two homozygous missense mutations in neighbouring genes *TMEM41B* and *DENND5A* on 11p15.4. These genes have not been implicated in human disease yet and encode distinct Golgi proteins. Different bioinformatic analyses suggest that both mutations in the neighbouring genes may underlie the pathogenesis. Messenger RNA levels of both genes are upregulated in osteoclast cell cultures obtained from normal controls. Functional studies show that significantly more osteoclasts are derived from patients' blood mononuclear cells compared to heterozygous individuals and normal controls; finally, patients' osteoclasts exhibit an enhanced bone resorption activity compared to controls. Further genetic studies in animal or cellular models are needed to sort out the role of each gene in the new locus in causing this rare recessive disorder.

P11.015-S

Acromegaloid Facial Appearance Syndrome should not be forgotten in the differencial diagnosis of pseudoacromegaly

B. Pereira[1], **A. Fortuna[2]**;
[1]Serviço Endocrinologia e Diabetes,Hospital Garcia da Orta, Almada, Portugal, [2]Centro Genética Medica Jacinto Magalhães,CHP, Porto, Portugal.

Acromegaloid facial appearance (AFA) syndrome is a very rare inherited cause of pseudoacromegaly characterized by progressive coarsening of facial features, overgrowth of oral mucosa and large, doughy hands. Six case reports have been described. Herein we describe a further family with AFA syndrome.

Probands were a 31 years female and his 37 years brother who were referred to our department due to suspected acromegaly. Both siblings had a previous history of oral surgery 13 and 20 years before due to hypertrophic intraoral tissue. Additionally, the male proband had mild learning difficulties, uncontrolled hypertension, left ventricular hypertrophy and a paroxystic atrial fluter. He was medicated with lisinopril, amiodarone and clobazam. Family history was remarkable for their mother, who was remembered by both siblings as having "rough facial features". At physical examination both patients were hypertensive, obese and had a raised cephalic perimeter. Their facial appearance was coarse with thickened lips and superior eyelids, enlarged nose and gingival hypertrophy. Biochemical surveys were normal. At follow-up both patients underwent repeated oral surgeries due to their evolving extensive gingival hypertrophy. AFA syndrome was considered the final diagnosis of this somatic overgrowth disease.

We highlight the importance of a careful family history and physical examination of a kindred with AFA syndrome to collect the striking features of each disorder associated with an acromegaloid phenotype and achieve an accurate diagnosis. The phenothype includes a progressively coarse acromegaloid-like facial appearance with thickened lips/gums, with learning difficulties in two consecutive generations, suggesting AD inheritance.

P11.016-M

A novel splice-site mutation in *NOTCH2* in a Norwegian family with Alagille syndrome

Y. Sejersted[1], *H. H. Mørk[1], A. B. Østensen[2], M. Kulseth[1], R. Almaas[2];*
[1]Department of Medical Genetics, Oslo University Hospital, N-0424 Oslo, Norway, [2]Department of Pediatrics, Oslo University Hospital, N-0424 Oslo, Norway.

The index patient, a boy, presented neonatally with conjugated hyperbilirubinemia which resolved in 2-3 months. He was born five days post term (birthweight 2840 g, length 50 cm, occipitofrontal head circumference 34 cm) after an uneventful pregnancy. His healthy non-consanguineous parents are of Norwegian descent. Of note is that his father was icteric for the first 2-4 months of life. In the non-dysmorphic index patient, hepatic ultrasound and scintigraphy were normal neonatally. Bile duct paucity, giant cell transformation and intracanalicular cholestasis was evident histologically. Serum cholesterol was <5mmol/L. His proteinuria improved over the first 12 months. Additional findings included posterior embryotoxon and bilateral mild peripheral pulmonary artery stenosis. Butterfly vertebrae were not demonstrated. No sequence or copy number variants were detected in *JAG1*. Sequencing of *ABCB4* and *CFTR* revealed no pathogenic variant. Sequencing of *NOTCH2* established heterozygosity for the novel synonymous variant c.2817G>A (p.P939P) (NM_024408.2) both in the child and his father. *In silico* analysis predicted introduction of a novel splice-site. cDNA sequencing confirmed the presence of a splice-site causing skipping of the 5'-end of exon 18 (r.2753_2818del). The deletion maintained the reading frame (p.Asn918-Gly940delinsSer), resulting in a protein lacking most of the 24th EGF-like domain (p.911-947). Amplification of the correctly spliced mRNA revealed monoallelic expression of the normal allele (c.2817G), confirming that c.2817G>A in *NOTCH2* is likely the cause of the variable Alagille syndrome phenotype in this family. To our knowledge, this is the first reported case of a synonymous variant in *NOTCH2* causing Alagille syndrome.

P11.017-S

A new mutation in the COL4A3 gene associated to autosomal dominant alport syndrome with hearing disorders as sole clinical manifestation

M. Fernández-Prieto[1,2], *C. Rosado-Rubio[1,3], E. Bueno-Martínez[1,2], P. Fraile[1,3], P. García-Cosmes[3], R. González-Sarmiento[1,2];*
[1]Medicine Unit. Department of Medicine. University of Salamanca., Salamanca, Spain, [2]IBSAL and IBMCC. University of Salamanca, CSIC and SACYL., Salamanca, Spain, [3]Department of Nephrology. University Hospital. SACYL., Salamanca, Spain.

The autosomal dominant Alport syndrome accounts for 5% of cases of Alport syndrome and, unlike the recesive and sex-linked forms, clinical expression is benign and appears in the later stages of life. Autosomal dominant Alport syndrome generates a form of late-onset mild sensorineural hipoacusia. However, as in the other forms of Alport syndrome, this is always accompanied by renal failure, the rate of hearing loss being directly linked to the progression of renal failure, and its progression suggests a poor prognosis of kidney disease. We have studied the COL4A3 and COL4A4 genes by PCR, CSGE and automatic sequencing of the full coding region and the exon-intron boundaries in a Spanish family with autosomal dominant Alport syndrome, in which most of its members are suffering from hearing loss only, one member suffers lenticonus, and only two suffer renal disease. We found a heterozygous c.345DelG/p.G115GFSX37 mutation in the COL4A3 gene, which generates a truncated protein. This mutation was found in all family members with symptoms but was absent in the healthy members of the family. Thus, we describe a new mutation in COL4A3 gene mainly associated to hearing loss and for the first time we describe a case of autosomal dominant Alport syndrome that presents lenticonus. Furthermore, we report that deafness and renal impairment could not be associated in the same individual, this being the first case of a family in which deafness occurs amongst several members who do not show any alteration in the kidney.

P11.018-M

Prenatal diagnosis using array CGH in 163 cases

A. Saberi[1,2], *g. Shariati[1,2], M. Hamid[3,2], H. Galehdari[4,2], N. Abdorasouli[2];*
[1]Ahvaz Jundishapour university of medical sciences, Ahvaz, Islamic Republic of Iran, [2]Narges Med. Genetics & PND Laboratory, Ahvaz, Islamic Republic of Iran, [3]pasteur Institute,, Tehran, Islamic Republic of Iran, [4]Ahvaz Shahid Chamran university, Ahvaz, Islamic Republic of Iran.

Karyotype analysis has been the standard procedure for prenatal cytogenetic diagnosis since the 1970s. However, the major limitation remains requirement for cell culture, resulting in a delay of as much as 14 days to get the test results. FISH and QF-PCR do not provide a genome screen for unexpected imbalances. CGH array technology has proven to be useful in postnatal diagnosis of mental retardation, development delay, and congenital malformation syndrome. We evaluated the use of array comparative genomic hybridization (aCGH) for prenatal diagnosis including assessment of variants of uncertain significance, and the ability to detect abnormalities not detected by karyotype. Women undergoing amniocentesis or chorionic villus sampling (CVS) for karyotype were offered aCGH analysis using a targeted cytochip ISCA 4x44K v1.0 oligonucleotide array. Parental samples were obtained at the same time to exclude maternal cell contamination and determine if copy number variants (CNVs) were de novo, or inherited.We analyzed 163 samples, most were CVS (75.5%) and amniotic fluid (19.6%). The most common indication were advanced maternal age (N=74), abnormal ultrasound finding (N=46) and a previous child with multiple congenital abnormalities (N=40).We detected 27 CNVs (16.7%). Of these 16 (9.8%) were interpreted as likely benign, 9(5.5%) were of defined pathological significance, while 2(1.2%) were of uncertain significance. We concluded that array CGH identified clinically significant abnormalities in approximately 5.5% of fetuses with ultrasonographic abnormalities and normal conventional karyotype. This study demonstrate the potential for array CGH to replace conventional cytogenetic in the great majority of prenatal diagnosis cases.

P11.019-S
Deletion of 9q22.3-33.1 in a child with corpus callosum hypoplasia and thymus asymmetry

M. Czakó, *B. Duga, K. Hadzsiev, K. M. Komlósi, P. Kisfali, G. Kosztolányi, B. Melegh; University of Pécs, Dept. of Medical Genetics, Pécs, Hungary.*

Interstitial deletion of chromosome 9q is reported in context of many types of cancer but congenital cases are rarely published. The authors report on a child presenting with multiplex congenital anomalies, muscle hypotonia and characteristic facial features. Because of the symptoms suggesting primarily chromosomal disease, high resolution array CGH was indicated among a series of examinations, which detected a *de novo* 15,8 Mb interstitial deletion of 9q (ch9:102,589,027-118,400,548x1). The genotype-phenotype analysis made it clear that there are many symptoms in the clinical picture which are not included in the description of similar cases as heart anomalies (patent foramen ovale and vitium), brain malformation (corpus callosum hypoplasia), and many minor anomalies. An excessive sweating and frequent falling asleep are also characteristics not reported at known 9q deletion patients. The analysis of the possible role of the genes affected by deletion drew our attention to *NR4A3* and *CTR1* which may be related to brain malformation. Two genes (*CTNNAL1* and *RAD23*) involved in DNA repair and cell cycle regulation may have also impact on the growth retardation and dysmorphic facial features observed in 9q deletion. The *TNC* may be a candidate in development of the heart defects, and in the background of muscle hypotonia, the *MUSK* gene may be significant. Probably the haploinsufficiency of *KLF4* might be associated with excessive sweating being present in our patient. The authors provide a detailed clinical report, and the possible pathogenic role of individual genes involved in the deletion will also be discussed.

P11.020-M
Novel mutations in GNAI3 in patients with Auriculocondylar Syndrome suggest a dominant negative effect with disruption of GTP/GDP binding

V. Romanelli Tavares[1], C. T. Gordon[2], T. Torres[3], N. Voisin[2], D. Bertola[1], R. Zechi-Ceide[4], **T. Y. Tan**[5]*, A. A. C. Heggie[6], E. Propst[7], B. C. Papsin[7], N. M. Kokitsu-Nakata[4], M. L. Guion-Almeida[4], S. Vendramini-Pittoli[4], S. Lyonnet[8], J. Amiel[8], M. R. Passos-Bueno[1];*
[1]Human Genome Center, Institute of Biosciences, University of São Paulo, São Paulo, Brazil, [2]INSERM U1163, Département de Génétique, Université Paris Descartes–Sorbonne Paris Cité, Institut ImagineVictorian Clinical Genetics Services, Paris, France, [3]Institute of Biosciences, University of São Paulo, São Paulo, Brazil, [4]Department of Clinical Genetics, Hospital of Rehabilitation of Craniofacial Anomalies, University of São Paulo, Bauru, Brazil, [5]Victorian Clinical Genetics Services, Parkville, Melbourne, Australia, [6]Royal Children's Hospital, Parkville, Melbourne, Australia, [7]Department of Otolaryngology - Head & Neck Surgery, The Hospital for Sick Children, Toronto, ON, Canada, [8]INSERM U1163, Département de Génétique, Université Paris Descartes–Sorbonne Paris Cité, Institut Imagine, Paris, France.

Auriculocondylar syndrome is a rare craniofacial disorder comprising core features of micrognathia, condyle dysplasia and question mark ear. Causative mutations have been identified in PLCB4, GNAI3 and EDN1, which are predicted to function within the EDN1-EDNRA pathway during early pharyngeal arch patterning. To date, two GNAI3 mutations in three families have been reported. Here we report an Australian patient with ACS with a novel de novo GNAI3 mutation. We also present two other novel GNAI3 mutations, one segregating with affected members in a family previously linked to 1p21.1-q23.3 and a de novo mutation in an unrelated simplex case. The mutations occur in known functional motifs common to G proteins and RAS family members. Structural modeling shows that all five mutated GNAI3 residues cluster in a region involved in GDP/GTP binding. Two of the five residues lead to dominant negative proteins when mutated in related proteins. We hypothesize that all GNAI3 mutations lead to dominant negative effects.

P11.021-S
A case of a microscopically balanced familial translocation t(5;14)(p13;q22) and phenotype of lacrimo-auriculo-dento-digital (LADD) syndrome

I. Bradinova[1]*, R. Vazharova[2], S. Andonova[1], A. Savov[1];*
[1]National genetic laboratory UHOG „Maichin dom", Sofia, Bulgaria, [2]Sofia University St. Kliment Ohridski, Faculty of medicine, Sofia, Bulgaria.

We report a 15 years old male patient with clinical presentation of MCA syndrome including facial dysmorphism with micrognatia and small dysplastic ears, absent lacrimal glands and limb anomalies (muscle hypotrophy and contractures of upper limbs, bilateral pes varus deformity). The boy's intellectual and growth development was in normal age ranges. The child was born from a second pregnancy of young and healthy couple. The first pregnancy in the family ended with birth of a baby with diaphragmatic hernia which died after three days. The performed cytogenetic analysis of the patient at one month revealed a microscopically balanced chromosomal translocation between chromosomes 5p and 14q: 46, XY, t(5;14)(p13;q22). The father's karyotype was normal 46,XY while the mother's karyotype was 46,XX,t(5;14)(p13;q22) identical with her son's rearrangement. The performed array-CGH of the patient identified a heterozygous deletion in 5p12 chromosome with 489 kb size, including only one mapped gene: FGF10 (fibroblast growth factor 10) gene. Mutations in FGF10 gene may underlie autosomal dominant conditions such as lacrimo-auriculo-dento-digital (LADD) syndrome and aplasia of lacrimal and salivary glands (ALSG). The main features of lacrimo-auriculo-dento-digital (LADD) syndrome are abnormal tear production, malformed ears with hearing loss, decreased saliva production, small teeth, and hand deformities. The haploinsufficiency of FGF10 gene caused by heterozygous loss of on gene copy may explain the phenotype in our patient. This rare case of a cytogenetically balanced familial translocation causing abnormal phenotype demonstrates the diagnostic importance of genome analysis in patients with chromosomal rearrangements detected on routine karyotype.

P11.022-M
Whole exome sequencing identifies a vertically transmitted novel ACTB mutation in a mother-son pair presenting with atypical Baraitser-Winter syndrome

D. Dyment[1], N. Leonard[2], **J. L. Marcadier**[1]*, J. Schwartzentruber[3], FORGE Consortium, C. Beaulieu[1], D. E. Bulman[1], J. Majewski[3], K. Boycott[1], O. Lehmann[4], M. Innes[5];*
[1]Children's Hospital of Eastern Ontario, Ottawa, ON, Canada, [2]Department of Medical Genetics, Edmonton, AB, Canada, [3]McGill University and Genome Quebec Innovation Centre, Montreal, QC, Canada, [4]Department of Ophthalmology, University of Alberta, Edmonton, AB, Canada, [5]Alberta Children's Hospital Research Institute for Child and Maternal Health, Calgary, AB, Canada.

Baraitser-Winter syndrome is a rare, congenital disorder characterized by distinctive facial features, brain malformations and intellectual disability. It is caused by *de novo* dominant mutations in the *ACTB* or *ACTG1* genes. We present the first case of a mother-son pair concordant for Baraitser-Winter syndrome. Both had the facial gestalt of Baraitser-Winter syndrome and were found to carry a novel *ACTB* mutation by whole exome sequencing. The mutation, c.593A>C (p.S199R), occurs in a conserved amino acid and is situated near a recurrent substitution (p.R196H) commonly seen in other cases of Baraitser-Winter syndrome. The observation of transmission from parent to child broadens the clinical spectrum of Baraitser-Winter syndrome to include a relatively milder form that includes additional features such as a severe, early onset glaucoma.

P11.023-S
A new compound heterozygous mutation in the *BBS7* gene in a Korean family with Bardet-Biedl syndrome

S. Lee[1]*, S. Shin[2], M. Kim[3,4], A. Kwon[4], H. Chae[3,4], Y. Kim[3,4];*
[1]Laboratory Medicine, Incheon St. Mary's Hospital, The Catholic University of Korea,, Incheon, Korea, Republic of, [2]Internal Medicine, Incheon St. Mary's Hospital, The Catholic University of Korea, Incheon, Korea, Republic of, [3]Laboratory Medicine, The Catholic University of Korea, Seoul, Korea, Republic of, [4]Catholic Genetic Laboratory Center, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic of.

Background: Bardet-Biedl syndrome (BBS) (OMIM 209900) is a rare autosomal recessive, pleiotropic ciliopathy. To date, at least fifteen genes causing BBS have been reported.
Case: A 26-year-old Korean male from non-consanguineous Korean parents presented with rod-cone dystrophy, truncal obesity, mental retardation and end stage of renal disease. A 28-year old his brother showed rod-cone dystrophy, truncal obesity, mental retardation and deep vein thrombosis. To rule out the BBS, genomic DNAs were obtained from the peripheral blood leukocytes of all the family members. All the exons and intron flanking regions of the fifteen *BBS* genes were analyzed by direct sequencing. A compound heterozygous mutation of *BBS7* gene (NM_176824) was identified in both brothers; one was a novel acceptor splice site c.103-1G>A mutation (IVS2-1G>A) altering the splicing recognition site at the intron 2 and exon 3 boundary of *BBS7* gene. The other was a novel missense mutation of c.728G>A changing codon 243 from cysteine to tyrosine. The father was a heterozygous carrier for c.103-1G>A, and the mother was a heterozygous carrier for c.728G>A. Array comparative genomic hybridization analysis revealed a normal hybridization pattern with no evidence of significant chromosome imbalance.
Conclusion: This is the first BBS case in Korean family genetically confirmed that had a compound heterozygous mutation in *BBS 7* gene. Considering that the BBS is genetically heterogeneous and the prevalence differs among ethnic group, our clinical experience would be helpful to diagnose these patients accurately and understand the genetic events in BBS.

P11.024-M
Genotype-Phenotype correlation for BBS1 gene in Bardet-Biedl Syndrome patients

S. Castro-Sánchez, *M. Alvarez-Satta, D. Valverde;*
University of Vigo, Vigo, Spain.

Bardet-Biedl syndrome (BBS, #209900) is a rare genetic disorder characterized by highly variable phenotype and genetic heterogeneity. BBS belongs to a group of diseases known as ciliopathies, which show partial overlapping phenotypes that further complicates the molecular diagnosis. *BBS1* gene accounts for 25% of total mutations described in BBS, of which p.M390R is the most frequent mutation in European population. Many efforts have been done to establish a genotype-phenotype correlation for *BBS* genes in order to facilitate diagnosis confirmation. In this sense, the objective of this study was to correlate different *BBS1* mutations with some clinical features. We selected 36 patients from 22 families for whom a *BBS1* mutation had been identified. Clinical features of these patients were analysed by SPSS v.19. p.M390R mutation was the predominant mutation identified in 33 patients (92%), 20 of them harboured this mutation in homozygous state (56%) and 13 were compound heterozygous (36%). Only 3 patients (8%) had two mutated alleles with *BBS1* mutations different from p.M390R. By comparing all clinical features of these three groups of patients, we found statistically significant differences between these groups: while homozygous p.M390R showed more frequently high blood pressure, compound heterozygous manifested more secondary features, especially psychomotor impairment/retardation, hearing loss and worse visual defects. In conclusion, we confirm the important role of p.M390R mutation in the diagnosis of BBS, and it seems that homozygous patients have a milder phenotype. This will be important for genetic counselling purposes in these families.

P11.025-S
Potential impact on splicing of *BBS12* variations found in Bardet-Biedl syndrome Spanish patients

M. Alvarez-Satta, *S. Castro-Sánchez, D. Valverde;*
University of Vigo, Vigo, Spain.

Bardet-Biedl syndrome (BBS, #209900) is a multisystem rare disease which belongs to the emerging group of diseases called ciliopathies, and is inherited within an autosomal recessive pattern. However, little is known about other molecular mechanisms which may be involved in BBS development. For example, it is well established that synonymous (sSNPs) and non-synonymous (nsSNPs) changes can affect the conformation and stability of mRNA, the splicing process, the accuracy of translation and the protein structure. The former would lead to the disruption of the highly conserved network of cellular pathways for maintaining proteostasis. In addition, those exonic mutations predicted as pathogenic could affect splicing process via the creation and/or elimination of Exonic Splicing Enhancer/Silencer sequences (ESEs/ESSs).
In this regard, we have sequenced the coding region and intron boundaries of *BBS12* gene in fifty BBS patients. Then, we have used specific software tools to predict the potential effect at protein level (PolyPhen, PMut and SIFT) or on the splicing process (NetGene2, NNsplice, SpliceView, Human Splicing Finder and Rescue ESE) of all variants identified.
We have found two pathogenic mutations in six patients and found at least one sequence variation in twenty-nine of them. Eight out of twenty changes were selected as putative to affect the splicing process since at least two software tools predicted this effect.
As these results are only computational predictions, further functional studies will have to confirm this effect on mRNA processing. Thus, minigenes and RNA assays will be performed in order to elucidate the role of these changes.

P11.026-M
Cognitive, behavioural, and adaptive functioning of patients affected with Bardet-Biedl syndrome (BBS)

E. N. Kerr, *A. Bhan, E. Heon;*
The Hospital for Sick Children, Toronto, ON, Canada.

Bardet-Biedl syndrome is a rare genetically heterogeneous multisystem disorder characterized by retinal degeneration, genital and kidney malformation/function, and other features. Variability in cognitive, social, and emotional impairment is reported; however, studies were small and completed prior to availability of molecular characterization. Our aim is to define neuropsychological function in a group of patients with molecular diagnosis of BBS to better understand phenotypic variability.
Methods: Eighteen patients (12 females; mean age: 20.95 years; range 6.4-38 years) completed standardized measures of cognition. Magnification was available. Standardized informant-proxy questionnaires were completed to assess behavioural and adaptive functioning. Results were compared to normative data (norms).
Results: Significant weaknesses ($p<.001$) in verbal and perceptual intellectual reasoning emerged compared to norms (mean= 8th and 3rd percentiles respectively; range < 2nd-53rd percentiles). More individuals displayed Average ability (25th-74th percentile) on verbal (33.3%) than visual (15.4%) domains. More individuals displayed Extremely-Low ability (<2nd percentile) on visual (53.9%) than verbal (11.1%) domains. Significant weaknesses in auditory attention span ($p\leq.01$), and auditory and visual working memory ($p<.001$) emerged. Informant ratings indicated significant patient challenges, relative to norms, in depression ($p=.004$), withdrawal ($p<.001$), atypical-behaviour ($p=.029$), social-communication ($p=.001$), unusual-behaviours ($p<.001$), aspects of executive functions ($p\leq.01$), and adaptive independence ($p<.001$); most patients (81.3%) fell below the 2nd percentile in functional independence; the remainder fell from the 2nd-5th percentiles. Verbal reasoning was correlated with independence ($p=.001$).
Conclusion: BBS impacts cognitive, behavioral, and adaptive functioning to various degrees. Assessment of these patients on a larger scale will allow further definition of the neurocognitive phenotype.

P11.027-S
Beckwith Wiedemann Syndrome in 9 Tunisian patients : From typical sporadic presentation to unusual familial isolated adrenocortical tumor

M. Haddaji Mastouri[1], **D. H'mida Ben Brahim**[1], *N. Sonia[2], F. Chioukh[3], S. Hamami[4], S. Trabelsi[1], M. Chourabi[1], S. Sassi[1], S. Mougou[1], M. Gribaa[1], A. Zakhama[5], M. T. Yacoubi[6], N. Gueddiche[4], H. Sebouï[2], K. Monastiri[3], A. Saad[1];*
[1]Department of cytogenetics and reproductive biology Farhat Hached university hospital, Sousse, Tunisia, [2]Department of neonatology Farhat Hached university hospital, Sousse, Tunisia, [3]Department of neonatology Fattouma Bourguiba university hospital, Monastir, Tunisia, [4]Department of pediatrics, Fattouma Bourguiba university hospital, Monastir, Tunisia, [5]Department of cytopathology Fattouma Bourguiba university hospital, Monastir, Tunisia, [6]Department of cytopathology Farhat Hached university hospital, Sousse, Tunisia.

Beckwith-Wiedemann syndrome (BWS) is a pediatric overgrowth disorder expressed through a highly variable clinical presentation involving a predisposition to tumor development, exomphalos, macroglossia, and gigantism. In addition to this clinical heterogeneity, BWS also exhibits etiologic molecular heterogeneity involving a variety of genetic and/or epigenetic alterations in growth regulatory genes on chromosome 11p15. The clinical heterogeneity turns out to be insufficient in diagnosis and prognosis of BWS, thus the need of genetic analysis of 11p15 region.
We conducted a study of 9 patients who underwent molecular analysis of chromosome 11p15 region. Reasons of referral vary from sporadic typical presentation encompassing abdominal wall defects, macroglossia and gigantism to atypical mild familial BWS revealed by isolated benign adrenocortical tumor. Molecular analysis using methylation specific multiplex ligation-dependent probe amplification revealed different methylation patterns along the BWS critical region.
6 patients showed complete KvDMR hypomethylation, one paternal uniparental disomy at 11p15 case with both H19DMR hypermethylation/ KvDMR hypomethylation confirmed by STR analysis, one patient ; the youngest; with mosaic paternal isodisomie and one patient; the eldest; with KvDMR methylation mosaic pattern. This mosaicism was associated in adrenocortical tumoral tissue to a complete KvDMR loss of methylation, however skin tissue analysis showed a normal methylation profile.
These results have allowed us to offer our patients adapted management and genetic counseling. BWS illustrates the complexity of the mechanisms involved and the need for collaboration between geneticists, pediatricians, neonatologists and pediatric surgeons.

P11.028-M
A novel IGF2/H19 domain triplication in the 11p15.5 imprinting region - new insights into the pathogenesis of Beckwith-Wiedemann and Silver-Russell syndromes

D. Jurkiewicz[1], *M. Kugaudo[1,2], R. Śmigiel[3,4], E. Ciara[1], D. Piekutowska-Abramczuk[1], M. Pelc[1], J. Trubicka[1], S. Łuczak[1], P. Kowalski[1], M. Borucka-Mankiewicz[1], K. Chrzanowska[1], M. Krajewska-Walasek[1];*
[1]Department of Medical Genetics, Children's Memorial Health Institute, Warsaw, Poland, [2]Department of Child and Adolescent Psychiatry, Medical University of Warsaw, Warsaw, Poland, [3]Department of Pediatrics and Rare Disorders, Wroclaw Medical University, Wroclaw, Poland, [4]Genetic Counseling Unit, Foundation of Wroclaw Medical University, Wroclaw, Poland.

The imprinted 11p15.5 region contains two domains (*IGF2/H19* and *KCNQ1OT1/CDKN1C*), each of them under control of its own imprinting control region. Defects of 11p15 imprinting result in two growth disorders with opposite phenotypes: Beckwith-Wiedemann (BWS) and Silver-Russell (SRS) syndromes. Various 11p15.5 genetic and epigenetic aberrations have been revealed, among them microduplications and microdeletions.

We report a novel *IGF2/H19* domain triplication in the 11p15.5 region identified in a girl with BWS and her father with symptoms of SRS. Methylation specific multiplex ligation-dependent probe amplification (MS-MLPA) performed in the patient's DNA revealed triplication of *IGF2/H19* domain as well as increased methylation of *H19* region. The same genetic change in the father's DNA was associated with reduced methylation of *H19* region. The presence of triplication was confirmed by aCGH.
This is the first report of *IGF2/H19* domain triplication associated with BWS or SRS. A few BWS patients with *IGF2/H19* domain duplication of paternal copy have been described so far. Duplications of maternal copy of this domain have been reported in three individuals and were not associated with an abnormal phenotype (i.e. Silver-Russell syndrome). The clinical outcome of 11p15.5 copy number variations depends on their size, localization and the parental inheritance. These aberrations may influence chromatin organization affecting the regulation of imprinted genes. Our findings bring new insights into the regulation of genomic imprinting at 11p5.5 region and underline difficulties of genetic counseling in patients with 11p15 defects.
The study was financed by National Science Centre, project 1149/B/P01/2011/40 (NN407114940) and EU Structural Funds, POIG.02.01.00-14-059/09.

P11.029-S
Uniparental disomy in Beckwith-Wiedemann syndrome: new insights from genotype-phenotype correlations

F. Cerrato[1], *A. Freschi[1], A. De Crescenzo[1], A. Sparago[2], P. Palumbo[3], O. Palumbo[3], M. Carella[3], A. Riccio[1,2];*
[1]DISTABIF, Second University of Napoli, Caserta, Italy, [2]Istituto di Genetica e Biofisica „Adriano Buzzati Traverso" – CNR, Napoli, Italy, [3]3IRCCS Casa Sollievo della Sofferenza, Unità di Genetica Medica, San Giovanni Rotondo, Italy.

Beckwith-Wiedemann syndrome (BWS) is the most common overgrowth syndrome, with a prevalence of about 1:10,000 live birth. Clinical findings include macrosomia, macroglossia, abdominal wall defects and other less frequent features, the most severe of which is predisposition to embryonal tumors.
The molecular etiology of BWS is complex, involving alterations in the expression of multiple imprinted growth regulatory genes on chromosome 11p15.5. Genes that are imprinted are expressed predominantly from one allele in a parent of origin-specific manner. Epigenetic and/or genetic alterations in the 11p15.5 imprinted gene cluster have been associated with BWS in approximately 80% of patients. One of the major categories of BWS molecular alteration (20% of cases) is represented by mosaic paternal uniparental disomy (pUPD), namely patients with two paternally derived copies of chromosome 11p15 and no maternal contribution. pUPD is also the molecular alteration associated with the most severe BWS phenotype because of the highest tumor risk.
Here we report a fine analysis of patients with BWS and pUPD from our cohort. By SNP array and microsatellite analysis we could distinguish three different categories of pUPD: whole genome, whole chromosome 11 and chromosome 11short arm.The three UPD subgroups show differences in some clinical features (hemihyperplasia, hypoglycemia, umbilical hernia, hepato/splenomegalia) and similarities in others (macrosomia, polyhydramnios). Our results highlight the importance of a fine molecular analysis of the UPD cases for a more accurate prognostic prediction to facilitate management and surveillance of patients.

P11.030-M
KCNJ8 mutation in a spanish family with Cantú syndrome including a case of fetal demise

M. Del Campo[1,2], *P. Fernández Álvarez[1], A. Sánchez[3], E. García Arumí[1,2];*
[1]Genetics Dept, Hospital Vall D´Hebron, Barcelona, Spain, [2]Research Network for Rare Disorders (CIBERER), Madrid, Spain, [3]Genetics Dept, Hospital Clínic, Barcelona, Spain.

Cantú syndrome, (MIM 239850) is an autosomal dominant disorder causing severe hypertrichosis, congenital and progressive coarseness of the facial features, thick skin with deep palmar and plantar creases, cardiomypathy and lymphedema. Polyhydramnios and macrosomia can be present in the affected fetus. ABCC9, a multimeric subunit of a ATP sensitive potassium channel K(ATP) has been the causal gene in most cases, but not all. A second gene KCNJ8, also a subunit of the same K(ATP) channel, was proposed to be causal after a de novo mutation (p.V65M) was found in a sporadic case with unusual cardiovascular findings. Another mutation in KCNJ8 (p.S422L) has been reported in at least 9 individuals with Brugada sudden death syndrome. A 30 week old fetus was followed due to macrosomia and polyhydramnios, unexplained fetal demise occurred at 34 weeks. Evaluation of the family identified the fetus, the father, the paternal grandmother and the aunt of the fetus had clinical features of Cantú syndrome. No cardiomyopathy or other potential causes for the fetal demise were identified. Sequencing and MLPA for ABCC9 did not detect any pathogenic changes. Subsequently, an inherited missense change in KCNJ8 (NM_004982.3: c.34T>C (p.Tyr12His) was identified. In silico prediction and segregation (4 affected, 1 unaffected) indicated the mutation is most likely pathogenic. The phenotype in the family is indistinguishable from typical Cantu syndrome caused by mutation in ABCC9, although fetal demise was never reported before. Mutation in KCNJ8 in families with Cantu syndrome may represent increased risk for sudden death.

P11.031-S
De novo mutations associated with sporadic cases of Caudal regresion syndrome

R. M. Porsch[1], *E. Merello[2], P. De Marco[2], M. So[3], P. Sham[1], P. Tam[3], S. S. Cherny[1], V. Capra[2], M. Garcia-Barcelo[3], D. Campbell[1];*
[1]Department of Psychiatry of the Li Ka Sing Faculty of Medicine, Hong Kong, Hong Kong, [2]U.O. Neurochirurgia, Ist. G.Gaslini, Genoa, Italy, [3]Department of Surgery of the Li Ka Sing Faculty of Medicine, Hong Kong, Hong Kong.

Aim: The identification of de novo disease causing mutations in three Caucasian patients with sporadic Caudal Regression Syndrome (CRS). CRS is a rare and diverse congenital disorder which is characterised by different degrees of agenesis of the caudal spine. Known genetic mutations are only able to explain a fraction of cases and are not accounting for sporadic occurrences or the diversity of the disorder. Methods: Exome sequencing assay was conducted of the three sporadic cases and their biological parents. We targeted rare genetic variants as the underlying cause of CRS as well as de novo mutations. Further we investigated de novo indels, copy number variations (CNV) and compound heterozygosity. Identified mutations were ranked and filtered based on genomic, genetic and statistical features. Results: Sanger sequencing confirmed two different de novo mutations in two cases (detailed results will be presented). In addition, our analysis revealed several potentially causal compound heterozygous mutations which are also under investigation. Conclusion: CRS may be caused by de novo or compound heterozy mutations thus, i) the diversity of the disorder is mirrored in the underlying genetic architecture and its mutations; ii) ranking of compound heterozygous mutations enables identification of candidate genes.

P11.032-M
A de novo microdeletion of chromosome 18q11.2q12.2 causes a new distinct clinical phenotype with coarctation of aorta and intellectual disability.

M. C. Cutrupi[1], *I. Loddo[1], M. G. Giuffrida[2], L. Bernardini[2], E. Moschella[1], C. Pidone[1], M. R. Pizzino[1], M. Crapanzano[1], A. Novelli[2], S. Briuglia[1];*
[1]Dipartiment of Paediatric Science, Messina, Italy, [2]CSS-Mendel Institute, Roma, Italy.

Cardiac abnomalities are diagnosed in 25-30% of the patients with 18q syndrome and the most common heart abnormalities are reported in patients with terminal 18q deletion (18q22): atrial septal defect, ventricular septal defect, polmonary valve anomalies and total anomalous polmonary venus return. We report on one girl with coarctation of the aorta, moderate development delay, behavioral problems, with an interstitial de novo deletion within chromosomal band 18q11.2 of 13.4Mb. The propositus was born at 37 weeks via caesarian section after a pregnancy complicated by gestosis. Her birth weight was 2400g (<10th centile), birth length was 45cm (3-10th centile) and occipital frontal circumference (OFC) 34 cm (5thcentile). Family history revealed no abnormalities or congenital heart diseases. At the age of one month, cardiac echo revealed tight istmic coarctation of the aorta and the patient underwent surgery. Clinical evaluation showed a distinctive craniofacial apparence characterized by brachicephaly, plagiocephaly, telecanthus, strabismus, low nasal bridge, smooth philtrum, thin lips, high arched palate, low set ears with hypoplastic lobule, proximally placed thumbs. The development milestones were delayed and the propositus developed behavioral problems: poor concentration, hyperactivity and distractibility. CGH analysis showed an interstitial proximal microdeletion of chromosome 18 of 13,4Mb [arr 18q11.2(22,032,122-35,430,900)x1]. In this region some genes are present that are involved in development of the heart, DSC2 ,DSG2, TTR, DTNA, FHOD3. This is the first report of aortic coarctation mapping to a proximal microdeletion involving the chromosome 18q11.2q12.2 segment. The report also expands the spectrum of clinical phenotype associated with 18q11.2q12.2 deletion.

P11.033-S
A further case of pure 15q deletion: Clinical and molecular cytogenetic findings

A. Ece Solmaz[1], *B. Durmaz[1], M. De Braekeleer[2], Ö. Çoğulu[1], F. Özkınay[1];*
[1]Department of Medical Genetics, Ege University, Faculty of Medicine, Izmir, Turkey, İzmir, Turkey, [2]Departments of Cytology, Cytogenetics and Reproductive Biology, CHRU Brest, Brest, France, Brest, France.

A deletion of the distal long arm of chromosome 15 is generally reported with the formation of ring chromosome 15, whereas an isolated 15q deleti-

on is rarely described. Here we report an 11 year-old girl, from non-consanguineous parents, was referred to the Pediatric Genetics Department with growth retardation and multiple congenital abnormalities. In her medical history, she was born at-term after an uncomplicated pregnancy. Her birth weight was 2200 g. She had a cleft palate, hip dislocation and crossed renal ectopia. On physical examination, her weight, height and head circumference were below the 3rd percentile. Dysmorphological evaluation revealed a triangular face, low-set ears, fissured cleft tongue, micrognathia, proximally placed hypoplasic thumbs, genu valgus, 2-3 toe skin syndactyly, clinodactyly and nail hypoplasia. Speech problems were also noticed. The complete blood count, basic biochemical parameters and hormones profile were within the normal range. The karyotype was normal. Subtelomeric fluorescene in-situ hybridisation (FISH) analysis showed a *de novo* terminal deletion of chromosome 15. BAC FISH analysis of the patient indicated that the deletion breakpoint was at 15q26.3 and the deletion comprised 700-870 kb. The deleted region includes the *CHSY1* gene that is responsible for Temtamy preaxial brachydactyly syndrome which shares clinical features with 15qter deletion syndrome. To the best of our knowledge, this deletion is the smallest among reported cases. It is considered that the case presented here significant contribution to phenotype-genotype correlation in 15q deletion patients.

P11.034-M
Association between HLA-G and non-syndromic Oral Cleft

F. Conte[1], *R. Brusati*[2], *G. Garattini*[2], *O. Calabrese*[3], *A. Franchella*[4], *M. Rubini*[1];
[1]*University of Ferrara, Ferrara, Italy,* [2]*Smile House, Hosp. San Paolo, Milano, Italy,* [3]*AOU Imola, Imola, Italy,* [4]*AOU Ferrara, Ferrara, Italy.*

Non-syndromic oral clefts (nsOCs) affect 1 per 1,000 live births worldwide. There is some evidence suggesting that embryo-maternal interaction can play a relevant role in the etiology of nsOCs. HLA-G has a protective function at the maternal-embryo interface, protecting the embryo from destruction by mother's immune system.
In this study we investigated the association between a functional variant in HLAG gene and the risk of nsOCs. A 14 nt insertion in the 3'UTR of HLAG was genotyped in a group of 222 Italian nsOC trios, including affected children and their parents.
The analysis of transmission disequilibrium resulted in no evidence of association in nsCL/P (p=0.16) nor in nsCP trios (p=1.00). However, when considering the length of pregnancy, a significant overtransmission of the insertion was observed in the trios with pregnancy length >38 weeks (p=0.005). In trios with affected children born after 38 weeks or less, the transmission of minor allele was reverse (p=0.031), so that in the effect of the asymmetric segregation was canceled when the two groups were pooled. In children born after more than 38 weeks of pregnancy the ins/ins genotype resulted specifically associated with a three-fold increased risk of the more severe phenotype (cleft lip and palate, CLP) (p<0.0001).
This results suggests the existence of a link between HLA-G genotype, length of pregnancy and chance of developing CLP. We hypothesize that HLA-G could be involved in prenatal loss of abnormal embryos (teratothanasia) and drive selection against those which fail to fuse lip and palate.

P11.035-S
Association between chromosome 8q24.21 and susceptibility for nonsyndromic cleft lip with or without cleft palate in Iraqi population

F. Mattioli[1], *F. Abenavoli*[2], *A. Franchella*[3], *F. Pacelli*[2], *C. Baluardo*[1], *V. Aiello*[1], *G. Astolfi*[1], *D. Balestra*[1], *F. Conte*[1], *A. Edris*[1], *E. Bonomo Roversi*[1], *P. Franceschelli*[1], *M. Rubini*[1];
[1]*University of Ferrara, Ferrara, Italy,* [2]*Emergenza Sorrisi ONG, Roma, Italy,* [3]*Pediatric Surgery Unit, S. Anna Hospital, Ferrara, Italy.*

Cleft lip without or without cleft palate (CL/P) are the most common craniofacial congenital malformations. Most of CL/P cases are non-syndromic (nsCL/P), with a multifactorial etiology. Recent genome-wide association studies (GWAS) have identified susceptibility loci for nsCL/P, among which one of the most relevant is located in 8q24.21. In particular, the polymorphism rs987525 has been shown to be highly associated with nsCL/P in population of European origin, while yielding only marginal significance in Oriental populations.
We present the result of case-control study of a sample of Iraqi population from Nasiryiah: 418 affected children, and 273 unaffected controls. The rs987525 C>A variant was genotyped using TaqMan assay. The frequency of minor allele (A) resulted significantly higher among cases compared to controls. Odd Ratio (OR) for carriers of heterozygous (C/A) genotype was 1.69 (95% C.I. 1.24-2.31), while OR for homozygotes (A/A) was 1.95 (95% C.I. 1.16-3.29). In the studied Iraqi sample the rs987525 variant acts in a dose dependent fashion, in agreement to what resulted from association studies in population of European origin, suggesting that 8q24.21 locus confers risk for nsCL/P also in Middle-East population.

P11.036-M
Haploinsufficiency of MEIS2 is associated with orofacial clefting and learning disability

G. Houge[1], *S. Berland*[1], *G. A. Gradek*[1], *E. Bongers*[2], *N. de Leeuw*[2], *M. Fannemel*[3], *O. Rødningen*[3], *R. Pfundt*[2], *A. Brendehaug*[1], *B. Haukanes*[1], *R. Hovland*[1], *S. Johansson*[1];
[1]*Haukeland University Hospital, Bergen, Norway,* [2]*Radboud University Medical Centre, Nijmegen, Netherlands,* [3]*Oslo University Hospital, Oslo, Norway.*

MEIS2 is a homeodomain-containing transcription factor of the TALE superfamily that has been proven important for development. We confirm and extend a recent single case report stating that deletions in MEIS2 can cause cleft palate (Crowley et al, Am J Med Genet 2010, 152A:1326-7). Here we report five additional cases with 15q14 deletions of sizes 0.6, 0.6, 1.0, 1.9 and 4.8 Mb, respectively, all involving MEIS2. In addition, we present a family with four affected individuals and an intragenic 58 kb direct duplication disrupting MEIS2. In total, 7/9 cases had clefting, from mild (submucous cleft palate) to severe (cleft lip and palate), and 3/9 cases had ventricular septal defects. All cases had delayed motor development and most had learning disability, at worst in the mild intellectual disability range. Our results show that MEIS2 clearly is a gene needed for palate closure. In syndromic cases of cleft palate, MEIS2 should be considered among the candidate genes, e.g. in cases without 22q11.2 deletions.

Introduction: Beckwith- Wiedemann Syndrome (BWS)(OMIM 130650) is a genetic disorder, caused by mutation or deletion of imprinted genes within the chromosome 11p15.5 region; with a prevalence of 1 in 13,700 births and characterized by overgrowth, macroglossia, organomegaly, exomphalos and predisposition to embryonal tumor development. **Objective:** To present a BWS familial case follow up. **Case Report:** Family data: Mother with 4 pregnancies, she presents ear pits. Case 1: 9 years 7 months female, product of the 2nd pregnancy term, obtained by caesarian section from non-consanguineous parents, with 28 years (he) and 29 years (she) at birth time. Apgar 9-10, weight and height >pc97, macroglossia, depressed nasal bridge, posterior helical ear pits and exomphalos surgically corrected, presented neonatal hypoglycemia. At first year of age presented overgrowth, renal ultrasonography reported right pyelic duplication. At 3 years was performed transversal and anteroposterior reduction glossectomy. At 8 years hemihypertrophy was detected. At present she has no complications. Case 2: 3 years 9 months female, product of the 4th pregnancy, obtained by cesarian section at 30 weeks, weight at birth 2500g. Physical examination: weight and height > pct 97, posterior helical ear pits, macroglossia, umbilical hernia; has not required surgical procedure. Renal ultrasonography without abnormalities. Actually with weight and height > pct 97. **Conclusion:** Clinical findings meet criteria diagnosis for BWS. In case 1 treatment consisted of surgical reduction of exomphalos and anterior-transversal reduction glossectomy and case 2 not required surgical intervention. The opportune diagnosis allows a complete treatment, genetic counselling and appropriate follow up.

Detection of PIK3CA somatic mutations in CLOVES syndrome

S. Boppudi[1], *I. Wieland*[1], *D. Emmrich*[2], *M. Kolanczyk*[2], *M. Zenker*[1], *S. Tinschert*[2,3,4];
[1]*Institute of Human Genetics, University Hospital Magdeburg, Magdeburg, Germany,* [2]*Institute for Medical Genetics and Human Genetics, Charité-University Medicine, Berlin, Germany,* [3]*Division of Human Genetics, Medical University Innsbruck, Innsbruck, Austria,* [4]*Institute of Clinical Genetics TU Dresden, Dresden, Germany.*

CLOVES syndrome (congenital lipomatous overgrowth, vascular malformations, epidermal nevi, and skeletal abnormalities (MIM 612918) is a non-hereditary regional overgrowth disorder distinct from Proteus syndrome. Gain-of-function mutations in PIK3CA have been identified in affected tissues demonstrating somatic mosaicism of varying degrees. Activating PIK3CA somatic mutations have also been shown in further regional overgrowth conditions predominantly affecting the limbs like in isolated macrodactyly and fibrolipomatous gigantism. In the current study, hot spot mutations of PIK3CA were identified in six patients presenting with CLOVES syndrome. Analysed tissues included epidermal nevi, skin, fatty tissues, and connective tissue. Blood was available from five patients. Molecular analysis was performed for all six patients by Sanger sequencing. Mutant allele ratios of 30-

50% were observed in scrapings from epidermal nevi or affected fatty tissue samples. In none of the blood samples PIK3CA mutations were detected. Because detection levels and quantification of mutant alleles were limited to 10-15% by Sanger sequencing, fragment analysis and amplicon-deep sequencing on a GS Junior platform (Roche) were applied. This increased the mutant allele detection to 1-5%. In blood samples mutant allele ratios were 2% or less. Our data confirm that cells from affected tissue are essential for mutation analysis in CLOVES syndrome whereas blood is an inappropriate source. Improved detection methods may be required for other tissues with low level somatic mosaicism.

P11.039-S
Endocrinological study in a new case of Coffin Siris syndrome due to ARID1B gene deletion

E. Lapi[1], *S. Stagi*[2], *M. Pantaleo*[1], *S. Romano*[1], *S. Bargiacchi*[3], *S. R. Giglio*[1,3];
[1]*Medical Genetic Unit, Meyer Children's Hospital, Florence, Italy,* [2]*Department of Health Sciences, Paediatric Endocrinolgy Unit , University of Florence, Florence, Italy,* [3]*Medical Genetic Unit, Department of Clinical and Experimental Biomedical Sciences, University of Florence, Florence, Italy.*

Coffin Siris syndrome (CSS) is a rare congenital anomaly syndrome (MIM135900), characterized by developmental delay with severe speech impairment, growth deficiency , coarse facial features, hypertrichosis, hypoplastic/absent fifth fingernails or toenails. Some CSS patients have mild microcephaly and hypoplasia/agenesis of the corpus callosum.
In 2012 Santen et al. showed that haploinsufficieny of ARID1B gene causes CSS and Tsurusaki et al. demonstrated that CSS can be due to de novo germline heterozygous mutations in one of five SWI/SNF subunit genes SMARCB1,SMARCA4, SMARCE1, ARID1A and ARID1B.
We describe a girl of four years of age, first daughter of healthy unrelated parents. She was born by caesarean section for IUGR, at 39 wks of pregnancy. Out first examination at the age of 18 months showed psycho-motor delay with absent language. Her weight, length and OFC were between 25th and 50th centile for age, but her facial and extremities features were suggestive of CSS. She had marked body hypertrichosis and moderate, non familial, joint laxity, usually not described in CSS phenotype.
Array-CGH analysis revealed a de novo 1,3 Mb interstitial deletion in 6q25.3, including ARID1B gene,
Because few hormonal data in CSS have been reported so far, we performed an extensive endocrinological study. Biochemical measurements showed normal values of electrolytes, venous blood gas, creatinine, glucose, fT4,TSH, aldosterone, renin activity,1-OH progesterone, DHEAS, cortisol, ACTH and normal slow response of cortisol and 17-OH progesterone to ACTH test. These results suggest that pituitary-adrenal axis anomalies are not responsible for hypertrichosis in CSS.

Cohen syndrome (CS) is a rare autosomal recessive disorder with multisystemic clinical features due to mutations in the *VPS13B* gene, which has recently been described encoding a mandatory membrane protein involved in Golgi integrity. As the Golgi complex is the place where glycosylation of newly synthesized proteins occurs, we hypothesized that VPS13B deficiency, responsible of Golgi apparatus disturbance, could lead to glycosylation defects and/or mysfunction of this organelle, and thus be a cause of the main clinical manifestations of CS. The glycosylation status of CS serum proteins showed a very unusual pattern of glycosylation characterized by a significant accumulation of agalactosylated fucosylated structures as well as asialylated fucosylated structures demonstrating a major defect of glycan maturation in CS. However, CS transferrin and α1-AT profiles, two liver derived proteins, were normal. We also showed that ICAM-1 and LAMP-2, two highly glycosylated cellular proteins, presented an altered migration profile on SDS-polyacrylamide gels in peripheral blood mononuclear cells (PBMCs) from CS patients. RNA interference against *VPS13B* confirmed these glycosylation defects. Experiments with Brefeldin A demonstrated that intracellular retrograde cell trafficking was normal in CS fibroblasts. Furthermore, early endosomes were almost absent in these cells and lysosomes were abnormally enlarged, suggesting a crucial role of VPS13B in endosomal-lysosomal trafficking. Our work provides evidence that CS is associated to a tissue-specific major defect of glycosylation and endosomal-lysosomal trafficking defect, suggesting that this could be a new key element to decipher the mechanisms of CS physiopathology.

P11.041-S
A Novel Frameshift mutation in the PIEZO2 gene in a Turkish pediatric patient with Distal Arthrogryposis 5A

S. G. Temel[1,2], *E. Evke*[1], *M. J. McMillin*[3], *M. J. Bamshad*[4];
[1]*University of Uludag, Faculty of Medicine, Department of Histology & Embryology, BURSA, Turkey,* [2]*Near East University, Faculty of Medicine,Histology & Embryology Department, Lefkosia-North Cyprus, Turkey,* [3]*Department of Pediatrics, University of Washington, Seattle, WA, United States,* [4]*Department of Genome Sciences, University of Washington, Seattle, WA, United States.*

The distal arthrogryposis (DA) are characterized by congenital contractures of two or more different body areas without a main neurological and/or muscle disease. Currently, DAs are subdivided into 10 types, depending on the number and nature of additional features. DA5 is unique among DAs because, in addition to contractures, affected individuals have ocular abnormalities. These abnormalities include ptosis, ophtalmoplegia, and/or strabismus. Recently, it has been shown that a subtype of DA5 that includes restrictive pulmonary disease is caused by gain-of-function mutations in the mechanically activated cation channel PIEZO2. We report 14 years old boy with DA5 who initially presented with multiple contractures at the age of 2 months. The main clinical findings included pitosis, ophtalmoplegia, micrognathia, clinodactyly, pectus excavatum, recurrant pulmonary infections, operated inguinal hernia/midpenil hypospadias, elbow extansion/bilaterale wrist supination restriction, knees lightly in flexion moode and pes valgus. Sequencing of the PIEZO2 gene in the proband revealed a de novo one base-pair deletion in Exon 52 of PIEZO2, which results in a frameshift mutation (c.8208delA). The mutation leads to a p.Y2737Ifs*7 change within the C terminal domain of PIEZO2. Recently electrophysiologic studies of E2727del variant showed that mechanically activated current inactivation were clearly slower and E2727del channels spend about two fold less time in an inactivated state following mechanical stimulation than in wild channels, thus can be reactivated quicker. Therefore because our pathologic variant is at the same domain as E2727del, it can be speculated that increased response to mechanical force may explain the phenotype of our patient also.

The contribution of discrepant DNA variations in discordant monozygotic twins with Congenital Diaphragmatic Hernia (CDH) or Esophageal Atresia/ Tracheoesophageal Fistula (EA/TEF).

E. Brosens[1], *R. W. W. Brouwer*[2], *D. C. M. Veenma*[1], *B. Eussen*[3], *T. Brands*[3], *R. M. H. Wijnen*[4], *D. Tibboel*[4], *W. F. J. van Ijcken*[2], *A. de Klein*[3];
[1]*Clinical Genetics & Pediatric Surgery, Erasmus Medical Centre – Sophia Children's Hospital, Rotterdam, Netherlands,* [2]*Centre for Biomics, Department of Cell biology, Erasmus Medical Centre, Rotterdam, Netherlands,* [3]*Clinical Genetics, Erasmus Medical Centre – Sophia Children's Hospital, Rotterdam, Netherlands,* [4]*Pediatric Surgery, Erasmus Medical Centre – Sophia Children's Hospital, Rotterdam, Netherlands.*

Congenital Hernia of the Diaphragm (CDH) and Esophageal Atresia with/or without Trachea-esophageal Fistula (EA/TEF) are congenital anomalies that can either be present as isolated anomaly or in association with other birth defects. Both anomalies likely have a multifactor etiology, are associated with known (genetic) syndromes and can occur in combination with specific chromosomal aberrations, Copy Number Variations (CNV) or mutations. When evaluating the genetic component of a disease twin studies help to elucidate potential causal or predisposing genetic factors. Monozygotic (MZ) twins are believed to have the same genetic content and share the same environment during development. We hypothesize that *de novo* mutations arisen early in embryonic development could explain the phenotypical differences in discordant MZ twins. In total of six EA/TEF and four CDH discordant MZ twins are characterized with SNP-arrays and exome-NGS in order to detect, complete or mosaic, DNA discrepancies. We could not detect any CNV (mosaicism) differences in these twins. Both SNP-array genotyping and exome-NGS variant calling with the Genome Analysis ToolKit revealed numerous discrepant SNPs and InDels. Visual inspection of hundreds events with Illumina's Genomestudio and the Broad institute's IGV indicated that most discrepancies were actually false positive differences due to technical limitations, analysis settings (thresholding) or limitations of the variant calling. Therefore, we compared different exome capturing and alignment techniques in addition to various variant callers, statistics and analysis stra-

tegies to determine if we could distinguish false positive differences from actual ones. Currently, we are evaluating with whether these remaining discrepancies are true differences.

P11.043-S
Associated noncardiac congenital anomalies among infants with congenital heart defects

C. Stoll, *Y. Alembik, B. Dott, M. Roth;*
Genetique Medicale, Strasbourg, France.

BACKGROUND: Although the majority of congenital heart defects (CHD) occur in isolation, a significant number varying in previous reports from 6 to 66% occur with noncardiac anomalies. The purpose of this investigation was to assess the prevalence and the types of associated anomalies in infants with CHD in a defined population. METHODS: The associated anomalies in CHD were collected during 26 years in 346,831 consecutive births of known outcome. RESULTS: Of the 4005 infants with CHD (116 per 10,000), 1055(26.3 %) had associated anomalies. There were 354 (8.8%) patients with chromosomal abnormalities including 253 trisomies 21, and 99 (2.5%) nonchromosomal recognized dysmorphic conditions. There were no predominant recognised dysmorphic conditions, but VA(C)TER(L) association. However, other recognised dysmorphic conditions were registered including Di George and Noonan syndromes. 15.0 % of the patients had multiple congenital anomalies, non syndromic, non chromosomal (MCA). Anomalies in the musculoskeletal, the urinary tract, the digestive, and the central nervous systems were the most common other anomalies. CONCLUSIONS: The overall prevalence of associated anomalies, which was one in four infants, emphasizes the need for a thorough investigation of infants with CHD. The most commonly associated major noncardiac anomalies involved the musculoskeletal system, followed by the urinary, the digestive, and the central nervous systems. A routine screening for other anomalies may be considered in infants and in fetuses with CHD. One should be aware that the anomalies associated with CHD can be classified into a recognizable anomaly syndrome or pattern in one out of nine infants with CHD.

P11.044-M
Informational-analytical system of registration, systematisation and counting of congenital and hereditary diseases

D. Zhanatayeva, *L. Nazarova, A. Nagimtaeva, G. Abildinova;*
National Research Center Maternal and Child Health, Astana, Kazakhstan.

Creation of an informational system of congenital and hereditary diseases's registration is very acute in today's world, which provides the ability to schedule medical - diagnostically and preventive measures to reduce infant morbidity and mortality.

Primary source of information is the patient's electronic registration card, which includes personal data, life history and disease, genealogical information, a description of the phenotype, the results of research. Information system consists of four main sections: congenital malformations, prenatal diagnosis, chromosomal abnormality, monogenic pathology.

The database contains information about 2685 cases of patients and fetuses with congenital and hereditary disorders. The structure is dominated by pathology congenital malformations - 1323 (49.3%) cases. The most frequent defects of congenital malformations: the nervous system's - 236 (17.8%), multiple malformations - 191 (14.4%), the genitourinary system's - 183 (13.8%), the circulatory system's genitourinary system's - 169 (12.7%). Chromosomal abnormality was 744 (27.7%) cases. Monogenic pathology was defined in 618 (23.0%) cases. Most frequent are osteogenesis imperfecta - 43 (6.9%), chondrodystrophy - 36 (5.8%), congenital adrenal syndrome - 28 (4.5%), congenital hypothyroidism - 23 (3.7%), mucopolysaccharidosis - 22 (3.5%), spinal muscular amyotrophy - 17 (2.7%), Duchenne myopathy - 11 (1.7%).

Thus, the informational registration system of congenital malformations and hereditary pathology's spectrum helps to improve health system of medical genetic counseling and allows setting the frequency and structure of congenital and hereditary diseases.

The clinical presentation of the bladder-exstrophy-epispadias complex (BEEC) ranges from epispadias (E) and classical bladder exstrophy (CBE), to the most severe form, cloacal exstrophy (CE), often referred to as the OEIS complex. The birth prevalence for the complete spectrum has been reported to be 1 in 10,000 live births, with a male-to-female ratio of 2.4:1. Although the etiology for the majority of cases remains elusive, there are several lines of evidence, that de novo copy number variations (CNVs) represent a major genetic contributor.

Here we array-based molecular karyotyping in a large cohort of 174 BEEC patients, aiming to identify disease related de novo CNVs. For array-based molecular karyotyping we used the Illumina HumanOmniExpress-12v1.1 bead-chip, comprising a total number of 719,665 markers. All genotype data were analyzed by QuantiSNP using an Objective-Bayes Hidden-Markov model. To narrow down the computed number of 13,828 putative CNVs, we used different filter criteria and implemented various procedures for data analysis.

In total, 17 putative disease related CNVs ranging from 2,52 kb to 6,08 Mb in size, including one duplication in the Cat eye syndrome relevant region (22pter-22q11.21) remained. Validation of the CNVs and testing for their de novo occurrence with parallel investigation of the parents using quantitative PCR and MLPA is currently performed. Array-based molecular karyotyping furthermore identified triple X syndrome in an isolated CBE patient.

Cornelia de Lange syndrome (CdLS) is a neurodevelopmental disorder caused by mutations in either regulators (NIPBL, HDAC8) or structural elements (SMC1A, SMC3, RAD21) of the cohesin complex. As regards X-linked CdLS, a higher prevalence of females is described for both SMC1A, partially escaping X-inactivation, and HDAC8, which is instead subject to X-inactivation. At present, 26 different mutations in 41 individuals with features partially overlapping with CdLS have been reported in the HDAC8 gene, confirming the key role of this lysine deacetylase in the proper functioning of the cohesin complex. We analyzed a group of NIPBL- and SMC1A-negative patients with CdLS by classical sequencing approaches and exome/gene panel next generation technology. Thus we identified eight de novo HDAC8-mutations. Interestingly, one of which is shared by two siblings. The R166* nonsense mutation, the frameshift deletion F207Nfs*2 as well as all six missense mutations C153R, N156K, P257L, T280I, C287Y, G320R all affect highly conserved residues and were predicted to be damaging by four bioinformatics algorithms. All patients show a mild to severe phenotype overlapping with CdLS; the craniofacial appearance is similar but with some distinctions like a broader nose, dental anomalies and delayed anterior fontanelle closure. Moreover, postnatal growth retardation is less severe, and limb malformations have not yet been observed. Given the high percentage of HDAC8 mutations identified in our cohort, we suggest the HDAC8 screening as an essential part of the routine molecular diagnostics for patients with CdLS-overlapping features.

P11.047-S
A new prognostic index of severity of intellectual disabilities in Cornelia de Lange syndrome

A. Cereda[1,2], *M. Mariani*[2], *P. Rebora*[3], *L. Bettini*[2], *C. Gervasini*[4], *S. Russo*[5], *M. G. Valsecchi*[3], *L. Larizza*[4], *A. Selicorni*[2];
[1]*Department of Pediatrics, Ospedale Papa Giovanni XXIII, Bergamo, Italy,* [2]*Pediatric Genetic Unit, Pediatric Department of Monza Brianza per il Bambino e la sua Mamma (MBBM) Foundation, S.Gerardo Hospital, Monza, Italy,* [3]*Center of Biostatistics for Clinical Epidemiology, Department of Health Sciences, University of Milano-Bicocca, Monza, Italy,* [4]*Department of Health Sciences, Medical Genetics, Università degli Studi*

di Milano, Milano, Italy, [5]Laboratory of Medical Cytogenetics and Molecular Genetics, IRCCS, Istituto Auxologico Italiano, Milano, Italy.

Cornelia de Lange syndrome is a well-known multiple congenital anomalies/mental retardation syndrome with genetic heterogeneity and wide clinical variability, regarding the severity of both the intellectual disabilities and the physical features, not completely explained by the genotype-phenotype correlations known to date.
The aim of the study was the identification of prognostic features, ascertainable precociously, of a better intellectual outcome and the development of a new prognostic index of severity of intellectual disabilities in CdLS patients.
In 66 italian CdLS patients aged 8 years or more, we evaluated the association of the degree of mental retardation with various clinical parameters ascertainable before 6 months of life and with the molecular data by the application of cumulative regression logistic model. Based on these results and on the previously known genotype-phenotype correlations, we selected 7 parameters to be used in a multivariate cumulative regression logistic model to develop a prognostic index of severity of intellectual disability.
In the table the parameters selected and their relative scores.

Parameter	Score
Small for gestationa age	1,5
Length <50° centile on CdLS growth charts	2
Heart malformation	1
Limb reduction	1
Moderate-severe sensorineural hypoacusia	3,5
NIPBL truncating mutation	0
SMC1A mutation	1,5

The probability of a mild MR increases with the reducing final score less than 2, the probability of a severe MR increases with the increasing final score more than 3.
This prognostic index allows to define, precociously in the life of a baby, the probability of a better or worse intellectual outcome in CdLS patients.

P11.048-M
SNP arrays in the diagnostic strategy of corpus callosum agenesis associated with intellectual disability (an update)

Corpus callosum agenesis is the most common cerebral malformation in patients with intellectual disability (CCA-ID) with a prevalence of 2-3% of cases. Known genetic causes are heterogeneous and in the majority of cases, no etiologies have been found. In order to achieve a genetic diagnosis, we performed chromosome analyses on microarrays (CMA) on 81 patients with CCA-ID and no known causes. We found 34 different CNVs (42%) which were not carried in control subjects of the Database of Genomic Variants (DGV). Among these CNVs, 14 (17%) were de novo and considered to be likely pathogenic, with sizes varying from 1,3Mb to 24Mb, including 13 deletions and one inverted duplication with terminal deletion. Moreover, 12 CNVs (4 deletions and 9 duplications) were also carried by healthy parents, and therefore, could not be considered as the main causes of the phenotype. We were not able to recover blood samples of the parents to verify the 8 remaining CNVs. Thus, CMA seems to be a powerful tool in the diagnostic strategy of patients with CCA-ID and no etiologies. However, most of the tested patients still remain with no identified genetic causes. In the near future, new techniques such as exome sequencing, or massively parallel sequencing on selected genes panels, could improve the detection rate of the genetic causes of CCA-ID.

P11.049-S
Molecular Diagnostic Algorithm of Syndromic Craniosynostosis

V. Karaman, *G. Toksoy, S. Avcı, B. Karaman, U. Altunoglu, S. Basaran, H. Kayserili, Z. O. Uyguner;*
Istanbul Medical Faculty, Istanbul, Turkey.

Craniosynostosis(CS) is a birth defect, with a prevalence of 1/2100-1/2500, caused by the premature fusion of one or more cranial sutures leading to specific cranial base and vault abnormalities. It is a highly heterogeneous group of disorders occurring both in syndromic and non-syndromic forms, associated with approximately 180 different syndromes. The identification of the responsible gene largely depends on the fact if it is syndromic or non-syndromic. Although 85% of the cases are reported to be non-syndromic with unknown etiology, syndromic forms arise from chromosomal anormalies or single gene defects of Mendelian inheritance, both together comprising the etiopathogenesis only in 40% of the cases and single gene defects contributing to three/fourth. Noteworthy genes in this group are FGFR1, FGFR2, FGFR3, TWIST1, EFNB1, MSX2, RAB23 and FREM1. EFNB1 can be excluded from this group due to its association with Craniofrontonasal Syndrome. Thirty syndromic CS patients with normal karyotype were included in the study cohort. Stepwise screening algorithm was applied, initial step being the sequencing of FGFR2, FGFR3 and FGFR1, followed by full gene sequencing of FGFR2 and FGFR3. Samples with unidentified etiology were further screened for deletion/duplication by craniofrontonasal MLPA kit (P080). The last step consisted of sequencing of FGFR1, MSX2, TWIST1, RAB23 and FREM1 genes, when the cases showed distinct related clinical phenotype.
We highly suggest that our ongoing research will lead to better insight for the clinical diagnosis, molecular diagnostic flow charts in CS and will contribute to the genotype-phenotype correlation.

P11.050-M
Craniosynostosis and Heart defects: Possibly a new autosomal recessive syndrome due to ZDHHC13 mutations

S. A. Boyadjiev[1], *M. Zwienenberg-Lee[2], J. Boggan[2], C. Senders[3];*
[1]Section of Genetics, Sacramento, CA, United States, [2]Department of Neurosurgery, UC Davis, Sacramento, CA, United States, [3]Department of Otorhinolaryngology, UC Davis, Sacramento, CA, United States.

We report two sisters with congenital craniosynostosis, heart anomalies and minor digital defects. They were born to non-consanguineous Hispanic parents. The mother is macrocephalic, but without other dysmorphisms. The first child was born with complex craniosynostosis involving the metopic, left coronal, and left lambdoidal sutures requiring two craniotomies and leading to significant cranial deformity despite the surgeries. In addition she had truncus areriosus with interrupted aortic arch that was successfully repaired. The second girl presented with metopic craniosynostosis and large atrial septal defect, both requiring surgeries. Both girls have apparently normal development at 6 and 4 years of age, respectively, but no formal evaluation has been performed. In addition, the older child has minor digital anomalies and mild pectus excavatum and the younger child has mild enamel hypoplasia. Their older brother has severe pectus excavatum, but no other anomalies. Chromosomal microarray and sequencing analyses of the hot-spot regions in FGFR1, FGFR2, FGFR3, and the TWIST gene were normal for both girls. There were no detectable metabolic abnormalities. Whole exome sequencing documented rare compound heterozygous variants in the ZDHHC13 genes in both children - c.629A>T (Asn219Ile, maternal inheritance) and c.1135A>G (Ser379Gly, paternal inheritance). The ZDHHC13 (zinc finger, DHHC-type containing 13) gene is located on ch.11p.15.1 and has palmitoyltransferase activity with possible role in the FGFR/RAS/MAPK pathway. The functional significance of these variants is under investigation. We propose that this condition represents a novel autosomal recessive syndrome, possibly due to mutations of ZDHHC13.

P11.051-S
Deletions in 14q24.1q24.3 are associated with congenital heart disease, brachydactyly and mild intellectual disability

B. Oehl-Jaschkowitz[1], O. Vanakker[2], A. De Paepe[2], B. Menten[2], T. Martin[1], G. Weber[1], A. Christmann[1], R. Krier[3], S. Scheid[3], S. E. McNerlan[4], S. McKee[4], **A. Tzschach**[5];*
[1]Practice of Human Genetics, Homburg (Saar), Germany, [2]Ghent University Hospital, Ghent, Belgium, [3]Practice of Pediatrics, Wittlich, Germany, [4]Northern Ireland Regional Genetics Service, Belfast, United Kingdom, [5]University of Tübingen, Tübingen, Germany.

Interstitial deletions of chromosome band 14q24.1q24.3 are rare. We report on three unrelated patients with overlapping de novo deletions of sizes 5.4 Mb, 2.8 Mb and 2.3 Mb in this region. While some clinical problems such as intestinal malrotation, cryptorchidism and ectopic kidney were only observed in single patients, all three patients had mild intellectual disability, congenital heart disease, brachydactyly, hypertelorism, broad nasal bridge, and thin upper lips. It appears likely that haploinsufficiency of one or several of the 19 genes in the common deleted interval (ACTN1, DCAF5, EXD2, GALNTL1, ERH, SLC39A9, PLEKHD1, CCDC177, KIAA0247, LOC100289511, SRSF5, SLC10A1, SMOC1, SLC8A3, ADAM21P1, COX16, SYNJ2BP, SYNJ2BP-COX16, ADAM21) was responsible for these problems, but apart from SMOC1, mutations in which cause autosomal recessive Waardenburg anophthalmia syndrome, no disease associations have so far been reported for the other genes. Functional studies and a systematic search for mutations or chromosome aberrations in this region will elucidate the role of individual

genes in the clinical manifestations and will provide insight into the underlying biological mechanisms.

P11.052-M
Non-mosaic 4p16.3 deletion concomitant with low-level mosaicism for deletion at 21q11.1q21.2

O. S. Kurinnaia[1,2,3], *S. G. Vorsanova*[1,2,3], *V. Y. Voinova*[1,2,3], *T. Liehr*[4], *A. D. Kolotii*[1,2], *Y. B. Yurov*[1,2,3], *I. Y. Iourov*[1,2,5];
[1]*Institute of Paediatrics and Paediatric Surgery, Ministry of Health, Moscow, Russian Federation,* [2]*Mental Health Research Center, Russian Academy of Sciences, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation,* [4]*Institute of Human Genetics, Jena, Germany,* [5]*Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.*

Multiple chromosome abnormalities are occasionally detected in live-born children. Furthermore, concomitant non-mosaic and mosaic chromosome aberrations are even less frequent. In the resent report, we describe a case of autism, moderate intellectual disability, epilepsy, cerebral palsy, osteoporosis, strabismus, speech delay, cardiac defect, enlargement of the left brain ventricle and kidney abnormalities in a 9 year old girl. Cytogenetic analysis has demonstrated a mosaic deletion of chromosome 21: 46,XX,?mos del(21)(q21q21)[5]/ 46,XX[15]. Molecular cytogenetic analysis using oligonucleotide array CGH has confirmed the presence of mosaic deletion spanning 21q11.1q21.2 chromosome region (11.423 Mb). Additionally, a non-mosaic deletion at 4p16.3 (size: 3.712 Mb) affecting 83 genes, 40 of which are listed in OMIM was found. Mosaic 21q11.1q21.2 was also confirmed using multicolor chromosome banding (MCB), which has shown this deletion to affect 19% of cells. It is to note, that the index case has demonstrated a phenotype atypical for 4p16 deletions. Nevertheless, the main phenotypic outcome was likely to result from non-mosaic 4p16.3 according to bioinformatics analysis, whereas mosaic 21q11.1q21.2 was concluded to be an additional co-factor modulating the phenotype. Thus, one can conclude that phenotypic heterogeneity of recurrent chromosome aberrations can be produced by concomitant genomic rearrangements. In this instance, multiple molecular cytogenetic techniques are warranted for the appropriate molecular diagnosis. Supported by the Russian Federation President Grant (MD-4401 .2013.7).

P11.053-S
Juvenile polyposis associated to hereditary hemorrhagic telangiectasia in an adolescent with complex chromosomal rearrangement and intellectual disability

M. M. Oliveira[1], *V. A. Meloni*[1], *R. Seidler*[2], *S. S. Takeno*[1], *A. Bortolai*[1], *C. B. de Mello*[1], *F. T. Lima*[1], **M. I. Melaragno**[1];
[1]*Universidade Federal de São Paulo, São Paulo, Brazil,* [2]*Hospital do Servidor Público do Estado de Sâo Paulo, São Paulo, Brazil.*

Juvenile polyposis can be associated to hereditary hemorrhagic telangiectasia (HHT) due to *SMAD4* gene mutations. We describe the first case of juvenile polyposis and HHT in a patient with *SMAD4* gene loss due to a chromosomal deletion. The male patient presents moderated intellectual disability, limited verbal language repertoire, attention-deficit/hyperactivity disorder, corpus callosum agenesis and brain arteriovenous malformation. Colonoscopy revealed inflammatory intestinal polyposis, with typical juvenile polyp histology, fulfilling juvenile polyposis syndrome clinical criteria. Three small haemangiomas in scalp and bilateral telangiectasias in Kiesselbach area were found. The patient presents a 46,XY,t(6;18)(q13;q21)dn karyotype. Chromosomal microarray detected two non-continuous *de novo* microdeletions encompassing 2.7 Mb and 0,4 Mb as follows: arr 18q21.1q21.2(47,553,468-50,257,792)×1,18q21.2(50,644,595-51,052,896)×1. FISH with BAC probes confirmed both deletions and the presence of a segment between them. This is the first case of juvenile polyposis and HHT in a patient with a chromosomal rearrangement that resulted in interstitial deletions of 18q and loss of the *SMADA4* gene, among others. The loss of a copy of the entire *SMAD4* gene, added to the fact that the patient had intestinal polyps at a young age, prompted us to look for telangiectasia. Thus, we showed the importance of the detailed screening for these phenotypes in patients in whom cytomolecular studies indicate deletion of *SMAD4* gene. Additionally, we demonstrate the relevance of cytogenomic investigation in patients with juvenile polyposis, dysmorphisms and intellectual disability. Financial support: FAPESP, Brazil.

Chromosome 19 is one of the densest chromosomes in genes. Consequently, rearrangements occurring in this chromosome, even small in size, can be lethal. This might explain why only a few cases of chromosome 19 rearrangements have been reported so far. 19p13.12 microdeletions of different sizes and partially overlapping, detected by Array Comparative Genomic Hybridization (Array CGH), have been described in nine patients. The associated phenotypes include a mild to moderate intellectual disability in seven patients. Among these patients, four of them have been reported with cerebral malformations (corpus callosum hypoplasia with vermis hypoplasia, pontocerebellar hypoplasia). Microcephaly, neurosensorial deafness, ear abnormalities, hypertrichosis or facial dysmorphism including synophrys have also been reported. All of them were diagnosed in postnatal, from the first months of life up to late childhood No prenatal case has been reported so far. We present the first case of a de novo 1.1 Mb 19p13.12 deletion including 29 genes in a fetus which has been interrupted at 38 weeks of gestation because of severe microcephaly associated with benign paraventricular cysts. Among the deleted genes, NOTCH3 seems to be a good candidate gene for cerebral abnormalities. NOTCH3 mutations are associated with CADASIL (Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leucoencephalopathy). It has been suggested that the mechanism involved in CADASIL was a gain-of-function of the mutated protein. The consequences of NOTCH3 haploinsuffisiency are poorly known. Considering its role in neurodegeneration, NOTCH3 haploinsuffisiency may contribute to cerebral malformations and to intellectual disabitility as observed in deleted patients.

P11.055-S
Molecular cytogenetic characterization of a 2q35-q37 duplication and a 4q35.1-q35.2 deletion in two cousins: a genotype-phenotype analysis

L. Ronzoni[1], *A. Peron*[1], *V. Bianchi*[1], *M. Baccarin*[2], *E. Cattaneo*[1], *S. Guerneri*[2], *M. F. Bedeschi*[1];
[1]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Medical Genetics Unit, Milan, Italy,* [2]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Laboratory of medical genetics, Milan, Italy.*

Derivative chromosomes usually display variable phenotypes and clinical expression.
We report two patients: a 37-year-old man (proband-1) and a 17-year-old girl (proband-2), two second-degree cousins, with a derivative chromosome leading to a 4q3 deletion-2q3 duplication.
Conventional karyotype revealed in both the patients the same rearrangement derived from unbalanced segregation of parental reciprocal translocation involving the long arms of chromosome 2 and 4. Proband-1 father and proband-2 mother were detected to be carrier of a balanced translocation t(2;4)(q35;q35).
Array-CGH analysis, performed to characterize the rearrangement, documented in both the probands the presence of a 26Mb duplication of 2q35-q37.3 region of chromosome 2 and a 6.3Mb deletion of 4q35.1-q35.2 region of chromosome 4.
The 2q3 duplication and 4q3 deletion are two distinct conditions with variable phenotypes including developmental delay, intellectual disability, Pierre-Robin sequence and cardiovascular, craniofacial, digital and skeletal anomalies.
Both the patients showed developmental delay, minor facial and non-facial anomalies, hearing, ocular and genitourinary problems. In particular, proband-1 showed a severe bilateral hypoacusia and hypergonadotropic hypogonadism secondary to bilateral orchiectomy for testicular seminoma. Proband-2 displayed principally ocular (microphtalmia, coloboma and visual loss) and urinary problems (nephrotic syndrome). The clinical phenotypes were similar to that reported by Rashidi-Nezhad, who first described a patient with a combination of 2q duplication-4q deletion, and to those reported in other cases of 2q3 duplication or 4q3 deletion. Our study contributes to further delineate the genotype-phenotype correlation and the combined effect of partial 2q duplication and 4q deletion syndromes in adulthood.

P11.056-M

A novel micro-deletion 7p14.3 associated with complex neurocognitive phenotypes and distinct Cardiac malformations

S. Huang[1], M. Speevek[2], L. Schultz[3], **C. Li[3];**
[1]Mcmaster University Medical School, Hamilton, ON, Canada, [2]Trillium Health Partner, Mississauga, ON, Canada, [3]Mcmaster University Medical Center, Hamilton, ON, Canada.

We report a 20 year old male with global developmental delay and a novel microarray finding. His past medical history included a diagnosis of supravalvular mitral ring moderate endocardial fibroelastosis at age two, following recurrent pneumonia and congestive heart failure. His neurocognitive history, in addition to global delay, also included a diagnosis of autism, attention deficit disorder and bipolar disorder with episodes of psychoses that required admission. Other medical issues included moderate bilateral hearing loss, eosinophilic esophagitis and sleep apnea. He had minor dysmorphic craniofacial features, a narrow palate and a bifid uvula, as well as hypoplastic nails. Psoriasis and striae were noted on skin exam. Chromosomal microarray analysis revealed a de novo deletion at 7p14.3p14.2 (chr7:33,453,828-36,924,450), confirmed by fluorescence in-situ hybridization. The genes in the deleted segment include BBS9, BMPER, NPSR1, DPY19L1, TBX20, HERPUD2, SEPT7, EEPD1, KIAA0895, ANLN, AOAH and ELMO1. BMPER mutations are thought to be associated with craniofacial dysmorphism. TBX20 is a transcription factor involved in the formation of cardiac chambers and valves. Other components within this 7p14.3 deletion with features of cardiac malformations and learning disabilities may also be implicated and will be discussed. By sharing these novel findings we hope to aid other healthcare providers in the care and management of similar patients.

P11.057-S

A futher case of de novo 10p14-pter deletion detected by multiplex ligation dependent probe amplification (MLPA) assay in a newborn

M. R. Piemontese, *A. I. Croce, L. Bisceglia, P. Stanziale, L. Zelante;*
Servizio di Genetica Medica, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy.

Chromosome 10p terminal deletion accounts for a rare subset of patients presenting DiGeorge syndrome, and is designated as DiGeorge2 syndrome.
We report on a neonate female with DiGeorge like phenotype, facial dysmorphism and hypocalcemia in which a de novo deletion of distal 10p (p14-pter) was found by MLPA (Multiplex Ligation-dependent Probe Amplification) analysis.
Additional FISH study of the proband with locus specific probes confirmed the presence of only one 10pter signal. Further microsatellite marckers analysis in the patient and in both parents revealed a de novo deletion occurring on the paternal allele.
In conclusion, we suggest MLPA analysis as a rapid test to confirm a clinical suspect of DiGeorge syndrome associated to HDR syndrome (hypoparathyroidier, deafness, renal dysplasia) in newborns.

P11.058-M

Distal 10q26.3 monosomy; three new cases and review of the literature

C. L. Goldsmith[1], *J. Majewski[2], M. Srour[3], J. Michaud[4], K. Boycott[1];*
[1]Children's Hospital of Eastern Ontario, Ottawa, ON, Canada, [2]McGill University, Montreal, QC, Canada, [3]Montreal Children's Hospital, Montreal, QC, Canada, [4]CHU Ste Justine, Montreal, QC, Canada.

Pure distal monosomy of the long arm of chromosome 10 is a rare cytogenetic abnormality; the location and size of the deletions described in this region are variable. The associated phenotype associated with this deletion is also variable but reported features include developmental delay/learning disability/mild to moderate intellectual disability, speech and language delay, poor attention, strabismus and distinctive facial features. We report two siblings; a male aged 15 and a female aged 21 years, with intellectual disability, microcephaly, motor impairment and ataxia. MRIs showed mild dilatation of the lateral ventricles and a prominent cisterna magna. Karyotype was normal. We performed whole-exome sequencing (WES) and they were found to have a 5.5 Mb terminal chromosome 10q26.3 deletion using the program FishingCNV. The deletion was confirmed by FISH and the mother was found to carry a pericentric inversion. A third child, age 6 years, presented in early childhood with global developmental delay, poor coordination and ataxia. MRI showed no abnormality of the posterior fossa. A high-resolution (105 K) comparative genomic hybridization microarray identified a deletion of the terminal 4.6 Mb of the long arm of chromosome 10, within cytogenetic band 10q26.3. This finding was confirmed by FISH analysis. The parents were tested and this is a de novo change. Our findings add three new cases of 10q26.3 monosomy to the literature; we summarize the previous cases and highlight the features of this emerging cytogenetic syndrome.

P11.059-S

Oxidative stress a Phenotypic Hallmark of Fanconi anemia and Down syndrome: The effect of antioxidants

H. T. El-Bassyouni[1], *H. H. Afifi[1], M. M. Eid[1], R. M. Kamal[2], H. H. El-Gebali[2], G. S. M. El-Saeed[1], M. M. Thomas[1], S. A. Abdel Maksoud[1];*
[1]National Research Center, Guiza, Egypt, [2]Institute of Postgraduate Childhood Studies, Ain Shams University, Cairo, Egypt.

Oxidative stress plays a major role in the pathogenesis of leukemia-prone diseases such as Fanconi anemia and Down syndrome. Objectives: To explore the oxidative stress state in children with Down syndrome and Fanconi anemia by estimating the levels of antioxidants (e.g., malondialdehyde, total antioxidant capacity and superoxide dismutase [SOD] activity) and DNA damage, and to evaluate of the effect of antioxidant treatment on these patients. Methods: The study included 32 children clinically diagnosed with Down syndrome (15 patients) and Fanconi anemia (17 patients) in addition to 17 controls matched for age and sex. Malondialdehyde, total antioxidant capacity, superoxide dismutase (SOD) activity and DNA damage were measured. Antioxidants including vitamin A, E and C were given to the patients according to the recommended daily allowance (RDA) for 6 months. Clinical follow-up and re-evaluation were conducted for all patients. Laboratory tests including complete blood count, karyotyping, DNA damage and oxidative stress were re-evaluated. Results: Children with Fanconi Anemia and Down syndrome had elevated levels of oxidative stress and more DNA damage than controls. Oxidative stress parameters and DNA damage improved in Fanconi anemia and Down syndrome patients after antioxidant administration. Conclusions: Early administration of antioxidants to Fanconi anemia and Down syndrome patients is recommended for slowing of the disease course with symptoms amelioration and improvement of general health.

P11.060-M

Report of the first case of robertsonian translocation in Down-Turner mosaicism (mos 45, X / 46,XX, + 21, rob (21;21)(q10;q10))

M. D. F. Carvalho[1], *E. D. F. Carvalho[2], M. Montenegro[3], K. M. Carvalho[4];*
[1]UECE/Unichristus/APAE-Fortaleza CE, Fortaleza, Brazil, [2]Unichristus/USP, Fortaleza, Brazil, [3]USP, São Paulo, Brazil, [4]UECE, Fortaleza, Brazil.

Double aneuploidy involving both autosomal and sex chromosomes is very rare. Down's/Turner's mosaic, occurs in about 1 in 2 000 000. We report the first case of Down's/Turner's mosaic with robertsonian translocation. The patient was the first child of non consanguineous parents. It was a female whom born a term, by uneventful cesarean section, weighting 2,220g and with length of 46 cm, without neonatal complications. At birth, the pediatrician made the diagnosis of Down syndrome. At 3 months, in consultation with routine pediatric a heart murmur was heard, so the patient was referred to a cardiologist. There were performed two surgeries to repair the heart defect, one with 6 months of life and another with 2 years. She also had mild developmental delay. At 3 years old she was examined at our outpatient Genetic unit. The patient showed more clinical findings of Down syndrome than Turner syndrome: low weight and height for age, microcephaly, flat facial profile, upslanting palpebral fissures, epicanthal folds, short nose with depressed nasal bridge, hypotonia with tendency to keep month open and protrude the tongue, short neck, single palmar creases, and prominent ears. Cytogenetic analysis of peripheral blood preparations using G-banding revealed mosaicism with 2 cell lines (mos 45, X [21] / 46,XX, + 21, rob (21;21)(q10;q10)[9]). Additional genetic studies (karyotypes) were made to define the cause which probably originated this double aneuploidy with this translocation. So we present the first case related of Down-Turner mosaicism with robertsonian translocation and we review all the previous reports.

P11.061-S

Trying to define the phenotype of 16p12.2-p11.2 duplication syndrome

A. Scatigno, *A. Pansa, B. Facchinetti, G. Cassina, U. Giussani;*
A.O. Papa Giovanni XXIII, Bergamo, Italy.

The short arm of chromosome 16 is rich in segmental duplications rendering this region susceptible to rearrengement through non-allelic homologous recombination. Several syndromes resulting from microdeletions or microduplications in this region have been reported. The chromosome 16p12.2-p11.2 deletion syndrome, 7.1-to 8.7-Mb [OMIM#613604] is characterized phenotypically by dysmorphic facial features, feeding difficulties, recurrent ear infections, developmental delay and cognitive impairement. Reciprocal duplication of 16p12.2-p11.2 has been observed in few patients with dysmorphic features, short stature, developmental delay and intellectual disability but a specific phenotype hasn't been established and more cases are needed.
We report two new unrelated cases of chromosome 16p12.2-p11.2 dupli-

cation analysed by 180K oligonucleotide arrayCGH (Agilent Technologies). Both children showed a de novo 7.8 Mb duplication extending from 21.5 Mb to 29.3 Mb, comprising the same region involved in the deletion syndrome. We discuss the phenotype and molecular findings of our cases with respect to previous reported ones to further define the syndrome.

P11.062-M
Redefining the contiguous gene syndrome in the era of high-throughput sequencing

J. Amiel[1], *M. Langouët*[1], *K. Siquier-Pernet*[1], *S. Sanquer*[2], *C. Bole-Feysot*[3], *P. Nitschke*[4], *A. Munnich*[1], *R. Barouki*[2], *L. Colleaux*[1];
[1]*Imagine Institute, Paris, France,* [2]*Metabolic and Proteomic biochemistry service, Necker-Enfants Malades hospital, AP-HP, Paris, France,* [3]*Genomic platform, Imagine Institute, Paris, France,* [4]*Bioinformatic platform, Imagine Institute, Paris, France.*

We ascertained an Algerian consanguineous family in which two sibs present with psychomotor delay, progressive microcephaly, spasticity, thin corpus callosum, and severe and early onset obesity. Exome sequencing identified two homozygous substitutions cosegregating with the phenotype and locating 170 kb apart on 7q22.1: a c.1137+1G>T splice mutation in *AP4M1* previously described in a Moroccan family and a c.595A>T misense variation in *AZGP1* which encodes zinc-alpha2-glycoprotein (ZAG). Haplotyping analysis indicated that the *AP4M1* mutation was a founder mutation shared between both families, whereas the *AZGP1* mutation is secondarily and unique in our family.
Mutations in *AP4M1* cause AP4-deficiency syndrome, a condition characterized by severe intellectual disability, progressive microcephaly and spasticity. Notably, none of the 25 previously reported cases with AP4-deficiency syndrome exhibited obesity. On the other hand, ZAG is an adipokine stimulating lipolysis in adipocytes; ZAG likely regulates body weight since administration of human ZAG to ob/ob mice resulted in progressive weight loss. We propose that the phenotype of our patients resulted from the additional effects of the two mutations in *AP4M1* and *AZGP1* accounting for the neurological signs and the precocious morbid obesity, respectively.
The contiguous gene syndrome was proposed in 1986 to explain the association of multiple and unrelated clinical features due to the deletion of multiple adjacent genes: the phenotype results from the combination of the endophenotypes of each contiguous gene sensitive to haploinsufficiency. Today, high-throughput sequencing allows us to enlarge this concept to describe simultaneous transmission of independent mutations that are genetically linked.

P11.063-S
Insight into genetic heterogeneity of complex diseases by exome sequencing

M. Sana, **C. Lodrini**, *L. Pezzoli, D. Marchetti, A. Lincesso, K. Migliorati, M. Iascone; Ao Papa Giovanni XXIII, Bergamo, Italy.*

Exome sequencing has become a successful strategy for genetic diagnosis, particularly for largely heterogeneous diseases. We report 4 cases of example, presenting complex diseases, for which it was possible to reach rapidly a correct diagnosis only by exome sequencing.
Patient 1 was a one month-old female presenting dilated aortic root, extensive arterial tortuosity, mild dysmorphisms and several musculoskeletal features (joint laxity, arachnodactyly and pectus excavatum). Patient 2 (female, 3 years-old) presented absent pulmonary valve, ectasia of the pulmonary trunk and aorta, motor developmental delay, joint laxity, strabismus, hypermetropia and mental retardation. Patient 3 was a 3 years-old male referred for low-set ears, micrognathia, generalized hypotonia, clubfeet and tricuspid regurgitation. Finally, Patient 4 (female, 3 years-old) presented Marfanoid habitus, with aortic dilation. Because these features overlap with several neonatal rare disorders, we performed on patients' (and parents') genomic DNA, Illumina TruSight Exome sequencing, generating a mean target coverage of 98.6% at >20X and a mean read depth of 257X. In Patient 1 we identified a homozygous mutation in fibulin-4 gene, associated with autosomal recessive cutis laxa syndrome. Sequencing of Patient 2 surprisingly revealed a *de novo* missense mutation in ITPR1 gene, which causes congenital non-progressive spinocerebellar ataxia, resulting in altered development of cerebellum. Patient 3 and 4 carry *de novo* mutations in genes that cause Loeys-Dietz syndrome, TGFBR1 and TGFBR2 respectively. In conclusion, these examples are significative for stressing that exome sequencing represents a helpful approach for differential diagnosis and for more closely specify therapeutic approach for individual patients.

P11.064-M
Stable expression of mutant FANCA: is there any correlation with mild Fanconi anemia clinical?

R. Bottega[1], *E. Cappelli*[2], *M. Zweyer*[1], *D. De Rocco*[1], *E. Valencic*[3], *J. Svahn*[2], *R. Bortul*[1], *E. Nicchia*[1], *S. Caruso*[4], *F. Bagnasco*[4], *C. Greco*[3], *C. Dufour*[2], *A. Savoia*[1];
[1]*Department of Medical, Surgical and Health sciences, University of Trieste, Trieste, Italy,* [2]*Clinical and Experimental Hematology Unit, G. Gaslini Children's Hospital, Genoa, Italy,* [3]*Institute for Maternal and Child Health – IRCCS Burlo Garofolo, Trieste, Italy,* [4]*Epidemiology and Statistics Unit, G. Gaslini Childrens Hospital, Genoa, Italy.*

Fanconi anemia (FA) is an inherited disease characterized by congenital malformations, pancitopenia, cancer predisposition, and sensitivity to cross-linking agents. The molecular diagnosis of FA is relatively complex, due to several aspects including genetic heterogeneity with mutations in at least 16 different genes. In this study, we report the mutations identified in 100 unrelated FA probands enrolled into the National Network of the Italian Association of Pediatric Hematology and Oncology. We identified 108 distinct variants of FANCA, FANCG, FANCC, FANCD2, and FANCB genes in 85, 9, 3, 2, and 1 families, respectively. Particularly, in FANCA we found mainly private mutations of all different categories (large intragenic deletions, nonsense, frameshift, splicing and missense mutations). Expression level of FANCA protein was studied in 32 lymphoblastoid cell lines of complementation group FA-A and a correlation between the type of mutation and the expression level of FANCA was observed. In case of nonsense or frame-shift mutations FANCA is not detectable whereas it is expressed at the same levels as in controls when alleles are hit by missense or in frame mutations. Since it will be interesting to determine whether there is a correlation between stable expression of mutant FANCA and phenotype, we have been evaluated a series of different aspects at both clinical and cellular levels in order to provide insights into potential residual activities of altered but expressed proteins.

P11.065-S
A familial case of Fanconi anemia-related VACTERL-H association due to a mutation of *FANCF* gene, identified using a next generation sequencing approach

F. Benedicenti[1], *E. Nicchia*[2], *D. De Rocco*[2], *E. Cappelli*[3], *C. Dufour*[3], *F. Stanzial*[1], *F. Inzana*[1], *A. Savoia*[2,4];
[1]*Genetic Counseling Service, Department of Pediatrics, Regional Hospital of Bolzano, Bolzano, Italy, Bolzano, Italy,* [2]*Institute for Maternal and Child Health – IRCCS Burlo Garofolo, Trieste, Italy, Trieste, Italy,* [3]*Clinical and Experimental Hematology Unit, G. Gaslini Children's Hospital, Genoa, Italy, Genoa, Italy,* [4]*Department of Medical Sciences, University of Trieste, Trieste, Italy, Trieste, Italy.*

VACTERL-H association is a rare and etiologically heterogeneous condition, characterized by a variable combination of many birth defects. It can represent a severe phenotype of Fanconi anemia (FA), a rare disease characterized by birth defects, bone marrow failure, cancer predispositions and increased chromosomal instability due to mutations in at least 16 genes. The genetic heterogeneity together with the wide spectrum of mutations make the molecular genetic testing in FA a complex and tiered task, which could benefit from application of next generation sequencing strategies (NGS). We describe a family with 3 aborted fetuses affected with hydrocephalia and radial ray defects, variously associated with cardiac, renal and other skeletal anomalies. Both healthy parents originate from the same alpine valley. A genetic counseling leading to a presumptive diagnosis of FA-related VACTERL-H was performed only after the second termination. Thus, a FA diagnostic diepoxybutane test could be performed only on cultured cells of the third fetus. The results confirmed the suspicion and complementation analysis excluded mutations in the two more frequent groups (FA-A and FA-G). We hence used the Ion PGM™ System and identified a homozygous c.484_485delCT mutation of *FANCF* gene. The same finding was found in DNA extracted from the first two fetuses. Only 1% of FA patients have mutations in *FANCF* and, to the best of our knowledge, the 3 fetuses represent the first cases of VACTERL-H association caused by mutations of *FANCF*. Application of NGS is suitable for a comprehensive molecular screening of FA and identification of rare disease-causing genes.

Frontonasal dysplasia is a well-known developmental abnormality of the anterior neurocranium and viscerocranium, characterized by findings involving the craniofacial midline, such as anterior cranium bifidum, hypertelorism, and clefting of alae nasi. While the genetic etiology for a number of different syndromes described within the FND spectrum is identified, no gene is known to cause classical FND. Recently, patients with autosomal recessive FND were linked to homozygous loss-of-function mutations in the ALX homeobox gene family. Biallelic mutations in *ALX1* are associated with a

severe frontofacionasal dysplasia phenotype with extreme microphthalmia and oblique facial clefts. It is shown that mice homozygous for deficiency in Cart1, the mice homolog to *ALX1* are born with acrania and meroanencephaly. In the limited number of ALX1-related FND patients, neural tube closure defects have not been reported.
We report a unique FND case, a 20-week-old male fetus terminated due to anencephaly. Postmortem examination showed severe hypertelorism, clinical anophthalmia, bifid nose and midline upper lip cleft. The parents were first degree cousins, and their first pregnancy was also terminated due to anencephaly.
Array-comparative genomic hybridization using the NimbleGen CGX-3 1.4M DNA oligoarray set revealed normal results. Molecular analysis of *ALX1* did not reveal any mutations. Trio exome sequencing revealed a homozygous mutation in a candidate gene, linked to a human phenotype for the first time. While the mouse model for this gene is well described, further studies are needed to establish its role in human development.

P11.067-S
High throughput analysis in Goldenhar syndrome

S. Dipresa[1], *A. D'eustacchio*[2], *A. Morgan*[1], *P. Gasparini*[2,1];
[1]*Università di Trieste, Trieste, Italy,* [2]*Burlo Garofolo, Trieste, Italy.*

Goldenhar syndrome (GS) is a developmental disorder involving first and second pharyngeal arches during blastogenesis. It is characterized by craniofacial anomalies (oculoauriculo vertebral (OAV) dysplasia, hemifacial microsomia, facioauriculo vertebral sequence), epibulbar tumours, ear malformation and vertebral anomalies; cardiac, pulmonary, renal, skeletal, and central nervous system anomalies have also been described. The etiology of GS is not fully understood, it seems related to vascular disruption, predominantly of the stapedial and the external carotid artery, which alters the morphogenesis of structures derived from the first and second branchial arches. Although most affected individuals are isolated cases in otherwise normal families, some familial cases suggest that GS might have a genetic basis. Linkage and array-CGH analysis have detected several candidate loci for this genetically heterogeneous condition (including deletions in 1p22.2-p31.1, 2q11, 5p14, 12p13.33, 14q31.1q31.3, 15q24.1q24.2, 18p, 22q11.2, 22qter; duplications in 14q23.1, 22q11q13, unbalanced translocations, trisomies of chromosomes 7,8,9,10p, 22). No recurrent chromosomal abnormalities were identified. In our study genotyping by High Density SNP-array (HumanOmniExpress BeadChip, Illumina, CA) was performed on five GS unrelated cases. No specific CNVs were detected (the data were analyzed by GenomeStudio software Illumina, CA, and compared to the Database of Genomic Variants http://projects.tcag.ca/variation/). Whole exome sequencing is now in progress to identify possible single gene mutations potentially involved in the disease pathogenesis. Updated data will be presented and discussed.

P11.068-M
A case of Goldenhar syndrome and microrearrangements of chromosome 12

I. Loddo[1], *A. Capalbo*[2], *L. Bernardini*[2], *M. R. Pizzino*[1], *E. Moschella*[1], *S. Meduri*[1], *M. Crapanzano*[1], *D. Pompili*[2], *M. C. Cutrupi*[1], *S. Briuglia*[1];
[1]*Dipartiment of Paediatric Science, Messina, Italy,* [2]*CSS-Mendel Institute, Roma, Italy.*

We report a case of a 10 months boy. During pregnancy, the amniocentesis was performed after the detection of congenital heart disease, with a normal fetal karyotypel. The heart defect was characterized by situs ambiguous in destrocardia, left atrial isomerism, muscular apical ventricular septal defect, atrial septal defect in fossa ovalis. He was also affected by bilateral severe hearing loss, iris and chorioretinal coloboma in the right eye, dermoid cyst in the left eye, two preauricular tags on the left ear and one tag on the left cheek, facial asymmetry and growth retardation. SNP-array release hg19 showed a microdeletion of chromosome 12q13.3 [(57,160,163-57,317,932) x1 pat] and a microduplication of chromosome 12q22.33 [(90,562,016-91-,612,832)x3 mat]. In the duplicated region there are two genes, KERA and DCN. The protein encoded by KERA gene is a Keratan Sulfate Proteoglycan that is involved in corneal transparency. It may be important in developing and maintaining corneal transparency and for the structure of the stromal matrix. The protein encoded by DCN gene is Decorine, a component of the extracellular matrix, involved in the organization of collagens. Collagens play an important role in the cornea, which is the clear outer covering of the eye. Bundles of collagen called fibrils must be strictly organized for the cornea to be transparent. Decorin ensures that these collagen fibrils are uniformly sized and regularly spaced. The clinical features are indicative of Goldenhar Syndrome and the involvement of these microrearrangements as a contributory cause of the disease cannot be ruled out.

P11.069-S
Unusual presentation of Goltz syndrome with minimal ectodermal involvement in a 3-year-old Iranian girl

A. Rajaee, **A. Rajaee**;
employee in genetics center, Tehran, Islamic Republic of Iran.

Goltz syndrome (MIM 305600) is a rare genetic disorder characterized by distinctive skin abnormalities and a range of defects affecting the eyes, teeth, limbs, skeletal, urinary, gastrointestinal, cardiovascular and central nervous system. It is inherited in an X-linked dominant mode with lethality in males. One of the main features in this syndrome is the skin changes which are usually present at birth. Ectodermal features include symmetric linear reticulated thin skin, linear hyperpigmentation, ulcerations, telangiectasias, inflammation, hernialike outpouchings of fatty tissue, and papillomas. Here we report on a 3-year-old girl, with asymmetric involvement, greater severity of findings on the right side. She had, sparse hair, hyperkeratosis on 2/3 of the right side of the forehead, lacrimal duct stenosis, hypoplastic alae nasi, hyperkeratosis of the nose, simple ear, narrow auditory canal and hypoplastic tragus,, partial cleft of upper lip and pitting on lower lip and slight defect on tongue, hypoplastic nipple, ectrodactyly of hand and foot (on the right side). She has bilateral dysplastic nails on feet, scoliosis, syndactyly of third and 4th toes on the left side. We only had a chest X-ray from our patient which did not show striated bones. Initially Ectrodactyly-Ectodermal dysplasia was suspected and genetic testing for TP73L did not reveal any pathogenic mutation. We then sequenced PORCN gene and identified c.611T>C (p.Leu204Pro) mutation. In conclusion we present a patient with Goltz syndrome with unusual findings. Our patient did not have any of the common ectodermal, skeletal or ocular findings seen in such patients.

P11.070-M
Xq26.2q26.3 microduplication in a boy with developmental delay, distinct facial appearance and genitourinary abnormalities

K. Writzl[1], *N. Teran*[1], *A. Liedén*[2], *B. Peterlin*[1];
[1]*Institute of Medical Genetics, University Medical Centre Ljubljana, Ljubljana, Slovenia,* [2]*Department of Molecular Medicine and Surgery and Center for Molecular Medicine, Karolinska Institutet, Stockholm, Sweden.*

Microduplications involving the long arm of chromosome X are rare and the phenotypic consequences of functional disomy of X-chromosome genes in men remain mostly unknown. We here report on a 4-year-old boy with a Xq26.2q26.3 microduplication. The boy was born at 41 weeks after an uneventful pregnancy, with birth weight 2580g (<1st centile), length 48 cm (3rd centile), head circumference (HC) 36 cm (75th centile). He sat at 13 months and walked at 18 months. At the age of 4.5 years he spoke no words and showed some autistic-like behaviour. He had normal growth parameters (75th centile). Examination revealed hypertelorism, small, low-set ears, small mouth, clinodactyly of toes, micropenis, hypoplastic scrotum, right-sided duplicated collecting system and bilateral ventriculomegaly. Chromosomal microarray analysis (180K oligo) showed a 0.77 Mb duplication of Xq26.2q26.3, encompassing the whole coding sequence of the PHF6, HPRT1, PLAC1 genes and the first exon of the GPC3 gene. The result from the array was confirmed by MLPA analysis The duplication was inherited from the phenotypically normal mother and not detected in two healthy maternal brothers. The phenotype of the reported patient shares some features with recently reported microduplication syndrome of Xq25q26 (Møller et al., 2014), like prenatal growth retardation, genital abnormalities, digital malformations and intellectual disability, but not the short stature, microcephaly, and facial features. The smaller size of duplication with only partial duplication of the GPC3 gene is a possible cause of phenotypic discrepancies. These observations suggest that the Xq26.2q26.3 duplication represents a distinct clinical entity.

P11.071-S
Three new patients with Hamamy syndrome: expanding the phenotype

H. Kayserili[1], *U. Altunoglu*[1], *C. Bonnard*[2], *A. Ayaz*[3], *Y. Guven*[4], *B. Reversade*[2];
[1]*Istanbul University, Istanbul Medical Faculty, Medical Genetics Department, Istanbul, Turkey,* [2]*Institute of Medical Biology, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore,* [3]*Pamukkale University Medical Faculty, Medical Genetics Department, Denizli, Turkey,* [4]*Department of Pedodontics, Faculty of Dentistry, Istanbul University, Istanbul, Turkey.*

Hamamy syndrome is a very rare, autosomal recessively inherited malformation syndrome characterized by craniofacial findings, bone fragility, conductive heart defects and sensorineural hearing impairment. Patients have common dysmorphic features such as severe telecanthus with hypertelorism, sparse lateral eyebrows, thin upper vermilion border, flat philtrum and dysplastic, protruding ears. High myopia with retinal changes, absent or dysfunctional nasolacrimal structures, teeth anomalies, mycrocytic hypochromic anemia and mild intellectual deficit may also be present.

The syndrome was clinically described as a new syndrome by Hamamy et al. in 2007, in two brothers born to double first cousin parents of Jordanian-Arabic origin. Identification of two further patients from a Turkish family led to the localization of the causative gene to 16q12.2-q21, using homozygosity mapping. By locus re-sequencing, two different homozygous missense mutations were identified in the *IRX5* gene. A member of the Iroquis family of transcription factors, *IRX5* plays an active role in face, heart, blood, brain, bone and gonad development.
We report here a clinical and molecular evaluation of three new patients carrying two novel homozygous mutations in *IRX5*, along with previously unreported clinical findings, including acute myeloid leukemia with maturation. The phenotypic and molecular features of the Hamamy syndrome patients will be reviewed to further delineate the clinical and mutational spectrum.

P11.072-M
Novel de novo heterozygous *FGFR1* mutation in two siblings with Hartsfield syndrome: suggesting gonadal mosaicism

R. Dhamija, S. Kirmani, X. Wang, **D. Babovic***;*
Mayo Clinic, Rochester, MN, United States.

We describe two siblings with Hartsfield syndrome(association of holoprosencephaly, ectrodactyly, cleft lip and palate) and a novel de novo *FGFR1* mutation suggesting gonadal mosaicism. The proband presented at age 6 years for genetic evaluation.He was a product of a non-consanguineous union.Multiple congenital anomalies were detected at birth.His phenotype was consistent with Hartsfield syndrome (global developmental delay with spastic quadriplegia due to holoprosencephaly, ectrodactyly of bilateral hand and feet and bilateral cleft lip and palate).Previous genetic evaluation included normal karyotype, oligonucleotide array and single gene testing for non-syndromic holoprosencephaly (*SHH, SIX3, ZIC2, TGIF*).At the age of 6 years, exome sequencing was performed on the patient *at* BCM, *Houston,TX* and a *de novo* novel missense variant was identified in *FGFR1* (coding for fibroblast growth factor-1) on chromosome 8p12:c.1880G>C (p.R627T).This variant affects a highly evolutionarily conserved area of the gene, replacing arginine with theorine.Online prediction programs suggest this variant is a deleterious mutation.Subsequently a younger sibling was born with the same phenotype (holoprosencephaly, ectrodactyly of bilateral hand and feet and bilateral cleft lip and palate).Sequencing of *FGFR1* revealed the identical variant. We report a novel heterozygous *FGFR1* mutation in Hartsfield syndrome in two siblings, making this as the first case of familial recurrence of this rare syndrome. Both parents were negative for the sequence variant in *FGFR1*, thus suggesting gonadal mosaicism. This report also expands the phenotypic spectrum associated with loss of function mutations in *FGFR1* gene to include Hartsfield syndrome and confirms autosomal dominant inheritance of this condition.

P11.073-S
Clinical and molecular dissection of two novel cases of hemihyperplasia

M. Magliozzi[1], *G. Pascolini*[1,2], *S. Loddo*[1,2], *F. Restaldi*[1,2], *C. Martinez*[3], *R. Ottaviani*[4], *A. Pizzuti*[2], *A. De Luca*[1], *L. Sinibaldi*[1,4];
[1]*"Mendel Laboratory, IRCCS Casa Sollievo della Sofferenza", San Giovanni Rotondo, Italy,* [2]*Division of Medical Genetics, Department of Experimental Medicine, Sapienza University, Rome, Italy,* [3]*"Pediatric unit, Belcolle Hospital, AUSL Viterbo", Viterbo, Italy,* [4]*"Cytology and Cytogenetic laboratory, Belcolle Hospital, AUSL Viterbo", Viterbo, Italy.*

Hemihyperplasia (HH) term describes an asymmetric body overgrowth, generally due to an increased or unregulated cell proliferation, which can involve one or both sides of the body, a single limb or a half of the face. There is clinical overlap between HH and Beckwith-Wiedemann syndrome. Both conditions have been associated with molecular abnormalities of the imprinted cluster of genes at 11p15. We report on two pediatric patients with typical features of asymmetric body overgrowth. The first subject is an 8 month-old baby having only one body side manifesting HH and left asymmetric macroglossia. Polyhydramnios, umbilical hernia and omphalocele were also noted during pregnancy. Molecular testing conducted using MS-MLPA analysis identified a mosaic hypermetilation of the imprinting center IC1-H19 and hypometilation of the imprinting center IC2-KVDMR1. Uniparental disomy testing with microsatellite markers and SNP-array analysis confirmed mosaic uniparental isodisomy of 11p15 region. The second patient, a 10-year-old girl, presented a crossed asymmetry in the length of upper and lower limbs. At one year of age, she developed a left hypochondrial lipoblastoma. In this patient, MS-MLPA analysis of 11p15 region identified a mosaic KVDMR1 hypomethylation in both blood and saliva. To our knowledge, this is the first description of a lipoblastoma in a HH patient with a chromosome 11p15 region-imprinting defect.
The present results highlight the importance of performing genetic testing for 11p15 region imprinting defects in subjects with clinical diagnosis of HH. Considering the high tumor risk, a careful clinical surveillance, regardless the different methylation patterns is mandatory in these individuals.

P11.074-M
Hepatoblastoma and severe neurodevelopmental phenotype in neurofibromatosis type I: a case report and review of the literature

E. M. M. Burkitt Wright[1,2], *S. Holden*[3], *S. Williams*[1], *M. Zenker*[4], *G. C. M. Black*[1,2], *B. Kerr*[1,2];
[1]*Manchester Centre for Genomic Medicine, Manchester, United Kingdom,* [2]*Institute of Human Development, University of Manchester, Manchester, United Kingdom,* [3]*East Anglia Regional Genetics Service, Cambridge, United Kingdom,* [4]*University of Magdeburg, Magdeburg, Germany.*

A male patient presented with severe neonatal hypotonia including bulbar muscle involvement, necessitating tracheostomy. Severe feeding difficulties and gastro-oesophageal reflux led to gastrostomy placement. Hepatoblastoma was diagnosed at 5 months, and successfully treated with surgery and chemotherapy. Clinical genetic examination revealed features suggestive of a Ras-MAPK pathway disorder: relative macrocephaly, ptosis, downslanting palpebral fissures, curly hair, thickened ear helices, short stature and moderate to severe developmental delay. Cardio-facio-cutaneous (CFC) syndrome was suggested as the most likely diagnosis, due to the severity of developmental delay and one previous report of hepatoblastoma in CFC syndrome. Genetic testing of exons of *BRAF, KRAS, MAP2K1* and *MAP2K2* was normal, as was testing of *HRAS* and Noonan syndrome associated genes. Features of neurofibromatosis type I developed in later childhood: skinfold freckling and café au lait patches were present, and a plexiform neurofibroma was identified in his left arm at 10 years of age. The SureSelect 50Mb exome enrichment kit and Illumina HiSeq were used to reveal a *de novo* 4 basepair deletion in *NF1*, with no other known pathogenic variants being identified in this analysis.
The degree of neurodevelopmental delay in this patient was highly atypical for NF1. There has been only one previous report of hepatoblastoma in NF1, suggesting that this too is a rare association. These two highly atypical phenotypic aspects led to difficulties in making the diagnosis. This patient's presentation emphasises the related nature of Ras-MAPK pathway disorders and the potential of massively parallel sequencing for effective diagnosis of these conditions.

P11.075-S
13q14.2 duplication in a patient with alobar HPE phenotype associated with large ears

B. F. Gamba[1], *A. Richieri-Costa*[2], *S. Costa*[3], *S. L. Lucas*[2], *C. Rosenberg*[3], *L. A. Ribeiro-Bicudo*[1];
[1]*Universidade Estadual Paulista - Unesp/Brazil, Botucatu, Brazil,* [2]*Hospital of Rehabilitation of Craniofacial Anomalies, Bauru, Brazil,* [3]*Institute of Biosciences, University of São Paulo, São Paulo, Brazil.*

Holoprosencephaly is a common developmental defect; affecting both the forebrain and the face and presenting a high mortality rate with only the minority of patients surviving after 1 year. The etiology of HPE is complex, with both environmental and genetic factors being implicated. Here we presented a girl with a classic alobar HPE phenotype associated with large ears. Investigation of copy number changes was performed by array-CGH using the whole genome Cytosure™, ISCA V2 array 4X180K (Oxford Gene Techology, OGT, UK) containing ~180.000 oligonucleotides. Result showed ~14Kb duplication at 13q14.2 (47.948.518-47.963.274pb) with partially duplication of RB1 gene (based on UCSC Genome Bioinformatis, Hg18, http://genome.ucsc.edu). Reports on partial 13q duplication are unusual and the phenotype resulting is very heterogeneous. Duplication of the 13q distal chromosomal region has been also reported in a fetus that showed dysmorphic features such as postaxial polydactyly of the right hand and left foot with short fingers, malformatation of the gut, and a micropenis with hypospadias. Cerebellar hypoplasia had been noticed at ultrasound examination in the 14-week of gestation. The main purpose of the present report is to stress the importance of array CGH in patients with midline defects, since it represents a paramount point concerning genetic counseling and management to families.

Grupo Clínico Vinculado al CIBERER-ISCIII (Madrid). Cátedra de Genética Médica. Universidad Católica San Antonio de Murcia, Murcia, Spain.

Introduction: Holt-Oram syndrome (HOS) is an autosomal dominant disorder characterized by upper-limb malformation in combination with congenital heart defect. More than 70% of patients who meet diagnostic criteria have an identifiable mutation in *TBX5*.
Clinical report: 32-year-old woman. Second gestation. Abortion at 20 weeks because of bilateral upper-limb amelia in a male fetus. Normal karyotype. No necropsy.
The patient had a healthy son. Her partner had required surgery to correct atrial septal defect in childhood. He displayed low-set thumbs with no major upper-limb anomalies.
In a further gestation, ultrasound detected again bilateral upper-limb amelia in a male fetus at 12 weeks. Karyotype and heterochromatic repulsion analysis were normal. The patient underwent abortion. Post-mortem examination didn´t reveal heart defects. No environmental hazards were identified.
A new pregnancy was followed closely by high-resolution ultrasound, without detecting anomalies in a female fetus. At birth, triphalangeal thumbs and atrial septal defect were present. TBX5 gene sequencing analysis revealed no mutations. MLPA showed a deletion in exon 9, not previously described. The same deletion was detected in the second affected fetus and the father, co-segregating with the disease.
Discussion: Upper-extremities abnormalities are variably expressed, even within families. Although phocomelia has been described in HOS, there are few reports of frank amelia. TBX5 analysis should be therefore considered in such finding, even in the absence of heart defect. We report on a new exonic deletion in TBX5. Upcoming expression and exome analysis will help elucidate the mechanisms and modifying factors underlying its remarkable variable expressivity.

P11.077-S
Three TBX5 gene mutations resulting in Holt-Oram syndrome

J. Pilch[1], *A. Sowińska-Seidler*[2], *A. Jamsheer*[2,3];
[1]Department of Child Neurology, Medical University of Silesia, Katowice, Poland, [2]Department of Medical Genetics, University of Medical Sciences, Poznan, Poland, [3]Center for Medical Genetics GENESIS, Poznan, Poland.

Holt-Oram syndrome (HOS) is characterized by the congenital malformations of the heart, limbs, often accompanied with variable skeletal abnormalities. HOS-associated limb malformations usually involve absent or hypoplastic radial bone(s) and often abnormal thumb(s), which may be digitalised, absent, hypoplastic, triphalangeal or bifid. In a subset of patients, the syndrome results from TBX5 mutations. To date, about 60 different TBX5 gene lesions resulting in HOS have been identified. In this report, we describe three index cases of Polish ethnicity suspected of HOS, in whom we performed TBX5 Sanger sequencing. In all three probands we identified heterozygous TBX5 causative mutations: c.255-256delCA(p.P85fs94X), c.C524T(p.S175F), c.C668T(p.T223M). The first two mutations were novel, whereas the latter one represented previously identified variant. In the first two probands we observed severe bilateral hypoplasia of the radial bones and absent thumbs. Both probands presented with complex congenital heart defect composed of ventricular septal defect and persistent foramen ovale. The third patient was born with inborn heart defect in the form of atrial septum defect with patent ductus arteriosus and skin syndactyly of thumbs with second fingers. Upon MRI of the head, hypoplasia of corpus callosum was noted. Similar hand anomaly was observed in her father without heart involvement. Although based on a small sample, our study shows that TBX5 mutations may account for a significant proportion of HOS causative alterations and points to the importance of TBX5 mutational screening in the patients clinically suspected of this syndrome.

P11.078-M
Diamond-Blackfan anemia and intellectual disability: a new contiguous gene syndrome at 15q25.2

A. Guichet[1], *E. Colin*[1], *M. Gorce*[1], *A. Donzeau*[2], *A. Ziegler*[1], *M. Barth*[1], *I. Pellier*[2], *D. Bonneau*[1];
[1]Department of Biochemistry and Genetics, CHU ANGERS, ANGERS, France, [2]Department of Pediatrics, CHU ANGERS, ANGERS, France.

15q25.2 microdeletion is an emergent CNV locus for intellectual disability, dysmorphic features and congenital anomalies. Two distinct microdeletions have been described at this locus: 1) a distal deletion (11 cases) responsible for neurodevelopmental and neuropsychiatric disorders and 2) a proximal deletion (8 cases) which is a susceptibility locus for cognitive deficit, diaphragmatic hernia and Diamond-Blackfan anemia (DBA). This proximal deletion is said to predispose to DBA because it contains the gene RPS17, encoding for a ribosomal protein, responsible for 2% of DBA. Until now, however, DBA has been diagnosed with certainty in only one case of 15q25 proximal deletion. The additional case reported here had a history of intrauterine growth retardation. Aged 18 months, the patient had a moderate developmental delay, dysmorphic features and musculoskeletal anomalies. He had a normochromic macrocytic aregenerative anemia with elevated erythrocyte adenosine deaminase activity and elevated HbF (3.2%) highly suggestive of DBA. A 15q25.2 microdeletion of 2.2Mb including RPS17 was identified using SNP array. The deletion of RPS17 was confirmed by FISH using a specific probe. The deletion was absent in the patient's father and was impossible to test in his mother. To date, only a few mutations in RSP17 have been reported in patients with DBA. Anemia was mentioned in 4 cases among the 8 previous reported cases of 15q25.2 proximal deletion but the definite diagnosis of DBA was made in only 1 case. The present report confirms that patients with 15q25.2 deletion involving RSP17 are at risk of DBA and possibly DBA-associated malignancies.

P11.079-S
Moderate intellectual disability, speech delay, strabism, pseudo Hirschprung disease and mild abnormalities of extremities in a girl with a 2q24.3q31.2 duplication.A new syndrome ?

M. Miguet[1], *Y. Alembik*[2], *J. Rebeuh*[2], *M. Dexheimer*[3], *V. Kremer*[1], *F. Girard*[1], *E. Flori*[1];
[1]Service de Cytogénétique, Strasbourg, France, [2]Service de génétique médicale, Strasbourg, France, [3]Service de Cytogénétique, Nancy, France.

We report on a 15-year-old girl presenting with moderate intellectual disability, delays in speech and language acquisition, **strabism** and severe chronic constipation looking like **Hirschsprung** disease in spite of the presence of ganglion cells. Her parents are not consanguineous and in good health but her paternal half-brother presents speech difficulties and moderate intellectual disability. Conventional chromosome analysis was considered as normal, but array CGH showed a 10,2Mb interstitial duplication of the 2q24.3q31.2 region. In situ hybridization of paternal metaphases revealed a direct intrachromosomal insertion of the long segment of chromosome 2 at band q32.3 between bands 2q24.3 and **2q31.2**. The duplication observed in the patient results from an abnormal meiotic recombination of the father's insertion. Given its risk of recurrence for another child, an abnormality of the same chromosomal region has now to be searched in the girl's half brother. The function of several duplicated genes can explain the phenotype of the patient. As it is, to our knowledge, the first 2q24.3q31.2 duplication reported, additional patients are needed to improve the description of the phenotype.

P11.080-M
Comprehensive sequencing of all known Joubert genes in a large Joubert syndrome cohort in search of oligogenicity

R. Bachmann-Gagescu[1], *I. Phelps*[2], *B. O'Roak*[3], *C. Isabella*[2], *D. O'Day*[2], *J. Dempsey*[2], *I. Glass*[2], *J. Shendure*[3], *D. Doherty*[2];
[1]University of Zurich- Medical Genetics, Zürich, Switzerland, [2]University of Washington-Dept of Pediatrics, Seattle, WA, United States, [3]University of Washington-Dept of Genome Sciences, Seattle, WA, United States.

Joubert syndrome (JS) is a ciliopathy characterized by a distinctive hindbrain malformation, ataxia and cognitive dysfunction. It is typically inherited in an autosomal recessive manner caused by biallelic mutations in one of >20 genes, but despite the large number of causal genes, the underlying cause remains unknown in more than one third of affected individuals. Affected individuals carrying multiple heterozygous rare deleterious variants (RDVs) in known JS-associated genes raise the possibility of more complex genetics. To search for evidence of oligogenicity (defined as disease causation through combined effects of two or more heterozygous RDVs) and genetic modifiers, we used a novel molecular inversion probe-based (MIP) capture technology to sequence all known JS-associated genes in a large JS-cohort. Using a recessive model where biallelic RDVs in any of the known JS-associated genes were considered causal, we were able to determine the cause in less than two thirds of our subjects. In the remaining subjects, only a small number carried heterozygous RDVs in two or more JS-associated genes, and this proportion was not significantly different from that observed in a control population. Moreover, Sanger sequencing identified a second RDV that had been missed by MIP sequencing in several subjects, thereby establishing a recessive cause in these individuals. Thus, our data do not support the hypothesis that a significant proportion of JS cases are due to oligogenicity involving RDVs in the known JS genes. Current analyses focus on determining whether genetic burden correlates with disease severity.

P11.081-S

Multi-gene-panel diagnostics detects MKS1- gene mutations in a boy with Joubert-Syndrome

I. M. Bader[1], *O. Rittinger*[1], *G. Sander*[1], *G. Kronberger*[1], *S. Wieser*[1], *J. Koch*[2], *P. Pietsch*[3], *M. Cohen*[3], *M. Jakobeit*[3], *B. Ertl-Wagner*[4], *E. Decker*[5], *H. Bolz*[5], *C. Bergmann*[5,6];

Mutations in the MKS1 gene are known to be a major cause for Meckel-Gruber-Syndrome, a genetically heterogeneous condition and the most common form of syndromic neural tube defect . The MKS1 gene also accounts for a minor fraction of the total mutational load in Bardet-Biedl-Syndrome.
We report the phenotype of a five year old boy from Austria with episodes of apnoe during the first 7 months of life, severe hypotonia, psychomotor retardation, congenital nystagmus and a molar tooth sign detected in the MRI of the brain, which suggested the diagnosis of Joubert syndrome.
Next-Generation sequencing based multi-gene-panel diagnostics from a blood sample revealed two mutations located in the MKS1 gene: The first mutation, c.1407-7_1408_35del29, is known to be a major cause for Meckel-Gruber-Syndrome in homozygous state. The second mutation is a missense-mutation that has not yet been reported. Five bioinformatic tools predict an alteration of protein function caused by the mutation. We therefore assume that these two mutations in the MKS1 gene in compound heterozygous state are causative for the phenotype.
Mutations in the MKS1 gene are primarily reported in patients with Meckel-Gruber-Syndrome, a phenotype which denotes the most severe (usually lethal) end of the spectrum of ciliopathies with occipital encephalocele and other early embryonic malformations. Here we describe a patient with classical Joubert syndrome which underlines the genetic heterogeneity in Joubert syndrome and illustrates the pleiotropy of MKS1 mutations.

P11.082-M

Kabuki syndrome: clinical and molecular diagnosis in the first year of Life

M. Dentici, *A. Di Pede, F. Lepri, M. Gnazzo, M. Lombardi, C. Auriti, S. Petrocchi, E. Pisaneschi, R. Capolino, A. Braguglia, A. Angiorni, A. Dotta, M. Digilio, B. Dallapiccola; Bambino Gesú Pediatric Hospital, IRCCS, Rome, Italy.*

Objective: To review the clinical and molecular characteristics of 18 patients presenting a suspected diagnosis of Kabuki Syndrome (KS) in the first year of life, in order to outline the clinical handles leading to a prompt diagnosis of KS in newborns. Clinical diagnosis of KS can be challenging during the first year of life, as many diagnostic features become evident only in subsequent years.
Methods: All patients were clinically investigated by trained clinical geneticists. A literature review was performed using the Pubmed online database and Diagnostic criteria suggested by DYSCERNE_ Kabuki Syndrome Guidelines (2010) were used. Molecular analysis of the known causative-genes of KS, MLL2 and KDM6A, was performed through targeted resequencing, using MiSeq® sequencing platform. All mutations identified were validated by Sanger sequencing standard protocols.
Results: Facial dysmorphisms (94%), feeding difficulties (100%) and hypotonia (100%) suggested the clinical diagnosis of KS. Notably, long palpebral fissures and large anteverted ears were present in 94% and 100% of the cohort, respectively. Other abnormalities such as brachydactyly, joint laxity and nail dysplasia were present in 15 (83%) patients. Congenital heart diseases occurred in 14 (77%) cases, the most common defects being septal defects (11/18;61%) and left-sided obstructive lesions (4/18; 22%). Mutations in MLL2 gene were identified in 16/18 (89%) of the patients, while none of the patients had KDM6A mutations.
Conclusions: We present an overview of patients with KS diagnosed during the first year of life. Early diagnosis is serviceable in terms of clinical management and for targeted genetic counselling.

Congenital heart defects in Kabuki syndrome, revisited after new molecular knowledges

M. Digilio[1], *M. Gnazzo*[1], *F. Lepri*[1], *M. Dentici*[1], *A. Baban*[1], *E. Pisaneschi*[1], *R. Capolino*[1], *P. Sirleto*[1], *A. Angioni*[1], *B. Marino*[2], *B. Dallapiccola*[1];
[1]*Bambino Gesù Pediatric Hospital, Rome, Italy,* [2]*University Sapienza of Rome, Rome, Italy.*

Kabuki syndrome (KS) is associated with CHD in 28%-80% of the cases, including left-sided obstructive lesions (LVOTOs), septal defects, and conotruncal anomalies. Our group has performed a clinical review of CHDs diagnosed in patients with KS in 2001, when molecular basis of the syndrome were unknown. At present, two causative genes for KS have been identified, the *MLL2* and the *KDM6A* genes. In this study we analyzed the prevalence of CHD, cardiac anatomic types and molecular characteristics of 41 patients with KS from a single institution. All patients underwent cardiological evaluation. Analysis of *MLL2* and *KDM6A* genes was performed through targeted resequencing, using MiSeq® sequencing platform. All mutations were validated through Sanger sequencing. *MLL2* mutations were found in 34/41 (83%), including nonsense, frameshift, in-frame duplication, and missense variants. Two/41 (5%) had *KDM6A* mutations. Additional chromosome rearrangements were detected in 3. CHDs in *MLL2* mutated patients (23/34=68%) included LVOTOs (bicuspid aortic valve, aortic coarctation, Shone complex) in 11/23 (48%), subaortic ventricular septal defect in 5/23 (22%), atrial septal defect in 4/23 (17%), abnormal pulmonary venous return (APVR) in 2/23 (9%), double outlet right ventricle (DORV) in one (4%). The patients with *KDM6A* mutation had normal heart. In conclusion, the high proportion of left-sided obstructions and the cardiac overlap with Turner syndrome (LVOTOs and APVR) have been confirmed. No specific hot spots for CHD have been identified, but mutations are preferentially located in proximal and terminal *MLL2*. Unusual CHD (DORV) is diagnosed in association with an additional chromosomal rearrangement.

P11.084-M

Hypermobility in Individuals with Kabuki Syndrome

C. Stumpel, *M. Klaassens, P. Staps, N. Schott;
Academic Hospital Maastricht, 6202AZ Maastricht, Netherlands.*

Kabuki Syndrome (KS; OMIM 147920) is a well-known congenital anomaly/intellectual disability syndrome caused by a mutation in the KMT2D gene (OMIM 602113). Hypermobility has been described as one of the major features of KS. However, no prevalence of hypermobility is known within the population of children with KS. On assessment of KS children in our clinic, we noticed that the degree and the pattern of hypermobility varies greatly amongst patients. Therefore, we aimed to assess the degree and pattern of hypermobility in the KS individuals.
Twenty individuals (age 3-30 years old) with KS and a known KMT2D mutation were assessed. The persons were evaluated using two systems: the Beighton and the Bulbena score.
The prevalence of hypermobility in this cohort was 25% using the Beighton score, and 45% using the Bulbena score. The difference between these two percentages is due to the items within each system and the pattern of hypermobility in the KS patients. These patients have a non-generalized pattern of hypermobility with the small joints of the hands and feet, hips and knees most affected. In contrast with the general population, boys with KS have a higher degree of hypermobility than girls with KS.
We present the data in a graphical way.
In conclusion, persons with KS have a specific non-generalized pattern of hypermobility with hips, patellae and the small joints of the hands most affected. Furthermore, boys are more severely affected than girls.

P11.085-S

Novel KDM6A (UTX) point mutations and a review of the X-linked Kabuki syndrome (KS2)

S. Banka[1], *D. Lederer*[2], *V. Benoit*[2], *E. Jenkins*[3], *E. Howard*[3], *S. Bunstone*[3], *B. Kerr*[1], *S. McKee*[4], *I. C. Lloyd*[5], *D. Shears*[6], *H. Stewart*[6], *S. M. White*[7], *R. Savarirayan*[7], *G. M. S. Mancini*[8], *D. Beysen*[9], *R. D. Cohn*[10], *B. Grisart*[2], *I. Maystadt*[2], *D. Donnai*[1];
[1]*University of Manchester, Manchester, United Kingdom,* [2]*Centre de Génétique Humaine, Charleroi, Belgium,* [3]*St Mary's Hospital, Manchester, United Kingdom,* [4]*Belfast City Hospital, Belfast, United Kingdom,* [5]*Manchester Royal Eye Hospital, Manchester, United Kingdom,* [6]*Churchill Hospital, Oxford, United Kingdom,* [7]*University of Melbourne, Melbourne, Australia,* [8]*Erasmus University Medical Center, Rotterdam, Netherlands,* [9]*Ghent University, Ghent, Belgium,* [10]*The Hospital for Sick Children, Toronto, ON, Canada.*

Autosomal dominant or *de novo KMT2D* (MLL2) mutations account for nearly one-third cases of Kabuki syndrome (KS1, MIM 147920). Large deletions and nonsense or frameshift point mutations involving *KDM6A* (UTX) on Xp11.3 are another very rare cause of this condition (KS2, MIM 300867).
Here, we describe seven new patients with *de novo KDM6A* mutations, which doubles the number of reported cases with point mutations in KS2. We report, for the first time, germline missense and splice-site *KDM6A* mutations and confirm their pathogenicity via multiple lines of evidence. Combined analysis from two centres shows that less than 5% cases of Kabuki syndrome are due to *KDM6A* mutations.
Our findings enable a detailed review of the clinical features of KS2. We demonstrate that the developmental delay and learning disability in KS2 is generally moderate-severe in boys and mild-moderate in girls. Speech and cognition tend to be more severely affected than motor development. Some girls with *KDM6A* mutations may have a normal developmental profile. Similar to the commoner KS1, KS2 patients are characterized by hypotonia and feeding difficulties during infancy and poor postnatal growth and short

stature. Increased susceptibility to infections, join laxity, heart, dental and ophthalmological anomalies are common. Hypoglycaemia is more common in KS2 than in KS1. Importantly, diagnosis on facial gestalt alone may be difficult in many patients because the facial dysmorphism with *KDM6A* mutations is highly variable. Hypertrichosis, long halluces and large central incisors may be useful clues to an underlying *KDM6A* mutation in some patients.

Examining Kabuki syndrome causing mutations in Czech population

J. Paderova[1], *A. Holubova*[1], *M. Simandlova*[1], *A. Puchmajerova*[1], *M. Vlckova*[1], *M. Malikova*[1], *R. Pourova*[1], *S. Vejvalkova*[1], *M. Havlovicova*[1], *M. Senkerikova*[2], *N. Ptakova*[1], *A. Krepelova*[1], *M. Macek Jr.*[1];
[1]*Department of Biology and Medical Genetics, Charles University - 2nd Faculty of Medicine and Faculty Hospital Motol, Prague, Czech Republic,* [2]*Department of Medical Genetics, Charles University - Faculty of Medicine and Faculty Hospital Hradec Kralove, Hradec Kralove, Czech Republic.*

Kabuki (make-up) syndrome (KS) is an autosomally dominant disorder caused by *de-novo* mutations and has an estimated prevalence of 1:32 000 newborns. KS1 is caused by mutations or deletions in *KMT2D* (lysine/K/specific MethylTransferase 2D) (formerly *MLL2*) gene, while KS2 is due to similar molecular defects in *KDM6A* (lysine/K/specific DeMethylase 6A) gene. Here we present molecular genetic analysis in a cohort of 14 Czech patients with clinical symptoms indicative of KS by DNA sequencing of coding regions of *KMT2D* and *KDM6A* genes, including MLPA-based analysis (kit P389-A1) of intragenic rearrangements within *KMT2D*. Mutations in *KMT2D* were detected in 6/14 (43%) of patients. All detected mutations were truncating, thereby predicting haploinsufficiency. Three mutations were previously published (c.16371_16374del, c.8743C>T, c.5627_5630del) and three are novel (c.2488G>T, c.4549_4549delG, c.6349_6350delinsA). No mutations were detected within the *KDM6A*, as well as intragenic rearrangements were not found in *KMT2D* gene (MLPA assay for *KDM6A* is not available, thus far). Our results substantiated the disease association with *KMT2D* gene. Since the clinical features of "*KMT2D* mutation-positive" cases did not differ from those, where aforementioned methods did not detect any DNA alterations, we plan to utilize next generation sequencing in an attempt to identify other loci that are potentially contributing to the genetic heterogeneity in KS.

P11.087-S
A novel mutation in KAT6B in a patient with genitopatellar syndrome and some features of SBBYSS

M. Vlckova[1], *M. Simandlova*[1], *V. Stranecky*[2], *H. Hartmannova*[2], *K. Hodanova*[2], *M. Havlovicova*[1], *Z. Sedlacek*[1], *S. Kmoch*[2];
[1]*Department of Biology and Medical Genetics, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic,* [2]*Institute of Inherited Metabolic Disorders, Charles University 1st Faculty of Medicine and General University Hospital, Prague, Czech Republic.*

Genitopatellar syndrome (GPS) and Say-Barber-Biesecker-Young-Simpson syndrome (SBBYSS) are two clinically overlapping syndromes. Recently de novo heterozygous truncating mutations in KAT6B have been identified in SBBYSS, and independently also in GPS.
KAT6B encodes lysine acetyltransferase 6B, a part of histone H3 acetyltransferase complex. KAT6B is highly conserved and expressed in adult neural stem cells. Most mutations are in exon 18 encoding the acidic (A) and transcriptional activation (TA) domains of KAT6B. Genotype-phenotype correlation showed that patients with mutations in the 5´ region of exon 18 leading to loss of both domains suffer from GPS, while patients with mutations in the 3´ region leading to loss of the TA domain suffer from SBBYSS.
We present an 8-year-old girl with intellectual disability, autism and multiple developmental anomalies. She has corpus callosum agenesis, flexion contractures, hypoplastic patella, renal cysts and tracheomalacia (symptoms frequent in GPS but rare in SBBYSS), as well as blepharophimosis, lacrimal ducts stenosis, long toes, hypotonia and normal head circumference (frequent in SYBBYSS but rare in GPS) and atrial septal defect, feeding difficulties and bulbous nose (common to both syndromes).
Karyotyping and aCGH analysis of the patient yielded normal results. Whole exome and Sanger sequencing of the family trio showed de novo heterozygous truncating mutation KAT6B:NM_001256469:exon18:c.3295G>T:p.E1099X located in the 5´ region of exon 18, which should cause GPS. However, our patient manifests also many features of SBBYSS. Therefore this case demonstrates that the phenotypic overlap between GPS and SBBYSS could be broader than expected previously.
Supported by 00064203, CZ.2.16/3.100/24022 and NT/14200.

P11.088-M
Familial case of KBG syndrome caused by a novel *ANKRD11* gene mutation

P. Louro[1], *A. Beleza-Meireles*[1], *L. Ramos*[1], *S. Maia*[1], *J. Pereira*[2], *J. M. Saraiva*[1,3];
[1]*Medical Genetics Unit, Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal,* [2]*Molecular Hematology Unit, Hospital Pediátrico, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal,* [3]*University Clinic of Pediatrics, Faculty of Medicine, University of Coimbra, Coimbra, Portugal.*

Background: KBG syndrome is an autosomal dominant disease characterized by intellectual disability, seizures, short stature, skeletal anomalies and distinct craniofacial features. It is caused by mutations in *ANKRD11* gene.
Methods: We report the cases of a 19-year-old woman and her 41-year-old mother presenting with intellectual disability, short stature and short 5th fingers. While the mother had already lost most of her teeth, we observed that her daughter had macrodontia of the upper central incisors. The diagnosis of KBG syndrome was suspected. Hence, we proceeded with mutation screen of the coding region of the *ANKRD11* gene.
Results: *ANKRD11* gene sequencing revealed a heterozygous pathogenic nonsense mutation, c.1318C>T [p.(Arg440*)], previously not described in the literature.
Conclusion: Our patients showed clinical features of KBG syndrome. The molecular analysis of *ANKRD11* gene confirmed our clinical hypothesis, which allows a more precise genetic counselling for our patients and their family.

P11.089-S
X chromosome-linked copy number variations in Klinefelter syndrome

M. S. Rocca[1], *V. Pecile*[2], *R. Selice*[1], *N. Caretta*[1], *C. Foresta*[1], *A. Ferlin*[1];
[1]*University of Padova, Padova, Italy,* [2]*IRCCS Burlo Garofolo, Trieste, Italy.*

Klinefelter syndrome 47,XXY (KS) is the most common sex-chromosome aneuploidy in men, characterized by at least one supernumerary X chromosome. The wide spectrum of clinical manifestations in KS often varies in severity. The clinical features of KS commonly include hypergonadotropic hypogonadism, gynecomastia, small testes and azoospermia, with a varying degree of androgen deficiency, gynecomastia, cognitive dysfunction, increased central adiposity, increased height with eunuchoid proportions, and increased frequency of diabetes, metabolic syndrome, osteoporosis, autoimmune disorders and psychosocial/behavioural abnormalities. The mechanism by which the supernumerary X-chromosome determines the clinical phenotypes in KS is poorly understood, although genetic background in conjunction with the parental origin of the supernumerary X chromosome and consequently with gene-dosage effects may contribute to the variability of the phenotype and increase risk of certain diseases in KS.
In order to understand the role of X-linked Copy Number Variations (CNVs) in Klinefelter subjects, we recruited 93 patients having non-mosaic KS and 85 healthy controls. We performed SNP array analyses using the Human OmniExpress-12 Bead Chip (Illumina Inc.). By the analysis of the X chromosome, we observed CNVs patient-specific not reported in Database of Genomic Variants (DGV). Furthermore the total length of duplications and deletions, and the length of duplications and deletions per patient were significantly different from controls.
This is the first study that shows CNVs on X-chromosome in KS patients and represents an important step forward a better understanding of clinical features of this syndrome.

P11.090-M
KMT2D and *KDM6A* mutations in Kabuki syndrome

N. Miyake[1], *E. Koshimuzu*[1], *N. Matsumoto*[1], *N. Niikawa*[2];
[1]*Yokohama City University, Yokohama, Japan,* [2]*Health Science University of Hokkaido, Hokkaido, Japan.*

Kabuki syndrome (KS; MIM 147920) is a congenital anomaly syndrome characterized by developmental delay, intellectual disability, specific facial features including long palpebral fissures and ectropion of the lateral third of the lower eyelids, prominent digit pads, and skeletal and visceral abnormalities. As mutations in *KMT2D* and *KDM6A* are known to cause KS, we screened 81 individuals with KS for mutations in these genes by conventional methods (n = 58) and/or targeted resequencing (n = 45) or whole exome sequencing (n = 5). We identified a mutation in *KMT2D* or *KDM6A* in 50 (61.7%) and five (6.2%) cases, respectively. Thirty-five *KMT2D* mutations and two *KDM6A* mutations were novel. Non-protein truncating-type *KMT2D* mutations were mainly located around functional domains, while truncating-type mutations were scattered through the entire coding region. The facial features of patients in the *KMT2D* truncating-type mutation group were typical based on those of the ten originally reported patients with Kabuki syndrome; those of the other groups were less typical. High arched

eyebrows, short fifth finger, and hypotonia in infancy were more frequent in the *KMT2D* mutation group than in the *KDM6A* mutation group. Short stature and postnatal growth retardation were observed in all individuals with *KDM6A* mutations, but in only half of the group with *KMT2D* mutations. The genetic basis of the patients who tested mutation-negative (20-45%) remains elusive. Further studies are necessary to understand the whole picture of the genetic aspects of KS and its genotype-phenotype relationships.

P11.091-S
Large cryptic genomic rearrangements with apparently normal karyotypes detected by array-CGH

E. Savin[1], *E. Di Gregorio*[1,2], *F. Fiocchi*[1], *V. G. Naretto*[1], *E. Biamino*[3], *E. Belligni*[3], *C. Mancini*[2], *S. Cavalieri*[1], *E. Pozzi*[2], *E. Giorgio*[2], *E. Colombo*[1], *F. Talarico*[1], *P. Pappi*[1], *E. Grosso*[1], *M. Cirillo Silengo*[3], *G. B. Ferrero*[3], *A. Brusco*[1,2];
[1]*S.C.D.U. Medical Genetics, Città della Salute e della Scienza, Turin, Italy,* [2]*University of Torino, Department of Medical Sciences, Turin, Italy,* [3]*Department of Pediatrics, University of Turin, Turin, Italy.*

Chromosomal abnormalities that result in genomic imbalances, such as numerical or structural changes, are one of the most common causes of congenital and developmental anomalies. Conventional karyotyping with a resolution of at least 550 bands should be able to identify chromosomal aberrations down to 5-10 Mb. In contrast, a-CGH analysis is known to detect submicroscopic imbalances increasing the diagnostic yield to 15-20% in patients with an cognitive impairment and/or multiple congenital anomalies.
Here we report a subgroup of patients referred for multiple malformations, developmental delay / cognitive impairment, and an apparent normal standard karyotype. Whole genome array-CGH analysis (60 K, Agilent Technologies) identified six patients with large terminal complex rearrangements, all beyond the threshold of 5Mb (6 to 18 Mb). Results were suggestive for the presence of an unbalanced translocation derivative, confirmed by FISH analysis. Five were inherited from a parent with a balanced translocation, and one was apparently de novo.
Comparison of the karyotype and array-CGH showed that cytogenetic rearrangements were all almost indistinguishable from a normal karyotype, swapping similar band patterns.
Only one case was recurrent in an affected brother with the same rearrangement and an identical phenotype. Miscarriages were reported in two families.
In conclusions, large complex rearrangements involving chromosomal regions with similar size and band appearance may be missed by conventional karyotype and detected by array CGH to allow a precise chromosomal diagnosis and recurrence risk definition.

P11.092-M
Family cases of Leopard syndrome

S. I. Iurian[1,2], *H. Brunner*[3], *H. Yntema*[3], *S. Iurian*[4], *A. Vidrighin*[2], *B. I. Mehedintu*[4];
[1]*Pediatric Clinical Hospital, Sibiu, Romania,* [2]*Lucian Blaga University, Sibiu, Romania,* [3]*Radboud University, Human Genetic Department, Nijmegen, Netherlands,* [4]*Pediatric Clinic Hospital, Sibiu, Romania.*

Background. LEOPARD syndrome is a complex disorder characterized by multiple dysmorphogenetic features. According to molecular studies, LEOPARD syndrome and Noonan syndrome are caused by different mutations in PTPN11 gene. Aims. Authors emphasize diagnosis peculiarities in two relatives with facial dysmorphism. Methods. Authors presents a 10 year-old boy admitted for airway infection symptoms. Family history: non-consanguineous parents; father and sister with face dysmorphism. Clinical exam: short stature, impaired nutritional status, axillary freckles, widespread café-au-lait spots, face dysmorphism (hipertelorism, mandibular prognathism, broad nasal root, high arched palate, large and posteriorly rotated ears, down slanted palpebral fissures), webbed neck, skeletal anomalies (thorax anomalies, bilateral wide hallux with exostosis), interdigital webs between hallux and 2nd toe, mental retardation. Results. Blood investigations didn't reveal anomalies. Cardiac ultrasound exam: no pulmonary stenosis. Differential diagnosis includes Noonan syndrome (see webbed neck, short stature), Greig syndrome (due to wide hallux, feet cutaneous sindactily), type 1 neurofibromatosis (because of café-au-lait spots, axillary freckles), Albright syndrome (see skin pigmentation). The patient was evaluated from genetic point of view: normal karyotype. Suspicion for Noonan syndrome has justified DNA sequencing that revealed mutation in PTPN11 gene (c.1403C>T, p.Met468Thr) suggestive for LEOPARD syndrome. Authors also found same mutation for probant's father. Conclusions. 1.Authors described two related cases with dysmorphic skull, skeletal anomalies, skin pigmentation, mental disabilities and short stature, justifying further genetic evaluation and revealing a very rare genetic disorder; 2.Genetic counseling and examination of other family members is important (probant's sister).

P11.093-S
Phenotype of two patients with mandibulofacial dysostosis with microcephaly (MFDM) associated with esophageal atresia and choanal atresia caused by EFTUD2 mutations

R. Smigiel[1], *A. Jakubiak*[2], *D. Patkowski*[3], *M. M. Sasiadek*[2];
[1]*Department of Paediatrics and Rare Disorders, Wroclaw Medical University, Poland, Wroclaw, Poland,* [2]*Genetic Department Wroclaw Medical University, Poland, Wroclaw, Poland,* [3]*Department of Paediatric Surgery and Urology, Wroclaw Medical University, Poland, Wroclaw, Poland.*

Mandibulofacial dysostosis (MFD) causes malar and mandibular hypoplasia, cleft palate and hearing loss. Several distinct MFD syndromes are recognized, one of them is MFD with microcephaly (MFDM), sometimes associated with major defect: choanal atresia (CA), esophageal atresia (EA), kidney and heart defects. We present two unrelated patients with MFDM confirmed by EFTUD2 mutations and associated with EA and CA.
1. Female, 36hbd, birth weight-1720g. EA, cleft palate and hearing loss were diagnosed. Facial dysmorphism includes microcephaly, asymmetric face, hyperplastic supraorbital ridges, broad base of nose, retromicrognatia, microtia, preauricular tags. The patient had gastrostomy and tracheostomy. Psychomotor, somatic and speech development is delayed but social development is correct. CHARGE, facio-auriculo-vertebral spectrum and syndrome described by Megabrane et al. were considered after birth.
2. Female, 37hbd, birth weight-2400g. Respiratory distress due to CA and hearing loss were diagnosed. Facial dysmorphism includes microcephaly, microtia, asymmetry, preauricular tags, hypertelorism, narrow palate, micrognathia. Psychomotor and speech development is delayed but social contact with child is correct. CHARGE and Bohring-Opitz syndromes were considered after birth..
MFDM in both patients was suspected. EFTUD2 gene was sequenced. The mutation c.1435dup was identified in patient 1 and c1859A>T in patient 2.
The full clinical spectrum of MFDM is heterogeneous. Facial phenotype with ear abnormalities and microcephaly of presented patients was distinctive, but observed major defects in neonatal period were considered as leading symptoms and correct diagnosis was delayed. We suggest that MFDM should be taken in the differential diagnosis of child with craniofacial malformations accompanied by EA or CA.

P11.094-M
A new case of MDP syndrome caused by recurrent single-codon deletion in the POLD1 gene

M. Murdocca[1], *C. Fiorillo*[2], *F. Trucco*[2], *M. Pedemonte*[2], *M. D'Apice*[3], *F. Sangiuolo*[1], *G. Novelli*[1], *C. Minetti*[2];
[1]*University of Tor Vergata, Rome, Italy,* [2]*G.Gaslini Hospital, Genoa, Italy,* [3]*Tor Vergata Hospital, Rome, Italy.*

Progeroid features with concomitant cardiac, skeletal, and muscular anomalies, lipodystrophy and insuline resistance define rare genetic diseases named laminopathies, caused by mutations in genes encoding nuclear proteins.
Here, we report a case of a 13-yr-old girl, second-born of non consanguineous parents, who showed retarded growth, anemia and xerotic skin at age 1. She showed triangular facies, micrognathia, low-set and small ears and sensorineural deafness at age 8. Other clinical features included hypertrichosis, a notable subcutaneous fat loss from her extremities with accumulation at abdomen level and insuline-resistance. She also presented generalized hypotonia, severe muscular hypotrophy and joint contractures. Given that the clinical overlapping with progeroid disorders, genetic analysis of known mutated genes was performed. We identified an in frame single codon deletion (c.1812_1814delCTC, p.S605del) in POLD1 gene, encoding DNA polymerase δ, has been recently associated to a multisystem disorder named MDP syndrome, characterized by Mandibular hypoplasia, Deafness and Progeroid features, detected in other four MDP patients.
The case underlines the clinical and genetic heterogeneity of patients with adipose tissue, skeletal and muscular anomalies, associated to progeroid features.

P11.095-S
Loss-of-function mutations in MED13L cause a distinctive clinical phenotype mimicking the 1p36 deletion syndrome

G. Marangi[1], *C. Cafiero*[1], *D. Orteschi*[1], *A. Moncada*[1], *V. Leuzzi*[2], *G. Mancano*[1], *D. Battaglia*[3], *I. Contaldo*[3], *M. Stefanini*[3], *E. Mercuri*[3], *M. Zollino*[1];
[1]*Institute of Medical Genetics, Catholic University, Rome, Italy,* [2]*Department of Pediatrics and Child Neurology and Psychiatry, Sapienza Università di Roma, Rome, Italy,* [3]*Department of Paediatric Neurology, Catholic University, Rome, Italy.*

Exome sequencing (WES) has already been proven to be an effective method for the identification of the causative gene in small groups of subjects clinically selected by sharing homogenous phenotypes.
We selected a group of 8 patients with overlapping phenotype, resembling

the 1p36 deletion syndrome and with normal array-CGH (15kb resolution). By means of WES in two of them, we found two causative mutations: p.M303K in SYT1 (subject 1) and p.P1255Pfs*3 in MED13L (subject 2). The missense mutation in SYT1 involves an essential functional domain. By Sanger sequencing of both genes in the other subjects, we identified another MED13L mutation (p.S203Sfs*32) in one. All mutations were de novo. Missense mutations involving MED13L have already been identified as responsible for isolated congenital heart defects. One only literature report deals with complete or partial gene deletion, which were also associated to intellectual disability (ID). Mutations in SYT1 have never been described in humans.
Our three patients presented with moderate ID and shared facial features, including brachycephaly, horizontal eyebrows, high forehead, long eyelashes, depressed nasal bridge, mid-face hypoplasia. Additional clinical signs were epilepsy (subject 1), cleft palate, clubfoot and conductive hearing loss (subject 2) and atrial septal defect (subject 3). Patient 2 was diagnosed with acute lymphoblastic leukemia.
These results suggest that the haploinsufficiency of MED13L causes a typical phenotype that should be considered in the differential diagnosis of the 1p36 deletion syndrome. We tentatively suggest SYT1 as another candidate gene for the same clinical presentation, but it needs to be further confirmed.

P11.096-M
An interstitial microdeletion of 20q11.21 in a boy with cheilognathopalatoschisis, anorectal malformation, severe microcephaly, craniofacial features, feeding difficulty, mild growth impairment, and mild intellectual disability

E. Nishi[1,2], *K. Wakui*[2], *M. Arakawa*[1], *H. Kawame*[1,3], *Y. Fukushima*[2], *T. Kosho*[1,2];
[1]Division of Medical Genetics, Nagano Children's Hospital, Azunimo, Japan, [2]Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan, [3]Division of Genomic Medicine Support and Genetic Counseling, Tohoku Medical Magabank Organaization, Tohoku University School of Medicine, Sendai, Japan.

Interstitial microdeletions involving 20q11.2 are very rare with only four reported patients. We
have identified a de novo interstitial 20q11.2 microdeletion in a 7-year-old boy, clinically showing cheilognathopalatoschisis, anorectal malformation, severe microcephaly, craniofacial features (triangular face, hypertelorism, hypoplastic alae nasi, long philtrum, low set ears), feeding difficulties, mild growth impairment, mild intellectual disability (IQ67), and attention-deficit hyperactivity disorder. G-banded chromosomes were normal, cytogenomic microarray (135K Oligo, Roche) revealed a de novo 1.15 ~ Mb microdeletion at 20q11.2 [arr[hg18] 20q11.21(29,297,619-30,447,117)x1 dn]. The deleted segment encompassed 15 OMIM genes (*COX4I2, MYLK2, ASXL1,* etc). The sizes of deleted segments in four reported patients were 2.6Mb, 6.5Mb, 6.6Mb, and 6.8Mb[Iourov et al.2013; Hiraki et al.2011; Callier et al.2006;Iqbal et al.2007;]. Clinical features shared by those with > 6Mb deletion included feeding difficulty, facial features (triangular face, hypertelorism, hypoplastic alae nasi, long philtrum, and low set ear), developmental delay and/or intellectual disability, though the other with 2.6Mb had a milder manifestation. The present patient with the smallest deletion showed clinical features of previously reported patients with 20q11.2 microdeletion. Although long-term follow-up and collection of additional patients is needed to delineate the phenotypic spectrum of the condition, we propose the microdeletions at 20q11.2 to be a clinically recognizable syndrome characterized by craniofacial features, feeding difficulty, growth impairment, and intellectual disability.

P11.097-S
The clinical phenotype of 3q29 microdeletion and 3q29 microduplication syndrome in three female patients

M. Gentile[1], *C. Cesarano*[2], *C. Ceccarini*[2], *A. D'Aprile*[2], *A. Pansini*[1], *L. Buonadonna*[1], *V. Bruni*[3], *M. Bruno*[2], *M. Gallicchio*[2], *M. Carboni*[2], *P. Zampetti*[1], *G. Cotoia*[2], *A. Manghisi*[4], *F. C. Susca*[3], *N. Resta*[3], *R. Antonetti*[2], *N. Bukvic*[4];
[1]Ospedale Di Venere, Laboratorio di Genetica Medica, ASL Bari, Bari, Italy, [2]OORR Foggia, Azienda Ospedaliero Universitaria, Dipartimento di Patologia Clinica - II Laboratorio, Sezione di Citogenetica, Foggia, Italy, [3]UOC Laboratorio di Genetica Medica – Dipartimento di Scienze Biomediche ed Oncologia Umana - Università degli Studi di Bari "A Moro", Bari, Italy, [4]Azienda Ospedaliero Universitaria Consorziale, Policlinico di Bari, UOC Laboratorio di Genetica Medica, Bari, Italy.

It has been demonstrated that whole genome scanning technologies (array-CGH) is especially suited to identify chromosome abnormalities in individuals with unclear or variable presentations. Application of this technology resulted in the delineation of several previously unrecognized microdeletion/microduplication syndromes such as recently described del3q29 (OMIM 609425; ORPHA65286) and dup3q29 (OMIM 611936; ORPHA251038) syndromes with highly variable clinical phenotypes.
The most common features of del3q29 phenotype include mild-to-moderate intellectual deficit and slightly dysmorphic facial features: microcephaly, long and narrow face/asymmetric face, short philtrum, large posteriorly rotated ears, high nasal bridge, crowded/dysplastic teeth, tapered fingers with occasionally observed autism and gait ataxia. Clinical features of dup3q29, included micro/macro-cephaly, round face, bulbous nose, short or downslanting palpebral fissures, excessive hand creases, obesity and pes planus.
Herein, we report on two unrelated female patients with different phenotypic consequences (high interindividual phenotypic variability) due to de novo deletion of an identical segment [spanning ~2.0Mb (start 195,438,699bp - 197,404,251bp)] and one female patient with de novo duplication of 3q29 which overlap this region [spanning ~1.58Mb (start 195,740,387bp - 197,317,074 bp)].

P11.098-M
Molecular analysis of ACTG2 in a cohort of patients with Megacystis Microcolon Intestinal Hypoperistalsis Syndrome suggests locus heterogeneity

M. M. Alves[1], *D. Halim*[1], *J. B. Verheij*[2], *C. S. van der Werf*[2], *Y. Sribudiani*[1], *Y. van Bever*[1], *F. Muller*[3], *J. Kerner*[4], *D. Tibboel*[5], *R. M. Wijnen*[5], *R. M. Hofstra*[1], *A. S. Brooks*[1];
[1]Department of Clinical Genetics, Erasmus MC, Rotterdam, Netherlands, [2]Department of Genetics,University Medical Center Groningen, Groningen, Netherlands, [3]Biochimie Prénatale, Hôpital Robert Debré, Paris, France, [4]Division of Gastroenterology, Hepatology, and Nutrition, Department of Pediatrics, Lucile Packard Children's Hospital, Palo Alto, CA, United States, [5]Department of Pediatric Surgery, Erasmus MC, Rotterdam, Netherlands.

Megacystis Microcolon Intestinal Hypoperistalsis Syndrome (MMIHS) was recently classified as an actinopathy: a disease caused by mutations in ACTG2, one of the 6 human actins. ACTG2 encodes for the enteric smooth muscle actin γ-2; heterozygous de novo mutations were found in 2 MMIHS patients1. Our aim was to study a cohort of MMIHS patients to determine whether a locus other than ACTG2 could be involved. Sanger sequencing of ACTG2 was performed in a cohort of 7 patients (5 single cases and 2 families: one consanguineous family and one family originating from a genetic isolate). We identified heterozygous ACTG2 mutations in 5/5 single cases. In both families a mutation in ACTG2 was excluded. All identified mutations were non-synonymous, affecting an arginine residue. These mutations were located in different exons of ACTG2: exon 3 (R40C), 4 (R63Q) and 7 (R178C and R178H) and were considered to have a pathogenic effect by at least 2 out of 3 prediction programs. Although several sib-pairs have been published, the majority of the patients were sporadic, consistent with the presence of de novo mutations in a single gene. Interestingly, the mutation affecting residue R178 has also been reported in 2 other MMIHS patients1, suggesting that this position could play a major role in MMIHS pathogenesis. Moreover, the fact that ACTG2 mutations were excluded in the 2 families, points towards the involvement of a second locus. Whole-exome sequencing of these families should prove the involvement of another gene.

P11.099-S
Mosaic deletion of 18q in lymphocytes represents a diagnostic challenge for clinicians and underlines the importance of CMA testing in children with ID

D. Niedrist, *B. Oneda, R. Baldinger, A. Rauch;*
Institute of Medical Genetics, University of Zurich, Schlieren Zurich, Switzerland.

We report on a 2½ year-old boy with mental retardation, muscular hypotonia, deafness with atresia of the external auditory canal and a preauricular tag on the right side. The boy was referred for global intellectual disability with very limited speech capabilities and autistic traits. The pregnancy had been uneventful except for an emergency Cesarean section because of breech position. Birth measurements were normal, however, the baby was hypotonic and exhibited difficulties in feeding. At physical examination at the age of 2½ years measurements were still normal but we noted discrete dysmorphic features: long eye lashes, broad mouth with cupid bow lips, small fingers with broad short endphalanges, clinodactyly of toes V on both sides, tender translucent skin, fine hair and cryptorchidism on the right side. On the MRI at the age of 2 years delayed myelinisation was visible. As the atresia of the external auditory canal is typical for a deletion 18q we performed a karyotype on lymphocytes which was first reported with no pathological findings.
The array (2.7 Affymetrix SNP-oligo array platform) analysis revealed a deletion in mosaic form of 20.7 Mb of the long arm of chromosome 18, encompassing 69 genes in total. The mosaic was confirmed with FISH, which also revealed that the mosaic ratio in this case was 13% in cultivated blood and 81% in buccal swab. Reevaluating the karyotype the deletion was visible.
This case demonstrates the higher sensitivity of SNParrayCMA testing for mosaic aberrations.

P11.100-M
Molecular diagnostics of rare hereditary diseases using next generation sequencing

O. Mazal, *J. Štika, J. Sabová;*
Synlab genetics, Prague, Czech Republic.

Next generation sequencing (NGS) is a rapidly evolving method for the molecular diagnostics of hereditary genetic disorders, NGS is based on parallel sequencing, capable of reading the sequences of whole genes in a single run. Using this technology, we analysed two causative genes - NF1 (neurofibromatosis) containing 58 exons, and PKHD1 (polycystic kidney disease) with 67 exons. Neurofibromatosis is an autosomal dominant disorder of the nervous system, characterised by café au lait spots, cutaneous neurofibromas and Lisch nodules in the iris, affecting 1 in 3-5,000 people. Polycystic kidney disease is an autosomal recessive disorder, characterised by the development of cysts affecting the collecting ducts. The population prevalence is 1:85,000 individuals. Methods: DNA was isolated from peripheral blood and amplicons prepared by PCR were analysed on a GS Junior system (Roche). Data were analysed by AVA (Roche) and Sequence Pilot (JSI medical systems) software. Results: We analysed 11 patients for PKHD1, and found the following mutations: Thr36Met, Leu2128X, Ile2957Thr, Ile2331Lys, Thr36Met, Gly112Arg, Arg92Trp, Gly1712Arg, Gln1122Ser (not described) and Ser3505Arg (with unknown effect). Four patients were negative. Of 5 NF1 patients, three were negative and two patients (who were related) had a deletion of TAACTT in exon 48. Conclusion: NGS is a very useful method for the analysis of large genes with many exons, such as NF1 and PKHD1. These genes can be sequenced in a single run, instead of multiple single reactions. In the future we intend to analyse more genes using NGS, namely COL2A1 (Stickler syndrome) and USH2A (Usher syndrome).

P11.101-S
Unusual RASopathy due to a novel and severe mutation in the NF1 gene.

Y. Lacassie[1], *B. R. Korf*[2], *L. M. Messiaen*[3];
[1]*Department of Pediatrics, Louisiana State University Health Sciences Center and Children's Hospital New Orleans, New Orleans, LA, United States,* [2]*Department of Genetics, University of Alabama Birmingham (UAB), Birmingham, AL, United States,* [3]*Medical Genomics Laboratory, Department of Genetics University of Alabama Birmingham (UAB), Birmingham, AL, United States.*

We report a Caucasian man first seen at age of 25 months, referred with the diagnosis of Cerebral Palsy due to prematurity. Furthermore, he presented severe developmental delay, hypotonia, seizures, failure to thrive, dysplasia of the right optic nerve, and pulmonic stenosis. We also found dolichocephaly, open fontanel, hypertelorism, large ears with posterior pits, wide neck, mild pectus excavatum, short 4th metacarpals, and minor ridge dysplasia and radial loops in the indexes and right 3rd finger. Chromosomes and metabolic tests were normal. Because features of a RASopathy, sequence analysis of the PTPN11, RAF1, SOS1 and KRAS genes was performed, but no mutations were found. At age 21, his older sister was diagnosed with plexiform neurofibromas, requiring amputation of a leg. CT scan of the proband after accident unexpectedly showed massive plexiform neurofibromas infiltrating the spine, pelvis and extremities. Molecular testing showed an NF1 mutation, c.2326-6T>G, resulting in in-frame skipping of exon 20 (r.2326_2409del), therefore expected to result in a protein lacking 28 amino acids from within the Cystein-Serine Rich Domain (CSRD) (p.Trp777_Ala804del). This is a "private" mutation, not previously reported and observed in 1/6,500 NF1-positive unrelated patients (UAB cohort). This was also found in his sister and father who both developed spinal neurofibromas but no classic skin findings (cutaneous neurofibromas, CALMs, freckling). This family illustrates the importance of molecular confirmation in patients with minimal or no pigmentary manifestations and with features of other RASopathies. Our proband, who was exceptional despite of all his limitations, died at age 26 (January 2014).

P11.102-M
Unexpected karyotypes in patients with non-syndromic phenotype studied in the postnatal period

A. Pragliola[1], *L. Renzi*[1], *A. Innoceta*[1], *A. Turci*[1], *B. Buldrini*[2], *R. Gruppioni*[2], *S. Fini*[2], *A. Sensi*[1];
[1]*Laboratorio Unico AVR Romagna U.O. Genetica Medica, Pievesestina di Cesena, Italy,* [2]*Università degli Studi di Ferrara U.O. Genetica Medica, Ferrara, Italy.*

We present 3 cases of patients with mild phenotypes, seen at the medical genetics clinical service of the Romagna AUSL, in which analysis of high-resolution karyotype showed rearrangements of about 10 Mb.
The first case concerns a boy who on examination showed obesity, overgrowth, flat feet, brachydactyly, reduced elbow extension, large testes and mild facial features with maxillary protrusion, but no cognitive defect. Cytogenetic analysis revealed a duplication in the long arm of chromosome 9 with karyotype: dup(9)(q32q33). The array-CGH analysis confirmed the duplication of the long arm of chromosome 9, locating it more precisely between bands q33.1 and q33.3 of 9.2 Mb not present in the mother (father not available).
The second case concerns a child who has no obvious dysmorphic features, cognitive levels borderline, anteverted nostrils, tendency to keep open his mouth, slight retrognathia, ears with large pinna and small lobe. Cytogenetic analysis revealed a karyotype: 46,XY,del(1)(q31.1q32.1) mat confirmed by the array-CGH analysis of 13Mb deletion. Mother with the identical deletion has normal cognitive profile and no relevant duymorphisms.
The last case concerns an adult come to our attention for couple infertility; karyotype analysis showed: 46,XY,del(18)(q21.3q22).ish del(18)(pter+,wcp18+,bcl2-,qter+) confirmed by FISH The array-CGH analysis confirms the deletion of about 9.4 Mb of maternal origin .
CONCLUSIONS
Generally chromosomal regions deletions of this magnitude are associated with malformations, dysmorphic features or with a pathology of the psychomotor development. However, chromosomal imbalances in specific regions can also be asymptomatic, due to the small number of dosage-sensitive genes present in these regions.

P11.103-S
RASopathy syndromes in Polish patients: a molecular study of Noonan, Cardiofaciocutaneous and Costello syndromes

M. Pelc[1], *E. Ciara*[1], *S. Łuczak*[1], *A. Tańska*[1], *J. Trubicka*[1], *D. Jurkiewicz*[1], *M. Kucharczyk*[1], *M. Kugaudo*[1,2], *D. Gieruszczak-Białek*[1,3], *A. Skórka*[1,3], *M. We present a group of 106 Polish RASopathy cases, including 81 unrelated patients of various age (from infancy to adulthood) with 52 different mutations in genes encoding components of the Ras/MAPK signaling pathway. About 65% of 61 unrelated patients with Noonan syndrome (NS), including 4 cases of NS with multiple lentigines (NS-ML), had mutations in *PTPN11*, 21% in *SOS1*, 12% in *RAF1* and 2% in *KRAS*. Nearly half of NS cases were family occurrences. In the group of 15 patients with cardiofaciocutaneous syndrome (CFCS) about 80% of all mutations occurred in *BRAF*, while 20% in *MAP2K1* or *MAP2K2*. The five cases of Costello syndrome had two most common mutations in *HRAS*. All identified changes were missense, 8 of them being novel substitutions in different Ras/MAPK genes, causative of NS, NS-ML or CFCS phenotype and one *RAF1* mutation so far reported only in a patient with t-AML. The aCGH studies of a group of 21 patients with Noonan-like phenotype (including cardiac defects, musculoskeletal and facial abnormalities) and no causative mutation detected in the known Ras/MAPK genes revealed in one patient a 8p23.3-p23.1 deletion and in the other a 12q12-q13.11 deletion. The molecular findings of our study mostly correspond to the data reported worldwide. We presume that our results will contribute to the existing databases of RASopathy patients and enable detailed phenotype-genotype correlations and differential diagnostics among the patients suspected of RASopathies. The research was supported by Projects: NCN UMO-2011/03/N/NZ2/00516, MNiSW PB 0056/B/P01/2008/35 and POIG.02.01.00-14-059/09.

A neuronal phenotype characterized in a mouse model for Noonan Syndrome

F. Altmüller[1,2], *D. Schanze*[1], *I. Schanze*[1], *C. Marini*[3], *A. Fejtova*[2], *M. Zenker*[1];
[1]*Institute of Human Genetics, University Hospital, Magdeburg, Germany,* [2]*Leibniz Institute for Neurobiology, RG Presynaptic Plasticity, Magdeburg, Germany,* [3]*Leibniz Institute for Neurobiology, Dept. Neurochemistry and Mol. Biology, Magdeburg, Germany.*

Constitutional dysregulation of the Ras-mitogen activated protein kinase (MAPK) signaling pathway can lead to Noonan Syndrome (NS) or similar disorders, the so-called "RASopathies", which are characterized by an overlapping pattern of physical abnormalities and cognitive impairment. Their molecular basis is an overactive Ras-MAPK signaling pathway caused by gain-of-function-mutations. In animal models, it has been shown that mutations in homologous genes can lead to impaired cognitive function and reduced synaptic plasticity. However, the molecular pathogenesis for the intellectual disability still remains unknown. This study was aimed at investigating the consequences of dysregulated Ras-MAPK signaling in neurons of a mouse model for NS expressing the oncogenic allele Ptpn11D61Y.
In the brain, reconfiguration of expression of neuronal genes represents an

important mechanism that underlies persistent activity-induced changes in the brain function in the process of neuronal plasticity. While the Ptpn11-D61Y mutation is usually found to evoke higher levels of phosphorylated ERK (pERK), we found no differences in the nuclear level of pERK comparing wild type and mutant cells under basal conditions. However, neuronal activity-driven induction of nuclear translocation of pERK was affected in the mutant neurons, suggesting a dysregulation of the activity-induced signaling. In line with this finding, we found differences in the size of total recycling synaptic vesicle pools, which is a subject of regulation during homeostatic adaptation in neurons.
The lacking response to stimulation found in the Ptpn11D61Y neurons suggest a deficit in cellular signaling underlying usage-dependent neuronal plasticity and might contribute to the intellectual disability found in patients with NS.

P11.105-S
Cryptorchidism and pulmonary stenosis as the most important features in Noonan patients with mutation in PTPN11 in Slovak population

M. Cizmarova[1], I. Haasová[1], L. Kostalova[1], Z. Priblilincova[1], Z. Lasabova[2], A. Hlavata[1], L. Kovacs[1], **D. Ilenčíková**[1];
[1]Department of Pediatrics Comenius University Medical School University Children´s Hospital, Bratislava, Slovakia, [2]2Department of Molecular Biology, Jessenius Faculty of Medicine, Martin, Slovakia.

Introduction: Noonan syndrome (NS) is an autosomal dominant disorder which together with Cardio-facio-cutaneous syndrome (CFC), Costello syndrome (CS) and Noonan-Neurofibromatosis syndrome (NFNS) belongs to a group of genetic syndromes called 'RASopathies'. These disorders are characterised by occurance of similar phenotypic features. Among the most common are short stature, specific dysmorphic facial features and congenital heart anomalies. 'RASopathies' are caused by mutations in genes resulting in dysregulation of RAS-MAPK signaling pathway. Mutations in PTPN11 account for approximately 50% of all cases of Noonan syndrome.
Aims: The comparism of phenotype features in patients with PTPN11 mutation and without PTPN11 mutation.
Methods: Mutation analysis of PTPN11 gene was performed in 19 Slovak patients with phenotype of NS. It consisted of polymerase chain reaction and direct sequencing of 15 coding exons and exon/intron boundaries of the PTPN11 gene.
Results: We identified PTPN11 mutations in 47% of our patients (N=19) with clinical diagnosis of Noonan syndrome. Comparing the prevalence of phenotypic features in patients with PTPN11 mutation with prevalence of the same features in patients without PTPN11 mutation, we found the most significant differences in cryptorchidism (100% vs. 0%), pulmonary stenosis (78% vs. 10%), pterygium colli (0% vs. 70%) and birth length which was short only in 22% of patients with PTPN11 mutation in comparison to 80% in patients without PTPN11 mutation.
Conclusions: Our findings show that cryptorchidism, pulmonary stenosis, pterygium colli and short birth length are the most important features that distinguish patients with mutation in PTPN11 from patients without PTPN11 mutation.

Noonan syndrome - the usefulness of whole exome sequencing in the identification of known and new causative genes and disease differential diagnosis.

M. Gos[1], *S. Fahiminiya[2], J. Klapecki[1], E. Obersztyn[1], A. Abramowicz[1], A. Kutkowska-Kaźmierczak[1], M. Piotrowicz[3], J. Pilch[4], R. Posmyk[5], J. Wierzba[6], J. Bal[1], J. Majewski[2];*
[1]Department of Medical Genetics, Institute of Mother and Child, Warsaw, Poland, [2]Department of Human Genetics, McGill University and Genome Quebec Innovation Center, Montreal, QC, Canada, [3]Department of Genetics, Polish Mother's Memorial Hospital - Research Institute, Łódź, Poland, [4]Department of Pediatric Neurology, Medical University of Silesia, Katowice, Poland, [5]NZOZ Genetics, Center for Clinical Genetics, Białystok, Poland, [6]Department and Clinic of Pediatrics, Hematooncology, Oncology and Endocrinology, Department of General Nursing, Medical University of Gdańsk, Gdańsk, Poland.

Noonan syndrome (NS) is a rare disease belonging to the group of RASopathies caused by the germline mutations in genes encoding proteins of RAS/MAPK signaling pathway. The majority (about 50%) of cases is caused by *PTPN11* mutations. Also mutations in *RAF1* and *SOS1* are quite common (up to 17 and 13%, respectively). The aim of the study was the identification of molecular defect responsible for the NS phenotype using whole exome sequencing (WES). Forty two patients with primary clinical diagnosis of Noonan syndrome and excluded mutation in *PTPN11*, *SOS1* and *RAF1* genes were included in the study. The WES was performed using Illumina sequencing platform. The WES analysis allowed for the identification of mutation in RASopathies-related genes in 7/42 (16.7%) NS patients. The p.Ser2Gly mutation in *SHOC2* was identified in 2 patients. The mutations in *NF1* (p.Met1035Arg, p.Tyr2556*), *BRAF* (p.Gln257Arg, p.Thr241Pro) and *KRAS* (p.Asp153Val) genes were found in 2, 2 and 1 patients, respectively. In two patients, mutations (p.Phe82Val and p.Met90Ile) in new NS-related gene *RIT1* were found and subsequent analysis of follow-up cohort identified p.Gly95Ala mutation in further two patients. In several cases, the primary NS diagnosis was refined to Kabuki syndrome (2 patients, *MLL2* mutation), Andersen-Tawil syndrome (1 patient, *KCNJ2* mutation) and Aarskog syndrome (1 patient, *FGD1* mutation). Our results support the usefulness of whole exome sequencing in the identification of known and new mutations related to specific disease as well as in the differential diagnosis. Supported from NCN research projects no. 2011/01/D/NZ5/01347 and 2013/09/B/NZ2/03164.

Noonan syndrome-like disorder with loose anagen hair (mazzanti syndrome): a new case with neuroblastoma

L. Garavelli[1], *S. Errico[1,2], M. Verna[3], M. Street[2], S. Rosato[1], A. Wischmeijer[1,4], E. Bacchini[5], A. Lombardi[5], G. Izzi[3], G. Biasucci[6], C. Del Rossi[7], C. Rossi[4], S. Bernasconi[2], M. Tartaglia[8];*
[1]Clinical Genetics Unit IRCCS, Arcispedale Santa Maria Nuova, Reggio Emilia, Reggio Emilia, Italy, [2]Department of Paediatrics, Parma University Hospital, Italy, Parma, Italy, [3]Pediatric Hematology and Oncology Unit, Department of Pediatrics, Parma University Hospital, Italy, Parma, Italy, [4]Department of Medical Genetics, Policlinico Sant'Orsola-Malpighi, University of Bologna, Italy, Bologna, Italy, [5]Department of Pediatrics Radiology, Parma University Hospital, Italy, Parma, Italy, [6]Department of Pediatrics, "Guglielmo da Saliceto" Hospital, Piacenza, Italy, Piacenza, Italy, [7]Department of Pediatric Surgery Parma University Hospital, Italy, Parma, Italy, [8]Department of Haematology, Oncology and Molecular Medecine, Istituto Superiore di Sanita`, Rome, Italy, Rome, Italy.

Mazzanti syndrome also known as Noonan-like syndrome with loose anagen hair (OMIM #607721) associates facial features resembling Noonan syndrome, cardiac defects, cognitive deficits, reduced growth generally associated with GH deficit, and hair anomalies. It is caused by an invariant mutation of the *SHOC2* gene. We report on a subject with molecular confirmed diagnosis of Mazzanti syndrome with neuroblastoma, first suspected at the age of 3 months by abdominal ultrasound.
At first evaluation he showed a round face, blond, thin and sparse hair, slightly down-slanting palpebral fissures, slightly posterior rotated ears, evident palmar creases, mild generalized hypotonia and dystrophy, especially in his face and legs. Because of severe feeding difficulty and failure to thrive he underwent an abdominal ultrasound and subsequently abdominal MRI, which confirmed the presence of a circumscribed retroperitoneal nodular lesion between inferior cava vein and aortic artery at the level of the liver (2.7 x 1.5 x 2.2 cm), hyperintense in T2 and isointense in T1, with slight enhancement with contrast. The mass was completely removed and the histological analysis documented a neuroblastoma, poorly differentiated with intermediate MKI. Tumoral cells were negative for the *MYCN* amplification and bone marrow aspirate was N-Myc negative. The patient did not require any subsequent chemotherapy or radiotherapy.
The present finding emphasizes the importance of monitoring these patients to obtain a precocious diagnosis of possible malignancies. The growing evidence of a variably increased cancer risk in apparently all RASopathies demands further studies to substantiate and specify risk figures and tumor spectrum.

P11.108-M
A de novo microduplication 3q29 in a patient with oculo auriculo vertebral spectrum

V. Guida[1], *L. Sinibaldi[1], M. Pagnoni[2], L. Bernardini[1], D. Cocciadiferro[1], S. Loddo[1], M. Digilio[3], T. Fadda[2], G. Iannetti[2], B. Dallapiccola[3], A. De Luca[1];*
[1]IRCCS Casa Sollievo della Sofferenza, Mendel Laboratory, Rome, Italy, [2]Maxillo-Facial Surgery, Policlinico „Umberto I", Rome, Italy, [3]Bambino Gesù Children Hospital, IRCCS, Rome, Italy.

Oculoauriculovertebral spectrum (OAVS; OMIM 164210) is a phenotypically and probably also a genetically eterogeneous disorder derived from an abnormal development of the first and second branchial arches. Main clinical characteristics include defects of the aural, oral, mandibular, and vertebral development. Anomalies of the cardiac, pulmonary, renal, skeletal, and central nervous systems have also been described. We report on a 25 year-old male with preauricular pits and tags, unilateral absence of the auditory meatus, dysgenesis of the inner ear and unilateral microphthalmia, clinical features fitting with the oculoauriculovertebral spectrum. Using SNP array analysis we identified a de novo microduplication of 723Kb on chromosome 3q29, which was absent in 52 OAVS patients and in 80 ethically matched non-OAVS individuals. This de novo microduplication was proximal to the 3q29 microdeletion syndrome region and reciprocal microduplication. The identified microduplication encompassed 9 genes including ATP13A3 and XXYLT1, which are involved in organogenesis and regulation of Notch pa-

thway, respectively. The present observation is in accordance with the hypothesis that OAVS is a genetically heterogeneous condition, underlying the importance of SNP array analysis in patients with OAVS features.

P11.109-S
Screening of CD96 and ASXL1 in twelve patients affected with Opitz C or Bohring-Opitz syndromes

[1]*Dpt.Genetics, Universitat de Barcelona, CIBERER, IBUB, Barcelona, Spain,* [2]*Dpt. Computational Genomics, Ctro. Investigación Príncipe Felipe,BIER, CIBERER, Valencia, Spain,* [3]*Istituto Genetica Medica, Università Cattolica Sacro Cuore, Policlínico A Gemelli, Roma, Italy,* [4]*University of Utah School of Medicine, Salt Lake City, UT, United States.*

Opitz trigonocephaly (or C syndrome, OTCS) and Bohring-Opitz syndrome (or C-like syndrome, BOS) are two rare genetic disorders which show phenotypic overlap. The genetic bases of these diseases are not well understood. Two genes have previously been associated with OTCS or BOS with a dominant pattern of inheritance. Whereas the CD96 gene has been related to OTCS (one case out of 25) and to BOS (one case in 4 patients analyzed), ASXL1 (Additional Sex Combs-Like 1) has been related to BOS only (around half of the patients). In this study we analyzed CD96 and ASXL1 in a cohort of twelve individuals, including two sibs. Eight of them were diagnosed with OTCS, two displayed a BOS phenotype and another two could not be accurately diagnosed. Exome sequences were available for six patients with OTCS and three couples of parents, in which CD96 and ASXL1 were inspected using bioinformatic tools. For the remaining patients, Sanger sequencing of all exons in these genes was carried out. Detailed scrutiny of the sequences allowed identification of only one potentially pathogenic mutation in one of the patients. In this subject, affected with BOS, we identified a de novo mutation in ASXL1 (c.2100dupT). By nature and location within the gene, this insertion resembles those previously described in other BOS patients and we conclude that it may be responsible for the disease. Our results indicate that for eleven out of the twelve patients, the disease (OTCS or BOS) is not caused by mutations in CD96 or ASXL1.

P11.110-M
A case of Opitz GBBB syndrome: clinical presentation

E. Caramaschi, *F. Lami, E. Bigi, A. Guerra, A. Percesepe;*
Università degli studi di Modena e Reggio Emilia, Modena, Italy.

Opitz G/BBB Syndrome is a multiple congenital anomaly disorder affecting midline structures, characterized by variable expressivity of clinical signs. Primarly clinical features are facial anomalies (including ocular hypertelorism, broad nasal bridge and cleft lip and/or palate), laryngotracheo-esophageal abnormalities and hypospadias. Imperforate anus and congenital heart defects are also present; patients may also show developmental delay and brain abnormalities. We report the case of a patient born prematurely with cleft lip and palate. Some dysmorphic features were evidenced: hypertelorism, flat nasal bridge and bifid nasal tip, macrocephaly. Systolic murmur and mild hypospadias were noted on clinical examination. An echocardiogram defined congenital heart disease (patent ductus arteriosus together with persistent left superior vena cava and coronary sinus). During follow-up neurological examination and EEG were normal, but delay in speech and motor development emerged. MRI examination showed inferior vermis hypoplasia and small pituitary gland. Differential diagnosis among a number of clinical entities was considered, but the hypospadia and the marked hypertelorism oriented towards the diagnosis of Opitz GBBB syndrome. The analysis of the MID1 gene confirmed a partial deletion, spanning from exon 3 to the end of the gene. Opitz Syndrome is genetically heterogeneous presenting with X-linked and autosomal dominant form; the two forms cannot be distinguished on the basis of clinical manifestations. The autosomal dominant form is linked to a still unidentified gene located on a large region of chromosome 22q11.2. The X-linked one is associated with mutations in the MID1 gene located on the short arm of the X chromosome (Xp22.2).

P11.111-S
Two cases of Opitz GBBB syndrome

S. Gümüs, *S. Sapmaz, U. Altunoglu, H. Kayserili;*
Istanbul University, Istanbul, Turkey.

Opitz GBBB syndrome is a rare congenital syndrome characterized by hypertelorism, hypospadias, cleft lip/palate, laryngotracheoesophageal abnormalities, imperforate anus, developmental delay, and cardiac defects. Opitz GBBB syndrome is genetically heterogeneous, with both X-linked and autosomal dominant forms. X-linked form of Opitz GBBB syndrome is caused by mutation in the *MID1* gene (OMIM 300552).
We here report two male cases with Opitz GBBB syndrome. One of them was referred with preliminary diagnosis of FND due to hypertelorism at the age of 14 months. On physical examination he showed hypertelorism, notched nares, bifid incisory tooth, pectus excavatus, accessory right nipple, Simian line, bilateral fifth finger clinodactyly, glandular hypospadias and hypoplastic scrotum. Clinical evaluation prompted the diagnosis of Opitz GBBB syndrome and *MID1* sequencing revealed homozygous c.1798dupC [p.His600ArgfsX12]. Since the mother had one of the major signs of the syndrome, widows peak, X-linked inheritance was suspected.
Second patient, at the age of three and a half, displayed hypertelorism and penoscrotal hypospadias on physical examination and displayed additional findings; such as sparse hair, telecantus, depressed and broad nasal bridge, micrognathia, long philtrum, v shaped upper lips, diastasis recti and umbilical hernia. He had a striking resemblance to the first one and his mother also had widows peak. He clinically diagnosed as Opitz GBBB syndrome and MID1 analysis is still pending.
We will discuss Opitz GBBB syndrome in view of the literature.

P11.112-M
Mutations in a new gene cause a novel overgrowth syndrome with macrocephaly, hypoglycemia, enlarged ventricles, mild/moderate intellectual disability and recurrent inflammatory diseases

Overgrowth syndromes (OGS) are a group of disorders in which all parameters of growth and physical development are above the mean for age and sex. Partial, localized, or regional OGS are those disorders in which excessive growth is confined to one or a few regions of the body. We evaluated a series of 270 families from the Spanish Overgrowth Syndrome Registry with no known overgrowth syndrome. We identified a deletion and three missense mutations in a new gene in six patients from 4 families with overgrowth, macrocephaly, intellectual disability, mild hydrocephaly, hypoglycemia and inflammatory diseases resembling Sjögren syndrome. Our studies of this gene point to disruption of three important signaling pathways as the putative final effectors.

P11.113-S
An apparently balanced translocation in a boy with multiple congenital anomalies of the eye

M. M. Alwasiyah[1], *L. M. Ries*[2], *E. V. Semina*[3], *C. Trujillo*[4];
[1]*Aziziah Maternity & Children Hospital, Jeddah, Saudi Arabia,* [2]*Department of Pediatrics and Children's Research Institute at the Medical College of Wisconsin and Children's Hospital of Wisconsin, Milwaukee, WI, United States,* [3]*Department of Pediatrics and Cell Biology, Neurobiology and Anatomy and Children's Research Institute at the Medical College of Wisconsin and Children's Hospital of Wisconsin, Milwaukee, WI, United States,* [4]*Erfan & Bagedo Hospital, Jeddah, Saudi Arabia.*

A 2 year old boy product of the 1st pregnancy was referred for karyotype testing because of multiple congenital anomalies, including bilateral cataracts diagnosed at birth, hypospadias and right cryptorchidia, hypotonia and failure to thrive Glaucoma was diagnosed at 3 months of age. MRI showed generalized brain atrophy. At one year of age developmental delay was noted and height, weight, and head circumference had fallen below the 3rd percentile. There was no family history of similar findings and the parents are first cousins. Karyotype showed an apparently balanced translocation 46,XY,t(3;6)(p25;q15). Karyotype of both parents was normal. Further testing for genes involved in anterior segment dysgenesis and/or congenital cataracts including PITX3, FOXE3, and CYP1B1 was done and all were negative for mutations. Sequencing the breakpoints of the translocation did not find genes at or near the direct breakpoint. Whole exome sequencing ruled out mutations in known cataract genes, but identified a homozygous mutation in the PAH gene (NM_000277:c.1139C>T, p.(Thr380Met). This mutation has been reported to cause Hyperphenylalaninemia (HPA) when combined with another deleterious mutation. Homozygosity for this mutation has not been reported previously, to our knowledge. We are confirming this result by Sanger sequencing and analysis of parental samples is ongoing. We are still investigating the link between HPA/PKU and congenital cataracts (and

reviewing variants in other genes in the WES data), but untreated PKU has been clearly linked to microcephaly and learning disabilities.

P11.114-M
New severe learning difficulty syndrome with skeletal features due to de novo missense mutation in the polycomb group ring finger protein 2 (*PCGF2*) gene

P. D. Turnpenny[1], *M. Wright*[2], *M. Sloman*[3], *D. D. D. Study*[4];
[1]Clinical Genetics, Royal Devon & Exeter Hospital, Exeter, United Kingdom, [2]Newcastle upon Tyne Hospitals, Newcastle, United Kingdom, [3]Molecular Genetics, Royal Devon & Exeter Hospital, Exeter, United Kingdom, [4]Wellcome Trust Sanger Institute, Cambridge, United Kingdom.

Two UK patients, each known to a clinical genetics service (Northern, Peninsula), were independently recruited to the Deciphering Developing Disorders (DDD) study, Cambridge. Patient 1 presented with poor weight gain and hypotonia in infancy, and subsequently global developmental delay. He had relative macrocephaly, enlarged cerebral ventricles, and normal myelination on brain MRI at 17 months. At 2½ years a skeletal survey revealed delayed epiphyseal ossification, particularly carpal bones, pseudo-epiphyses of many metacarpals, hypoplasia of L1, and thoraco-lumbar kyphosis. He has severe intellectual disability, no clear speech, drools heavily, has short tapering fingers and valgus deformity of the feet, and multiple pigmented naevi. Patient 2 presented at 6 months of age with poor weight gain. Subsequently her development was delayed with a moderate learning disability. She has relative microcephaly; an MRI scan performed at 7 years of age was normal. She developed constipation which was sufficiently severe to require an ACE procedure aged 12 years. She has fine hair, a long face with high arched palate and prognathism, long thin hands and fingers and mild generalised joint hypermobility. She does not have spine or foot abnormalities. Both subjects were found through DDD to have a de novo p.P65L (c.194C>T) missense variant in exon 4 of the *PCGF2* gene (17q12). Previously, *PCGF2* had no associated human phenotype. This identical de novo finding in 2 subjects is strong evidence for a new syndrome associated with a novel morbid gene, despite some divergence of clinical features.

P11.116-M
A nonsense mutation in BMP2 causes a syndromic form of Pierre Robin sequence

M. Vincent, *P. Joset, S. Papuc, M. Papik, R. Asadollahi, S. Azzarello-Burri, K. Steindl, A. Rauch;*
Institute of Medical Genetics, University of Zürich, Zürich, Switzerland.

Pierre Robin sequence is a disorder of craniofacial development comprising mandibular hypoplasia, cleft palate and glossoptosis. It can be isolated or associated with other malformations in a syndromic form, with a high genetic heterogeneity.
Here we report on a 7 years old boy presenting with Pierre Robin sequence, developmental delay, microcephaly, growth retardation, brachydactyly, deep palmar flexion creases and supra-ventricular tachycardia. Exome sequencing revealed the heterozygous, nonsense mutation c.460C>T (p.R154X) in exon 2 of BMP2 (Bone morphogenetic protein 2). Microdeletions at 20p12 encompassing BMP2 have been described in 3 other patients with similar phenotype, and have been also implicated in Wolff-Parkinson-White syndrome. Duplications of the region located downstream the BMP2 gene and containing a cis-acting enhancer element were described in patients with brachydactyly type A2. BMP2 is also known to stimulate SOX9 expression, and contribute to the postnatal development of normal growth plate and articular cartilages.
We suggest that BMP2 causes a new syndromic form of Pierre Robin sequence, associating intellectual disability, microcephaly, growth retardation, brachydactyly and risk of heart rhythm disorder.

P11.117-S
Functional validation of a novel germline mutation in the *PIK3CA* gene in a child without the typical segmental overgrowth

N. Di Donato[1], *A. Rump*[1], *G. Mirzaa*[2], *D. Alcantara*[3], *E. Schrock*[1], *W. Dobyns*[2], *M. O'Driscoll*[3];
[1]Institut für Klinische Genetik, Technische Universität, Dresden, Germany, [2]University of Washington, Seattle Children's Research Institute, Seattle, WA, United States, [3]Genome Damage & Stability Centre, University of Sussex, Brighton, United Kingdom.

We report on a 6 year boy with body overgrowth at birth, megalencephaly and motor delay, who is a carrier of a de novo heterozygous mutation in PIK3CA (NM_006218.2):c.335T>A, p.Ile112Asn. The mutation appeared germline in peripheral blood, buccal swabs and skin fibroblasts (Sanger sequencing); it has not been observed in published PIK3CA-related segmental overgrowth patients. Phosphatidylinositol-3,4,5-triphosphate immunostaining of patient cells and Epidermal Growth Factor-mediated PI3K-AKT-mTOR pathway stimulation proved that p.Ile112Asn leads to increased PI3K activity. The p.Ile112Asn change lies adjacent to the p85 (PIK3R2) regulatory binding domain on the p110 (PIK3CA) catalytic subunit of PI3K. Altered stoichiometry within the p85-p110 complex could underlie the hyperactive PI3K-AKT-mTOR signaling in this instance. Further experiments to investigate this are currently ongoing.
Interestingly, the phenotype of this child appears unique comparing to published PIK3CA-related segmental overgrowth patients. The boy did not show somatic asymmetry, focal overgrowth, capillary malformations, epidermal nevi, or digital abnormalities. His brain MRI at 6 years showed a thick corpus callosum, large cerebellar vermis and possible restricted right posterior persiylvian polymicrogyria but his cerebral cortex otherwise looked largely normal.
Our observation adds an isolated megalencephaly with mild body overgrowth to the PIK3CA-associated clinical spectrum. The identified novel mutation is among the few known germline PIK3CA mutations. We demonstrate robust and rapid functional assays to enable interrogation of PI3K-activity in this context from patient-derived cells. The constitutional distribution of PIK3CA mutation might be of prognostic advantage regarding somatic overgrowth, cortical malformations and consecutively favorable development. However, this hypothesis needs further assessment.

P11.118-M
A clinical score system as useful tool in selecting subjects with clinical presentation in the spectrum of Pitt-Hopkins syndrome

M. Zollino[1], *S. Ricciardi*[1], *D. Orteschi*[1], *M. Murdolo*[1], *R. Tenconi*[2], *A. Baroncini*[3], *B. Dallapiccola*[4], *E. Ponzi*[1], *A. Asaro*[1], *E. Mercuri*[5], *G. Marangi*[1];
[1]Institute of Medical Genetics, Catholic University, Roma, Italy, [2]University of Padova, Padova, Italy, [3]Medical Genetics Unit, ASL of Imola, Imola, Italy, [4]Bambino Gesù Children's Hospital and Research Institute, Roma, Italy, [5]Department of Paediatric Neurology, Catholic University, Roma, Italy.

Pitt-Hopkins syndrome (PTHS) is characterized by ID, typical facial gestalt, and additional features, including breathing abnormalities.
The overlapping phenotype of severe ID, epilepsy, and constipation makes it difficult to differentiate the PTHS phenotype from that of Angelman (AS), Rett (RTTS), and Mowat-Wilson (MWS) syndrome. However comprehensive analysis of many patients led us to define a checklist of the most consistent phenotypic manifestations of this condition, and to suggest a clinical score ≥13 as tool for enrolling patients into *TCF4* analysis first.
We analyzed a total of 176 patients, of whom 22 had a proven mutation in *TCF4* (and on average a clinical score of 14-15), and 154 did not. Of them, 53 were selected by means of the same score system, as having a clinical presentation within PTHS. These 53 subjects were grouped in two clinical categories:
1) Group A (tot 11), clinical score > 13 and facial phenotype highly consistent with PTHS;
2) Group 2 (tot 42), clinical score of 10-11; 2A (tot 16): PTHS-like phenotype that appears homogenous to large extend to each other; 2B (tot 11): PTHS-like phenotype that appear different from 2A, but homogenous as well; 2C (tot 15): with certain clinical heterogeneity. We performed semiquantitative analysis of *TCF4* mRNA in 5 subjects in Group A, and found that it was significantly increased in two. Sequencing of the promoter region and UTRs regions is ongoing. Strategies and preliminary results of the diagnostic approach in the remaining patients, including saliva analysis and exome sequencing, are presented.

P11.119-S
Xq22.1-q22.3 deletion including PLP1 gene in a girl with global developmental delay, hypotonia, and brain retarded myelination

L. Sinibaldi[1], *L. Bernardini*[2], *M. Giuffrida*[2], *B. Torres*[2], *A. Novelli*[2], *A. Ferraris*[1];
[1]Clinical Genetics Unit, Mendel Laboratory, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo (FG), Italy, [2]Cytogenetics Unit, Mendel Laboratory, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo (FG), Italy.

We describe the case of a 3 years 6/12 old girl presenting marked developmental delay, hypotonia, and dysmorphisms. She was born at term from apparently healthy, non consanguineous parents. Pregnancy and delivery were uncomplicated except for polyhydramnios. Neonatal growth parameters were in the normal range. She showed right choanal stenosis and velopharyngeal incompetence which made feeding difficult. A brain magnetic resonance imaging at age 14 months showed a retarded myelination in parietal and periventricular areas.
At last evaluation general hypotonia was still present, with global developmental delay and absent speech. Weight and height were in the upper part of the normal range, while cranial circumference was slightly under the average. She presented facial and skeletal dysmorphisms, including depressed nasal bridge, alternating esophoria, protruding tongue, pectus excavatum, hyperextensible ligaments, thoracic kyphosis, bilaterally recessed IV toes, broad halluxes.

Array-CGH analysis disclosed a de novo 5.6 Mb microdeletion of Xq22.1-q22.3 chromosomal region. The pattern of X-inactivation was markedly skewed. The microdeleted region includes 52 genes 3 of which are OMIM morbid: PLP1, RAB40AL and SERPINA7.
There have been only a few reports of whole PLP1 gene deletions. PLP1 mutations have been associated with a continuum of neurologic phenotypes from severe forms of Pelizaeus-Merzbacher disease (PMD) to spastic paraparesis. Null alleles tend to associate with milder PMD features in hemizygous males but higher rate of neurological manifestations in heterozygous females. PLP1 haploinsufficiency could explain at least part of the girl's neurological phenotype since it encodes for a primary constituent of myelin in the brain.

P11.120-M
Dissecting the genetic bases of Poland Syndrome by exome sequencing

Poland syndrome (PS) is a congenital disorder presenting with agenesis/hypoplasia of the pectoralis major muscle variably associated with thoracic and/or upper limb anomalies. Incidence was reported to be 1/30000 births, with higher prevalence in males. Most cases are sporadic. Familial recurrence has been observed but PS genetic etiology remains to be clarified. Since PS involved structures may originate from the same embryonic tissues, genes controlling cell proliferation, migration, and differentiation of these tissues might be involved. Alternatively, one common assumption is that PS may origin from an embryonic vascular insult indicating genes controlling vessels development as indirectly involved.
We recruited a large cohort of PS patients (more than 250, about 10% familial). Karyotype analysis in 128 patients did not show any relevant alterations. ArrayCGH revealed the presence of chromosome anomalies in 19 out of 119 analyzed patients (10 duplications and 9 deletions); bioinformatic data analysis indicates gene enrichment in different pathways including those involved in cell-cell adhesion and muscle structure development. We selected 3 sporadic and 6 apparently dominant familial cases for whole-exome sequencing. Patients' parents, affected and non-affected siblings to a total of 31 subjects were sequenced. Preliminary data from one trio confirm involvement of genes regulating cell-cell and cell-matrix interaction and also indicate a possible contribution by genes implicated in vascular development. Analysis of other sequenced families is now ongoing in order to check sharing and segregation of newly identified variants between different patients, and to clarify their role in pathogenesis of PS.

Noonan syndrome (NS) is a genetically heterogeneous developmental disorder characterized by reduced growth, dysmorphic facial features, congenital heart defects, skeletal and hematological anomalies, and variable cognitive deficits. NS is caused by aberrant signaling through the RAS-MAPK cascade, and we previously identified *PTPN11* as the major gene underlying this condition. *PTPN11* encodes SHP2, an SH2 domain-containing protein tyrosine phosphatase functioning as a signal transducer that positively modulates RAS function. Mutations in the same gene are implicated in LEOPARD syndrome (LS), a disease clinically related to NS, or contribute to leukemogenesis. Here, we explored further the molecular spectrum of germline *PTPN11* lesions and their associated phenotype. Mutation scanning of the entire *PTPN11* coding sequence was performed in large NS/LS cohorts collected in the frame of the NSEuroNet Consortium. Among the 452 mutation-positive subjects, 68 different variants deemed to be of pathological significance, including 12 novel missense changes and 2 in-frame indels, were identified. Besides the previously characterized mutations destabilizing SHP2's inactive state or increasing binding to phosphotyrosyl-containing partners, a novel mutation cluster was recognized. Specifically, eleven changes affecting Leu^{261}, Leu^{262} and Arg^{265} were identified in ten unrelated subjects with clinical features fitting NS. Biochemical and structural characterization of these mutants provided novel insights on disease pathogenesis. Finally, these data and published records were used to define more accurately the mutational spectrum of germline and somatic *PTPN11* mutations in human disease.

P11.122-M
A paternally inherited interstitial deletion of 15q11.2 causing clinical features of PWS: refinement of the PWS-IC

T. N. Nelson[1], *L. Brown*[1], *K. Schlade-Bartusiak*[1], *E. Gagne*[1], *J. Livingstone*[1], *S. Anson*[2], *L. Armstrong*[1];
[1]*University of British Columbia, Vancouver, BC, Canada,* [2]*Children's & Women's Health Centre of British Columbia, Vancouver, BC, Canada.*

Imprinting occurs on chromosome 15q11.2-q12 by differential methylation of genes on the paternal and maternal chromosomes. Prader-Willi syndrome (PWS) is caused by the absence of paternally imprinted genes at chromosome 15q11.2, whether by deletion, uniparental disomy, or imprinting center (IC) defect. The PWS-IC is defined by the 4.1 kb shortest region of overlap (SRO) of reported deletions, which includes the promoter and exon 1 of the SNRPN gene. Mutation of the PWC-IC blocks the switch from maternal-to-paternal imprint within the male germ line.
We present an infant with a classical clinical presentation of PWS. As a neonate, he was hospitalized for severe hypotonia and required tube feeding. He has bitemporal narrowing, and typical facial features and hand morphology. Methylation-sensitive (MS) PCR across the differentially methylated CpG island of SNRPN showed amplification of only the maternal-specific product. High-resolution chromosome microarray analysis detected a copy loss at 15q11.2 which overlaps the 4.1 kb PWS-SRO; this copy loss is at least 1.6 kb in size and may be as large as 5.8 kb. MS-MLPA confirmed the deletion and showed a methylation pattern identical to that seen in other individuals affected with PWS due to paternal deletion. Familial studies showed that the father carried the mutation but the paternal grandparents did not, consistent with a *de novo* deletion occurring on the grand-maternal allele. To the best of our knowledge, this is the smallest copy loss causing PWS reported to date, and further refines the PWS-IC to a 1.8 kb region.

P11.123-S
Clinical phenotypes in patients with genomic anomaly detected by aCGH

D. Durovcikova[1,2], *M. Hikkelova*[3], *E. Cmelova*[4], *S. Machalova*[5], *A. Gencik*[6], *J. Simko*[3];
[1]*Slovak Medical University, Bratislava, Slovakia,* [2]*Dept Med Genet, University Hospital, Bratislava, Slovakia,* [3]*Gendiagnostica, Bratislava, Slovakia,* [4]*Slovak medical university, Dept.Med.Genet,University Hospital, Bratislava, Slovakia,* [5]*Slovak Medical University,Dept Med Genet, Bratislava, Slovakia,* [6]*Medgene, Bratislava, Slovakia.*

High resolution molecular karyotyping has been implemented recent years in our group of 11 outpatients as a diagnostic test for nonsyndromic dysmorphia or developmental delay. Genomic imbalance in different chromosomal region was detected in seven cases. Principally there were detected deletion/duplication in the range of 110 kb to 2,8 Mb. Clinical features and aCGH data will be summarised. In two patients was found a genomic rearrangments in more than one region. In one child patient with skeletal dysplasia like phenotype was identified a duplication at three different chromosomes. Genotype/Phenotype correlation in our patients with different genomic anomaly as a deletion/duplication has a direct impact on a health care managment including reproductive outcome in the family. An assesment of significance of genomic imbalance along with the incidence of benign CNV in the light of acquiring new knowledge is still a considerable dynamic process A broadening spectrum of aCGH data, clinical phenotypes in probands and their parents will be provide in the registry. Many of them may have a important role in creating potentional new nomenclature for this extremely rare genomic diseases.

P11.124-M
An alternate unbalanced recombinants of chromosome 10 due to familial pericentric inversion

Ž. Čiuladaitė[1,2], *O. Liaugaudienė*[1], *A. Utkus*[1,2], *V. Kučinskas*[1,2];
[1]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [2]*Centre for Medical Genetics at Vilnius University Hospital Santariškių Klinikos, Vilnius, Lithuania.*

13 years old female was referred for genetic counseling because of intellectual disability (ID), short stature, microcephaly, dysmorphic features (low frontal hairline, left convergent strabismus, wide nose root, abnormal shape of the pinnas, flat philtrum, large mandible, hypodontia, malocclusion of teeth), club-foot, partial syndactyly of II-III th toes. A sister of proband`s mother presented with ID, delay of speech, club-foot and additional features not common to proband: normal stature, obesity, short philtrum, high narrow palate, crowded teeth, IIth toes overlapping thumbs. Mother's second sister died in infancy because of multiple congenital anomalies. Array-CGH of proband`s DNA revealed trisomy of the distal bands of chromosome 10 short arm (10pter-->10p15.1) and monosomy of the distal bands of chromosome 10 long arm (10q26.12-->10qter). Subtelomeric FISH analysis confirmed a rearranged chromosome 10 [rec dup(10p] due to a large, maternal pericentric inversion. A reverse segmental imbalance [rec dup(10q)] was detected in proband`s aunt by subtelomeric FISH. The high frequency of recombinants in this family and data from literature review suggests a high recurrence risk in similar cases with large pericentric inversions comprising almost entire chromosomes. The research leading to these results was funded by the Lithuanian-Swiss cooperation programme to reduce economic and social disparities within the enlarged European Union under project agreement No. CH-3-ŠMM-01/04, UNIGENE project.

P11.125-S

Functional characterization of L440Xfs mutation in the thyroid hormone receptor beta (TRβ) in an individual with RTH syndrome

M. C. Lozano[1], *L. Mejía*[2,3], *P. Durán*[4], *M. C. Lattig*[1];
[1]Universidad de Los Andes, Bogotá, Colombia, [2]Fundación Valle del Lili, Cali, Colombia, [3]Clínica Infantil Club Noel, Cali, Colombia, [4]Fundación Cardioinfantil, Bogotá, Colombia.

Resistance to thyroid hormone is an autosomal dominant disorder that affects 1 in every 40,000 births. It is characterized by reduced soft tissue responsiveness to thyroid hormone, with increased levels of T4 and T3 and non-suppressed thyroid hormone (TSH), due to mutations present in the thyroid hormone receptor β gene (TRβ), particularly in its T3 binding domain. The clinical phenotype varies both between different families and between affected family members. Individuals with RTH can have variable resistance in different tissues, as a consequence of mixed features of hypo- and hyperthyroidism. Our goal was to assess whether there was a functional alteration due to the mutation L440Xfs in TRβ gene that may generate RTH in our patient. In this study, we performed molecular and functional characterization of the L440Xfs mutation found in a male patient, who was diagnosed with RTH at 15 months of age. The patient harbors a new mutation in exon 10 of the TRβ gene, which consists of a deletion of a cytosine at nucleotide 1609 in the position 440, leading to a stop codon. The mutation was found in neither his parents nor his two healthy sisters, indicating a *de novo* mutational event. Transfection studies showed that the mutant TRβ was unable to carry out the transcription of luciferase gene in the presence of T3. Therefore, it is likely that the impaired receptor generates the severe RTH phenotype in our propositus.

Restrictive dermopathy (RD) is a very rare, lethal genetic condition with peculiar phenotypic, histologic and genetic characteristics. The first case we describe was clinically diagnosed after death and confirmed thanks to precise histological and molecular characterization. The fetus was stillborn at 31+1 weeks of gestation by cesarean section. He did not show any spontaneous respiratory activity at birth nor after cardiopulmonary resuscitation. Post mortem, clinical examination showed multiple joint contractures and peculiar facial features like thick hair, absent eyelashes and eyebrows, hypertelorsim, small nose, small mouth in the "O" position with thin lips, micrognathia, low-set ears. The skin was thin, erythematous and translucent with evident superficial vessels. Fissures and erosions were evident in particular in the axillary and inguinal folds, nails were long. It was hypothesize the diagnosis of RD, confirmed by the microscopic examination of the skin. Molecular analysis performed on fetal DNA, showed a homozygous duplication in ZMPSTE24 gene, already described as causative for RD. The second patient is a SGA boy, born at 32 weeks of gestation by urgent cesarean section because of premature membrane rupture and pathologic CTG. Apgar was 3-0 and cardiopulmonary resuscitation was effective only after orotracheal intubation because of choanal stenosis, midface hypoplasia, micrognathia, microstomia and tight trismus. At this moment, spontaneous breathing is maintained through respiratory support. The clinical diagnose of RD is supported by the typical facial dysmorphisms, multiple joint contractures, arthrogryposis, thin, tense and translucid skin with some erosions, long nails. Molecular characterization is still in progress.

P11.127-S

Rubinstein-Taybi syndrome lymphoblastoid cells show impaired DNA damage response to oxidative stress

I. Dutto[1], *M. Tillhon*[1], *C. Gervasini*[2], *M. Savio*[3], *L. Larizza*[2], *E. Prosperi*[1];
[1]CNR Institute of Molecular Genetics, Pavia, Italy, [2]Medical Genetics Unit, Dept. Health Sciences, Milan University, Milano, Italy, [3]Pathology Unit, Dept. Molecular Medicine, University of Pavia, Pavia, Italy.

The Rubinstein-Taybi syndrome (RSTS) is a genetic disorder associated with growth defects, intellectual disability, and increased risk of tumors. About 60% of RSTS individuals carry heterozygous mutation/deletion of CREBBP gene, while ~3-8% of RSTS are caused by mutations in the EP300 gene. CREBBP and p300 proteins play a key role in many aspects of DNA metabolism, such as DNA repair. However, the efficiency of DNA damage response (DDR) in RSTS is not yet elucidated. Here, we have investigated DDR in lymphoblastoid cell lines from RSTS patients carrying monoallelic deletion, or mutations of CREBBP gene. RSTS cells showed signs of histone H2AX phosphorylation, indicating an endogenous DNA damage. In addition, all RSTS cell lines tested were more sensitive to treatment with the oxidative agent KBrO3. No significant differences were observed in protein expression levels of PCNA, and DNA repair proteins, such as XP proteins, PARP-1, XRCC1 and DNA polymerase β. The analysis of the recruitment of DNA repair proteins (PCNA, DNA polymerase β, XRCC1) to DNA damage sites, suggests that in RSTS the DNA repair process is slowed or impaired. Preliminary results on the efficiency of DNA repair, as assessed by the Comet test, has suggest a delayed kinetics in the repair of oxidative lesions in RSTS cells, in particular at the level of DNA incision. These results suggest that RSTS cells show a reduced efficiency in DNA repair, explaining the greater sensitivity to oxidative DNA damage, and accounting for the increased susceptibility to cancer of RSTS patients.

Schinzel-Giedion syndrome was first described in 1979, and is characterized by typical facial gestalt, severe developmental delay, frequent epilepsy and various malformations (urinary tract, genitalia, heart and skeletal). The reported cerebral malformations are ventriculomegaly, thin or absent corpus callosum, cortical atrophy, gyration anomalies. Hypoplastic pons was found in 2 patients.
In 2010, SETBP1 gene was identified as responsible for Schinzel-Giedion syndrome, with identification, by exome, of de novo missense mutations, some recurrent, all localized in the SKI oncogene homologous domain.
We present 5 novel patients with Schinzel-Giedion syndrome (2 girls and 3 boys) with mutation in SETBP1 (proven de novo for 3). Two mutations were previously reported (c.2602G>A, c.2608G>A) and the 3 others were novel (c.2607C>A, c.2608G>T, c.2606G>C). All patients had typical facial gestalt, severe developmental delay, epilepsy, genitalia anomalies. Hydronephrosis was present in 4 patients, and the 5th patient had coralliform kidney stones with recurrent infections. Cerebral MRI showed constant corpus callosum anomalies, and frequent cortical atrophy, ventricular dilatation, septal rupture. Two patients had gyration anomalies. Four patients displayed similar posterior fossa anomalies with hypoplastic pons and enlarged medulla oblongata, 3 patients had dysplastic cerebellar hemispheres. Atrophic caudate nuclei was noted in 4 patients.

These novel cases further delineate the cerebral spectrum of malformations in Schinzel-Giedion syndrome, in particular with similar posterior fossa anomalies.
The 3 novel mutations, as all the previously described mutations, are localized in the known mutational hotspot.

P11.129-S
Towards a better understanding of *de novo* germline mutations in *SETBP1* in Schinzel-Giedion syndrome

R. Acuna-Hidalgo[1], *P. Deriziotis*[2], *B. W. van Bon*[1], *M. Chaisson*[3], *M. Malig*[3], *S. E. Fisher*[2], *J. A. Veltman*[1], *E. E. Eichler*[3], *A. Hoischen*[1];
[1]*Department of Human Genetics, Radboud university medical center, Nijmegen, Netherlands,* [2]*Department of Language and Genetics, Max Planck Institute for Psycholinguistics, Nijmegen, Netherlands,* [3]*Department of Genome Sciences, University of Washington, Seattle, WA, United States.*

Schinzel-Giedion syndrome (SGS) is a rare and severe developmental disorder characterized by malformations in multiple organ systems. Exome sequencing recently identified the cause of SGS as *de novo* germline mutations clustering within a 12-bp exonic region in *SETBP1*. Mutations in this *SETBP1* hotspot are presumed to be gain-of-function mutations which disrupt a degron (a consensus motif for protein degradation), disturbing normal SETBP1 proteolysis. Interestingly, somatic mutations in this hotspot have also been found in leukemic cells and shown to increase cell proliferation in this context.
We have collected clinical information and samples from over 25 SGS patients, which to our knowledge constitutes the largest cohort of SGS patients yet. To better understand germline *de novo* mutations in *SETBP1*, we investigated the parental origin of the allele in which these mutations occur in SGS. Using a combination of long range PCR and single molecule real time sequencing (Pacific Biosciences), we determined the parent of origin for four out of five trios analyzed. In three out of four cases, the *de novo* mutation in *SETBP1* occurred in the paternal allele and only in one in the maternal allele. Additionally, we examined the molecular and cellular consequences of *SETBP1* mutations in the context of SGS. When compared to controls, fibroblast and lymphoblastoid cell lines of SGS patients have alterations in downstream targets of *SETBP1*, such as higher levels of SET protein and deregulated gene expression.
Our studies provide insight into the occurrence and molecular consequences of *de novo* germline *SETBP1* mutations causing SGS.

P11.130-M
5p15.33-31 deletion and unilateral open lip schizencephaly: causal or casual association?

A. V. Gulino[1,2], *G. Traficante*[1], *I. Sani*[3], *S. Guarducci*[3], *A. Petracca*[1], *S. Bargiacchi*[1], *C. Barba*[4], *M. Falchi*[4], *R. Guerrini*[4], *S. R. Giglio*[1,3];
[1]*Department of Clinical and Experimental Biomedical Sciences, University of Florence, Florence, Italy,* [2]*Paediatric Department, Assisi Hospital, Assisi, Italy,* [3]*Medical Genetics Unit, Meyer Children's University Hospital;, Florence, Italy,* [4]*Department of Neurology, Meyer Children's University Hospital, Florence, Italy.*

We report on a case of a 3 year-old girl, with left hemiplegia, psychomotor delay and high pitched neonatal crying, epilepsy with MRI evidence of right open-lip schizencephaly; CGH array analysis disclosing a paternal inherited 5p complex rearrangement consisting of a 7.6 Mb deletion (del5p15.33-31) and a 2,6 Mb duplication (dup5p15.31). Indeed, the 5p15.2 critical Cri du Chat (CdC) region is spared and accordingly our patient does not present the typical dysmorphic and severe developmental features of CdC syndrome.
The proband's father has a high pitched voice, a history of hyperactivity and poor school performances and normal EEG. Intrafamilial phenotype variability is not uncommon in contiguous gene syndromes and it can be explained by differences in modifying genes and in critical allele polymorphisms.
Schizencephaly is a full-thickness cleft within the cerebral hemispheres, that can result from disruption or malformation. It has never been reported before in patients with 5p- syndrome, who typically show a variable degree of hypoplasia, especially of subtentorial structures.
Based on the already published phenotypic data and CNV databases as well as on the increasing knowledge on the function of the genes located in the deleted fragment, we discuss the genotype-phenotype correlation in our patient and the consequence of haploinsufficiency of NSUN2 in determining speech delay and hyperactivity, and of ADAMTS16 in causing abnormal larynx cartilages development. We also speculate on a potential pathogenic mechanism linking loss of Iroquois homeobox gene cluster and/or TPPP leading to schizencephaly.

P11.132-M
Novel Deletion within the translated sequence of the SHOX gene leading to Leri-Weill Syndrome with emphasizing severity in females

G. Tanteles, **A. Alexandrou**, *I. Alexandrou, C. A. Sismani;*
The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

Leri-Weill dyschondrosteosis (LWD) is a dominantly inherited genetic disorder characterized by short stature, mesomelia and Madelung wrist deformity. The LWD is caused by haploinsufficiency of the Short Homeobox containing gene (SHOX), located in the 2.6 Mb pseudoautosomal (PAR1) region. At the heterozygous level most mutations found are of different size deletions, point mutations within the coding sequence or mutations on regulatory enhancers downstream of the SHOX gene. We present the clinical and molecular data of a three generation family with LWD. The index patient is a 43 year old female with disproportionate short stature, reduced arm span to height ratio (particularly mesomelic shortening), a muscular body habitus and no evidence of a classic Madelung deformity. We report for the first time a novel 15kb deletion detected by microarray-CGH using a chromosome X exon-specific array (OGT) in the index patient. The deletion resides in the coding region of the SHOX gene, includes exons 3-6 containing the homeodomain region. RT-PCR studies confirmed the deletion and revealed the same 15 kb deletion in her sister, father and son. The youngest male member of the family has a very mild form of LWD, a phenomenon previously observed, that SHOX deficiency is more pronounced in females than in males and it can also exhibit inter-familial and intra-familial variable expressivity. Extended family studies (paternal side) have identified another 5 members to carry the deletion. Detailed clinical evaluation of these family members is ongoing which will shed more light in the phenotypic effect of this deletion.

P11.133-S
SKI gene analysis clarifies the diagnosis in cases suspected of Shprintzen-Goldberg syndrome

S. Krüger[1], *L. Graul-Neumann*[2], *M. Grossmann*[1], *A. Bier*[1], *S. Tinschert*[3,4], *P. N. Robinson*[5], *D. Müller*[6], *B. Albrecht*[7], *J. Plaschke*[1], *D. Horn*[5];
[1]*Gemeinschaftspraxis für Humangenetik, Dresden, Germany,* [2]*Ambulantes Gesundheitszentrum der Charité – Universitätsmedizin Berlin, Berlin, Germany,* [3]*Division für Klinische Genetik an der Medizinischen Universität Innsbruck, Innsbruck, Austria,* [4]*Institut für Klinische Genetik, TU Dresden, Dresden, Germany,* [5]*Institut für Medizinische Genetik und Humangenetik der Charité, Berlin, Germany,* [6]*Institut für Humangenetik, Universitätsklinikum Leipzig, Leipzig, Germany,* [7]*Institut für Humangenetik, Universitätsklinikum Essen, Essen, Germany.*

Shprintzen-Goldberg syndrome (SGS) is a genetic disorder characterised by craniosynostosis, dysmorphic facial features, a marfanoid habitus and cardiovascular, connective tissue, neurological, and skeletal anomalies. The phenotype overlaps with Marfan (MFS) and Loeys-Dietz syndrome (LDS). Recently, mutations in *SKI* have been described as causative for SGS. All mutations are located in the SMAD binding or the DHD domain of the SKI protein, a repressor of TGFß-activity. TGFß signaling is also affected in MFS and LDS explaining some of the shared features.
Here we report on the *SKI* analysis in four patients suspected of SGS (Table, n/a no information available). Two of them (T7178, T7424) have previously been described (Robinson et al. Am J Med Genet A. 2005;135:251-62).

Patient ID	T6857	T7178	T7386	T7424
Sex, Age	female, 2y	male, 28y	male, 46y	male, 29y
SKI sequence variant	c.95T>A (p.Leu32Gln)	c.100G>T (p.Gly34Cys)	none	c.185C>G (p.Ala62Gly)
Craniosynostosis	+	n/a	n/a	-
Dolichocephaly	+	+	+	+
Hypertelorism	+	+	+	-
Down slanting palpebral fissures	+	-	-	-
Exophthalmos	+	+	-	-
High arched or cleft palate	+	+	+	+
Micrognathia or retrognathia	+	+	+	+
Low set posteriorly rotated ears	+	+	+	+
Arachnodactyly	+	+	+	-
Camptodactyly	+	-	-	-
Scoliosis	-	+	-	-
Pectus deformity	-	+	+	-
Joint hypermobility	+	+	+	+
Mitral valve prolapse	-	-	-	n/a
Aortic dilatation	-	-	-	n/a
Hernias	-	+	-	-
Muscular hypotonia	+	+	-	+
Developmental delay	+	+	+	+

Sanger sequencing of the whole coding region of *SKI* (NM_003036.3) revealed heterozygous mutations in two patients. The mutation c.100G>T (p.Gly34Cys), but not the sequence alteration c.95T>A (p.Leu32Gln) has already been described as a pathogenic mutation for SGS. However, the description of two other pathogenic missense mutations in the same codon 32 within the SMAD binding domain as well as *in silico* predictions underline the role of the sequence alteration c.95T>A as a pathogenic mutation. Furthermore, we identified an unclassified heterozygous variant, c.185C>G (p.Ala62Gly) in the third patient (Table).

In conclusion, the molecular analysis of *SKI* should be considered to differentiate between marfanoid phenotypes such as MFS, LDS and SGS.

P11.134-M
Submicroscopic genomic alterations detected by array CGH analysis in a cohort of patients with Silver Russell syndrome found negative to classical genetic and epigenetic tests

M. Crippa[1], C. Picinelli[1], S. Galletti[1], A. Sironi[1], L. Calzari[1], C. Castronovo[1], M. Cisternino[2], G. B. Ferrero[3], A. Riccio[4], A. Selicorni[5], M. T. Bonati[6], S. Russo[1], L. Larizza[1,7], **P. Finelli**[1,8]*;*
[1]Laboratory of Medical Cytogenetics and Molecular Genetics, IRCCS Istituto Auxologico Italiano, Milano, Italy, [2]Department of Pediatrics, IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy, [3]Department of Pediatrics, University of Torino, Torino, Italy, [4]Department of Environmental, Biological and Pharmaceutical Sciences and Technologies, Second University of Naples, Caserta, Italy, [5]Department of Pediatrics, University of Milano Bicocca, Hospital S. Gerardo, Monza, Italy, [6]Clinic of Medical genetics, IRCCS Istituto Auxologico Italiano, Milano, Italy, [7]Division of Medical Genetics, Department of Health Sciences, University of Milan, Milano, Italy, [8]Department of Medical Biotechnology and Translational Medicine, University of Milan, Milano, Italy.

Silver Russell syndrome is characterized by pre- and postnatal growth retardation, variable facial dysmorphisms, clinodactyly of the fifth fingers, and sometimes asymmetry of face, trunk and extremities. Genetic and epigenetic aberrations on chromosomes 7 and 11 are commonly found in SRS, leaving out however, a fraction of up to 50% of cases with unknown genetic aetiology. A cohort of 32 clinically selected SRS patients, without detected genetic or epigenetic alterations was analyzed by high resolution array CGH analysis to identify possibly pathogenetic CNVs. Twenty-eight patients (87.5%) were found to carry one or more rare CNVs, according to the Database of Genomic Variants and, overall, 55 rare CNVs, 25 gains (45.5%) and 30 losses (54.5%) were identified. Inheritance, established for 36 of the identified rare CNVs, showed that 7 occurred de novo (19.5%). Interrogation of public databases allowed us to pinpoint genomic regions containing genes, either imprinted or not, that according to their function, appeared plausible candidates for SRS. Interestingly 4 CNVs span genomic regions already associated with growth defects, 3 CNVs contain known genes found altered in previously described SRS patients and 3 CNVs include genes implicated in growth control pathways not yet associated with SRS. These results confirm the genetic heterogeneity of SRS and the high percentage of potentially causative imbalances, attesting the wide clinical expressivity of patients with a phenotype strongly suggestive for this syndrome. Genome-wide scan is reconfirmed an appropriate and powerful tool to achieve a differential diagnosis between SRS and SRS-like patients.

P11.135-S
Mosaicism of the H19 hypomethylation in a patient with very low weight and severe insulin resistance

G. Traficante[1], *S. Romano[2], S. Russo[3], A. Petracca[1], S. Bargiacchi[1], E. Andreucci[2], S. Giglio[1,2], S. Stagi[4];*
[1]Department of Clinical and Experimental Biomedical Sciences, University of Florence, Florence, Italy, [2]Medical Genetics Unit, Meyer Children's University Hospital, Florence, Italy, [3]Department of Molecular Genetics, Auxological Institute, Cusano Milanino, Italy, [4]Department of Health Sciences, Meyer Children's University Hospital, Florence, Italy.

A 6-year-old boy, born to healthy non-consanguineous parents, presented a history of severe staturo-ponderal deficiency, bilateral cryptorchidism and hypogenitalism. The propositus was delivered at 38 weeks by cesarean section for intrauterine growth retardation (IUGR). Birth weight was 1400 g (-3SD), birth lenght 38 cm (-4SD) and OFC 32 cm (-2SD). He had moderately delayed developmental milestones, a poor appetite and feeding difficulties since the first year. Physical examination showed dysmorphic features suggestive of Silver-Russell Syndrome (SRS): triangular facies, relative macrocephaly with frontal bossing, prominent forehead, mild low-set prominent ears, micrognathia, downturned mouth, thin lips, fifth finger brachidactyly/clinodactyly. Psychomotor development was normal.
At 6 years he was 90 cm (-5.12 SD) tall and weighed 8,900 kg (-9.22 SD). His basal levels of free thyroxine, TSH, cortisol and coeliac disease screening were normal. Plasma concentrations of IGF-I and IGFBP-3 were low for age and sex (-2.30 and -1.95 SD). Growth hormone stimulation tests revealed a classic growth hormone deficiency. He also had severe insulin deficiency and normal glucose response after OGTT, negative diabetes autoantibodies and normal glycated haemoglobin, features not reported in association with SRS.
Molecular studies revealed a hypomethylation of the paternal H19/IGF2 Imprinting Control Region. Insulin like growth factor 2 (IGF2) is an imprinted gene, which has an important role in foetal growth. IGF2 is downregulated through hypomethylation of a differentially methylated region in SRS, characterised by growth restriction. Insulin metabolism abnormalities have never been described in SRS: could it be a specific manifestation of reduced IGF2 expression?

P11.136-M
Regulatory element deletion cause a down-regulation of *ZDHHC15* gene in a proband with Smith Magenis syndrome phenotype

C. Picinelli[1], I. Bestetti[1,2], S. Sirchia[3], **C. Castronovo**[1]*, L. Paganini[4], F. Menni[5], A. Selicorni[6], M. F. Bedeschi[7], L. Larizza[1,3], P. Finelli[1,2];*
[1]Laboratory of Medical Cytogenetics and Molecular Genetics, IRCCS Istituto Auxologico Italiano, Milano, Italy, [2]Department of Medical Biotechnology and Translational Medicine, Università degli Studi di Milano, Milano, Italy, [3]Medical Genetics, Department of Health Sciences, Università degli Studi di Milano, Milano, Italy, [4]Division of Pathology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [5]Pediatric Highly Intensive Care Unit, Department of Pathophysiology and Transplantation Università degli Studi di Milano Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [6]Clinical Genetics and Pediatrics Division, San Gerardo Hospital, Monza, Italy, [7]Medical Genetic Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy.

Here, we describe a boy aged 3 years who showed mild facial minor anomalies such as brachycephaly, square face, thick eyebrows, broad palate, generalized hypotonia, developmental delay, behavioural problems (self injury), sleep disorders and congenital heart defect.
Based on suspected Smith Magenis syndrome (SMS), chromosomal analysis was performed and showed a 46,XY karyotype. FISH analysis of the SMS locus at 17p11.2, as well as MLPA, mutational analyses and quantitative expression of the *RAI1* gene, gave normal results. High-resolution array-CGH analysis disclosed two rare maternal deletions at 4q35.2 and Xq13.3, both yet unreported in healthy subjects according to the Database of Genomic Variants. Whereas it is not possible to assign a pathogenetic role to the 4q35.2 deletion, the Xq13.3 loss of 54 kb involves a predicted conserved insulator that maps 29 kb far from the 5' end of the *ZDHHC15* gene. *ZDHHC15* acts as a palmitoyl-transferase in brain, and its null expression has been reported in a syndromic patient. We thus investigated in the patient's blood the causative role of the identified CNV on *ZDHHC15* by RT-qPCR. The *ZDHHC15* expression level was significantly reduced in the male proband compared to controls, whereas the expression level in the mother was within the control range.Our results suggest the involvement of *ZDHHC15* perturbation in the onset of the proband's phenotype and point to this gene, sharing interactors with *RAI1*, as a novel candidate gene for SMS.

P11.137-S
A novel NSD1 mutation in Sotos syndrome with constriction of vena cava

A. Bakken[1]*, C. F. Rustad[2], Ø. L. Holla[1], Ø. L. Busk[1], G. J. Braathen[1,3,4];*
[1]Department of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway, [2]Department of Medical Genetics, Oslo University Hospital, Oslo, Norway, [3]Head and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Norway, [4]Campus AHUS, Akershus University Hospital, University of Oslo, Oslo, Norway.

Background: Sotos syndrome, first described in 1964, is characterized by typical facial appearance, overgrowth (height and/or head circumference ≥2 SD above the mean), and sometimes other features such as learning disability behavioral problems, congenital cardiac anomalies, neonatal jaundice, renal anomalies, scoliosis, and seizures.
The occurrence of Sotos syndrome is 1 in 10,000 to 1 in 14,000 newborns. However, many cases are assumed to be undiagnosed.
Methods: Genetic analyses including karyotype, array Comparative Genomic Hybridization and exome High Throughput Sequencing (HTS) was performed in a two year old girl with an unknown syndrome.
Results: HTS analysis revealed a novel de novo nonsense mutation in the NSD1 gene.
Her facial appearance was consistent with Sotos syndrome whereas her associated balloon dilated vena cava inferior constriction has not previously been assigned to Sotos syndrome.
Conclusion: We describe a novel NSD1 nonsense mutation causing Sotos syndrome. To our knowledge, this is the first time a Sotos patient has presented with a vena cava constriction.

P11.139-S
Unbalanced translocation t(8;17)(q23;q24) in a patient with developmental delay and epilepsy

C. Pinato[1]*, C. Rigon[1], A. Friso[1], A. Volzone[2], E. Osanni[2], M. Cassina[1], L. Salviati[1], M. Clementi[1];*
[1]Department of Women's and Children's Health, University of Padova, Padova, Italy, [2]La Nostra Famiglia-IRCCS "E. MEDEA", Conegliano (TV), Italy.

We present a 2 year-old male patient with poor growth, developmental delay and epilepsy. He is the second-born child of healthy non-consanguineous parents, with an unremarkable family history. He was born at gestational week 40 after an uncomplicated pregnancy. Seizures appeared at 16 months and the EEG revealed focal abnormalities in the left frontal and parietal regions during sleep. The array-CGH analysis identified a de novo 2.32 Mb

deletion on chromosome 8q23.1q23.2 due to an unbalanced translocation t(8;17)(q23;q24). The analysis detected two additional anomalies which were both inherited from the healthy father: a 165.8 Kb duplication involving chromosome 7p15.2 and a 914.6 Kb duplication involving 22q13.2. In the deleted region, SYBU and KCNV1 appear to be candidate genes for the patient's neurologic and electroclinical phenotype. In fact, SYBU encodes a protein which is part of a kinesin motor-adaptor complex that is critical for the anterograde axonal transport and contributes to activity-dependent presynaptic assembly during neuronal development. KCNV1 encodes a neuronal modulatory subunit of a voltage-gated potassium channel and it is predominantly expressed in the brain.

P11.140-M
TBC1D7 mutations are associated with intellectual disability, megalencephaly, patellar dislocation and celiac disease

Mutations in both TSC1 and TSC2 cause the tuberous sclerosis complex (TSC), a multisystemic disorder characterized by the development of hamartomas or benign tumors in various organs as well as epilepsy, intellectual disability (ID) and autism. Whereas the binding of TBC1D7, the third constitutive subunit of the TSC1-TSC2 complex, is required to maintain its integrity, sequencing of TSC patients with no TSC1-TSC2 mutations indicated that TBC1D7 is unlikely to represent a "TSC3" gene. Loss of function of TBC1D7 results in an increase in mTORC1 signaling, and consequently a delay in the induction of autophagy.

Mutations in TBC1D7 were recently reported in a family with ID and macrocrania. Using exome sequencing we identified two sisters homozygote for a novel TBC1D7 truncating mutation. In addition to the already described macrocephaly and mild ID, they share osteo-articular defects, patella dislocation, behavioral abnormalities, psychosis, learning difficulties, celiac disease, prognathism, myopia and astigmatism. Consistent with a loss-of-function of TBC1D7 the proband's cell lines show an increase in the phosphorylation of 4EBP1, a direct downstream target of mTORC1 and a delay in the initiation of the autophagy process.

This second family allows enlarging the phenotypic spectrum associated with TBC1D7 mutations and defining a TBC1D7 syndrome. Our work reinforces the involvement of TBC1D7 in the regulation of mTORC1 pathways and suggests an altered control of autophagy as possible cause of this disease.

P11.141-S
Temple syndrome - introducing a new name for a characteristic chromosome 14 imprinting disorder

I. K. Temple[1], *Y. S. Ioannides[1], K. Lokulo-Sodipe[1], D. J. G. Mackay[1], J. H. Davies[2];*

[1]University of Southampton, Southampton, United Kingdom, [2]University Hospital Southampton, Southampton, United Kingdom.

Chromosome 14 harbours an imprinted locus at 14q32. Maternal uniparental disomy of chromosome 14, paternal deletions and loss of methylation at the intergenic differentially methylated region, result in a human phenotype of low birth weight, hypotonia, early puberty and short stature. This rarely diagnosed imprinting disorder has considerable overlap with other better known imprinting conditions such as Russell Silver and Prader Willi syndromes.

We have reviewed the world literature of 51 cases to identify the key diagnostic features to increase awareness, enhance diagnosis and improve treatment.

Key findings

1) Small for gestational age: The median birth weight standard deviation score (SDS) was -1.88 and none had a birth weight SDS >0. The median birth length SDS was -1.64.

2) Hypotonia and motor delay (93% and 83%).

3) Mildly reduced intellectual ability; IQ, 75-95.

4) Small hands and feet (87% and 96%)

5) Early puberty (86%)

6) Short stature in adulthood; the median final height SDS was -2.04

7) Metabolic syndrome; the median final adult weight SDS was -1.07 demonstrating a relatively greater weight for height in adults; median BMI of 27. Of 15 patients over the age of 11 years, three developed non-insulin dependent diabetes mellitus at the ages of 12 years, 19 years and 20 years.

The facial appearance distinguishes this condition from other imprinting disorders.

The use of the name Temple syndrome is not universal, as yet, but rather than the somewhat cumbersome use of 'maternal uniparental disomy of chromosome 14 related conditions' we propose this name change.

P11.142-M
Testicular regression and cerebral abnormalities: a new syndrome

D. Sanlaville[1,2], *A. Labalme[1], A. Vasiljevic[3], L. Guibaud[4], M. Till[1], Y. Morel[5], P. Edery[1,2], M. Rossi[1,2];*

[1]Service de Génétique, Centre de référence des Anomalies du Développement, Hospices Civils de Lyon, Bron, France, [2]INSERM U1028 UMR CNRS 5292, UCBL, CRNL TIGER Team, Lyon, France, [3]Service d'Anatomie Pathologique, Hospices Civils de Lyon, Bron, France, [4]Service d'Imagerie Pédiatrique et Fœtale, Hospices Civils de Lyon, Bron, France, [5]Service d'Endocrinologie Moléculaire et Maladies Rares, Hospices Civils de Lyon, Bron, France.

We report three male siblings affected by a Multiple Congenital Abnormalities/Intellectual Disability (MCA/ID) syndrome which, to the best of our knowledge, has not been reported to date. Patient 1 presented with a clinical phenotype including micropenis, anorchia and a very low serum level of antimullerian hormone, consistent with progressive testicular regression; severe developmental delay; spasticity; epilepsy; dysmorphic features; deafness; retinopathy; cerebral atrophy, corpus callosum hypoplasia and periventricular cysts. The two subsequent pregnancies were terminated at 34 weeks gestation because of recurrences. The fetuses (patients 2 and 3) showed cerebral cysts (2/2), thin corpus callosum (1/2), very low levels of antimullerian hormone in the amniotic fluid (2/2) associated with ambiguous genitalia in patient 2. Pathological examination of patient 2 showed a testicular atrophy, micropenis, a thin corpus callosum, white matter abnormalities (gliosis, cysts), and cerebellar focal neuronal migration anomalies. A large genetic and metabolic assessment performed in patient 1 was normal: standard karyotype and array CGH (105k, Agilent®); molecular analysis of the genes *SRY, SF1, ARX, ATRX, KAT6B* (exon 18); analysis of cholesterol precursors, screening for peroxysomal disorders (blood and fibroblasts), CDG syndromes, creatine deficiencies, adenylosuccinate deficiency, blood lactate and pyruvate, maternal X inactivation pattern. Magnetic resonance spectroscopy was normal. An exome sequencing analysis has been performed and we are interested to study other possible patients showing a similar clinical picture. In conclusion, we report the preliminary results of the clinical and molecular study of a previously unreported MCA/ID syndrome, characterized by testicular regression and cerebral abnormalities.

P11.143-S
Autosomal recessive *POLR1D* mutation with decreasing of *TCOF1* mRNA is responsible for Treacher Collins syndrome

E. Schaefer[1,2], *C. Collet[3], D. Genevieve[4], M. Vincent[4], D. Lohmann[5], E. Sanchez[4], E. Sanchez[4], C. Bollender[6], M. Eliot[7], G. Nürnberg[8], M. Passos-Bueno[9], D. Wieczorek[5], L. Van Maldergem[10], B. Doray[1,2];*

[1]Service de Génétique Médicale, Hôpitaux Universitaires de Strasbourg, Strasbourg, France, [2]Laboratoire de Génétique Médicale, U1112, Faculté de Médecine, Université de Strasbourg, Strasbourg, France, [3]Inserm U606, Assistance Publique–Hôpitaux de Paris (AP-HP), Hôpital Lariboisière, Service de Biochimie et de Biologie Moléculaire, Paris, France, [4]Service de Génétique Médicale, CHRU Montpellier, Université de Montpellier 1, Montpellier, France, [5]Institut für Humangenetik, Universitätsklinikum Essen, Universität Duisburg-Essen, Essen, Germany, [6]Service de Pédiatrie, Centre hospitalier de Haguenau, Haguenau, France, [7]Service ORL, Hôpitaux Universitaires de Strasbourg, Strasbourg, France, [8]Center for Genomics, University of Cologne, Cologne, Germany, [9]Human Genome Center, Department of Genetics and Evolutive Biology, Institute of Bioscience, University of Sao Paulo, Sao Paulo SP, Brazil, [10]Centre de Génétique Humaine, Université de Franche-Comté, Besançon, France.

Purpose: Treacher Collins syndrome (TCS) is a mandibulofacial dysostosis caused by mutations in genes involved in ribosome biogenesis and synthesis. *TCOF1* mutations are observed in around 80% of the patients and are inherited as an autosomal dominant manner. Recently, two other genes have been reported in less than 2% of patients, *POLR1D* in patients with autosomal dominant inheritance, and *POLR1C* in patients with autosomal recessive inheritance. **Methods:** We performed direct sequencing of *TCOF1*, *POLR1C* and *POLR1D* in two unrelated consanguineous families. **Results:** The four affected children shared the same homozygous mutation in *POLR1D* (c.163C>G, p.Leu55Val). This mutation is localized in a region encoding the dimerization domain of the RNA polymerase. It is supposed to impair RNA polymerase resulting in a lower amount of mature dimeric ribosomes. A functional analysis of the transcripts of *TCOF1* by RT-qPCR was performed in the first family demonstrating a 50% reduction in the index case compatible with this hypothesis. **Conclusion:** This is the first report of *POLR1D* mutation responsible for an autosomal recessive inherited Treacher Collins syndrome. These results reinforce the concept of genetic heterogeneity of Treacher Collins syndrome and underline the importance of combining clinical expertise and familial molecular analyses for appropriate genetic counseling.

P11.144-M
Molecular and cytogenetic characterization of an unusual case of partial trisomy 13q mosaicism

A. Pansa, *A. Scatigno, B. Facchinetti, G. Cassina, P. Fruscella, C. Perico, D. Nicoli, F. Comi, U. Giussani;*
A.O. Papa Giovanni XXIII, Bergamo, Italy.

Trisomy 13 (Patau syndrome) is a rare multiple malformation syndrome and includes anomalies of the central nervous system, cardio-vascular and urogenital system. The probability of survival for live-born to one year is 3%. Partial or mosaic forms of trisomy 13 can occur and they cause a variable phenotype.
We report a case of a live-born baby with multiple congenital anomalies including severe Fallot tetralogy, bilateral postaxial polydactyly of fingers and toes, monolateral hydronephrosis, microcephaly with trigonocephaly and brain anomalies (hypoplastic corpus callosum and dismorphic cerebellar vermis). The child also presents some facial anomalies (sloping forehead, hypotelorism, low set ears and microretrognathia) and scalp defect (aplasia cutis of vertex). Cytogenetics, fluorescence *in situ* hybridisation and array-CGH analysis showed the presence of two cell lines in which a normal chromosome 13 was replaced in one by a isochromosome (13q) and in the other by a isochromosome 13 derivative, with a deletion spanning from 13q11 to 13q14, resulting in partial trisomy 13q. The two cell lines were present either in peripheral blood lymphocytes or skin fibroblasts.
Chromosomal mosaics made up of cell lines with distinct intrachromosomal structural rearrangements are unusual. Two cases reported by Reardon *et al.* (1981) and by Fogu *et al.* (2008) showed similar karyotypes with rearrengements of the same region on isochromosome 13 derivative. We suggest a common mechanism producing the coexistence of distinct structural rearrangements at common breakpoints on chromosome 13.
Phenotype of the baby is discussed with respect to other cases showing partial trisomy mosaicism in Patau syndrome.

P11.145-S
Classical karyotyping vs molecular karyotyping (arrayCGH) in a case of trisomy 9 mosaicism

E. E. Fiedler, *B. Glaeser, C. Spaich, D. Bartholdi, S. Biskup;*
Institut für Klinische Genetik, Stuttgart, Germany.

Trisomy 9 mosaicism is considered to be a rare chromosomal abnormality with limited survival and a characteristic pattern of multiple anomalies. The features commonly associated with trisomy 9 include growth retardation, facial dysmorphisms, skeletal abnormalities, congenital heart disease and intellectual disability. More than 50 cases have been reported, most of which were diagnosed after birth. We report a case of a one month old baby girl with craniofacial abnormalities, hydronephrosis and multiple contractures. ArrayCGH analysis was performed and detected a trisomy 9 mosaicism in approximately 40% of the cells. Classical karyotyping of lymphocytes revealed trisomy in about 3% of the metaphases. Previous prenatal analysis of cell cultures from amniotic fluid had not shown the mosaic trisomy 9 constitution. Mosaicisms are expected to be exhibited at different levels in different tissues. In addition, cell culturing leads to a bias in terms of the ratio between trisomic and disomic clones and very likely underestimates the percentage of trisomic cells in conventional karyotyping. Our data show the importance of using uncultured samples (amniotic fluid and blood) and the value of microarray technology in the assessment of mosaicisms.

P11.146-M
Cytogenetic-molecular characterization of an idic (Xq) in a female with Turner syndrome and her daughter

C. Ardisia[1], *D. Rogaia[1], V. Ottaviani[1], C. Gradassi[1], R. Romani[1], M. Schippa[1], P. Prontera[1], G. Angeletti[2], E. Donti[1];*
[1]Medical Genetics, University of Perugia, Italy, [2]Department of Medicine, University of Perugia, Italy.

The following is the case of a patient born 2 weeks preterm weighing 2.800 kg. She had a multicystic kidney that was removed immediately after birth. At age 9, due to a significant growth delay, a cytogenetic analysis was made on peripheral blood revealing a homogeneous 45,X karyotype thus leading to Turner syndrome. Growth hormone treatment contributed to stature increase but with the development of secondary sex characters and the menstrual cycle, it became necessary to repeat blood cytogenetic analysis that confirmed the 45,X karyotype. At 30 years, following absence of menstrual cycle , she realized she was pregnant. She had to undergo a caesarian delivery and was simultaneously operated for ovariectomy. Karyotype obtained from gonadic tissue was mos 45,X/46,X,der(X). The insufficient amount of cells however did not help to investigate on marker nature. As the daughter presented the same stature growth delay, at 5 years her constitutional karyotype was analyzed and was the same one found in her mother's ovarian culture: 46,X,der(X), in this case present homogeneously. Cytogenetic-molecular characterization by FISH with various X specific probes allowed to define, beyond doubt, that the X derivative is a dicentric isochromosome with an inactive centromere and with symmetric point in Xp21: 46,X,idic(X)(qter→p21::p21→qter). This data allowed to demonstrate : 1) the presence of phenotype atypia. 2) ovarian functionality, 3) the short stature of both mother and daughter due to SHOX gene deletion.

P11.147-S
SNP array revealed maternal UPD16 in a boy with short stature, craniosynostosis and psychomotor retardation.

M. Trkova[1], *K. Vesela[2], V. Becvarova[1], L. Hnykova[1], H. Hroncova[1], J. Horacek[1], D. Stejskal[1];*
[1]Gennet, Prague, Czech Republic, [2]First Faculty of Medicine, UK, Prague, Czech Republic.

We report on a 15 months old boy (gemini after IVF, healthy sister) with positive prenatal anamnesis (IUGR, oligohydramnion), craniosynostosis, short stature, hypotonia, hypospadia, cryptorchidia, pulmonary vein stenosis and delayed psychomotor development. Chromosomal examination revealed normal male karyotype 46, XY. The whole genome genotyping was performed using SNP array (300K, Illumina) and no pathogenic CNV was found. However, three extensive blocks with loss of heterozygosity spanning almost one third of the whole chromosome 16 were found. Parental DNAs were analyzed and the maternal UPD16 was confirmed. Chromosome 16 showed the mixture of isodisomy and heterodisomy with homozygous haplotype within the centromere. This haplotype arrangement implies the following origin of the UPD16: meiosis II nondisjunction, recombination and mitotic loss of the paternal chromosome 16 (trisomy rescue). Data for UPD16 are inconsistent, prominent phenotype of maternal UPD16 is IUGR with or without catch-up growth. Other features may include heart defects, inguinal hernia, hypospadia, pulmonary hypoplasia, although these features may be partly due to hidden mosaic trisomy 16. Mental development ranges from normal to severely delayed. We consider a potential impact of two imprinted genes and five predicted imprinted genes on chromosome 16 to the distinct phenotype of the UPD16.

P11.148-M
Whole exome sequencing identifies novel genetic variants in the PRDM5 gene in Brittle cornea syndrome and Axenfeld-Rieger syndrome

S. Micheal[1], *F. Islam[2], S. N. Zafar[2], F. Akhtar[2], M. Khan[3,4], R. Qamar[4], A. I. den Hollander[3,5];*
[1]Radboud University Medical Center, Nijmegen, Netherlands, [2]Al-Shifa Eye Trust Hospital Jhelum Road, Rawalpindi, Pakistan, Rawalpindi, Pakistan, [3]Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands, [4]Department of Biosciences, COMSATS Institute of Information Technology, Islamabad, Pakistan, [5]Department of Ophthalmology, Radboud University Medical Center, Nijmegen, Netherlands.

Background: Brittle cornea syndrome (BCS) and Axenfeld-Rieger syndrome (ARS) are disorders affecting the anterior segment of the eye, often leading to secondary glaucoma. BCS is an autosomal recessive disorder associated with mutations in the *PRDM5* and *ZNF469* genes, while Axenfeld-Rieger syndrome is inherited in an autosomal dominant fashion that has been associated with genetic defects in *PITX2* and *FOXC1.* The purpose of current study is to identify the underlying genetic causes in a family with autosomal recessive BCS and in a family with autosomal dominant ARS by whole exome sequencing (WES).
Methods: WES was performed for a single affected individual of both families. Missense, nonsense and splice site variants identified by WES were prioritized based on pathogenicity prediction scores (PhyloP, Grantham). Segregation analysis of selected variants was performed in family members.
Results: A homozygous splice site variant (c.93+5G>A) was identified in the *PRDM5* gene, which was found to segregate with the disease in the BCS family. In the ARS family, a novel heterozygous *PRDM5* missense variant (c.877A>G; p.Lys293Glu) was prioritized from the WES data, and was found to segregate with the disease in an autosomal dominant fashion. Both variants were absent from population-matched controls, the Exome Variant Server and an in-house exome variant database.
Conclusions: In the current study we identified a homozygous splice site variant in a BCS family and a heterozygous missense variant in an ARS family in the *PRDM5* gene. This suggests that genetic variants in *PRDM5* can lead to different disorders affecting the anterior segment.

P11.149-S
WHSC/NSD2 is the major candidate gene for growth delay and facial dysmorphisms in Wolf-Hirschhorn syndrome: expression analysis and functional studies on primary fibroblasts and immortalized peripheral lymphoblasts from three patients.

C. Cafiero[1], *G. Pani*[2], *D. Samengo*[2], *G. Marangi*[1], *M. Zollino*[1];
[1]*Institute of Medical Genetics, Catholic University, Rome, Italy,* [2]*Institute of General Pathology, Catholic University, Rome, Italy.*

Wolf-Hirschhorn Syndrome (WHS, OMIM194190) is a contiguous gene syndrome caused by partial deletion of the short arm of one chromosome 4. The core WHS phenotype includes growth delay, intellectual disability, distinctive facial appearance and seizures. It maps within the terminal 1.9 Mb region on 4p16.3, where the critical region, WHSCR-2, was described. With respect to pathogenic genes falling within WHSCR-2, WHSC1 is the major candidate gene for both facial characteristics and growth delay. WHSC1 is expressed mainly in embryonic tissues and presents homology with Drosophila dismorphy genes. Its PWWP, HMG-box, PHD and SET structural domains suggest an histone methyltransferase activity and a role in the epigenetic regulation of morphogenetic transcriptional programmes. However, to which extent whsc1 expression and activity are reduced in patients'cells due to 4p16 deletion has not been thoroughly investigated. Additionally, while very little is known about whsc1 regulation, it is intriguing that this gene is a potential target of hsa-miR948, that also maps to 4p16.3, and whose concomitant deletion may, in a subset of patients, reduce the effect of WHSC1 monosomy by increasing the expression of the residual allele. Based on these consideration, we decided to evaluate at a mRNA and protein level the expression of WHSC1 and of hsa-miR948 in primary and immortalized cell lines from selected patients and healthy individuals as controls. Furthermore, the expression levels have been correlated with biochemical characteristics (H3K36 and H4K20 methylation) and cellular phenotypes (DNA damage response, inflammatory signaling) reportedly related to WHSC1 biological activity at least in tumor cells.

P11.150-M
Coeliac disease in Williams syndrome

M. Ercan[1], *B. G. Nur*[1], *S. B. Karaüzüm*[2], *A. Yilmaz*[3], *R. Artan*[4];
[1]*AkdenizUniversity School of Medicine Department of Pediatric Genetics, Antalya, Turkey,* [2]*AkdenizUniversity School of Medicine Department of Medical Biology and Genetics, Antalya, Turkey,* [3]*AkdenizUniversity School of Medicine Department of Pediatric Gastroenterology, Antalya, Turkey,* [4]*Akdeniz University School of Medicine Department of Pediatric Gastroenterology, Antalya, Turkey.*

Williams syndrome is a multi-system disorder characterized by distinctive facial features, growth delay, mental retardation with typical neurobehavioral profile, cardiovascular anomalies, endocrine anomalies including autoimmune pathologies, and hypercalcemia. Coeliac disease is an autoimmune, gastrointestinal disorders characterized by intolerance to the dietary grain protein gluten. An increased prevalence of Coeliac disease has been reported in Down syndrome and Turner syndrome, but there has been only few previous report which respect to the association of Coeliac disease in Williams syndrome.
The aim of this study was to estimate the prevalence of Coeliac disease in our 24 molecularly confirmed Williams syndrome patients (12 girls, 12 boys, mean age 9.4 years). All patients were analysed by the dosage of tissue transglutaminases IgA and IgG HLA genotyping and intestinal biopsy was performed to the patients with positive serology. Celiac disease symptoms and gastrointestinal problems were recorded. Biochemical profile (calcium, urine calcium/creatinin ratio, thyroid functions), IgA tissue transglutaminases (IgA tTG) and IgG tissue transglutaminases (IgG tTG) were assessed in all cases. Serum total IgA levels assessed only in tTG positive patients. Patients were selected for the haplotypes in the HLA class II region (HLA DQ), endoscopy and intestinal biopsy on the basis of tTG positivity.
The results show that the prevalence of Coeliac disease in Williams syndrome was higher than in the general population. As our results, Coeliac disease questioning and serologic screening is recommended at certain intervals in all cases with Williams syndrome to explain the cause of growth retardation and gastrointestinal problems.

P11.151-S
A novel ZCD2 intragenic deletion in Wolfram Syndrome 2

M. Carella[1], *E. Mozzillo*[2], *M. Delvecchio*[1], *P. Palumbo*[1], *L. Fidanza*[1], *E. Grandone*[1], *A. Salina*[3], *C. Aloi*[3], *P. Buono*[2], *F. Cirillo*[4], *A. Izzo*[5], *G. D'Annunzio*[3], *G. Vecchione*[1], *A. Orrico*[6], *R. Genesio*[7], *F. Simonelli*[6], *A. Franzese*[2];

Wolfram Syndrome type 2 (WFS2) is considered a phenotypic and genotypic variant of WFS, whose minimal criteria for diagnosis are diabetes mellitus and optic atrophy.
The responsible gene for WFS2 is named CISD2, a highly conserved zinc-finger gene encoding for the Endoplasmic Reticulum Intermembrane Small (ERIS) protein, which plays a pivotal role in calcium homeostasis. It was identified for the first time in three consanguineous families of Jordanian descents who carried a point mutation in exon 2 that disrupts messenger RNA splicing by eliminating exon 2, causing a premature stop codon. After this first report of Jordanian patients, no further CISD2 mutations have been reported worldwide.
We describe the first case in Europe of WFS2 with a novel homozygous CISD2 exon 2 deletion in a 17 year-old girl, identified using both PCR and high density SNP array. She presented diabetes mellitus, optic neuropathy, intestinal ulcers, sensorineural hearing loss, and defective platelet aggregation. Her brother and parents carried the heterozygous mutation and were apparently healthy, although they showed subclinical defective platelet aggregation.
Since the mutation had never been reported, consanguinity was hypothesized. Long runs of homozygosity analysis from SNP-array data did not show any degree of parental relationship, while microsatellite analysis confirmed the hypothesis of a common ancestor.
This report provides novel clinical and molecular insights about WFS2.

P11.152-M
Early diagnosis of Kallmann syndrome in a 4 year old boy with a familial X;Y translocation

Y. Kido[1], *S. Soh*[2], *T. Yoshimura*[3], *S. Kuwashima*[4], *Y. Tanaka*[3], *H. Okada*[2], *S. Sakazume*[1];
[1]*Department of Pediatrics, Dokkyo Medical University Koshigaya Hospital, Saitama, Japan, Koshigaya, Japan,* [2]*Department of Urology, Dokkyo Medical University Koshigaya Hospital, Saitama, Japan, Koshigaya, Japan,* [3]*Department of Otorhinolaryngology, Dokkyo Medical University Koshigaya Hospital, Saitama, Japan, Koshigaya, Japan,* [4]*Department of Radiology, Dokkyo Medical University, Tochigi, Japan, Mibu, Japan.*

X;Y translocation (tXY) is a rare chromosomal rearrangement typically inherited from a tXY carrier mother. Patients with tXY commonly display 46, X or Y, der(X),t(X;Y)(p22.3;q11). Women with tXY show a mild phenotype due to X inactivation and are fertile. Men with tXY show a range of phenotypes with variable degree of severity according to the size and position of the deletion of the X chromosome, comprising short stature, chondrodysplasia punctata, ichthyosis, ocular-albinism, mental retardation, and Kallmann syndrome (KS). Here we describe a boy with tXY inherited from a carrier mother. His phenotype was characterized by mesomelic short stature, midface retrusion, ichthyosis, micropenis, bilateral undescended testes, hypoplastic scrotum, agenesis of right kidney and central hypogonadism as assessed by gonadotropin-releasing hormone (GnRH) and human chorionic gonadotropin (hCG) stimulation tests. Magnetic resonance imaging (MRI) of the olfactory tracts showed hypoplastic olfactory bulbs bilaterally, aplasia of the left olfactory sulcus and hypoplasia of the right olfactory sulcus. The patient's mother and sister showed mesomelic short stature and his mother displayed Madelung deformity. Single nucleotide polymorphism (SNP) array analysis defined the breakpoint in intron 7 of the KAL1 gene. Conclusion: For early diagnosis in patients with KS, it would be useful to search for other symptoms including renal abnormalities (agenesis of right kidney) and to assess the presence of olfactory tracts by MRI (hypoplastic olfactory bulbs bilaterally).

P11.153-S
Chromosome Xq21 deletion syndrome - rare cause of deafness and mental retardation

A. Klímová;
Department of Medical Genetics, Ústí nad Labem, Czech Republic.

Our case is a family, where Chromozome Xq21 deletion syndrome was diagnosed.
Genetic counselling was recommended because of mental retardation, bilateral hearing loss and paleocerebellar syndrome at 5-year boy. He also had hypotonia, developmental delay and hyperactivity. We started genetic examination and we found normal karyotype 46,XY,9qh+. Molecular genetic examination excluded X-Fragile syndrome, Prader-Willi-Angelman syndrome and mutations in the GJB2 gene. Microarray comparative genomic hybridisation identified a 5-Mb deletion of Xq21, which include the POU3F4, ZNF711 and CHM genes. The boy did not have any symptoms of choroideremia. Multiplex ligation-dependent probe analysis (MLPA) showed that the unaffected mother also carried the deletion. The boy had no siblings.

Next time the family was examined in the following pregnancy of the mother, but the case was complicated because of twin pregnancy. Prenatal diagnosis was recommended and chorionic villus sampling was performed with the result one male and one female foetus. Molecular genetic examination of the Chromozome Xq21 deletion syndrome in the male foetus was performed and the same familiar deletion was identified. Mother underwent selective fetocide of the affected male foetus at 16 weeks' gestation. Further course of gravidity is normal.

P11.154-M
17q21.31 microdeletion syndrome: neurocognitive functioning in two italian young patients

*M. Vendemiale[1], **F. Ortolani**[2], M. Settembre[1], A. Rossiello[1], D. Cornacchia[1], G. D'Aniello[1], A. Labbate[1], R. Tripoli[1], M. Riccardi[1], M. Lucarano[1], F. Nicastro[3], M. Carella[4], M. Gentile[5], E. Piccinno[6], F. Papadia[6], R. Fischetto[6];*

[1]Servizio Psicologia Clinica-Dir.Medica P.O.Giovanni XXIII AOU Policlinico, Bari, Italy, [2]UOC Malattie Metaboliche Genetica Clinica e Diabetologia Ospedale Pediatrico, Bari, Italy, [3]UOC Malattie Metaboliche Genetica Clinica e Diabetologia, Ospedale Pediatrico „Giovanni XXIII", Bari, Italy, [4]UOC Genetica Medica IRCCS "Casa sollievo sofferenza", San Giovanni Rotondo, Foggia, Italy, [5]UOC Genetica Medica ASL BA4 P.O.Di Venere, Bari, Italy, [6]UOC Malattie Metaboliche Genetica Clinica e Diabetologia Ospedale Pediatrico „Giovanni XXIII", Bari, Italy.

The 17q21.31 microdeletion syndrome causes a wellknown syndrome recently described in the scientific literature. Clinical features are: neonatal hypotonia, low birth weight, craniofacial dysmorphism, developmental delay, intellectual disability and amiable behaviour disposition. The present study analyzes neuropsychological assessment in two young italian patients with a genetically described 17q21.31 microdeletion. Case 1: 18-year-old male. Case 2: 13-year-old female.
Neuropsychological Assessment Wechsler Adult and Children Intelligence Scales Revised, Italian Neuropsychological Battery, Peabody, Vineland Adaptive Behavior Scales, Adaptive Behavior Inventory, Parent Stress Index, Brief Cope, Multidimensional Scale of Perceived Social Support, Child Behavior Checklist. Case 1: severe mental retardation (Intelligence Quotient, IQ = 32), immature representative capacity, impairment of receptive and expressive communication, anxiety and apprehension. The Adaptive functioning is impaired in all areas (communication, skills of daily living, socialization and motor skills). Mental Age 4y2m. Case 2: moderate to severe mental retardation (IQ<40), expressive and receptive language deficits, decline in all areas of adaptive functioning (M.A. 5y7m), socially indiscriminate attachment behavior, hyperactivity. Reading and writing disabilities, semantic memory deficits, verbal and visuospatial short-term memory deficits, ideational and motor dyspraxia, deficit in scheduling tasks and spatio-temporal organization were present in both patient. The emotional systems are characterized by trust in peers and adults, kindness, dependence and poor individual autonomy. The attachment is secure with important people.To our knowledge these observations can be added to preliminary evidences already present in literature: 17q21.31 microdeletion syndrome correlates to low intellectual capacities, learning disability, good interpersonal skills and an approaching behaviour.

Impact of Aberrant Promoter Hypermethylation on down-regulation of MTS2 and MTS1 in Childhood ALL

K. MalekZadeh[1,2];

[1]Molecular Medicine Research Center, Bandar Abbas, Islamic Republic of Iran, [2]Moleculr MEdicine Research Center; Hormozgan University for Medical Science, Bandar Abbas, Islamic Republic of Iran.

The tumor suppressor genes MTS1 and MTS2 are cycline dependent kinas inhibitors inactivated in some human neoplasms via several mechanisms such as hypermethylation. We have investigated the methylation status of MTS1 and MTS2 in its effect on transcriptional down-regulation in 125 bone marrow aspirate (7 cases T-cell and 118 cases B-cell phenotypes) from childhood ALL patient and 100 healthy control in north Indian population by using MSP-PCR ,bisulfite sequencing, SQRT-PCR and RT-PCR. There were significant differences in pattern of hypermethylation between patients and healthy controls of MTS2 (p=0.000) and MTS1 (p=0.001) and also when both genes methylated. Patients with hypermethylated of both genes showed an increasing risk for 2.33 fold (95%CI=2.33(1.97-2.77), p=0.03). Significant association of MTS1 hypermethylation was observed only among the male patients (p=0.004) in contrast hypermethylation of MTS2 was significantly associated with increasing risk of ALL among both genders. Down-regulation of mRNA expression was found in cases in which MTS1 and MTS2 were hypermethylated. In conclusion our data also indicate the impact of hypermethylation mediated inactivation of these genes which is associated with risk of childhood ALL. This abnormality particularly in promoter of MTS2 occurs in leukemogenesis and can be considered as an important factor in predicting the clinical outcome of ALL and it is able to suggest a diagnostic tool for some stage of ALL and even provide the better prospective for treatment strategy by applying some demathylating agents.

P12.002-M
The A785G CYP2B6 germline polymorphism may affect the risk of de novo Acute Myeloid Leukemia

K. Kakosaiou[1,2], *A. Daraki[1,2], S. Zachaki[1], K. Stavropoulou[1], P. Nakopoulos[1], C. Sambani[1], V. Aleporou-Marinou[2], P. Kollia[2], K. Manola[1];*

[1]NCSR Demokritos, Athens, Greece, [2]National and Kapodistrian University of Athens, Athens, Greece.

The etiology of acute myeloid leukemia (AML) is currently unknown although genetic background and environmental exposure postulated to be a possible cause of AML development. The CYP2B6 enzyme plays a vital role in the degradation of many genotoxic compounds, protecting cells from oxitative damage. CYP2B6 gene is subjected to the A785G germline polymorphism which reduces enzyme activity. Thus, individuals homozygous or heterozygous for mutant allele (G/G or A/G) present decreased enzymatic activity. The purpose of this study was to investigate the role of the A785G polymorphism in the AML susceptibility. Possible associations with specific AML-chromosomal abnormalities were also investigated. CYP2B6 genotyping was performed in 220 de novo AML patients and 243 healthy donors by RCR-RFLP and Real-Time PCR assays. Cytogenetic analysis was successful in 98% of patients. Among them, 72.7% presented an abnormal karyotype. A significantly higher incidence of the mutant genotypes (A/G and G/G) was observed in de novo AML patients compared to the controls (p<0.0001). The mutant allele frequency was similar between the different gender and age groups. Interestingly, a higher frequency of heterozygotes A/G was observed in normal karyotypes compared to abnormal (51.7% vs 30.0%, p=0.010). Furthermore, a significantly higher incidence of G/G genotype was observed in patients with t(8;21) and MLL rearrangements compared to patients with normal karyotypes (28.5% and 20.0% vs 6.6%, respectively). Our study comprises the first investigation of the A785G CYP2B6 polymorphism in AML susceptibility. Our results reveal a possible implication of this genetic variant in AML development and its specific chromosomal aberrations.

P12.003-S
Higher incidence of co-existing Anaplastic Lymphoma Kinase (ALK) rearrangements and Epidermal Growth Factor Receptor (EGFR) mutations in Non-Small Cell Lung Cancer (NSCLC) in a South-East Asian population

T. Lim[1], *A. Lim[1], L. Oon[1], T. Lim[1], D. Tan[2], Y. Ng[1], Y. Yeap[1], E. Chen[1], J. Ho[1], S. Tien[1];*

[1]Pathology Department, Singapore General Hospital, Singapore, Singapore, [2]Medical Oncology, National Cancer Centre Sinagpore, Singapore, Singapore.

Both EGFR mutations and ALK rearrangements in NSCLC are associated with sensitivity to EGFR and ALK tyrosine kinase inhibitors, respectively. The incidence of ALK rearrangements is about 5% worldwide and EGFR mutations and ALK translocations are generally known to be mutually exclusive. The aim of this study is to determine the incidence of ALK rearrangements and incidence of co-existing EGFR and ALK mutations in a South-East Asian population. FISH using an ALK break-apart probe was performed on formalin-fixed paraffin embedded (FFPE) tumor tissues from 1183 NSCLC cases from year 2011 till 2013. EGFR mutation test was performed using direct sequencing of EGFR exons 18-21. ALK FISH results were obtained from 1152 samples (97.4%). A total of 105 cases showed a rearranged ALK gene (9.1%) of which 76.2% showed the typical FISH pattern while 21.9% showed an atypical pattern with loss of the 5' ALK gene segment and 1.9% showed loss of the 3'ALK gene. Among the ALK rearranged patients, 95 cases had concurrent EGFR mutation assays performed out of which EGFR mutations were identified in 17 cases (17.9%). The incidence of concomitant ALK and EGFR alterations in the entire cohort was 1.48%. In our cohort study, the incidence of ALK gene rearrangement is relatively similar to the reported incidence. The co-existence of ALK rearrangements and EGFR mutations has been found to be rare in Western populations (0.33-6%). The higher incidence of concomitant mutations in our South-East Asian population suggests ethnic differences in terms of genetic alterations.

P12.004-M
FISH analysis of four unbalanced translocations involving chromosome 1q in hematologic neoplasms

A. Simone[1], *L. Militti[1], R. Di Gianfilippo[2], A. Soranno[1], A. Di Tecco[2], D. Fantasia[1], G. Calabrese[1,3];*

[1]Medical Genetics, Università di Chieti, Chieti, Italy, [2]Genetics, Pescara Hospital, Pescara, Italy, [3]Medical Genetics, Pescara Hospital, Pescara, Italy.

Unbalanced whole-arm translocations (WATs) of the long arm of chromosome 1 result in complete trisomy 1q. These are rare chromosomal abnorma-

lities detectable in both solid tumors and hematologic neoplasms including cases of myelodysplastic syndrome and acute myelogenous leukemia (AML), in most cases described as dicentric derivative chromosomes. We report on 1q unbalanced WATs detected at diagnosis in 4 patients as resulting from a t(1;15)(p10;p10) in a case with myelofibrosis (MF) and in one with AML, t(1;14)(p10;p10), and t(1;22)(p10;p10) in two other AML patients. Conventional cytogenetics was supplemented by FISH analysis using specific probes for the centromeric alpha-satellite region of chromosome 1 (D1Z7; 1p11.1-q11), chromosomes 14/22 (D14Z1/D22Z1; 14p11.1-q11.1/22p11.1-q11.1), and chromosome 15 (D15Z4; 15p11.1-q11.1). FISH analysis showed that the signal of chromosome 1 alphoid region D1Z7 was absent on derivative chromosomes in all patients suggesting that breakpoint on chromosome 1q is distal to the centromere, while D14Z1 on t(1;14), D15Z4 on t(1;15), and D22Z1 on t(1;22) were present. Therefore all derivative chromosomes showed unique centromere (monocentric) derived from the acrocentric chromosome rearranged with 1q, then resulting in reclassification of 1q WATs as der(15)t(1;15) (both cases), der(14)t(1;14) and der(22)t(1;22). Moreover, during follow up in the MF case cytogenetic analyses revealed progressive expansion of the clone with der(15) up to homogeneity, thus suggesting a proliferative advantage for the der(15)-related clone. Although studies on a large cohort of patients are needed, present results confirm 1q pericentromeric region instability in leukemia, and support trisomy 1q role to favor leukemogenesis and hematopoietic tissue alterations.

P12.005-S
Involvement of APC gene in Acinar Cell carcinomas of the Pancreas

N. Sahnane[1], *D. Furlan*[1], *B. Bernasconi*[1], *M. Frattini*[2], *F. Molinari*[2], *S. La Rosa*[3], *F. Sessa*[1], *M. Tibiletti*[3];
[1]*Department of Surgical and Morphological Sciences, University of Insubria, Varese, Italy,* [2]*Laboratory of Molecular Diagnostic, Institute of Pathology, Locarno, Switzerland,* [3]*U.O. Anatomia Patologica, Ospedale di Circolo – Polo Universitario, Varese, Italy.*

Pathogenetic mechanisms of pancreatic acinar cell carcinomas (ACCs) are poorly characterized. There is no data about gene hypermethylation and chromosomal aberrations in ACCs. In a subset of ACCs is reported the impairment of APC/β-catenin pathway including mutations of APC gene. However, it is not known whether the loss of APC function can occur even through alternative genetic and epigenetic mechanisms. In this study, we investigated the methylation profile of 34 tumor suppressor genes, Copy Number Alterations (CNA) of 52 chromosomal regions, and APC alterations (mutation, methylation, and loss) together with the measurement of APC mRNA level in 45 ACCs and related available peritumoral pancreatic tissues using different methodologies: MS-MLPA, FISH, mutation analysis, and reverse transcription-droplet digital PCR. ACCs did not show an extensive global gene hypermethylation profile. RASSF1 and APC were the only two genes frequently methylated (60% and 56% of cases, respectively). APC mutations were found in 7% of cases, while APC loss and methylation were more frequently observed (48% and 56% of ACCs, respectively). They were also found in pancreatic tissues adjacent to ACCs showing these alterations. APC mRNA low levels were found in 58% of cases and correlated with higher levels of CNAs. In conclusions, ACCs are frequently polysomic and mainly characterized by CNAs and gene methylation. APC alterations are crucial events in the pathogenesis of ACCs and the reduction of APC mRNA levels mainly depends on gene loss and promoter hypermethylation rather than gene mutation.

P12.007-S
The role of BIRC5 polymorphisms in oral and oropharyngeal squamous cell carcinoma

V. Musani[1], *M. Levacic Cvok*[1], *P. Ozretic*[1], *M. Conda*[1], *D. Leovic*[2], *S. Levanat*[1];
[1]*Rudjer Boskovic Institute, 10000 Zagreb, Croatia,* [2]*Clinical Hospital Osijek, 31000 Osijek, Croatia.*

Survivin, encoded by *BIRC5* gene, belongs to the family of inhibitors of apoptosis (IAP) proteins. In healthy organisms it is not expressed in differentiated tissues, while its expression is markedly increased in tumors. *BIRC5* polymorphisms have been previously associated with increased expression, stability and localization of survivin, all of which can affect tumor development.
In this study we investigated the role of *BIRC5* polymorphisms in oral and oropharyngeal squamous cell carcinoma. Genetic testing of 38 patients and 74 healthy controls was conducted using high resolution melting analysis and Sanger sequencing.
Results showed different significance of individual *BIRC5* polymorphisms. c.-235G>A showed significantly higher frequency in patients compared to control samples. For c.-644T>C and c.-625G>C, minor homozygous genotypes were significantly associated with higher Broders' grade, which was also observed for c.-235G>A. The minor homozygous genotypes of either c.9194G>A or c.9809T>C were associated with higher TNM stage. For c.-644T>C and c.-625G>C, the presence of minor allele was associated with higher survivin mRNA expression. Besides eight frequent, six rare polymorphisms were found, c.9349G>C found in 3' UTR previously unpublished.
This was the first study in Croatia which demonstrated correlation between *BIRC5* polymorphisms with the level of survivin expression and the risk of oral and oropharyngeal squamous cell carcinoma. Since it is known that increased expression of survivin is associated with increased resistance to chemotherapy and radiation, as well with poorer survival, *BIRC5* polymorphisms could be used as predictive and prognostic biomarkers in the etiology of head and neck squamous cell cancer.

P12.008-M
Bladder cancer risk in relation to DNA repair capacity, gene expression and epigenomic profiles.

A. Allione[1,2], *B. Pardini*[1], *S. Guarrera*[1,2], *V. Turinetto*[3], *G. Fiorito*[1,2], *F. Rosa*[1], *A. Russo*[1,2], *F. Modica*[1], *C. Giachino*[3], *P. Vineis*[1,4], *C. Sacerdote*[1,5], *G. Matullo*[1,2];
[1]*Human Genetics Foundation, Turin, Italy,* [2]*Dept. Medical Science, University of Turin, Turin, Italy,* [3]*Dept. Clinical and Biological Sciences, University of Turin, Turin, Italy,* [4]*Imperial College, London, United Kingdom,* [5]*University of Turin and Centre for Cancer Epidemiology and Prevention (CPO Piemonte), Turin, Italy.*

The ability to repair DNA damage is strongly associated with the risk of cancer and inter-individual variation in DNA repair capacity (DRC) might account for different susceptibility of developing cancer. DRC represents a complex marker comprising the sum of several factors such as gene variants, gene expression, stability of gene products, and effect of inhibitors/stimulators. Individuals with low DRC will tend to accumulate more damage than those who have a better ability to repair such damage. This variability is modulated by the genetic background to which SNPs/haplotype combinations in DNA repair genes, as well as epigenetic regulation are likely to contribute.
Phenotypic assays to evaluate DNA repair activity (in particular NER comet assay, H2AX phosphorylation and micronucleus assay) were performed on cryopreserved lymphocytes from 159 bladder cancer cases (collected before treatment) and 159 controls matched by age and smoking habits, enrolled in Turin Bladder Cancer Study (TBCS). We aimed at studying the relationship between DRC (evaluated by comet assay, micronuclei and H2AX phosphorylation assay) and bladder cancer integrating, gene expression and epigenetic profile data (methylation levels and microRNA expression). In particular, we performed an integrated analysis on the genotype/phenotype correlation in a population of bladder cancer cases and controls provided with detailed description of the follow-up for response to therapy/recurrence/survival. This integrated approach will help in elucidating the role of DRC (and its determinants) as predictive and prognostic marker and to identify DNA repair phenotypic assays to be performed in blood cells as non-invasive predictive method.

P12.009-S
Mutation detection in urines from bladder cancer patients as non-invasive prognostic tool

R. Critelli[1,2], *A. Naccarati*[1], *M. Assumma*[1], *S. Polidoro*[1], *C. Sacerdote*[3], *A. Russo*[1,2], *G. Fiorito*[1], *F. Modica*[1], *E. Zwarthoff*[4], *G. Matullo*[1,2], *P. Vineis*[1,5];
[1]*Human Genetics Foundation, Turin, Italy,* [2]*University of Turin, Turin, Italy,* [3]*Center for Cancer Prevention, Turin, Italy,* [4]*University Medical Center Rotterdam, Rotterdam, Netherlands,* [5]*Imperial College London, London, United Kingdom.*

In Europe, bladder cancer (BC) is the sixth most commonly diagnosed tumour and the second most common cause of death among patients with genitourinary tract malignancies. Patients with non-muscle-invasive bladder cancer (NMI-BC) have excellent survival; however two-thirds develop recurrences. Tumour specific mutations can be used to detect recurrences in urine assays, presenting non-invasive diagnostic procedure respect to cystoscopy. The present study involves male subjects recruited between 1994 and 2012 and diagnosed with BC. Urine samples have been collected for the first time at the time of diagnosis and exfoliated cells have been extracted. A subgroup of patients have been followed up for three years, collecting a urine sample every six months. The mutation spectrum of hTERT, FGFR3, HRAS, KRAS, NRAS and PIK3CA in 286 patients has been investigated at diagnosis. Thirty-eight patients have completed six samplings, twenty-five patients have five samplings and nineteen patients have four samplings, for a total of 454 follow-up samples. Mutations are detected using three different multiplexed SNaPshot assays. The first allows to detect in one reaction the nine most frequent FGFR3 mutations. The second multiplex screens simultaneously for nineteen RAS mutations. The last multiplex detects seven mutations, three in hTERT gene and four in PIK3CA gene. Preliminary analyses show that mutations in hTERT gene promoter and in FGFR3 gene are the most frequent somatic mutations in tumours of the urinary bladder. Mutational profiler will be correlated with recurrences and survival in order to verify the usefulness of urinary exfoliated cells to follow-up BC progression.

P12.010-M

SEPT9/SYHR1, novel fusion gene identified in bladder cancer by RNA-seq.

T. Kekeeva[1], *A. Tanas*[1], *A. Shikeeva*[1], *L. Zavalishina*[2], *Y. Andreeva*[2], *G. Frank*[2], *D. Zaletaev*[1];
[1]Research Centre for Medical Genetics, Moscow, Russian Federation, [2]Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation.

Bladder cancer is one of the most common genitourinary malignancies in the world. The urothelial carcinoma (UC) has multiple genetic alterations, but only a few low-frequency fusion genes have so far been reported for this disease. In this study, we present a thorough search for novel fusion transcripts in UC sample using high-throughput RNA sequencing.
Sequencing was performed according to the paired-end RNA sequencing protocols from Illumina for Solexa sequencing on a Genome Analyzer II. We used the fusion discovery software tool Chimerascan. From 51 million paired-end sequence reads, we identified 563 candidate fused transcripts.
By stringent requirements, we nominated the one candidate fusion transcript for further experimental validation, which was positive by RT-PCR and Sanger sequencing. The transcript was intrachromosomal SEPT9/CYHR1 fusion gene. Septin 9 (17q25) is a member of the septin family of GTPases that have diverse cellular activity, including roles in cytokinesis, apoptosis, and vesicle trafficking. A chromosomal translocation involving this gene and MLL gene is described for acute myelomonocytic leukemia. CYHR1 (8q24) (cysteine and histidine-rich cytoplasmic protein) is involved in cellular trafficking transport of galectin 3. We founded two transcript variants: SEPT9 exon 2 was fused to CYHR1 exon 3 and SEPT9 exon 1 was juxtaposed to CYHR1 exon 3. We also revealed SEPT9/CYHR1 in 1/12 of UC FFPE samples.
Further investigation of functional and clinical relevance of novel fusion gene remains to be elucidated to reveal the role of SEPT9/CYHR1 in the carcinogenesis of bladder.

P12.012-M

Phenotypic and clinical characteristics of 3300 Israeli BRCA1 and BRCA2 mutation carriers

R. Michaelson-Cohen[1], *B. Kaufman*[2], *I. Kedar*[3], *E. Dagan*[4], *V. Adir*[5], *O. Reish*[6], *H. Baris*[7], *S. Shtemer*[3], *E. Evron*[6], *V. Libman*[6], *E. Levy*[1], *M. Simeonov*[8], *R. Gershoni-Baruch*[7], *R. Catane*[2], *E. Friedman*[8], *E. Levy-Lahad*[1];
[1]Shaare Zedek Medical Center, Hebrew University, Jerusalem Israel, Jerusalem, Israel, [2]Institute of Oncology Sheba Medical Center, Tel Hashomer, Israel, [3]Rabin Medical Center, Petach-Tikva, Israel, [4]University of Haifa, Haifa, Israel, [5]Bnai-Zion Medical Center, Israel Institute of Technology, Haifa, Israel, [6]Assaf Harofeh Medical Center, Tel-Aviv University, Zerifin, Israel, [7]Rambam Health Care Campus, Haifa, Israel, [8]Sheba Medical Center, Tel Hashomer, Israel.

Background: BRCA1/BRCA2 mutations are the most common cause of hereditary breast and ovarian cancer (HBOC). The HBOC-Consortium was created for unified data collection on Israeli BRCA carriers.
Methods: A uniform computerized-database was used by 12 cancer-centers
Results: Data were collected on 2145 BRCA1, 1131 BRCA2, and 22 double-mutation carriers.
BRCA1 vs. BRCA2 mutation carriers had more breast cancer (BC) (40.0% vs. 36.3%, p=0.06), ovarian cancer (OC) (17.1% vs. 10.6%, p<0.001), were younger at cancer diagnosis (BC 45yrs. vs. 49 yrs., p<0.001, OC 53yrs. vs. 62yrs., p<0.001), had more familial BC (64.5% vs. 59.0%, p<0.001), and familial OC (36.7% vs. 27.3% p<0.001).
BRCA1 carriers of 185delAG vs. 5382insC had less BC (38.6% vs. 46.4%, p=0.02), at older age (46yrs. vs. 40yrs., p=0.023), but more OC (17.6% vs. 12.9%, p=0.04).
Risk-reducing-bilateral-salpingoooporectomy (RR-BSO) rates were assessed in carriers 38-80yrs. BC patients had higher rates than unaffected carriers (92.6% vs. 78.1%, p<0.001), but underwent RR-BSO later (51yrs. vs. 48yrs., p<0.001). Carriers with familial OC had higher rates than carriers without (83.0% vs. 74.7%, p=0.05). Carriers with familial-cancer had RR-BSO earlier than those without (48 yrs. vs. 50yrs., p=0.037), especially BRCA2 carriers with familial OC (47 yrs. vs. 51yrs., p=0.018).
18/497(3.6%) male carriers had BC. 1/3 were BRCA1 carriers, and were younger at cancer diagnosis compared to BRCA2 mutation carriers (50yrs. vs. 57yrs., NS).
Conclusions: RR-BSO rates in Israeli carriers are very high, particularly in women affected with BC and family history of OC. Consortium data are consistent with lower cancer rates for BRCA2 mutations.

P12.013-S

Setting up the basis for translating "omic" data for BRCA1/2 into clinical practice

F. Buscherini, *C. Diquigiovanni, F. Isidori, L. Godino, R. Zuntini, S. Ferrari, D. Turchetti, E. Bonora;*
Unit of Medical Genetics Policlinico S. Orsola-Malpighi, BOLOGNA, Italy.

Germline mutations in BRCA1 or BRCA2 genes account for about 60% of inherited breast cancer and, subsequently, for approximately 3% of all breast cancer (BC) cases. It is of chief importance that women who carry a hereditary mutation are identified and given options for prevention; for this reason BRCA testing is increasingly offered to women with suspected BRCA mutations, implying a rapid growth of testing requests to the molecular laboratory. In this regard, we are currently comparing the analysis of these genes with the Ion AmpliSeq next generation sequencing technology with the classic Sanger method. Preliminary data on 14 samples, already analysed using Sanger method, were obtained using the BRCA1/2 Ion Ampliseq kit on Ion Torrent PGM: data indicated a reliable and robust variant identification and sequence coverage ranging from 99.995 to 100%. Data comparison will be presented for 40 patients. In addition, recent data suggest that constitutive epimutations in BRCA1 might be relevant to breast carcinogenesis. We identified in a pilot study on Sequenom MassARRAY system that blood DNA from BC patients (negative for BRCA1/2 mutations) was consistently more methylated in a region corresponding to chr17:38531627-38532076, compared to controls (60-90% vs 30-40%). Therefore an epigenetic and quantitative expression analysis of BRCA1 is currently carried out in a larger group of patients with or without BRCA mutations, and controls, in order to establish a correlation between the degree of methylation and the expression levels in our cohort of patients. This study is supported by grant PRUa1GR-2012-001 "DIANE".

P12.014-M

Characterization of *BRCA1* and *BRCA2* variants of unknown clinical significance identified in a Norwegian cancer cohort

E. Jarhelle[1,2,3], *H. M. F. R. Stensland*[1,2], *L. Mæhle*[4], *M. V. Ghelue*[1,2,3];
[1]Department of Medical Genetics, Division of Child and Adolescent Health, University Hospital of North Norway, Tromsø, Norway, [2]Northern Norway Familial Cancer Center, University Hospital of North Norway, Tromsø, Norway, [3]Department of Clinical Medicine, University of Tromsø, Tromsø, Norway, [4]Department of Medical Genetics, Oslo University Hospital, Oslo, Norway.

The most commonly mutated high penetrance genes in hereditary breast and ovarian cancer (HBOC) are *BRCA1* and *BRCA2*. Germline loss-of-function mutations in these genes confer a high risk of breast cancer to the individual carrier. However, besides the clear loss of function mutations, there are still a large number of sequence variants of uncertain clinical significance (VUS) in both genes. These VUS generate a huge challenge both for genetic counseling and prophylactic surgery.
In the current study, the consequences of some *BRCA1* and *BRCA2* VUS identified in Norwegian cancer patients were evaluated. Initially, their possible influence on RNA splicing was investigated by targeted sequencing of cDNA. In addition, the complete *BRCA1* and *BRCA2* cDNA were sequenced in order to uncover eventual alternatively spliced transcripts. Some of the variants affecting the BRCT domains of BRCA1 were tested for their influence on BRCA1 trans-activation function. In total, 19 individuals with *BRCA1* VUS and 18 individuals with *BRCA2* VUS from families with HBOC were included in this study. Three of the variants, *BRCA1* c.213-5T>A, *BRCA1* c.5434C>G and *BRCA2* c.68-7T>A, were shown to influence RNA splicing. Investigation of the full-length cDNA of *BRCA1* and *BRCA2* proved to be challenging due to the presence of several alternatively spliced transcripts which were also present in the controls. A functional assay, developed to assess the trans-activation ability of BRCA1, indicated that some of the variants may have a deleterious effect.

P12.015-S

Two new cases of double heterozygosity for BRCA1 and BRCA2 gene mutations identified in a cohort of Italian breast and ovarian cancer families

F. Vignolo Lutati[1], *G. Casalis Cavalchini*[1], *A. Sapino*[2], *B. Pasini*[1];
[1]Department of Genetics, Biology and Biochemistry, University of Turin, Torino, Italy, [2]SC Anatomia e Istologia Patologica – AOU Città della Salute e della Scienza di Torino - Presidio Molinette, Torino, Italy.

Double heterozygosity for BRCA1 and BRCA2 mutations is a very rare finding, particularly in non-Ashkenazi individuals, and only a few cases have been reported to date. Here we describe genetic and clinical data of two female double heterozygotes for both BRCA1 and BRCA2 mutations found in a cohort of 201 mutated Italian breast/ovarian cancer families out of 942 cases analyzed. The first one is a female patient affected by bilateral breast cancer at 47 and 49 years of age, carrying both a BRCA2 nonsense mutations (c.7408A>T - p.Arg2394X) and a BRCA1 proven splicing defect (IVS5-12A>G or c.331_332ins11 - p.Arg71SerfsX21). The second one is a female patient affected by ductal breast cancer at 42 years of age, carrying both a BRCA1 nonsense mutations (c.3726C>T - p.Arg1203X) and a BRCA2 frameshift mutation (c.3036_3039delACAA - p.Ala938ProfsX21). Although this event is rare (2/201: 1% in our clinical records, consistent with literature

data) and the phenotype is not worse than carriers of a single mutation, it has to be considered in the assessment of the biological effect of variants of uncertain biological effect. Furthermore the presence of a second mutation has important consequences for genetic counselling of relatives. We suggest that mutation analysis of index cases should always be extended in order to avoid missing a second BRCA mutation.

P12.016-M

BRCA mutation testing in all newly diagnosed patients with breast- or ovarian cancer: The DNA BONus study

C. Bjorvatn[1,2], T. Aas[3], B. E. Fiane[4], K. Woie[5], H. Espelid[6], T. Rusken[7], H. P. Eikesdal[8,2], M. T. Henanger[1], W. Listøl[1], P. M. Knappskog[1,2], V. M. Steen[1,2], N. Hoogerbrugge[9], **H. H. Vetti**[1]*;*
[1]Western Norway Familial Cancer Center, Haukeland University Hospital, Bergen, Norway, [2]Department of Clinical Science, University of Bergen, Bergen, Norway, [3]Department of Surgery, Haukeland University Hospital, Bergen, Norway, [4]Department of Gynaecology and Obstetrics, Stavanger University Hospital, Stavanger, Norway, [5]Department of Gynecology and Obstetrics, Haukeland University Hospital, Bergen, Norway, [6]Department of Surgery, Haugesund Hospital, Haugesund, Norway, [7]Department of Surgery, Førde Central Hospital, Førde, Norway, [8]Department of Oncology, Haukeland University Hospital, Bergen, Norway, [9]Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

Introduction: *BRCA*-mutation carriership affects treatment, follow-up and further cancer prevention in patients newly diagnosed with breast- or ovarian cancer. Therefore indications for *BRCA* mutation testing grow rapidly. We investigate prospectively 1) the frequency of *BRCA* mutation carriers among unselected breast- and ovarian cancer patients, 2) current criteria for *BRCA* mutation testing by age and family history, and 3) psychosocial effects of *BRCA*-mutation testing in newly diagnosed patients.
Materials and methods: *BRCA*-mutation testing is offered consecutively since September 2012 (ongoing) to unselected newly diagnosed patients with breast- or ovarian cancer at four hospitals in Western Norway. Initial testing is performed by a selected panel of 40 most frequent *BRCA*-mutations, covering more than 90% of *BRCA*-mutations in the native Norwegian population. Additionally, patients with a positive family history are invited for genetic counseling and further genetic testing.
Results: By February 2014 N=208 breast cancer patients (40% response rate) and N=40 ovarian cancer patients (67% response rate) have been included in the study. A pathogenic *BRCA*-mutation has been found in 5 (2.4%) breast cancer patients and 6 (15%) ovarian cancer patients; 9 *BRCA1* and 2 *BRCA2* mutations. Only one of these mutation carriers would have been missed by current guidelines. 42% of the participants have been invited for genetic counseling.
Conclusion: Less than half of the patients with breast cancer and two thirds of patients with ovarian cancer choose genetic testing at diagnosis. The incidence of *BRCA*-mutations is particularly high among unselected patients with ovarian cancer. The updated results will be presented.

P12.017-S

Involvement of the *RNU2* macrosatellite in breast cancer susceptibility

C. Tessereau[1], *M. Buisson[1], M. Imbert[1], L. Barjhoux[1], F. Damiola[1], M. Dondon[2], S. Eon-Marchais[2], GENESIS investigators, F. Lesueur[2], D. Stoppa-Lyonnet[2], N. Andrieu[2], O. Sinilnikova[1,3], S. Mazoyer[1];*
[1]Cancer Research Centre of Lyon, Lyon, France, [2]Institut Curie, Paris, France, [3]Unité Mixte de Génétique Constitutionnelle des Cancers Fréquents HCL/CLB, Lyon, France.

The *RNU2* macrosatellite is a tandem array of a 6.1 kb repeat unit containing the 190 bp-long gene coding for snRNA U2, *RNU2-1*, and 3.8 kb of interspersed repetitive DNA. Although located 124 kb telomeric to the breast and ovarian cancer susceptibility gene *BRCA1*, the *RNU2* locus is absent from the human genome assembly due to the inherent difficulty to assemble repetitive sequences. Thus, the influence that these large tandem repeat arrays might exert on neighbouring gene expression, stability or architecture and their contribution to the genetic basis of common human diseases remains largely unexplored. We have recently characterized in more details the *RNU2* locus and tested the association between *RNU2* copy number and breast cancer risk. Indeed, the proximity of this macrosatellite to *BRCA1* combined with its high degree of polymorphism raises the interesting possibility that it could be involved in breast cancer susceptibility, especially as no mutation is identified in *BRCA1/2* in 80% of the families tested in a diagnostic setting. We conducted a case-control study by genotyping the *RNU2* macrosatellite with a qPCR assay in 1452 familial breast cancer cases, 1457 affected and unaffected relatives and 1241 unrelated controls of the French study GENESIS. We found that mean *RNU2* global copy number (GCN) is higher in cases (52 copies) than in controls (50 copies). In addition, we found more very high *RNU2* GCN (>100) in affected women. We are presently investigating the functional impact of extremely large *RNU2* GCN on the *BRCA1* locus.

Investigating the management of symptomatic and pre-symptomatic BRCA gene mutation carriers in an Irish Tertiary referral centre

T. P. McVeigh[1], *R. Irwin[1], N. Cody[2], K. J. Sweeney[1], A. J. Green[2], N. Miller[1], M. J. Kerin[1];*
[1]National University of Ireland Galway, Galway, Ireland, [2]National Centre for Medical Genetics, Dublin, Ireland.

Aims: Germline mutations in BRCA1 and 2 confer a high risk of breast cancer. The aim of our study was to outline the disease phenotype and management of BRCA gene mutation carriers in the West of Ireland.
Methods: A longitudinal cohort study was undertaken. The study group included patients proven to carry a single gene mutation in BRCA1 or BRCA2 between 2000 and 2013. Clinicopathological information was obtained by chart review.
Results: Fourteen pathogenic mutations were identified in BRCA1 in 45 individuals from 24 families. The most common mutations were large genomic rearrangements, with deletion of exons 1-23 in 5 families, deletion exons 14-20 in 3 families and deletion exons 21-24 in 2 families. Fourteen pathogenic mutations were identified in BRCA2, in 32 individuals from 19 families. The most common was frameshift mutation 8525delC, in 5 families. Of forty-one patients affected with breast cancer, 17 carried mutations in BRCA1 and 24 mutations in BRCA2. Median age of onset of breast cancer in BRCA1 mutation carriers was 40years(25-67), and 45years(35-64) in BRCA2 mutation carriers (p=0.02, Mann-Whitney). Eight patients developed bilateral breast cancers including 6 BRCA1 mutation carriers. Five of six patients with ovarian cancer carried BRCA1 mutations. Ten of 51 pre-symptomatic carriers underwent surgical prophylaxis, including 9 prophylactic mastectomies and 5 oophorectomies.
Conclusions: BRCA gene mutations account for a small proportion of inherited predisposition to breast cancer. Carriers of these mutations require intensive surveillance or surgical prophylaxis. Counselling and testing of pre-symptomatic family members can facilitate intervention and modify disease phenotype.

P12.019-S

Characteristics of Greek patients with breast cancer rearrangements in BRCA1 gene

A. Vratimos[1], *F. Fostira[1], P. Apostolou[1], I. Konstanta[1], G. Fountzilas[2], I. Konstantopoulou[1], D. Yannoukakos[1];*
[1]Molecular Diagnostics Laboratory, National Center of Scientific Research Demokritos, Athens, Greece, [2]Department of Medical Oncology, Papageorgiou Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece.

In most countries large genomic rearrangements (LGRs) in *BRCA1* and *BRCA2* genes occur in a small percentage of patients tested for hereditary breast-ovarian cancer. Instead, in the Greek population, four specific LGRs have been identified in *BRCA1* [deletions of exon 20 (4kb), exon 20 (3kb), exon 24 (4,5kb), and exons 23-24 (11kb)], the latter three of which have been characterized as founder mutations. Several factors may be associated with LGRs, such as younger age at breast cancer (BC) diagnosis, bilaterallity and estrogen receptor–negative status.
The study's objective was to assess the possible establishment of criteria leading to targeted screening, as well as to increase our insight into the role and clinical significance of specific *BRCA1* pathogenic findings.
In a cohort of 2.100 hereditary BC or OC patients, 74 (3,5%) were found to carry one of the four LGRs. We have investigated the possible association between *BRCA1* LGRs and the aforementioned factors. The mean age at diagnosis was 40,6 years. Among the 74 patients, 43 (60%) developed BC, 15 (20%) both BC and OC, where 16 (20%) developed OC only. 14 out of 74 developed bilateral (3/14), contralateral (9/14) and ipsilateral (2/14) BC. Histopathology data was available for 40 out of 58 BC patients, demonstrating that 29/40 (72%) were triple-negative, 6/40 (15%) were ER+/PR+/Her2-, 3 (7,5%) were ER-/PR-/Her2+, 1 (2,5%) was ER+/PR-/Her2- and 1 (2,5%) was ER+/PR+/Her2+.
In conclusion, LGRs compared to other loss-of-function mutations of *BRCA1* gene do not seem to be associated with specific clinical or histopathological features.

TAp73α regulates Otx1 expression during breast cancer stem cells differentiation and in response to cisplatin treatment

I. S. Pagani[1,2], *C. Pirrone[1], E. Amelotti[1], A. Terrinoni[2], F. Bernassola[2], A. G. Sanarico[2], M. Agostini[3], F. Pasquali[1], F. Lo Curto[1], I. Zucchi[4], E. Candi[2], G. Melino[2,3], G. Porta[1];*
[1]University of Insubria, Varese, Italy, [2]Tor Vergata University, Rome, Italy, [3]Medical Research Council Toxicology Unit, University of Leicester, Leicester, United Kingdom, [4]Institute of Biomedical Technologies, National Research Council, Milan, Italy.

Breast cancer is the most fatal disease for women in Western countries, despite mammography screening and adjuvant therapy with tamoxifen and polychemotherapy. Knowing the molecular mechanisms underlying this

disease may contribute to the identification of new targets for future therapies. Tp53, Tp63 and Tp73 tumor suppressor family members encode for transcription factors which control genome integrity. They take part in cell response and in tumor suppression. Wild-type p53 protein is a growth modulator and its inactivation is a critical event in malignant transformation of breast cancer stem cells (CSCs). Otx1 is an homeobox gene involved in central nervous system development, and when deregulated, plays a role in tumorigenesis. We showed that Otx1 is over-expressed in ductal and lobular invasive breast cancers and that is involved in adult mammary gland development. We demonstrated that p53 directly regulates Otx1 gene expression binding to the 3'p53 responsive element (RE) on its promoter, and that this pathway regulates the LA7 breast CSCs differentiation. Here we will show that the TAp73α isoform of p73 is able to bind the 5'p53RE on the Otx1 promoter, leading to the LA7 cell differentiation and the asymmetric division of breast CSCs. Furthermore we will demonstrate that Otx1 and TAp73 are over-expressed in ductal and lobular invasive breast carcinoma. Finally we will show the functions of the TAp73α/Otx1 pathway in differentiation of mammospheres obtained from wild-type and c-ErbB2 transgenic mice, and the response to cisplatin treatment in MCF7 and MBA-MB-231 breast cancer cells.

P12.021-S

One in three Greek patients with early onset or familial breast cancer carries a loss of function mutation in a known or candidate breast cancer gene

F. Fostira[1], *T. Walsh*[2], *S. Casadei*[2], *M. K. Lee*[2], *P. Apostolou*[1], *G. Fountzilas*[3], *I. Konstantopoulou*[1], *M. King*[2], *D. Yannoukakos*[1];
[1]*NSCR Demokritos, Athens, Greece,* [2]*University of Washington, Seattle, WA, United States,* [3]*Aristotle University of Thessaloniki, Thessaloniki, Greece.*

The antiquity of the Greeks as a population defined by language and culture, and the complexity of Greek historical demography, present challenges to genetic testing for predisposition to cancer. The Greek population harbors ancient founder mutations in many genes, including five BRCA1 damaging alleles, as well as many disease alleles that are specific to one or a few families. The aim of this study was to identify loss-of-function mutations in 22 genes in 736 patients with breast cancer diagnosed at a young age (<35 years) or with a strong family history of breast, ovarian, and/or pancreatic cancer.
Targeted capture and multiplexed sequencing was carried out using BROCA, which captures the entire loci of 22 genes. Of 736 patients with young onset or familial breast cancer, 252 (34%) carried loss-of-function mutations in one of 11 genes. Frequencies were: 103 BRCA1 founders, 61 other BRCA1, 45 BRCA2, 29 CHEK2, 7 PALB2, 7 ATM, 2 PTEN and 1 in each in RAD51C, FAM175A, BRIP1, PIK3CA and TP53. PALB2 p.R753X was observed in four Greek families and may be a founder allele. We conclude that among Greek patients with familial or early onset breast cancer more than a third carry loss-of-function mutations in a breast cancer-related gene. Founder mutations account for about 50% of the BRCA1 and BRCA2 mutational burden and about 40% of the mutational burden in all known and candidate breast cancer genes. Given genetic heterogeneity, patients benefit from an approach that detects all classes of mutations in known breast cancer genes.

P12.022-M

Mutations in CHEK2 and NBN genes among Macedonian breast cancer patients

M. Jakimovska[1], *I. Maleva*[1], *L. Stojanovska*[2], *A. Arsovski*[2], *D. Plaseska-Karanfilska*[1];
[1]*Research Centre for Genetic Engineering and Biotechnology „Georgi D. Efremov", Macedonian Academy of Sciences and Arts, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Re-Medika Hospital, Skopje, Macedonia, The Former Yugoslav Republic of.*

Heterozygotes for mutations in CHEK2 and NBN genes were found to be associated with increased risk of developing cancers, including breast cancer (BC). The aim of our study was to determine the frequency of three common mutations in CHEK2 gene (1100delC, I157T and IVS2+1G>A) and two mutations in NBN gene (R215W and 657del5) among Macedonian BC patients and controls from the general population. For this purpose we have designed a multiplex PCR followed by SNaPshot analysis. A total of 299 BC patients, of whom 112 with a cancer family history and 283 controls were included in the study. Mutations were more frequent among BC patients (n=13, 4.3%) than among controls (n=5, 1.8%), although without statistical significance. Twelve patients were heterozygous for one of the analyzed mutations, while one patient had two mutations (NBN R215W and CHEK2 I157T). The most frequent mutation was CHEK2 I157T, found in 10 BC patients and 4 controls. The frequency of this mutation was statistically higher among BC patients with a cancer family history when compared to the controls (p=0.028). NBN R215W was found in one BC patient and one control, while CHEK2 1100delC and NBN 657del5 were found each in one BC patient and no control. CHEK2 IVS2+1G>A has not been found in our study. In conclusion, our study suggests that mutations in CHEK2 and NBN genes might play a role in the development of breast cancer among Macedonian patients. A study including larger number of patients and controls are needed to confirm these results.

P12.023-S

BRCA1 and BRCA2 mutation detection by a Next Generation Sequencing approach: an epidemiological study conducted in Southern Italy

M. Esposito[1,2], *M. D'Aiuto*[3], *A. Telese*[1], *V. Precone*[1,2], *M. Nunziato*[1,2], *A. Calabrese*[3], *G. Frisso*[1,2], *G. D'Aiuto*[3], *V. D'Argenio*[1,2], *F. Salvatore*[1,2,4];
[1]*Ceinge - Biotecnologie Avanzate, Naples, Italy,* [2]*Department of Molecular Medicine and Medical Biotechnologies, University of Naples Federico II, Naples, Italy,* [3]*Department of Senology, Istituto Nazionale Tumori – IRCCS Fondazione Pascale, Naples, Italy,* [4]*IRCCS-Fondazione SDN, Naples, Italy.*

Hereditary breast and ovarian cancer (HBOC) accounts for about 10% of all breast cancers and BRCA1 and BRCA2 are the most prevalent genes causing this pathology. BRCA1/BRCA2 germline mutations escalate the risk of developing HBOCs by up to 20 fold. Testing for BRCA gene mutations is important to improve the clinical management of the high-risk patients and of their mutation carriers family members.
A NGS screening for BRCA1/2 germline mutations of 300 patients, with early-onset breast cancer ("*under forty*") and/or with positive family history, is reported in order to identify mutation carriers. BRCA1/BRCA2 coding regions were amplified using the BRCA MASTR v2.1 Assay (Multiplicom). Sequencing reactions were performed with the 454 GS FLX System (Roche) and the downstream data analysis was carried out through the SeqNext tool (JSI Medical Systems).
More than 15% of the analyzed patients, including a few men, carried a causative mutation. Several novel variants were identified: 1 splice variant, causing the loss of a canonic donor splice site at position +2 in the intron 21 of BRCA1 gene, and 1 missense variant falling in the BRCA2-DNA binding region; one double mutation including 1 missense mutation on BRCA1 gene causing a premature stop codon; 2 synonymous variants and 1missence variant predicted without clinical significance were found. Functional *in vitro* evaluations are ongoing to assess their pathogenicity.
Subsequent analysis of the mutation carriers families, allowed the identification of at higher risk subjects, including men healthy carriers, that have been involved in surveillance program of preventing health care.

The MRE11A-RAD50-Nibrin (MRN) complex plays several critical roles related to repair of DNA double-strand breaks. Inherited biallelic mutations in any one of the three components predispose to genetic instability disorders. Inherited heterozygous mutations in the MRN genes have been implicated in breast cancer (BC) susceptibility, but the underlying data are not entirely convincing. In order to verify if rare MRN variants are intermediate-risk BC susceptibility alleles, we mutation screened the coding exons and proximal splice junctions of the MRN genes in 1,313 early onset BC cases and 1,123 population controls.
Considering the extremely low frequency of likely pathogenic variants in these genes in the general population, we have decided to evaluate the genes as if they constitute one relatively large gene (though still smaller than ATM, another gene in the same pathway).
Limiting our analyses to variants with MAF<0.1% and combining protein truncating variants, likely spliceogenic variants, and key functional domain rare missense substitutions, we found significant evidence that the MRN

genes are indeed intermediate-risk BC susceptibility genes (OR= 2.88, P= 0.0090). In addition we found that key domain missense substitutions were more frequent (24 vs 12 observations) than the truncating variants and conferred a slightly higher OR (3.07 vs 2.61) with a lower P-value (0.029 vs 0.14). Thus, the spectrum of pathogenic variants in MRN genes includes, as for ATM and CHEK2, a relatively high proportion of missense, and differs notably from the BRCA1/2 pattern where most susceptibility alleles are protein-truncating variants.

P12.025-S

Search for recessive cancer predisposition genes: the advantage of multiple primary cancer cases vs. family history-positive patients

E. Kuligina[1,2], *A. P. Sokolenko*[3], *N. V. Mitiushkina*[2], *S. N. Abysheva*[2], *T. V. Gorodnova*[2], *G. A. Yanus*[3], *S. G. Kuznetsov*[4], *E. N. Imyanitov*[2,3];
[1]Polo d'Innovazione di Genomica, Genetica e Biologia, University of Perugia, Perugia, Italy, [2]N.N. Petrov Institute of Oncology, St.-Petersburg, Russian Federation, [3]St.-Petersburg Pediatric Medical Academy, St.-Petersburg, Russian Federation, [4]Institute for Molecular Medicine Finland, Helsinki, Finland.

Virtually all known tumor predisposing genes have been identified via the analysis of familial cancer cases. Here we argue that this approach is likely to miss recessively acting cancer genes and suggest the analysis of family history-negative patients with multiple primary malignancies for identifying homozygous at-risk genotypes. We performed calculations showing that in cases of transmission of a recessive cancer predisposing allele (a), which has a frequency of 0.1 and a penetrance of 100%, only a minority of patients with the aa genotype (19%) will have one or both parents with the same genotype and hence report a family history of cancer. Therefore, while the focus on familial cancer clustering is a powerful tool for identifying dominant mutations, the cases of disease caused by the homozygous recessive at-risk alleles may be easily missed. We further revealed that the c.2515_2519delAAGTT homozygous mutation in a Holliday junction resolvase, GEN1, was over-represented in women with bilateral breast cancer (BC) as compared to healthy controls [11/360 (3.1 %) vs. 18/1305 (1.4 %); OR = 2.25 (1.02 - 4.75); p = 0.031], although this trend was not pronounced in unilateral BC patients. Noticeably, the presence of biallelic c.2515_2519delAAGTT mutation was associated with the absence of BC in mothers of both bilateral and unilateral BC patients [7/239 (3.0 %) vs. 0/41 (0 %) and 21/1,558 (1.3 %) vs. 0/215 (0 %), respectively; p = 0.041]. This study confirms that patients with multiple cancers may be particularly fruitful for the identification of recessive determinants of cancer predisposition.

P12.026-M

High-throughput genetic analysis in 100 hereditary breast cancer patients

U. E. A. Faust, *T. C. Benkert, M. Heilig, S. Hertler, M. Sturm, H. Nguyen, C. Schroeder, O. Riess, P. Bauer;*
Dept of Medical Genetics and Applied Genomics, Tuebingen, Germany.

Objective: Here, we report our first results from our HBOC-NGS-panel that includes 56 genes associated with breast and ovarian cancer. So far, 100 samples were analyzed in a diagnostic setting.
Methods: A custom NGS-panel (HaloPlex, Agilent) was used to target 56 genes. Depending on the patient's family history, a set of "diagnostic" genes (mostly BRCA1/2, RAD51C/D) as well as "screening" genes were defined. DNA was isolated from all samples, enriched and sequenced on the Illumina MiSeq (2x 150 bp paired-end) following standard protocols. For diagnostic genes, regions with low depth (< 20x) were complemented by Sanger sequencing as well as MLPA. All mutations were confirmed by conventional Sanger sequencing.
Results: So far, we have sequenced 100 hereditary breast cancer patients. Overall 91-99 % of all targeted exons were represented with a "diagnostic" average depth of > 20x. Roughly 70 SNVs were identified per sample and stringent filtering resulted in less than seven variants for validation.
We identified 15 mutations that are known to cause HBOC as well as mutations likely to cause HBOC. Further experiments and segregation analysis is required to determine the pathogenicity in the latter. In addition heterozygous mutations were found in genes relevant for different autosomal recessive cancer syndromes.
Conclusion: Taken together, we demonstrate that NGS is a fast and cost efficient genetic screening tool to analyze for variants in genes associated with the development of hereditary breast cancer. By applying this approach we were able to uncover both known and novel sequence variants

P12.027-S

BRCA1 and BRCA2 germline mutational spectrum among Macedonian women with breast cancer detected by next generation sequencing

D. Plaseska-Karanfilska[1], *I. Maleva*[1], *M. Jakimovska*[1], *K. Popovska-Jankovic*[1], *K. Kubelka*[2], *M. Karagjozov*[2], *L. Stojanovska*[3], *A. Arsovski*[3];
[1]Research Centre for Genetic Engineering and Biotechnology „Georgi D. Efremov", Macedonian Academy of Sciences and Arts, Skopje, Macedonia, The Former Yugoslav Republic of, [2]Adzibadem-Sistina Hospital, Skopje, Macedonia, The Former Yugoslav Republic of, [3]Re-Medika Hospital, Skopje, Macedonia, The Former Yugoslav Republic of.

The contribution of *BRCA1/2* mutations to hereditary breast cancer (BC) in women from R. Macedonia is largely unknown. Our previous small study revealed the presence of seven mutations (c.181T>G, c.1102G>T, c.5266dupC, c.81-?_547+?del and c.5407-?_5467+?del in *BRCA1* and c.8167G>C and c.1-?_6937+?del in *BRCA2* gene) in 10 unrelated BC families.
Here we describe the next generation sequencing analysis of *BRCA1* and *BRCA2* genes in 94 BC patients using TruSeq Custom Amplicon for library preparation and sequencing on Illumina MiSeq personal sequencer. In addition to the standard inclusion criteria, patients with triple negative tumors and *BRCA1*ness profile determined by MLPA analysis were included in this study.
Eight BC patients have been previously analyzed by Sanger sequencing; all sequence variations previously determined were correctly identified. Among the 94 analyzed BC patients we detected a total of 78 sequence variations (30 in *BRCA1* and 48 in *BRCA2*). Thirty five of these variants were found with a frequency between 2.7% and 42.9% among the analyzed patients, while 43 variants were found in only one or two patients. A total of 14 pathogenic mutations were detected of which 11 have been previously described (c.5266dupC, c.3700_3704delGTAAA, c.2596C>T in *BRCA1* and c.5351dupA, c.5848_5851delGTTA, c.7811_7814delTGTG, c.7879A>T, c.7916 C>T, c.8168A>G, c.9104A>C, c.9350_9351delAT in *BRCA2*), while three mutations were novel (c.4360delT in *BRCA1* and c.3186_3189delTCAG and c.8315_8328delAATCTCTTAT in *BRCA2*).
In conclusion, our work demonstrates that using TruSeq Amplicon technology and sequencing on MiSeq system is a fast, reliable and cost effective approach for mutational screening of *BRCA1* and *BRCA2* genes.

P12.028-M

Testing for genetic predisposition to breast cancer by NGS

S. Ivanov[1], *R. Vazharova*[1], *L. Balabanski*[1], *D. Serbezov*[1], *I. Dimova*[2], *M. Malinov*[1], *D. Toncheva*[2,1];
[1]Genomics Laboratory of Malinov Clinic, Sofia, Bulgaria, [2]Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria.

About 5-10% of breast cancer is due to inherited mutations. Genetic testing for predisposition in individuals with family history is recommended to determine their risk for developing this cancer type. Next generation sequencing enables us to perform analysis for large number of predisposing genes.
In this study, DNA samples were obtained from 27 individuals with positive family history – affected or still not affected. Informed consent was obtained from all the subjects. Sequence analysis for BRCA1/BRCA2 or 94 cancer-predisposing genes and 284 variants associated with cancer was performed on Illumina MiSeq system.
A wide range of variants were identified in the BRCA1 and BRCA2 genes. Four pathological variants were detected (14.8%): mutation in BRCA2 at the chromosomal (chr) position chr13:32890665, which affected the first position of the 5' splice region following exon 2; mutation in BRCA1 at chr17:41219635, causing an inframe triple nucleotide deletion of valine 1688 (8.3%); mutation in TP53 - c.775T>AT; 193H>LH; frameshift mutation in BRCA2 - c.2808_2811delACAA, p.Ala938ProfsTer21.
To the best of our knowledge, this study was the first to identify 3 common polymorphisms in BRCA2, characteristic solely of the Bulgarian population, including chr13:32973737, T/, a singlenucleotide polymorphism (SNP) within the 3'UTR of exon 27; chr13:32973280, A/, mononucleotide deletion within the 5'UTR of exon 27; and chr13:32973924, T/, mononucleotide deletion downstream of the gene sequence. Furthermore, this study was the first to apply nextgeneration sequencing of cancer-predisposing genes in Bulgarian population, prompting further investigation for local founder mutations and variants characteristic for this particular region.

P12.029-S

A PALB2 high-risk mutation recurrent in familial breast cancer cases from the province of Bergamo

Bernard*[7], *M. Barile*[8], *B. Bonanni*[8], *B. Peissel*[9], *S. Manoukian*[9], *C. Tondini*[4], *P. Radice*[2];
[1]IFOM, Fondazione Istituto FIRC di Oncologia Molecolare, Milano, Italy, [2]Unit of Molecular Bases of Genetic Risk and Genetic Testing, Department of Preventive and Predictive Medicine, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy, [3]Unit of Medical Statistics, Biometry and Bioinformatics, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy, [4]Unit of Medical Oncology, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, [5]Department of Immunohematology and Transfusion Medicine, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, [6]Associazione Italiana Volontari Sangue (AVIS) Comunale Milano, Milano, Italy, [7]Department of Experimental

Oncology, Istituto Europeo di Oncologia, Cogentech, Milano, Italy, [8]Division of Cancer Prevention and Genetics, Istituto Europeo di Oncologia, Milano, Italy, [9]Unit of Medical Genetics, Department of Preventive and Predictive Medicine, Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy.

Germline deleterious mutations of PALB2 are associated with breast cancer risk and have been reported in several populations. In our initial survey, truncating PALB2 mutations were detected in 12/575 (2.1%) familial breast cancer cases negative for BRCA gene mutations (BRCAX), recruited at two large cancer centres in Milan (Istituto Nazionale Tumori and Istituto Europeo di Oncologia). One mutation (c.1027C>T; p.Gln343X) recurred in three cases, two of whom originally from the province of Bergamo. The genotyping of the c.1027C>T in 113 BRCAX cases ascertained at Azienda Ospedaliera HPG23 of Bergamo, detected a total of 6 carriers (5.3%), while only 2 carriers were observed among 477 female blood donors recruited in the same area (0.4%). The estimated age-adjusted odds ratio of these frequencies was 13.4 (95% confidence interval: 2.7–67.4). This value is similar to those previously observed for a few PALB2 mutations recurrent in other countries and suggests that the c.1027C>T is associated with a relatively high breast cancer risk. Of note, we also found that among breast/ovarian cancer families recruited in Bergamo the mutational spectra or both BRCA1 and BRCA2 were much less heterogeneous than in families ascertained in Milan. In particular, one BRCA1 founder mutation was observed in >8% of Bergamo families (Caleca et al., 2014). Further analyses are required to verify whether genotyping for specific recurrent mutations can be proposed as a cost-effective strategy for the rapid identification of individuals genetically predisposed to breast/ovarian cancer in the Bergamo area.

RNA-Sequencing in MCF-7 cells: identification of a new transcript of SEMA3F and its expression in breast cancer

R. Aversa[1], *M. R. Ambrosio[1,2], A. Zambelli[3], A. Ciccodicola[1], L. D'Apice[4], V. Costa[1];*
[1]Institute of Genetics and Biophysics „A. Buzzati-Traverso" (IGB), National Council of Research (CNR), Naples, Italy, [2]Department of Translational Medical Sciences (DiSMeT), University of Naples "Federico II", Naples, Italy, [3]Oncology Department, IRCCS S. Maugeri Foundation, Pavia, Italy, [4]Institute of Protein Biochemistry, National Council of Research (CNR), Naples, Italy.

Breast cancer is the most common tumor in women, and the second leading cause of death. Tumor cells invasiveness is mainly due to an alteration of cell-cell and cell-matrix connections. Thus, an altered expression of adhesion molecules and their receptors is a crucial event in this process. Among them, semaphorins, a large family of transmembrane or secreted molecules that regulate cell migration and adhesion, are of peculiar interest. A growing number of studies - and our recent work on *SEMA6B* in breast cancer among these - has demonstrated their involvement in cancer progression, often with divergent functions.
In order to simultaneously investigate gene expression and alternative splicing for all the genes encoding adhesion molecules, and particularly for semaphorins, their receptors and co-receptors, we performed RNA-Sequencing experiment on MCF-7 cells, a well-established and widely used cellular model of breast cancer. Interesting preliminary results were obtained, particularly for *SEMA3F* gene. Indeed, we identified a novel transcript generated by alternative splicing, predicted to encode for a truncated semaphorin. Moreover, through semiquantitative PCR and quantitative Real-Time assay we measured SEMA3F expression on a panel of breast cancer tissues compared to their healthy counterpart. The analysis revealed a strong and significant up-regulation of *SEMA3F* in breast cancer and, intriguingly, the sole presence - in the healthy tissues - of the newly identified transcript. These evidences suggest *SEMA3F* to be a potential biomarker for onset/progression of breast cancer.

P12.031-S
Investigating the importance of variants at 12p11, 12q24 and 21q21 in breast cancer in the west of Ireland

U. M. McVeigh, *T. P. McVeigh, K. J. Sweeney, M. J. Kerin, N. Miller;*
National University of Ireland Galway, Galway, Ireland.

Introduction: Recent genome-wide association studies have identified novel breast cancer susceptibility loci in women of European ancestry at 12q24 (rs1292011); 12p11 (rs10771399) and 21q21 (rs2823093). The aim of our study was to investigate the prevalence of variants at these three loci in a specific Irish subpopulation, and to examine the association between these variants and breast cancer in this cohort.
Methods: DNA was extracted from the whole blood of patients with breast cancer and from healthy female controls using a salting out method. Genotyping of each sample for each of the three targets was carried out using a Taqman®-based platform. Statistical analysis was performed using SPSS software after testing for Hardy-Weinberg equilibrium.
Results: A total of 1639 samples were included in the study group, comprising 1191 cases and 448 controls. The minor allele at locus 12p11 was found to confer a significant protective effect, with a per allele odds ratio of 0.7 (0.5-0.9, p=0.002, X2). The minor allele at 12q24 had a slight protective effect (per allele OR =0.9 (0.8-1.1, p =0.29, X2)). The minor allele 21q21 did not confer a protective effect, and was in disequilibrium as per test of Hardy-Weinberg.
Conclusion: All three genetic variants were detected in the population in the west of Ireland. The G allele at 12p11 was associated with reduced breast cancer risk. Population-specific genome wide association studies are required to identify susceptibility loci specific to the Irish subgroup

DNA-diagnostics for inherited breast and/or ovarian cancer: standard approaches and novel technologies

L. N. Lyubchenko[1], I. S. Abramov[2], E. I. Bateneva[1], A. S. Tyulyandina[1], O. V. Krokhina[1], I. K. Vorotnikov[1], V. A. Sobolevsky[1], S. M. Portnoy[1], **T. V. Nasedkina**[2];
[1]N.N.Blokhin Russian Cancer Research Center, Russian Academy of Medical Sciences, Moscow, Russian Federation, [2]Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, Moscow, Russian Federation.

Modern molecular techniques allow revealing the most characteristic genetic changes responsible for hereditary breast and/or ovarian cancer (hBC/OC), calculating the risk of neoplasia development, defining treatment and prevention. In routine diagnostics of hBC/OC two methods: biochip-based approach and real-time PCR were used for the analysis of founder mutations in Russian Federation, namely, 185delAG, 300T>G, 4153delA, 4158A>G, 5382insC, 6174delT, 1100delC. However, only 15% of patients were found to carry the BRCA1/2 or CHEK2 mutation. Other genes, like TP53, PALB2, ATM, BRIP1, RAD50, BLM and so on, are widely tested in patients with hBC/OC susceptibility. The aim was to study an impact of TP53 germline mutations and polymorphisms into predisposition to bilateral BC and/or secondary-primary multiple neoplasia (SPMN). Genomic DNA was isolated and exons 4-11 of TP53 gene were amplified with commercial primer set SeqPlateTP53. Next-generation sequencing was performed using a platform GS Junior (454/Roche). The results were validated by Sanger sequencing. Exons 4-11 of TP53 gene in 22 patients with SPMN including BC or bilateral BC and without founder mutations in BRCA genes (wtBRCA) were analyzed. The findings included several rare variants with population frequency less than 0.001%. Previously found nonsense mutation 2637C/T, leading to stop-codon instead of arginine (codon 306) in patient with bilateral BC was confirmed by NGS. A heterozygous germline missense mutation in codon 241 (c.722C>A) was diagnosed in patient with SPMN (Li-Fraumeni syndrome). The mutation was confirmed by Sanger sequencing. The data demonstrated the clinical utility of TP53 testing in selected patients with SPMN and/or bilateral BC.

The experiences and views of health care professionals and researchers regarding the feedback of results in the context of next generation sequencing in oncology

H. Howard[1,2,3], A. Mahalatchimy[1,2,4], **A. Soulier**[1,2], *A. Blassime[1,2], A. Cambon-Thomsen[1,2];*
[1]INSERM, Toulouse, France, [2]Université Paul Sabatier, Toulouse, France, [3]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [4]IRDEIC Université Toulouse 1 Capitole, Toulouse, France.

Next generation sequencing (NGS) allows the production of large volumes of sequence data (and potentially genetic results) and the ethical and practical issues regarding feedback of results become particularly pertinent to address. Should (any) results be given to research participants? If so, which results and who should provide them? Within two EU funded projects in oncology (CAGEKID and EUROTARGET), in order to gather researchers' and health care professionals' views and experiences on providing results we distributed a questionnaire to attendees of genetics meetings in Europe in 2013.
Of the 95 respondents, 88% work as researchers and/or clinicians in a field related to oncology and half (52%) use NGS in some aspect of their work; 56% of respondents state that they provide specific information about NGS to participants or patients before enrolling them in a study or using their samples for sequencing. The majority, 83% had never received requests from physicians or patients for access to NGS data to inform treatment decisions. Regarding feedback of results in a research setting, 54% or respondents think that results stemming from NGS studies should be provided to individual participants and 72% think that actionable incidental findings should be disclosed to participants. Finally, 53% of respondents think that specific measures and/or limitations should be implemented for the sharing of NGS data/results with colleagues in the scientific community. Such empirical data from stakeholders is a valuable contribution to the ongoing discussion of how to responsibly handle and feedback results to patients and research subjects.

Whole-genome profiling of cervical carcinomas patients with CGH+SNP microarrays: correlations with clinical outcome

K. Kašíková[1,2], *J. Smetana*[1,2,3], *V. Vallová*[1,2], *L. Mouková*[4], *M. Cvanová*[3], *L. Brožová*[3], *P. Kuglík*[1,2];

[1]*Masaryk University, Faculty of Science, Institute of Experimental Biology, Brno, Czech Republic,* [2]*University Hospital, Department of Medical Genetics, Brno, Czech Republic,* [3]*Masaryk University, Faculty of Medicine and Faculty of Science, Institute of Biostatistics and Analyses, Brno, Czech Republic,* [4]*Masaryk Memorial Cancer Institute, Department of Gynaecological Oncology, Brno, Czech Republic.*

Alterations in the genome that lead to changes in DNA sequence copy number are characteristic features of solid tumors. In this study, we used GGH+SNP microarray technique for detailed screening of copy number alterations (CNAs) in a cohort of 26 patients with uterine cervical carcinoma (UCC), and the findings were correlated with the incidence of lymph node metastasis and lymphangioinvasion. The whole-genome screening discovered CNAs in 73.1% of samples. Frequent areas of gains were observed in 3q (50.0%), 1q (42.4%), 19q (23.1%), while losses were commonly observed in 11q (30.8%), 4q (23.1%), 13q and 2q (both 19.2%). Regions of loss of heterozygosity were observed in 15.4% in 11q23, 14q21, 18q12.2 and 8q21. The incidence of gain 3q was associated with gain 1q (P=.033), while loss of 4p was commonly observed with loss of 13q (P=.010). Higher occurrence of CNAs was associated with patients under 45 years (P=.016). Patients with adenocarcinoma have statistical trend to carry genomic profiles without CNAs (P=.051). Incidence of lymph node metastases was associated higher number of CNAs (12 vs 9; P=0.452) and patients without LVSI had trend to higher incidence of gains in chromosome 15q. Taking together array-CGH techniques allowed us to precisely detect specific cytogenetic lesions in UCC, which can be used for prognosis of the disease as well as novel genomic markers associated with the development of invasive cervical cancer.

Human bile contains microRNA-laden extracellular vesicles that can be used for cholangiocarcinoma diagnosis

C. Tomuleasa[1], *F. Selaru*[2], *I. Berindan-Neagoe*[1];

[1]*Iuliu Hatigenu University of Medicine and Pharmacy, Cluj Napoca, Romania,* [2]*The Hohns Hopkins Hospital, Baltimore, MD, United States.*

Cholangiocarcinoma (CCA) presents significant diagnostic challenges, resulting in late patient diagnosis and poor survival rates. Primary Sclerosing Cholangitis (PSC) patients pose a particularly difficult clinical dilemma, since they harbor chronic biliary strictures that are difficult to distinguish from CCA. MicroRNAs (miRs) have recently emerged as a valuable class of diagnostic markers; however, thus far, neither extracellular vesicles (EVs) nor miRs within EVs have been investigated in human bile. We aimed to comprehensively characterize human biliary EVs, including their miR content. Conclusion: We have established the presence of extracellular vesicles in human bile. In addition, we have demonstrated that human biliary EVs contain abundant miR species, which are stable and therefore amenable to the development of disease marker panels. Furthermore, we have characterized the protein content, size, numbers and size distribution of human biliary EVs. Utilizing Multivariate Organization of Combinatorial Alterations (MOCA), we defined a novel biliary vesicle miR-based panel for CCA diagnosis which demonstrated a sensitivity of 67% and specificity of 96%. Importantly, our control group contained 13 PSC patients, 16 patients with biliary obstruction of varying etiologies (including benign biliary stricture, papillary stenosis, choledocholithiasis, extrinsic compression from pancreatic cysts, and cholangitis), and 3 patients with bile leak syndromes. Clinically, these types of patients present with a biliary obstructive clinical picture that could be confused with CCA. These findings establish the importance of using extracellular vesicles, rather than whole bile, for developing miR-based disease markers in bile.

Functional studies on post-transcriptional regulation of FAS/FASL in chordoma

L. Ferrari[1], *S. Zanoli*[1], *A. Calastretti*[1], *N. Boari*[2], *G. Canti*[1], *P. Mortini*[2], *P. Riva*[1];

[1]*Dipartimento di Biotecnologie Mediche e Medicina Traslazionale, Università degli Studi di Milano, Milan, Milan, Italy,* [2]*Dipartimento di Neurochirurgia, IRCCS Ospedale San Raffaele, Milan Italy, Milan, Italy.*

Chordoma, originating from notochord remnants, is characterized by chemoresistance. Since the apoptotic Fas/Fasl pathway is involved in notochordal cell apoptosis, we investigated its possible role in chordoma. Accordingly we detected the lack of FASL mRNA and the presence of both FAS anti- and pro-apoptotic isoforms and the inactive Caspases 8 and 3 forms in most of the tumors analyzed, suggesting the Fas/Fasl pathway inactivation in chordoma. The enhancement of apoptosis in U-CH1 chordoma cells, expressing Fasl and Fas anti- and pro-apoptotic isoforms after Soluble Fasl treatment, indicates that this pathway can be re-activated. These findings lead us to hypothesize that Fas receptor binds Soluble Fasl that, undermining Fas antiapoptotic isoform, activates apoptosis. Soluble Fas isoform could have a key role as antiapoptotic factor as the alternative splicing underlying the expression regulation of the two Fas isoforms. Knowing that HuR is one of the splicing factors leading to Fas transmembrane isoform, we are performing functional studies aimed at modulating the reciprocal amount of Fas isoforms by interfering with the expression of HuR. U-CH1 apoptosis, cellular vitality and migration will be evaluated after HuR iperexpression and silencing to assess the role of Fas antiapoptotic isoform in chordoma apoptosis regulation. We are also silencing miR-21 targeting FASL mRNA to verify whether the increase of endogenous Fasl may activate apoptosis. This study, providing findings on the involvement of Fas/Fasl pathway in chordoma could help to elucidate the role of apoptosis in chordoma tumorigenesis, addressing the identification of new potential pharmacological targets.

Transcriptome analysis of cancer cells in chronic myeloid leukemia

A. V. Lavrov[1], *S. Smirnikhina*[1], *E. Adilgereeva*[1], *E. Chelysheva*[2], *O. Shukhov*[2], *A. Turkina*[2], *S. Kutsev*[1,3];

[1]*Research Center for Medical Genetics, Moscow, Russian Federation,* [2]*Hematological Research Centre, Moscow, Russian Federation,* [3]*Russian National Research Medical University named after N.I. Pirogov, Moscow, Russian Federation.*

Long term observation studies confirm high efficiency of targeted therapy of chronic myeloid leukemia (CML) by tyrosine kinases inhibitors (TKI). However part of CML patients demonstrate primary resistance to TKI. This resistance appears to be connected with activation of alternative BCR-ABL-independent signaling pathways. Transcriptome analysis of cancer cell in CML is a perspective approach to elucidate molecular mechanisms of TKI-resistance and to find new approaches to CML treatment. We aim to find and to study differences in expression levels of cancer cells in primary CML patients, who demonstrated sensitivity or resistance to TKI. Gene expression profiles were analyzed using Illumina HT-12 Expression Bead Chip. These chips quantitate expression levels of more than 47000 transcripts. According to European Leukemia Net (2013) criteria patients were divided into resistant to TKI therapy - molecular response >10% in 6 months of therapy and optimal responders with molecular response <1% in 6 months of therapy. Comparative transcriptome analysis revealed 2672 of differently expressed genes in responders and non-responders. Enrichment analysis of the differently expressed genes showed the following molecular networks involved ($p < 0,05$): HTLV-1 infection (FZD10, ADCY1, MYB); PPAR signaling pathway (SCD-1, OLR1); Transcriptional misregulation in cancer (MPO, CEBPE, ELANE); Melanogenesis (ADCY1, FZD10). Detailed analysis demonstrated that all of the selected genes are overexpressed in cancer cells of patients sensitive to TKI therapy. Differently expressed genes and expression particularities of the selected pathways may be useful molecular markers for prognosis of the TKI therapy efficacy and may be used to optimize treatment of CML.

P12.038-M

XRCC4 gene (Intron 3 VNTR) polymorphism predisposition to chronic phase chronic myeloid leukemia (CML) and XRCC1 gene (399) polymorphism in associated with event-free survival in CML treated with imatinib in Turkish population

K. Ozdilli[1,2], *M. Pehlivan*[3], *F. Oğuz Savran*[4], *H. Issever*[5], *H. Haydaroğlu Sahin*[6], *S. Pehlivan*[7];

[1]*Medipol University Hospital Istanbul, ISTANBUL, Turkey,* [2]*İstanbul University Faculty of Medicine, Department of Medical Biology, Istanbul, Turkey,* [3]*2Gaziantep University Faculty of Medicine, Department of Hematology., Gaziantep, Turkey,* [4]*3İstanbul University Faculty of Medicine, Department of Medical Biology, ISTANBUL, Turkey,* [5]*Istanbul University Faculty of Medicine, Department of Public Health, ISTANBUL, Turkey,* [6]*Gaziantep University Faculty of Medicine, Department of Hematology, Gaziantep, Turkey,* [7]*Istanbul University Faculty of Medicine, Department of Medical Biology, ISTANBUL, Turkey.*

The aim of this study was to explore the association between polymorphisms of three DNA repair genes (XPD, XRCC1 and XRCC4) and clinical parameters in patients with Philadelphia-positive (Ph+) Chronic Myeloid Leukemia (CML) treated with imatinib. Sixty-two patients with CML and 70 healthy controls were examined for XPD (A-751G), XRCC1 (A399G), XRCC4 (intron 3 VNTR and G-1394T) polymorphisms. DNA was extracted from peripheral blood samples using salting out procedure. All polymorphisms were genotyped by PCR and/or PCR-RFLP and analyzed. All data were analyzed using de Finetti program and SPSS version 14.0 for Windows. No significant differences were detected between CML group and healthy controls with respect to the distributions and numbers of genotypes and alleles in XPD, XRCC1 and XRCC4 (-1394). However, intron 3 VNTR polymorphism in

XRCC4 gene was showed an association with CML patients. The distribution of DD, DI and II genotypes for the gene was 3.2%, 51.6% and 45.2% in CML compared with 14.3%, 60% and 25.7% in the controls. In the univariate analyses of clinical parameters, there was no significant prognostic factor found to influence overall survival. The four factors that were predicted for better event-free survival from univariate analysis were younger age (< 60) (p=0.020), absence of splenomegaly (p=0.011), lower Sokal risk score at diagnosis (p=0.0148) and XRCC1 GG genotype (p=0.033). Our results suggest that XRCC1 GG genotype may be a useful marker for CML prognosis and II genotype of intron 3 VNTR polymorphism in XRCC4 may be associated with susceptibility.

P12.039-S
Polymorphism in genes CYP2C9 and ODC1 involved in aspirin handling influence colorectal cancer risk

H. J. Sheth[1], *E. Northwood*[2], *F. Elliot*[2], *J. Barrett*[2], *M. Jackson*[1], *M. Koref*[1], *J. Burn*[1], *D. Bishop*[2];
[1]*Institute of Genetic Medicine, Newcastle upon Tyne, United Kingdom,* [2]*Leeds Institute of Cancer and Pathology, Leeds, United Kingdom.*

Long term regular use of aspirin is associated with a reduced risk of colorectal cancer (CRC) of up to 60%. However, not all aspirin users receive the beneficial chemopreventive effect. This is potentially attributable to the presence of single nucleotide polymorphisms (SNPs) in genes involved in aspirin's pharmacokinetic and pharmacodynamic pathways. We investigated the impact of 32 SNPs within 9 genes and 2 SNPs in intergenic regions on CRC risk using the Leeds Colorectal Cancer Panel which contains 1910 cases and 1276 controls; these SNPs were chosen for their potentially functional effect. Sixteen out of 34 SNPs were removed from analysis as they had frequency of <3%. All remaining SNPs were in Hardy-Weinberg equilibrium. P values for the tests of association were adjusted for sex and age. The presence of rs11694911 T allele (OR=0.79, 95% CI=0.63-1.0, p=0.04) and rs2302615 T allele (OR=0.81, 95% CI=0.67-0.99, p=0.024) at *ODC1* locus were associated with a reduced CRC risk. When the data was stratified (colon versus rectum), *CYP2C9* rs1799853 T allele (OR=0.73, 95% CI=0.60-0.90, p=0.003) and *ODC1* rs2302615 T allele (OR=0.76, 95% CI=0.61-0.93, p=0.005) showed significant association with colon cancer suggesting influence may be dependent on the tumor location. Both variant alleles have previously been shown to modulate chemopreventive activity of aspirin in colorectal adenoma occurrence, but this is the first dataset to indicate their effect on carcinoma risk. This data suggests that the presence of these variants modulates CRC risk which in turn may provide insight into the variation in aspirin's chemopreventive efficacy.

P12.040-M
Identification of novel candidate genes for early-onset colorectal cancer susceptibility

R. M. de Voer[1], *M. Hahn*[1], *R. D. A. Weren*[1], *A. R. Mensenkamp*[1], *W. A. van Zelst-Stams*[1], *L. Spruijt*[1], *M. Kets*[1], *J. Zhang*[1], *C. Gilissen*[1], *M. Tychon*[1], *R. Derks*[1], *H. K. Schackert*[2], *A. Geurts-van Kessel*[1], *N. Hoogerbrugge*[1], *M. J. L. Ligtenberg*[1], *R. P. Kuiper*[1];
[1]*Radboud university medical centre, Nijmegen, Netherlands,* [2]*Carl Gustav Universität Dresden, Dresden, Germany.*

Approximately 25-30% of colorectal cancer (CRC) cases are expected to result from a genetic predisposition, but only in 5-10% of these cases high-penetrant germline mutations are found. Therefore, the majority of CRC heredity is still unexplained. This missing heritability is thought to result from the presence of rare variants with a moderate-penetrant risk. Whole-exome sequencing (WES) has made it possible to identify such risk factors. As hereditary CRC is marked by an early age of onset, we performed WES on a cohort of CRC patients (*n*=55) with an onset of disease before 45 years of age. To identify potentially pathogenic variants, we searched for rare protein-truncating variants or highly conserved missense variants. A total of 272 protein-truncating variants and 1537 missense or in-frame insertions and deletions were identified. Recurrence filtering and selection of genes potentially involved in CRC development revealed three novel candidate genes: *EMR3*, *PTPN12* and *LRP6*. A screen of the coding region of these genes in a cohort of early-onset or familial CRC patients (*n*=181) revealed additional rare variants in *PTPN12* and *LRP6*. *PTPN12* encodes a protein tyrosine phosphatase and is described to be a driver of cancer development. *LRP6* encodes a component of the Wnt-Fzd-LRP5-LRP6 complex that triggers beta-catenin signaling. This study contributes to the further understanding of the heterogeneity of the genetic susceptibility for CRC. Follow-up studies on the frequency of mutations in these genes in larger cohorts, and their functional assessment, will provide conclusive evidence for the role of these genes in CRC development.

Colorectal cancer (CRC) represents one of the most frequent neoplasms in Europe. Besides classical hereditary forms, around 30% of cases present familial aggregation mostly with an unknown inherited cause. Next generation sequencing permits to characterize genetic variation in one individual and to discover new disease predisposition genes.
Material and methods: Patients were selected from high-risk clinics from Spanish hospitals as well as from the EPICOLON consortium. Forty-two individuals from 29 families with strong CRC aggregation compatible with an autosomal dominant pattern of inheritance and without alterations in the known CRC hereditary genes were selected. Exome sequencing was performed in germline DNA with subsequent quality control, removal of sequencing artifacts, data annotation and variant filtering. An automatic CRC-specific pipeline was used for prioritization.
Results: Sequencing mean coverage was >95x. Only very rare variants, producing a clear loss of function and located in genes with a function related to CRC or cancer were selected as final candidates. Afterwards, they were validated by Sanger sequencing and segregation was studied in additional affected family members when available. Loss of heterozygosity in tumor DNA was analyzed in variants with correct disease segregation. Best candidate variants included those located in interesting genes such as CDKN1B, XRCC4, EPHX1, NFKBIZ, SMARCA4, BRCA2 and BARD1. Three variants are expected to abolish protein function and 4 missense changes had strongly deleterious in silico predictions.
Conclusions: We identified variants in DNA repair genes that represent good candidates to become new CRC predisposition genes, some of them previously involved in other neoplasms.

P12.042-M
Whole Exome Sequencing of Hereditary Colorectal Cancer Families from Canada

D. R. Evans;
Memorial University of Newfoundland, St. Johns, NL, Canada.

Familial Colorectal Cancer Type X (FCCTX) is an inherited predisposition to colorectal cancer (CRC) in families fulfilling the Amsterdam-I criteria. A syndrome of unknown etiology, FCCTX is genetically heterogeneous. FCCTX families appear to have a moderate to high lifetime risk of developing CRC. A cohort of 91 FCCTX patients (66 families) from the Canadian provinces of Ontario and Newfoundland & Labrador (NL) were selected for whole exome sequencing of genomic DNA. A pooled segregation analysis of all missense variants recurrent in patients within two or more families identified 93 candidate missense variants. We then prioritized missense variants with low minor allele frequency (<1%), deleterious prediction of protein consequence and absence of identified variants in population controls. This refined our list of genetic culprits to variants within seven candidate genes. An age, sex and ethnically matched case-control cohort will be analyzed for statistical enrichment of candidate variants. We further queried our exome data for all deleterious rare variants in a set of CRC susceptibility genes identified by review of the current literature. Among these variants we identified POLE p. L424V; a missense substitution described in several patients of families with predisposition for CRC. In a final query involving the proband of a single, large NL family, we screened the exome for variants within two regions of linkage disequilibrium on chromosome 19 (LOD 3.49, 4.51), to refine the disease locus using segregation analysis. Studies of whole exomes continue to highlight the potential for identifying rare deleterious variants in CRC families worldwide.

Towards personalized cellular adoptive immunotherapy targeting immunogenic neo-antigens in microsatellite unstable colorectal cancers

P. Maby[1], *M. Hamieh*[1], *D. Tougeron*[2], *B. Mlecnik*[3], *G. Bindea*[3], *H. Angell*[3], *T. Fredriksen*[3], *N. Elie*[4], *A. Drouet*[1], *E. Fauquembergue*[1], *J. Mauillon*[5], *R. Sesboüé*[1], *J. Galon*[3], *T. Frebourg*[6], *J. Latouche*[6];
[1]*Inserm U1079, Rouen, France,* [2]*Department of Gastroenterology, University Hospital, Poitiers, France,* [3]*Inserm U872, Laboratory of Integrative Cancer Immunology, Paris, France,* [4]*Imaging Core Facility, CMABIO, University Hospital, Caen, France,* [5]*Department*

of Genetics, Rouen University Hospital, Rouen, France, [6]Inserm U1079 and Department of Genetics, University Hospital, Rouen, France.

Colorectal cancers (CRCs) with microsatellite instability (MSI) represent 15 % of all CRCs, and occur in patients with Lynch syndrome. MSI CRCs have a more dense cytotoxic T lymphocyte (CTL) infiltration and a better prognosis than microsatellite stable CRCs. Stronger immunogenicity of MSI CRCs is commonly explained by the presence of frameshift mutations in genes containing repeated coding sequences which could lead to the synthesis of neo-antigens recognized by specific CTLs. First, to explore the direct link between infiltrating CTL density and frameshift mutations, we quantified within 121 MSI tumors from two independent series CTL (CD8+) density, using tissue microarrays, and we searched for frameshift mutations in repeated coding sequences of 19 genes. We found that infiltrating CTL density significantly increased with the number of frameshift mutations, and was particularly correlated with frameshift mutations in *ASTE1*, *HNF1A* and *TCF7L2* genes. Second, we undertook to stimulate, *in vitro*, patients' peripheral blood CTLs specific of their own tumor neo-antigens, using artificial antigen presenting cells (AAPCs) developed in our laboratory and expressing the corresponding neo-peptides derived from their own tumor specific frameshift mutations. We could indeed easily and efficiently activate such CTLs, in two tested Lynch syndrome patients. These results suggest that, in MSI CRC patients, and especially in Lynch syndrome patients, it should be possible to propose new personalized adoptive cell immunotherapy strategies based on the characterization of frameshift mutations within their tumour and on the construction of AAPCs expressing the corresponding neo-peptides.

Objective: Recognizing colorectal cancer (CRC) patients with Lynch syndrome (LS) can increase life expectancy of these patients and their close relatives. To improve identification of this under-diagnosed disease, experts suggested raising the age limit for CRC tumour genetic testing from 50 to 70 years. The present study evaluates the efficacy and cost-effectiveness of this strategy.
Design: Probabilistic efficacy and cost-effectiveness analyses were performed comparing tumour genetic testing of CRC diagnosed at age 70 or below (experimental strategy) versus CRC diagnosed at age 50 or below (current practice). The proportions of LS patients identified and cost-effectiveness including cascade screening of relatives, were calculated by decision analytic models based on real life data.
Results: Using the experimental strategy, 4 times more LS patients can be identified among CRC patients as compared to current practice. Both the costs to detect one LS patient (€ 9,437/carrier versus € 4,855/carrier) and the number needed to test for detecting one LS patient (42 versus 19) doubled. When including relatives the experimental strategy was found to be highly cost effective because CRC prevention in relatives neutralised the extra genetic testing costs, resulting in lower costs (-€ 2180 per extra tested patient) and an average of 9 life years gained.
Conclusion: Testing all CRC tumours diagnosed at or below age 70 for LS is cost-effective. Implementation is important as relatives from the large number of LS patients that are missed by current practice, can benefit from life-saving surveillance.

P12.045-S

Clinical relevance of 8q23.3, 15q13.3 and 18q21.1 SNP genotyping to evaluate colorectal cancer risk

S. Baert-Desurmont[1,2,3], F. Charbonnier[1,2], E. Houivet[4,5], L. Ippolito[1], J. Mauillon[2], M. Bougeard[1], C. Abadie[1,6], D. Malka[7], J. Duffour[8], F. Desseigne[9], C. Colas[10], P. Pujol[11], S. Lejeune[12], C. Dugast[6], B. Buecher[13], L. Olivier-Faivre[14], D. Leroux[15], P. Gesta[16], O. Caron[7], Q. Wang[9], B. Bressac-de Paillerets[7], J. Rey[11], M. Buisine[12], A. Cailleux[5], H. Sebaoui[17], J. Blot[17], J. Tinat[1,2,3], J. Benichou[4], **T. Frebourg**[1,2,3];

The aim of this study was to determine if the at risk SNP alleles for colorectal cancer (CRC), previously identified by GWAS studies, could either alone or in combination contribute to clinical presentations suggestive of an increased genetic risk for CRC. We performed a prospective national case-control study based on highly selected patients (CRC in two first degree relatives, one being diagnosed before 61 years; or CRC before 51 years; or multiple primary CRCs, the first before 61 years; exclusion of Lynch syndrome, adenomatous and hamartomatous polyposes), and appropriate controls corresponding to healthy volunteers, between 45 and 60 years of age, without personal or familial history of CRC. We included 1029 patients and 350 controls. We confirmed the association of CRC risk with 4 SNPs, with odds ratio (OR) higher than previously reported : *rs16892766* on 8q23.3 (OR: 1.89; p=0.0006); *rs4779584* on 15q13.3 (OR: 1.45; p=0.0033), and *rs4939827* and *rs58920878/Novel 1* on 18q21.1 (OR: 1.49; p=0.0061 and OR: 1.48; p=0,0039). We found a significant cumulative effect of the at risk alleles or genotypes with OR at 1.62, 2.11, 2.92 and 3.95 for 1, 2, 3 and at least 4 at risk alleles and OR at 1.71, 2.32 and 6.31 for 1, 2 and 3 at risk genotypes. This study shows that genotyping of a limited number of SNPs, such as 8q23.3 *rs16892766*, 15q13.3 *rs4779584* and 18q21.1 *rs58920878*, should allow to identify subjects at increased risk of CRC who might benefit from early CRC detection.

Constitutional mismatch repair deficiency (CMMR-D) syndrome is a distinct childhood cancer predisposition syndrome that results from biallelic germline mutations in one of the four MMR genes, *MLH1*, *MSH2*, *MSH6*, or *PMS2*. The tumour spectrum is very broad, including mainly haematological, brain and intestinal tract tumours. Patients show a variety of non-malignant features that are indicative of CMMR-D. However, currently no clinical criteria that should entail diagnostic evaluation of CMMR-D exist. The recently established European consortium care for CMMR-D (C4CMMRD) proposes a 3-points scoring system for the suspected diagnosis CMMR-D in a pediatric/young adult cancer patient. Tumours highly specific for CMMR-D syndrome are assigned 3 points, malignancies overrepresented in CMMR-D 2 points and all other malignancies 1 point. According to their specificity for CMMR-D and their frequency in the general population additional features are weighted with 1 - 2 points. They include multiple hyper- and hypopigmented skin areas, brain malformations, pilomatricomas, a second childhood malignancy, a LS-associated tumour in a relative and parental consanguinity. According to the scoring system CMMR-D should be suspected in any cancer patient who reaches a minimum of 3 points by adding the points of the malignancy and the additional features. We expect that application of the here suggested strategy for CMMR-D diagnosis will increase the number of patients being identified at the time when they develop their first tumour. This will allow adjustment of the treatment modalities, offering surveillance strategies for second malignancies and appropriate counselling of the entire family.

P12.047-S
Constitutional mismatch repair deficiency due to a homozygous MSH6 mutation in a 14-year-old boy with colonic polyps, colorectal cancer and retinal lesions

L. S. Penney[1,2], *A. L. Rideout*[1], *S. Dyack*[1,2], *M. Bernstein*[1,2], *M. Rashid*[1,2], *W. Huang*[2], *G. R. LaRoche*[2];
[1]*The IWK Health Centre, Halifax, NS, Canada,* [2]*Dalhousie University, Halifax, NS, Canada.*

Constitutional Mismatch Repair- Deficiency (CMMR-D) is a rare cancer predisposition syndrome in patients with biallelic mutations in one of *MLH1, MSH2, MSH6* or *PMS2*. Heterozygous mutations cause the adult onset, dominant cancer syndrome Lynch syndrome. However, CMMR-D causes childhood onset cancers, particularly hematological, brain and gastrointestinal malignancies. Children with CMMR-D also may have skin pigmentation findings suggestive of neurofibromatosis type 1.
We report on a 14-year-old boy with a previous kaposiform hemangioendothelioma who was diagnosed with at least 100 colonic polyps and 6 invasive adenocarcinomas of the colon and rectum. He had café au lait macules, axillary and inguinal freckling and bilateral, multifocal congenital hypertrophy of the retinal pigment epithelium (CHRPE). Therefore he fit diagnostic criteria for both NF1 and Familial Adenomatous Polyposis. He also had a previous clinical diagnosis and family history of Cleidocranial Dysplasia. There was no family history of colon cancer and he had 2 siblings.
The colon cancers were MSI-H and by immunohistochemistry the tumour cells and adjacent normal mucosa were negative for MSH6 and positive for MLH1, MSH2 and PMS2. A homozygous pathogenic MSH6 mutation was identified (c.3202C>T) in the patient and both parents were found to be heterozygous. Genetic testing of the *APC* and *MUTYH* genes was normal.
To our knowledge, this is the first reported case of CMMR-D with CHRPE and demonstrates difficulties in making this diagnosis in a patient who fits the clinical criteria for both NF1 and FAP. It also illustrates ethical dilemmas around genetic testing of at risk siblings.

P12.048-M
Recurrent copy number alterations in prostate cancer: an in silico meta-analysis of publicly available genomic data

J. A. Squire[1], *P. Greer*[2], *J. Williams*[2];
[1]*University of Sao Paulo, Ribeirão Preto, Brazil,* [2]*Queen's University, Kingston, ON, Canada.*

We present a meta-analysis of somatic copy number alterations (CNAs) from eleven publications that examined 662 prostate cancer patient samples, derived from 546 primary and 116 advanced tumors. Normalization, segmentation and identification of corresponding CNAs for meta-analysis was achieved using established commercial software (Nexus). Unsupervised analysis identified five genomic subgroups in which ~90% of the samples had an abnormal profile characterized by 8q gains. The most common loss was at 8p (NKX3.1). The CNA distribution in other genomic subgroups was characterized by losses at 2q, 3p, 5q, 6q, 13q, 16q, 17p, 18q and 10q (PTEN), and acquisition of 21q deletions associated with the TMPRSS2:ERG fusion rearrangement. Parallel analysis of advanced and primary tumors in the cohort indicated that genomic deletions of PTEN and the gene fusion were enriched in advanced disease. A supervised analysis of PTEN deletion and the fusion gene showed that when PTEN was deleted the overall percentage of the genome altered was significantly higher, suggesting that this important genomic subgroup was likely characterized by intrinsic chromosomal instability. Predicted alterations in expression levels of candidate genes in each of the recurrent CNA regions characteristic of each subgroup showed that signaling networks associated with cancer progression and genome stability were likely to be perturbed at the highest level in the PTEN deleted genomic subgroup.

P12.049-S
In-depth comparison of available targeted resequencing strategies for BRCA gene panels

S. Zuñiga, *O. Rodriguez, G. Marco, J. Durban, L. Cabornero, S. Santillan, C. Collado, V. Fernández-Pedrosa, J. C. Triviño;*
Sistemas Genomicos, Valencia, Spain.

Next-Generation Sequencing is currently the technique of choice for genetic testing in genetic heterogeneous diseases. The broad spectrum of available target enrichment methods complicates the selection of the most suitable technique considering the size of the targeted region, the required depth of coverage to correctly identified variants, the number of samples to be sequenced, the turnaround time and the overall cost. Here we report a comprehensive comparison of four different commercial targeted enrichment kits (Haloplex, Nextera, Multiplicom and SureSelect) for the selection of the most convenient strategy to fully characterize the coding regions of BRCA genes in an Illumina benchtop sequencer. Most of samples were analysed with 1-3 different kits. Following clinical standards, we evaluated the analytical sensitivity, the analytical specificity, false positive and negative rates, the assay robustness and the precision for each of the considered capturing techniques. Our results demonstrate that technical and functional differences exist between capturing methods that could compromise clinical diagnosis if specific method-associated deviations are not considered.

P12.051-S
Mutually exclusive RAS-RTK and JAK2 mutations drive sub-clonal expansions in the majority of acute lymphoblastic leukaemia cases in Down syndrome

S. I. Nikolaev[1], *M. Garieri*[1], *F. Santoni*[1], *E. Falconnet*[1], *P. Ribaux*[1], *M. Guipponi*[1], *A. Murray*[2], *J. Groet*[2], *E. Giarin*[3], *G. Basso*[3], **D. Nizetic**[2], *S. E. Antonarakis*[1];
[1]*University of Geneva, Geneva, Switzerland,* [2]*The Blizard Institute, Barts and The London School of Medicine, Queen Mary University of London, London, United Kingdom,* [3]*University of Padua, Padua, Italy.*

Children with Down syndrome (DS) and acute lymphoblastic leukaemia (ALL) have poorer survival and more relapses, than euploid ALL children, highlighting the need for a molecular understanding of DS-ALL. Using full exome or cancer genes-targeted sequencing of 42 ALL samples from 39 DS patients, we discover driver mutations in RAS (KRAS and NRAS) recurring to a similar extent (13/42) as JAK2 (10/42) mutations or P2RY8-CRLF2 fusions (14/40). RAS/RTK mutations were mutually exclusive with JAK/STAT mutations (p=0.018), driving a combined total of two thirds of analysed cases. Clonal architecture analysis shows that both JAK/STAT and RAS/RTK mutations are mostly sub-clonal. The study of clonal evolution in the cases with primary leukaemias and relapses shows that JAK-STAT mutations are exclusively associated with primary leukaemias and RAS mutations - with relapses. This indicates that JAK2-mutated sub-clones respond well to conventional therapy, but then is replaced with RAS-mutated sub-clones. The dominant clones (including those persisting in primary and relapse leukaemias) were a combination of mutations in chromatin modifiers (62%), tumour suppressors, lymphocyte differentiation factors, and/or CRLF2 rearrangements. These events were cumulatively present in 93% of cases, with no association with JAK/STAT or RAS/RTK groups. Additionally, novel differences in number and profile of driver events were observed between cALL and preB immunophenotypic subtypes of BCP-ALL.
Overall our data provide a better molecular understanding of DS-ALL and suggests a personalized therapeutic approach to driver-mutations, with individual mutation profile-tailored inclusion of RAS (particularly KRAS) inhibitors (such as deltarasin) and/or chromatin modifier enzyme inhibitors.

P12.052-M

Neoantigen in esophageal squamous cell carcinoma for dendritic cell-based cancer vaccine development

M. M. Forghanifard[1], *M. Gholamin*[2], *O. Moaven*[3], *M. Farshchian*[4], *M. Ghahraman*[5], *M. R. Abbaszadegan*[5];
[1]*Islamic Azad University, Damghan Branch, Damghan, Islamic Republic of Iran,* [2]*Division of Human Genetics, Immunology Research Center, Avicenna Research Institute, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran,* [3]*Department of Surgery, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States,* [4]*Department of Biology, Faculty of Science, Ferdowsi University of Mashhad, Mashhad, Islamic Republic of Iran,* [5]*Medical Genetics Research Center, Medical School, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran.*

Esophageal squamous cell carcinoma (ESCC) is a highly malignant tumor which usually is diagnosed in advanced stages due to its asymptomatic course of tumorigenesis. Current therapeutic modalities are not effective enough and the 5-year survival rate of the disease is still very low which prompts the urgent need for finding novel efficient therapeutic methods. In this study we evaluated ex vivo immune response of ESCC patients against our newly designed chimeric construct consisting of highly immunogenic cancer/testis antigens (CTAs). After confirming effective expression of the in vitro transcribed chimeric mRNA in ex vivo electroporated dendritic cells of the ESCC patients, the patients' CTLs were primed by DCs and cytotoxicity assay was performed to evaluate how the primed CTLs can recognize and target the chimeric mRNA-loaded cells. The chimeric protein was strongly expressed relative to the housekeeping gene expression in electroporated cells. The cytotoxicity of the CTLs were significantly higher in DCs loaded with chimeric mRNAs compared to mock DCs ($p < 0.05$) in all of the tested ESCC patients. We are introducing a novel construct that our functional study showed can stimulate and induce an effective immune response in ESCC patients. The designed chimeric mRNA-loaded DCs are capable of priming CTLs effectively, and induce cytotoxicity against tumor. Therefore, loading dendritic cells with chimeric epitopes of highly immunogenic antigens, such as cancer testis antigens are potentially interesting and effective therapeutic modalities for immunotherapy of ESCC.

P12.053-S

Aberrant expression of BMP signaling pathway target genes are involved in esophageal squamous cell carcinoma progression and development

A. Javdani-Mallak[1], *M. Forghanifard*[2], *M. Abbaszadegan*[1];
[1]*Human genetic division, immunology research center, Avecina research institute, Mashhad, Islamic Republic of Iran,* [2]*Department of biology, faculty of sciences, Mashhad branch, Islamic Azad university, Mashhad, Islamic Republic of Iran.*

Esophageal cancer is one of the lethal malignancies in northeastern of Iran and esophageal squamous cell carcinoma (ESCC), as a frequent kind of cancer, shows striking variations in geographic distribution reflecting exposure to specific environmental factors which are remained to be completely defined. According to the importance of ESCC in this high risk area and the great attention in studying the malignant progression of cells through a converging pathway of oncogenesis, the present study aimed to estimate the expression analysis of VentX and Evx1, two critical target genes of bone morphogenic protein (BMP) signaling pathway. In this study a total of 50 tumoral and margin normal tissues from treatment-naive ESCC patients were enrolled to expression analysis using comparative real-time PCR. VentX was significantly underexpressed in 76% of ESCC tissues ($P<0.05$). Underexpression of VentX was significantly correlated with increased tumor size. The overexpression of Evx1 was detected in 82% of ESCC samples significantly ($P<0.05$). This overexpression was inversely correlated with the progress of tumor stage and increased depth of tumor invasion. Our results show that aberrant expression of VentX and Evx1 genes in ESCC tissues may have significant effects in the progress of ESCC tumorigenesis and may play roles in development of the disease through malfunction of BMP signaling pathway. To the best of our knowledge, this is the first report of VentX and Evx1 gene expression analysis in ESCC patients globally.

P12.054-M

Retrospective analysis of genomic and transcriptional changes in a case of Ewing sarcoma tumor progression determined by whole transcriptome and exome semiconductor-based sequencing

G. Meredith[1], *Y. Sun*[1], *N. Hernandez*[1], *M. Taylor*[1], *B. Sanderson*[1], *K. Giorda*[1], *K. Giorda*[1], *T. Woodburn*[2], *D. Dhingra*[1], *G. Bee*[1], *J. Bishop*[1], *S. Ghosh*[1], *P. Kapranov*[3], *J. Buckley*[4], *K. Bramlett*[1], **O. Stephan**[5], *C. Reynolds*[6], *T. Triche*[7];

Ewing sarcoma is a cancer that often presents in the second decade of life and is usually associated with a chromosomal translocation that results in a EWS/FLI1 gene fusion. Four independent cell-lines have been established from a subject who succumbed to metastatic disease following relapse after myeloablative chemotherapy. Whole-transcriptome and exome sequencing of normal primary bone marrow-derived stromal fibroblasts, Epstein-Barr Virus (EBV) transformed normal lymphoblasts, a pre-therapy primary tumor-derived cell-line, and a post-chemotherapy metastatic tumor-derived cell-line, was conducted on an Ion Torrent Proton™ system to profile the differences in gene expression and in exonic DNA sequence to characterize the molecular changes associated with primary tumorigenesis and disease persistence after treatment. The presence of the EWS/FLI1 fusion gene in the tumor cells was confirmed and the breakpoint determined from both observation of chimeric reads in the RNA-seq data and exome sequence analysis. Exome datasets indicate apparent loss of heterozygosity genome-wide in CHLA10 consistent with cytogenetic analysis that shows tetraploidy in this cell-line. Results from RNA-seq also indicate numerous instances, genome-wide, of differing transcript isoform expression and exon usage between normal, primary tumor, and metastatic tumor cells suggesting an increasing genomic mutational burden in the evolution of the disease, and pointing in particular toward aberrant regulation of RNA-splicing components. Taken together, the combination of RNA-seq and exome-sequencing on normal cells and primary vs. post-chemotherapy tumor is providing a broad and deep view of molecular signatures in tumor progression and indicating that a significant role is played by changes in non-coding RNA expression.

P12.055-S

Beyond BRCA1 and BRCA2: results from screening 94 genes in 100 patients with familial breast and ovarian cancer using panel sequencing and custom array-CGH

E. Schröck[1], *A. Rump*[1], *K. Hackmann*[1], *M. Beer*[1], *A. Beyer*[1], *B. Klink*[1], *N. Di Donato*[1], *P. Wimberger*[2], *K. Kast*[2];
[1]*Institut für Klinische Genetik, Medizinische Fakultät Carl Gustav Carus, TU Dresden, Dresden, Germany,* [2]*Klinik und Poliklinik für Frauenheilkunde und Geburtshilfe, Universitätsklinikum Carl Gustav Carus, TU Dresden, Dresden, Germany.*

Breast and ovarian cancer predisposition has been associated with a number of high-, moderate-, and low-penetrance susceptibility genes. Here we report on the results of high-resolution custom array-CGH for deletion/duplication analysis and panel-based screening of 94 genes associated with hereditary cancer predisposition.
Selection criteria for the 100 patients were defined by the German Consortium for Breast and Ovarian Cancer. NGS was performed on an Illumina MiSeq and target enrichment was done with the Illumina TruSight cancer panel, whereas custom array CGH was performed using Agilent technology. In 28 % of the patients, BRCA1 or BRCA2 variations have been found. These were either clearly pathogenic protein truncating mutations (12 %) or very rare, unclassified missense variations with high probability of effect (16 %). In 39 % of the patients we found rare, unclassified missense variants in low penetrance susceptibility genes, especially NBN and ATM. In one case with early onset of breast cancer and no familial history, a putative splice relevant mutation in TP53 could be identified, which is currently being investigated on cDNA level. 33 % of the patients did not reveal any convincing sequence variation. In 10% of the patients we identified deletions in either BRCA1, CHEK2, or ATM.
The extension of mutation screening beyond BRCA1 and BRCA2 reveals disease-causing mutations in high-penetrance genes, like TP53, as well as mutations in low-penetrance susceptibility genes. However, the enormous number of unclassified sequence variants and the detection of carriers for other hereditary diseases pose a huge challenge for genetic counselling.

P12.057-S

First evidence for *FANCM* as a novel breast cancer predisposing gene

G. Neidhardt[1], *J. Hauke*[1], *H. Hellebrand*[2], *S. Heilmann*[3], *K. Klaschik*[1], *E. Mangold*[4], *H. Thiele*[5], *J. Altmüller*[5], *P. Nürnberg*[5], *A. Meindl*[2], *E. Hahnen*[1], *R. K. Schmutzler*[1];
[1]*University Hospital of Cologne, Cologne, Germany,* [2]*Department of Gynaecology and Obstetrics, Klinikum rechts der Isar at the Technical University, Munich, Germany,* [3]*Institute of Human Genetics and Department of Genomics, Life&Brain Center, University of Bonn, Bonn, Germany,* [4]*Institute of Human Genetics, University of Bonn, Bonn, Germany,* [5]*Cologne Center for Genomics (CCG), Cologne, Germany.*

Several members of the FANC (Fanconi anaemia complementation group) gene family such as *BRCA2* (*FANCD*), *RAD51C* (*FANCO*), *PALB2* (*FANCN*) and *BRIP1* (*FANCJ*) have been associated with breast cancer (BC) and ovarian cancer (OC) predisposition. Given the fact that most risk families do not carry mutations in established BC/OC genes, we hypothesized that yet unknown disease genes exist. In the course of an exome sequencing project aimed to identify novel BC predisposing genes, we identified a heterozygous nonsense mutation (p.Gln1701Ter) within the *FANCM* gene in a *BRCA1/2*-negative patient affected by early-onset BC (46y). The FANCM protein is a central com-

ponent of the Fanconi anaemia core complex and promotes the recruitment of the S-phase checkpoint machinery after binding to DNA damage sites. The nonsense mutation removes the ERCC4-like domain (aa1802-1922) of the 2022aa FANCM protein. A subsequent Sequenom-based case-control study including 1896 independent *BRCA1/2*-negative BC index cases and 1726 controls revealed a significant association with BC occurrence (9/1896 cases vs. 2/1726 controls; p<0.05). The carrier frequency of the p.Gln1701Ter mutation in controls (0.12%) is similar to that identified in the framework of the NHLBI Exome Sequencing Project (5/4300; european ancestry; 0.12%). Taken together, our data provide first evidence for *FANCM* as a novel BC predisposing gene (9/1896 cases vs. 7/6026 controls; p=0.00242) at a moderate penetrance level (OR: 4.101; CI95%:1.401-12.199; RR=2.357; CI95%:1.27-3.326). Due to the low frequency of the *FANCM* p.Gln1701Ter mutation, however, large collaborative studies are required to quantify the RR of *FANCM* alterations for BC and potentially other cancer entities.

P12.058-M
First clinical experience with screening formalin fixed and paraffin-embedded (FFPE) archival tissue for mutations in BRCA1 and BRCA2 - A new paradigm in genetic investigation and counseling

A. H. Petersen[1], M. M. Aagaard[1], M. Waldstrøm[2], **A. Bojesen**[1]*;*
[1]Vejle Sygehus, Department of Clinical Genetics, Vejle, Denmark, [2]Vejle Sygehus, Department of Clinical Pathology, Vejle, Denmark.

Background: Women carrying a germline mutation in BRCA1 or BRCA2 (BRCA1/2) have a very high lifetime risk of breast- and ovarian cancer. Men carrying the same mutations are facing an increased risk of prostate- and breast cancer. Until now, screening for BRCA1/2 mutations required high quality DNA (from blood or other fresh specimens). This has ruled out families in which the relative(s) suffering from breast or ovarian cancer have already died. Several attempts to screen for mutations in archival formalin-fixed, paraffin-embedded (FFPE) tissue have so far been with limited success. **Aim:** We present the first clinical data from our newly developed NGS based analysis, screening archival FFPE samples of non-tumor tissue for germline mutations in BRCA1/2. **Results:** In 33 FFPE samples we found 3 pathogenic BRCA1 mutations, 3 pathogenic BRCA2 mutations and 2 variants of unknown significance in BRCA2. In 17 samples coverage was sufficient to disclose a negative result and in 8 samples the coverage was too low, and hence the result was designated inconclusive. The quality of the data varied between samples with a strong negative correlation between age of the tissue and sequence quality. **Conclusions:** Mutations in BRCA1/2 can now be sought after in deceased relatives, in families with suspected germline mutations. For clinical use, mutations found in FFPE samples should always be confirmed in other samples from either the same individual, or from samples from close relatives.

P12.059-S
Comprehensive genetic characterization of pediatric patients with B-lineage ALL reveals novel mutations and gene fusions

C. Schroeder[1]*, M. Walter[1], C. Kyzirakos[2], M. Sturm[1], U. Pflückhahn[2], R. Handgretinger[2], S. Ebinger[2], O. Kohlbacher[3], O. Riess[1], H. Rammensee[4], P. Lang[2], M. Bonin[1], P. Bauer[1];*
[1]Instiute of Medical Genetics and Applied Genomics, Tübingen, Germany, [2]Children's Hospital University Tübingen, Tübingen, Germany, [3]Applied Bioinformatics, Center for Bioinformatics, Quantitative Biology Center, and Dept. of Computer Science, Tübingen, Germany, [4]Department of Immunology, Institute for Cell Biology, Tübingen, Germany.

High-throughput sequencing technologies provide new opportunities for personalized treatment approaches as well as for the identification of novel genetic biomarkers in cancer. We analyzed a total of 9 tumor and reference samples of patients with primary and relapsed B-lineage ALL by whole-exome-/transcriptome sequencing and SNP-microarrays. The results were combined to obtain a comprehensive overview on the genomic landscape of B-lineage ALL. Only few genes were altered recurrently and our data confirms the hypothesis that the interindividual heterogeneity requires highly individualized therapeutic approaches. Besides common and well known genetic variations like mutations (e.g. in NRAS, JAK, ILR7), CNVs (e.g. a deletion of PAX5) and fusion genes (e.g. BCR:ABL) a novel gene, PYGO2, was identified to be altered in three patients. Besides a fusion gene (MEF2D:PYGO2), a mutation and a duplication of PYGO2 were found in different patients. Our data suggest that PYGO2 plays a role in leukomegenesis.

Unraveling the genetic predisposition of early-onset and familial gastric cancer

N. Hoogerbrugge[1]*, R. S. van der Post[1], H. J. M. van Krieken[1], J. Lubinski[2], A. Jakubowska[2], C. M. Aalfs[3], L. P. van Hest[4], C. Oliveira[5,6], H. Pinheiro[5], S. Jhangiani[7], D. Muzny[7], R. A. Gibbs[7], J. R. Lupski[7,8], J. de Ligt[1], L. E. L. M. Vissers[1], H. K. Schackert[9], G. N. Ranzani[10], V. Molinaro[10], I. P. Vogelaar[1], M. J. L. Ligtenberg[1];*
[1]Radboud university medical center, Nijmegen, Netherlands, [2]Pomeranian Medical University, Szczecin, Poland, [3]Academic Medical Centre, Amsterdam, Netherlands, [4]VU University Medical Center, Amsterdam, Netherlands, [5]Institute of Molecular Pathology and Immunology of the University of Porto, Porto, Portugal, [6]University of Porto, Porto, Portugal, [7]Baylor College of Medicine, Houston, TX, United States, [8]Texas Children's Hospital, Houston, TX, United States, [9]Technische Universität Dresden, Dresden, Germany, [10]University of Pavia, Pavia, Italy.

Introduction: Gastric cancer is a multifactorial disease and results from a combination of environmental factors and genetic alterations. Approximately 8-10% of cases are familial. Germline *CDH1* mutations explain a small part of these families. In the majority of cases with early-onset or familial gastric cancer the underlying genetic cause remains unknown. Therefore, we aim to find new genetic predisposition genes for gastric cancer. **Patients**: 41 patients with early-onset (<35 years of age at diagnosis) or familial gastric cancer (two first-degree relatives with gastric cancer diagnosed below the age of 50) were included in our study. **Results**: Exome sequencing was performed on germline DNA of the 41 patients. High-quality variants were selected and common variation was excluded from the data set. Next, both truncating variants and missense variants predicted to be damaging to protein function were selected. In total, 225 variants were validated by Sanger sequencing (average 5.5 variants per patient, range 1-12 variants): 63 truncating variants and 162 missense variants in 191 genes. Thirty-eight genes were recurrently affected in maximally three patients. Homozygous and compound heterozygous missense variants were identified in 8 and 3 patients, respectively. Three truncating and 26 missense variants are in known cancer predisposing genes. Other variants are located in genes previously associated with or functionally linked to gastric cancer. **Conclusion**: Using exome sequencing we identified several candidate genes for gastric cancer predisposition. Their contribution to gastric cancer predisposition will be investigated by screening larger cohorts of patients with early onset and/or familial gastric cancer.

P12.061-S
Impaired Th17 mucosal host defense against *Helicobacter pylori* in an early-onset gastric cancer patient with a homozygous germline variant in *MYD88*

I. P. Vogelaar, *M. J. L. Ligtenberg, R. S. van der Post, M. C. M. Kets, R. M. de Voer, T. J. G. Jansen, L. Jacobs, G. Schreibelt, H. J. M. van Krieken, J. M. de Vries, M. G. Netea, N. Hoogerbrugge;*
Radboud university medical center, Nijmegen, Netherlands.

Introduction: The main causes for gastric cancer are *Helicobacter pylori* (*H. pylori*) infection, diet and genetic factors. Germline *CDH1* mutations underlie a gastric cancer predisposition syndrome with autosomal dominant inheritance, characterized by early-onset diffuse gastric cancer. In the majority of cases with early-onset or familial gastric cancer the underlying genetic cause remains unknown. We aimed to find new genetic predisposition genes for gastric cancer. **Patient**: A 23-year old female patient with diffuse-type gastric cancer and without a germline *CDH1* mutation also suffered from recurrent fungal infections. Family history revealed a consanguineous relation of her parents. There were no other cases of gastric cancer in the family. **Results**: Whole exome sequencing of the patients' germline DNA identified a homozygous missense variant (c.712C>T, p.Arg238Cys) in the gene encoding MYD88, which plays a central role in the immune response against *H.pylori* infections. Immunological assays on peripheral blood mononuclear cells revealed normal immune responses to *Staphylococcus aureus,* but impaired immune responses upon stimulation with *H.pylori* and *Candida albicans*, characterized by a specific defect in production of Th17 cytokines IL-17 and IL-22. This was due to defective IL1-beta responses, a crucial cytokine for Th17 development. **Conclusion**: Impaired Th17 mucosal host defense against *H.pylori,* which is associated with gastric cancer development, was observed in a patient with early onset gastric cancer and a homozygous *MYD88* variant. These defective Th17 responses were also likely the cause of fungal infections. Our data suggest that genetic defects leading to defective anti-*Helicobacter* innate pattern recognition predispose to gastric cancer.

P12.062-M
Prohibitin 3' untranslated region 1630 C>T polymorphism and copy number variation contributes to its gene expression deregulation in gastric cancer

M. F. Leal[1]*, P. D. R. Cirilo[2,3], T. K. F. Mazzotti[2,3], D. Q. Calcagno[1,4], F. Wisnieski[1], S. Demachki[4], M. C. Martinez[2,3], P. P. Assumpção[4], R. Chammas[2,3], R. R. Burbano[4], M. C. Smith[1];*
[1]Federal University of São Paulo, São Paulo, Brazil, [2]University of São Paulo, São Paulo, Brazil, [3]São Paulo State Cancer Institute, Sao Paulo, Brazil, [4]Federal University of Pará, Belém, Brazil.

Gastric cancer is the second leading cause of cancer-related deaths worldwide. *PHB* has been reported as an oncogene and tumor suppressor in several neoplasias, including in gastric cancer. Here, we evaluated whether the *PHB*

copy number and the rs6917 polymorphism affect its expression in gastric cancer. Forty-eight pairs of gastric cancers and corresponding non-neoplastic gastric samples were evaluated. *PHB* expression was analyzed by real-time quantitative PCR and by immunohistochemistry. Gene copy number was investigated by quantitative PCR. Allele-specific expression was determined by sequencing and by TaqMan assay. Down-regulation and up-regulation of *PHB* was observed in the tumors (45.5% and 20.5%, respectively). Reduced *PHB* expression was associated with dedifferentiation (P=0.029), lower invasion (P=0.002), absence of lymph node metastasis (P=0.040) and early gastric cancer (P=0.002). In all cases, the PHB immunoreactivity was detected in neoplastic and non-neoplastic cells. PHB was mainly expressed in the cytoplasm. *PHB* amplification was observed in 34.2% tumors. *PHB* gain was associated with higher gene expression (P=0.003) and late-onset gastric cancer (P=0.022). In our sample, 22% patients were heterozygous and 4.17% were homozygous for the minor allele in the rs6917 polymorphism. The presence of the T allele in this polymorphism was associated with reduced expression in GC (P<0.001) and in non-neoplastic samples (P<0.001). Only one patient presented a higher C/T ratio in both tumor and non-neoplastic samples. In most cases, lower C/T ratio was detected. Thus, *PHB* copy number variation and differential expression of the rs6917 polymorphism may have a role in *PHB* transcriptional regulation.

P12.063-S
Extrachromosomal driver mutations in glioblastoma and low grade glioma

S. I. Nikolaev[1], *F. Santoni*[1], *M. Garieri*[1], *P. Makrythanasis*[1], *E. Falconnet*[1], *M. Guipponi*[1], *A. Vannier*[1], *I. Radovanovic*[1], *F. Bena*[2], *K. Schaller*[1], *V. Dutoit*[2], *V. Clement-Schatlo*[1], *P. Dietrich*[2], *S. E. Antonarakis*[1];
[1]*University of Geneva, Geneva, Switzerland,* [2]*Geneva University Hospitals, Geneva, Switzerland.*

Alteration of the number of copies of Double Minutes (DMs) with oncogenic EGFR mutations in response to tyrosine kinase inhibitors (TKIs) is a novel adaptive mechanism of glioblastoma. In this study we provide evidence that such mutations in DMs, called here Amplification Linked Extrachromosomal Mutations (ALEMs), originate extrachromosomally and could therefore be completely eliminated from the cancer cells. By exome sequencing of 7 glioblastoma patients we revealed ALEMs in EGFR, PDGFRA and other genes. These mutations together with DMs were lost by cancer cells in derived gliomaspheres. We confirmed the extrachromosomal origin of such mutations by showing that wild type and mutated DMs may coexist in the same tumor. Analysis of 4198 tumors from TCGA collection suggested the presence of ALEMs across different tumor types with the highest prevalence in glioblastomas and Low Grade Gliomas. In these tumors, driver oncogenic mutations in DMs were 13 - 25 fold more frequent as compared to the distribution of passenger mutations confirming the effective expansion of extrachromosomal drivers. The extrachromosomal nature of ALEMs provides a powerful mechanism of rapid regulation of the copy-number of mutated oncogenes including their massive increase or complete loss in response to extracellular stimuli such as RTK inhibitors or growth factors.

P12.064-M
New loci of loss of heterozygosity (LOH) in glioblastoma

E. Alekseeva[1,2], *A. Tanas*[1,2], *E. Prozorenko*[3], *A. Zaytsev*[4], *V. Strelnikov*[1,2], *D. Zaletayev*[1,2];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation,* [3]*N.N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation,* [4]*P.A. Hertzen Moscow Research Institute of Oncology, Moscow, Russian Federation.*

Despite recent advances in the diagnosis and treatment of glioblastoma, the prognosis for patients with this highly malignant tumor remains poor. Research of glioblastoma at the molecular genetic level can help reveal changes underlying this tumor, identify potential markers of prognosis of the disease and response to therapy. An efficient approach of identifying candidate genes, the disturbance of structure and functioning of which may be associated with the development of cancer, is the analysis of LOH. We have assessed 7 genomic loci for which LOH in glioblastoma have not been previously reported: 2q31.2, 3p25.1, 5q14.3, 7q21.2, 12q21.33, 18q11.2 and 21q21.1. None of these loci is associated with glioblastoma susceptibility according to OMIM. The selected loci were examined by microsatellite analysis in 86 glioblastoma samples. Four of the seven loci, 2q31.2, 12q21.33, 18q11.2 and 21q21.1 revealed no LOH cases. However, LOH was identified at 3p25.1, 5q14.3 and 7q21.2 with a frequency of 25.8% (8/31), 20.0% (3/15) and 30.3% (10/33), respectively. Identified areas of LOH can contain potential candidate genes that may be of interest in terms of the molecular pathology of glioblastoma. Some of these genes are SLC6A6 (3p25.1), CCNH (5q14.3), AKAP9 (7q21.2). Thus, we have identified new loci of LOH in glioblastoma, in which candidate genes that play a role in tumor development and represent potential molecular genetic markers may be located. We have also confirmed LOH at 8q21.3 and 14q13.3 with a frequency of 17.9% (5/28) and 60.0% (9/15), respectively, which other authors have reported.

P12.065-S
Effects of NDRG2 downregulation on glioblastoma patient survival

G. Steponaitis, *D. Skiriute, P. Vaitkiene, M. Mikuciunas, A. Kazlauskas;*
Lithuanian University of Health Sciences, Neuroscience institute, Laboratory of Neurooncology and Genetics, Kaunas, Lithuania.

Background. Glioblastoma multiforme (GBM) is the most lethal malignant human brain tumor with the poor survival prognosis exceeding to 12-15 months after diagnosis. No reliable molecular marker has been verified for GBM diagnostics up to date. Therefore, extensive research in molecular changes of GMB is essential to better understand this pathology. *NDRG2* gene has been reported to be downregulated in GBM, whereas overexpression of this gene represses glioblastoma cell proliferation *in vitro*. To further address the role of *NDRG2* in gliomagenesis, we analyzed *NDRG2* expression at mRNA and protein level in gliomas of different malignancy grade. **Material and Methods.** The study included 78 different malignancy glioma tumors (9 astrocytomas grade-I, 29 grade-II, 14 grade-III and 26 glioblastomas). *NDRG2* mRNA expression study was performed using quantitative real-time Reverse-Transcription PCR analysis, while protein expression was estimated by using Western blot technique. **Results**. We found a strong decrease of *NDRG2* mRNA expression in glioblastoma to about 10-fold compared to I-III grade gliomas (Kruskal-Wallis, p<0.0001). In line with the mRNA data, NDRG2 protein level was markedly reduced in glioblastomas (to about 3-4-fold) as compared to grade I-III gliomas (p<0.0001). Spearman correlation analysis demonstrated significant correlation of *NDRG2* transcripts and protein expression levels (r=0.662, p<0.0001). Survival analysis showed negative correlation between *NDRG2* expression and tumor progression (Log-rank p=0.0001). Our results highlight the importance of *NDRG2* for glioma tumorigenesis as well as being as an indicatory factor for glioma malignancy and patient survival.

Molecular changes associated with the relapse of glioblastoma after standard radiochemotherapy remain poorly understood. Here we compared genomic profiles of 27 pairs of primary and recurrent *IDH1/2* wild-type glioblastomas by genome-wide array-based comparative genomic hybridization. By bioinformatic analysis, primary and recurrent tumor profiles were normalized and segmented, chromosomal gains and losses called taking the tumor cell content into account, and difference profiles deduced. Seven of 27 (26%) pairs lacked DNA copy number differences between primary and recurrent tumors (Equal pairs). The recurrent tumors in 9/27 (33%) pairs contained all chromosomal imbalances of the primary tumors plus additional ones, suggesting that a major subclone sequentially accumulated aberrations (Sequential pairs). In 11/27 (41%) pairs, the profiles of primary and recurrent tumors were divergent, i.e. the recurrent tumors contained additional aberrations but had lost others, suggesting a polyclonal composition of the primary tumors and considerable clonal evolution (Discrepant pairs). Losses on 9p21.3 harboring the *CDKN2A/B* locus were significantly more common in primary tumors from non-Equal pairs. Non-Equal pairs showed ten regions of recurrent genomic differences between primary and recurrent tumors harboring 46 candidate genes associated with tumor recurrence. In particular, copy numbers of genes encoding apoptosis regulators were frequently changed upon recurrence. In summary, approximately 25% of *IDH1/2* wild-type glioblastoma pairs have stable genomic imbalances. In contrast, approximately 75% of *IDH1/2* wild-type glioblastomas undergo further genomic aberrations and alter their clonal composition upon recurrence impacting their genomic profile, a process possibly facilitated by loss on 9p21.3 in the primary tumor.

Glioblastoma multiforme (GBM; WHO-grade IV), the most frequent primary malignant brain tumor in adults, accounts for approximately 7-9% of all central nervous (CNS) tumors in childhood. Adult and paediatric GBMs (pGBMs) have distinct genetic and molecular pathways of tumorigenesis and different studies, based on array-CGH analysis, reported that there are significant differences in Copy Number Alterations (CNA). In our previous study we identified, using array-CGH, recurrent CNA in 8 pGBMs establishing minimum common regions (MCR) of duplication/amplification and deletion. Based on these results, we developed a next-generation sequencing (NGS) approach to screen the genetic profile of tumors. NGS has provided a new paradigm in biomedical research to delineate the genetic basis of human diseases. The panel was designed to cover 420 genes selected within of MCRs to try to identify new genes involved in tumorigenesis and/or progression of pGBMs. In 8 patients we found 18 heterozygous mutations in different genes. The same mutations were also found in DNA extracted from blood and in two cases we demonstrated the parental origin of 12 mutations. Given the rarity of the disease and the scarcity of data in the literature, our findings may better elucidate if there is a genomic background in development and progression of pGBM. The recognition of candidate genes underlying this disease could then improve treatment strategies for this devastating tumor.

P12.068-M
Distinctive expression profiles of lncRNAs in glioma subtypes

A. Matjašič[1], *M. Tajnik*[1], *M. Popovič*[2], *B. Matos*[3], *E. Boštjančič*[1], *D. Glavač*[1];
[1]*University of Ljubljana, Faculty of medicine, Institute of pathology, Department of molecular genetics, Ljubljana, Slovenia,* [2]*University of Ljubljana, Faculty of medicine, Institute of pathology, Ljubljana, Slovenia,* [3]*University medical center, Department of neurosurgery, Ljubljana, Slovenia.*

Background: Gliomas are the most malignant and common primary brain tumors, classified upon malignancy grade and histological characteristics. Correct diagnosis that relies solely on histopathological characteristics might be difficult and inadequate, particularly in cases that lack typical features. Glioma subtypes have distinct molecular features and gene expression analyses could uncover molecular biomarkers for deciphering glioma subtypes. Our purpose was to identify lncRNAs that might play role in gliomagenesis and investigate potential association of differential expression profiles with different glioma subtypes. **Patients and methods:** Sixty-four patients were included in the study. We used quantitative real-time PCR (qPCR) in order to determine differentially expressed lncRNAs using LncRNA array profiler on a smaller cohort of pathohistologically evaluated glioma samples normalized to human brain reference RNA. A subset of differential lncRNAs was further validated by qPCR approach on a biger cohort of glioma samples and statistically evaluated using Mann-Whitney and Kruskal-Wallis tests. **Results:** LncRNA profiling revealed a total of 74 among 90 analysed lncRNAs to be widely expressed and statistical tests identified a subset of 10 significantly differentially expressed lncRNAs. Further analyses of 7 dysregulated lncRNAs (*7SL*, *EGOA*, *HOTAIR*, *JPX*, *MEG3*, *RNCR3* and *ZNFX1-AS1*) have showed statistically significant differences in relative gene expression ratios implicating distinctive expression profiles in glioma subtypes. **Conclusions:** Our findings support the concept of lncRNAs as molecular biomarkers by determining distinctive subtype-related lncRNA expression patterns between glioma subtypes, which suggest an important role of lncRNAs in glioma biogenesis and implicate the potential use of lncRNAs in glioma histological classification.

Genomic hallmarks in glioma

E. Bonaparte[1], *R. Falcone*[1], *C. Augello*[2], *M. Ciboddo*[2], *M. Caroli*[3], *P. Colapietro*[4], *S. M. Sirchia*[1,4], *M. Miozzo*[1,2], *S. Tabano*[1,2];
[1]*Division of Pathology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy,* [2]*Department of Pathophysiology and Transplantation; Università degli Studi di Milano, Milano, Italy,* [3]*Division of Neurosurgery, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy,* [4]*Department of Health Sciences, Università degli Studi di Milano, Milano, Italy.*

Recent genome-wide studies have been developed to support hystologic classification of gliomas and different molecular abnormalities have been linked to tumor grading and disease progression.
In our study we investigated MGMT promoter methylation, 10q loss of heterozygosity (LOH) and IDH1 R132H mutation in tumor specimens from 103 patients with glioblastoma and II and III grade gliomas, to further understand: 1) correlation with grading, 2) prognostic value.
Pyrosequencing analysis of MGMT promoter showed that methylation levels decrease from low to high grade tumors (p <0,001), confirming that hypermethylation (methylation levels >20%) correlates with a better progression free survival (PFS). Interestingly, a mildly methylated subgroup (methylation 20%-40%) revealed a better PFS. Microsatellite and a-CGH analyses showed that 10q LOH is common in high grade tumors and associates with MGMT hypomethylation, while absence of LOH and hypermethylation correlate with low grade tumors. IDH1 mutation was investigated by pyrosequencing and detected in all of low grade gliomas (10 cases), in 7/11 II grade gliomas. We did not find mutations in IV grade gliomas, indicating a strong association between tumor grading and IDH1 mutation status (p<0,001). In addition, we found a correlation between IDH1 mutation and MGMT methylation level (p<0,001), both decreasing with increasing tumor grade. In conclusion, our data reinforced the role of MGMT methylation and IDH1 mutation as hallmarks of better prognosis, and conversely 10q LOH as a poorer one. Moreover, we evidenced the existence of a mildly methylated glioma subtype correlated with a better PFS.

P12.070-M
miRNA expression profile in tumor cell lines treated with the histone deacetylase inhibitor LBH589

D. Martín-Sánchez[1,2], *C. Jiménez-Criado*[1,2], *J. González-Valero*[1], *N. Gutiérrez*[2], *J. García Hernández*[1], *J. Cruz-Hernández*[2], *R. González-Sarmiento*[1,2];
[1]*Centro de Investigación del Cáncer, Salamanca, Spain,* [2]*Institute of Biomedicine Research (IBSAL), Salamanca, Spain.*

Introduction: The presence of HDAC proteins is necessary for the correct regulation of gene expression. Multiple studies have demonstrated that inhibition of these proteins can lead to deregulation of gene expression and abnormal cell proliferation. In our study we have analyzed the miRNA profile of three epithelial cell lines (HCT116, HT29 and HCC1937) and two mesenchimal cell lines (H929 and MM1S) after treatment with a histone deacetylase inhibitor, currently in phase III clinical trial.
Materials and methods: We have analyzed miRNA expression comparing the profiles before and after treatment. RNA was isolated from cell lines and miRNA labeling was performed using a conventional assays. An Exiqon chip miRCURY LNA Array microRNA ™ was used for analysis. Comparisons between the different study groups were performed using SAM to identify those miRNAs whose expression showed statistically significant differences.
Results: Comparing the expression profiles of the cell lines between 24h and 72h after treatment with the histone deacetylase inhibitor, we found that epithelial cells show a group of 18 up-regulated and 16 down-regulated miRNAs. Whereas mesenchymal cells show 20 up-regulated and 20 down-regulated miRNAs. Both types of cells share 3 up-regulared miRNAs at 24h, 8 at 72 hours and 1 down-regulated miRNA.
Conclusions: These data show that treatment with histone deacetylase modifies miRNA expression patterns. Specifically depending on the cellular origin of tumor cells, which could explain different outcome of patients treated with this approach.

[1]*BGI, Shenzhen, China,* [2]*Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,* [3]*Pfizer Inc., San Diego, CA, United States.*

To gain biological insights on tumor metastases, we used whole-genome sequencing at 33X-43X coverage to profile somatic mutations in primary HCC (HBV+) and metachronous lung metastases (> 2 years interval). In total, 5,027-13,961 and 5,275-12,624 somatic single-nucleotide variants (SNVs) were detected in primary HCC and lung metastases, respectively. Generally, 38.88-78.49% of SNVs detected inmetastases were present in primary tumors. We identified 65-221 structural variations (SVs) in primary tumors and 60-232 SVs in metastases. Comparison of these SVs shows very similar and largely overlapped mutated segmentsbetween primary and metastatic tumors. Copy number alterations between primary and metastatic pairs were also found to be closely related. Together, these preservations in genomic profiles from liver primary tumors to metachronous lung metastases indicate that the genomic features during tumorigenesis may be retained during metastasis.Additionally, a few mutations were found specifically in lung metastases, which may explain the clinical observationthat

both primary and metastatic tumors are usually sensitive or resistant to the same systemic treatments.

P12.073-S
Identification of a novel CDH1 gene mutation in a family with hereditary diffuse gastric cancer

M. Lopez[1], *P. Santibañez*[1], *C. Cervera-Acedo*[1], *J. Aguirre-Lamban*[1], *A. Martin-Carnicero*[2], *R. Salazar*[2], *E. Dominguez-Garrido*[1];
[1]*Fundacion Rioja Salud-CIBIR, Logroño, Spain,* [2]*Hospital San Pedro, Logroño, Spain.*

Introduction: Hereditary diffuse gastric cancer (HDGC) is an autosomal dominant genetic predisposition syndrome caused by CDH1 germline mutations, with incomplete penetrance. HDGC is relatively uncommon, representing about 2% of gastric cancer. The majority of inactivating mutations in HDGC families are of the truncating type (75%), whereas the remaining are missense type. The estimated lifetime risk for DGC is more than 80% in mutation carriers and prophylactic total gastrectomy is recommended. **Subjects and methods:** A 47 year-old female patient diagnosed with DGC was screened for CDH1 gene mutations. DNA and RNA extraction was carried out from blood and tissue (gastric biopsy) and the entire coding sequence and flanking intronic portions of the CDH1 were sequenced. Other family relatives *(*three sisters, an uncle and a nephew*)* were also screened. **Results:** A deletion in exon 9 of CDH1 gene (c.1220delC, p.407*), not previously described, has been found. This mutation generates a stop codon that leads to a pathogenic variant. The presence of the mutation was corroborated both, at DNA and RNA level in blood and tissue. The proband died during the study. One of the sisters presented also the deletion and had a previous history of malignant colorectal polyp at the age of 49. Her son (nephew of the proband) presented also the mutation. Neither of the other relatives harboured the mutation. **Conclusion:** HDCG has a poorly prognosis, mainly because of its difficult early detection. The identification of CDH1 mutations offers the opportunity of carry out prophylactic strategies for unaffected at-risk individuals.

P12.074-M
Novel mutations in Juvenile polyposis syndrome

N. Sharon Schwartzman[1], *H. N. Baris*[1], *E. Reinstein*[2], *E. Sabo*[3], *A. Suissa*[4], *I. Kedar*[2], *M. Mei Zahav*[5], *A. Mory*[1], *E. E. Half*[a];
[1]*The Genetic Institute, Rambam Health Campus, Haifa, Israel,* [2]*The Recanati Genetic Institute, Rabin Medical Center, Petach Tikva, Israel,* [3]*The pathology department, Rambam Health Campus, Haifa, Israel,* [4]*The Gastroenterology Institute, Rambam Health Campus, Haifa, Israel,* [5]*Respiratory Unit, Schneider Medical Center, Petach Tikva, Israel.*

Juvenile polyposis syndrome (JPS) is an autosomal dominant disorder characterized by multiple juvenile polyps (JP) mainly in the colon with increased risk of colorectal cancer. Subsets of patients develop severe gastric polyposis with increased risk of gastric cancer.
Of fifty patients evaluated for polyposis in 2013, two JPS patients with novel mutations were diagnosed.
1st: 27yrs after right colectomy for multiple hyperplastic, and JPs resulting in recurrent rectal bleeding and anemia, normal gastroscopy. Sequencing and MLPA for SMAD4 were negative. BMPR1A sequencing yielded c.367G>T (p.123E>*), a novel nonsense mutation.
2nd: At 32 yrs total colectomy for multiple adenomatous polyps suspicious of Familial Adenomatous Polyposis. Gastroscopy detected multiple hyperplastic polyps. APC sequencing and two common MUTYH mutations were normal. Due to severe bulky gastric polyposis a revision of the pathology was performed and JPS was clinically diagnosed. A total gastrectomy was performed for persistent anemia and cancer risk. Epistaxis and telangiectases on his back and chest raised the possibility of hereditary hemorrhagic telangiectasia (HHT). Sequencing of SMAD4 found c.406_407delGT (p.V136CfsX6), a de novo novel frameshift mutation.
JPS composes 10% of polyposis syndromes. About 20% of SMAD4 patients have JPS-HHT combined syndrome. Phenotypically, patients with SMAD4 mutations may have gastric polyposis with a significant risk of gastric cancer. These JPS patients illustrate the need for careful history collection and thorough pathological analysis, that should guide the genetic evaluation. Genetic workup of JPS patients is important for family counseling and to establish the need for HHT evaluation in patients with SMAD4 mutations.

P12.075-S
Targeting the functional relevance of the novel tumor suppressor gene FOCAD (KIAA1797) in glioma pathogenesis

F. Brand, *A. Kosfeld, M. Bucher, R. G. Weber;*
Hannover Medical School, Hannover, Germany.

Malignant gliomas have a highly invasive phenotype, which is a main determinate for the poor prognosis of patients suffering from these tumors despite multimodal therapy. In previous studies, we used 24-color-FISH to characterize the chromosomal translocation events in glioblastoma cell lines, and detected a t(7;9) disrupting the FOCAD (KIAA1797) gene encoding a then uncharacterized protein. FOCAD was deleted in around 50% of primary glioblastomas, and its gene product, focadhesin, had an impact on glioblastoma growth in vivo and cell motility in vitro. The aim of this project was to further characterize focadhesin by targeting its unknown binding partners. Therefore, we performed two independent yeast two-hybrid screens using a human brain cDNA library. In total, we isolated 206 clones, from which we eliminated 155 clones, because they could grow without auxotrophic marker expression. The DNA sequences of the remaining 51 prey inserts were identified. In 26 prey plasmids, the cDNAs were protein-coding and in frame. Finally, 8 distinct potential binding partners were identified, which can be categorized into the functional groups of calcium signaling, mitosis, protein folding, RNA processing and cell metabolism. To confirm these interactions, we performed retransformation experiments using fresh yeast. Three candidates were also analyzed by pull-down assays and co-localization studies using human cells. Two interactions have been confirmed so far. In the next step, the functional relevance of the verified interactions will be investigated in glioblastoma cells with stable focadhesin knockdown and cells with homozygous deletion of the FOCAD gene with or without FOCAD-rescue by viral transduction.

Targeted deep sequencing of fusion transcripts - developing clinical assays for leukemia samples

A. Ameur[1], *M. Sevov*[2], *I. Bunikis*[1], *S. Häggqvist*[1], *I. Höijer*[1], *I. Jonasson*[1], *U. Gyllensten*[1], *M. Hermanson*[2], *L. Cavelier*[2];
[1]*IGP, National Genomics Infrastructure, SciLifeLab, Uppsala, Sweden,* [2]*IGP, Uppsala University, Uppsala, Sweden.*

One of the main focuses of the National Genomics Infrastructure-Sweden (NGI) is to bring high-throughput sequencing to clinical use. Here we describe recent work on PCR- and hybridization-based deep sequencing of specific targeted fusion transcripts using Pacific Biosciences RSII (PacBio) and Ion Torrent PGM/Proton instruments, methods that can help to guide the treatment of leukemia patients.
By long-read PacBio sequencing we are developing clinical workflow for detection of BCR-ABL1 tyrosine kinase inhibitor (TKI) resistance mutations in chronic myeloid leukemia (CML). Our assay enables rapid sequencing of a 1578bp *BCR-ABL1* cDNA amplicon without the need of a nested PCR. Mutations down to a level of 1% are clearly detected using this approach. Moreover, the long PacBio reads makes it possible to resolve the mutational composition of all different clones present in CML patient samples. Since compound mutations might confer cross-resistance to multiple TKIs, the information provided by our assay can directly influence the choice of therapy.
In another project we study MLL-rearranged leukemias, characterized by chromosomal translocations involving the *MLL* gene at 11q23. *MLL* can form fusions transcripts together with several different genes, some of which are still unknown. In some cases conventional assays like G-banding and FISH fail to detect these fusion partners. We are therefore evaluating a hybridization-based assay for targeted capture of *MLL* cDNA, in combination with Ion Torrent sequencing. Our preliminary results indicate that our method increases the sensitivity for detecting *MLL* fusion genes by several orders of magnitude compared to a regular RNA-sequencing approach.

P12.077-S
Results of 20 years of Li-Fraumeni syndrome diagnosis in France

G. Bougeard[1], *S. Baert-Desurmont*[1], *R. Sesboüé*[1], *M. Renaux-Petel*[1], *J. M. Flaman*[1], *L. Brugières*[2], *T. Frebourg*[1], *The French LFS working group;*
[1]*Inserm U1079 and Rouen University Hospital, Rouen, France,* [2]*Department of Pediatric Oncology - Gustave Roussy Institute, Villejuif, France.*

The Li-Fraumeni syndrome (LFS), due to germline *TP53* mutations, represents a remarkable cancer predisposition characterized by the extent of tumour spectrum. For 20 years, analysis of over 1700 families allowed us to identify 214 French families with *TP53* mutation, thanks to the Chompret's criteria gradually elaborated by the French LFS working group. Updated data from 322 LFS patients with 552 tumours revealed that the median age of first tumour onset was 27 years, that the most frequent tumours were breast cancers (167), soft-tissue sarcomas (103), osteo/chondro-sarcomas (58), brain tumours (43) and adrenocortical carcinomas (42), and that 43% of patients developed multiple primary tumours. Germline *TP53* mutations were detected in 50% of children with adrenocortical carcinoma, choroid plexus carcinoma, or rhabdomyosarcoma. Sixty-four percent of *TP53* alterations were missense mutations and 4% genomic rearrangements. We found that *TP53* mutation carriers harbouring the *MDM2* 285-309GG haplotype developed tumours 5 years earlier than others. The most striking observation was that patients with dominant-negative missense mutation developed first-tumour earlier (22 y) than patients with null-mutation (42 y). Twenty

years after the identification of LFS molecular basis, this report reveals that 2 forms of LFS probably exist: an aggressive, characterized by early-onset tumours, due to highly penetrant dominant-negative missense mutations, and a moderate, characterized by later age of onset, due to mutations with lower penetrance. The remarkable high incidence of multiple primary tumours is probably explained by genotoxic effects of chemo- and radio-therapy and the key role of p53 response to DNA damage.

Identification of a characteristic copy number alteration profile by high-resolution SNP arrays associated with metastatic sporadic colorectal cancer

J. Sayagués[1], *M. González-González[1], C. Fontanillo[2], M. Abad[3], M. Gutiérrez[1], I. Mota[1], O. Bengoechea[3], Á. Santos-Briz[3], O. Blanco[3], E. Fonseca[4], J. Ciudad[1], M. Fuentes[1], J. De Las Rivas[5], J. Alcazar[6], J. García[6], L. Muñoz-Bellvis[6], A. Orfao[1];*
[1]Centro de Investigación del Cáncer (IBMCC-CSIC/USAL), Universidad de Salamanca, Salamanca, Spain, [2]Bioinformatics and Functional Genomics Unit, IBMCC-CSIC/USAL, Celgene Research SL, Salamanca, Spain, [3]Departament of Pathology, University Hospital of Salamanca-IBSAL, Salamanca, Spain, [4]Service of Medical Oncology, University Hospital of Salamanca-IBSAL, Salamanca, Spain, [5]Bioinformatics and Functional Genomics Unit, IBMCC-CSIC/USAL, Salamanca, Spain, [6]Service of General Surgery and Digestive Apparatus, University Hospital of Salamanca-IBSALnvestigación del Cáncer (IBMCC-CSIC/USAL), Universidad de Salamanca, Salamanca, Spain.

Background: Metastatic dissemination is the most frequent cause of death in sporadic colorectal cancer (sCRC). The metastatic process is considered, at least in part, to be related to a specific background of genetic alterations accumulated in cells from primary tumors, the identification of such genetic alterations being critical for the identification of sCRC patients at risk of developing metastases.
Methods: In this study we used high-resolution 500K SNP-arrays for the identification of copy number alteration profiles present at diagnosis in primary tumors from metastatic (n=23) versus non-metastatic (n=26) sCRC.
Results: Our results showed a characteristic pattern of copy number alterations among metastatic sCRC which involved losses of 23 regions at chromosomes 1p, 17p and 18q, together with gains of 35 regions at chromosomes 7 and 13q.
Conclusion: As could be expected, such copy number profile involved multiple genes previously associated with sCRC (i.e. SMAD2) and/or the metastatic process (i.e. PODXL) and it was further associated with a poorer outcome.

P12.079-S
Oligogenic germline mutations predispose to early lung adenocarcinoma in non-smokers

E. Frullanti[1], *M. A. Mencarelli[1], M. Baldassarri[1,2], F. Cetta[3], F. Mari[1,2], S. Furini[4], P. Piu[5], T. A. Dragani[6], F. Ariani[2], A. Renieri[1,2];*
[1]Medical Genetics, Azienda Ospedaliera Universitaria Senese, Siena, Italy, [2]Medical Genetics, University of Siena, Siena, Italy, [3]IRCCS MultiMedica, Milan, Italy, [4]Department of Medical Biotechnology, University of Siena, Siena, Italy, [5]Department of Medicine, Surgery & Neuroscience, University of Siena, Siena, Italy, [6]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy.

Despite the great bulk of research to identify genetic susceptibility genes in lung cancer by genome-wide association studies, only three loci have been identified and replicated consistently in subsequent studies. In addition to confer a very low risk, they have been associated with lung cancer in smokers, but not in non-smokers. The polygenic nature of common cancers has frequently been suggested, but its biological basis still remains elusive. We tested the hypothesis that genetic susceptibility may rely on germ-line mutations of a restricted number of genes. A combination between an advanced technical tool, i.e. the exome sequencing, and a new patient selection strategy was used. Among 964 lung adenocarcinoma patients we selected two patients with very early onset disease (mean age 43) in absence of cigarette smoking, and having a first degree healthy sibling available for genome comparison older than at least 7 years. Germ-line truncating mutations were detected in 8 and 5 different cancer predisposing genes in each affected subject, respectively, but not in the healthy sib (p=0.0026). Some of them are well known cancer players in lung tumors and others are genes previously identified in other cancer tissues. This study demonstrated for the first time that never-smoker patients with lung adenocarcinoma carry a specific and private oligogenic combination of germ-line mutations in cancer predisposing genes. Exome sequencing of another pair of sibs with slightly later age onset is ongoing. These findings, if replicated with further studies, support the hypothesis of an oligogenic nature of early onset common cancers.

It is becoming evident that Lynch Syndrome (LS) is one of the most common cancer syndromes. Diagnosis is not always trivial and may be costly. Knowledge of incidence, spectrum of mutations and genes involved in specific populations, facilitates the diagnostic process and contributes to clinical work-up. AIM: To report a cohort of LS families in the Israeli population, gene distribution, mutations detected and co-occurrence of related syndromes. METHODS: Patients were studied at high risk clinics. Diagnostics followed a multi-step process. It included testing for founder mutations, tumor testing, gene sequencing and MLPA. LS was defined by positive tumor analysis and/or positive mutation testing. RESULTS: We describe a cohort of 318 carriers from 169 families with LS. We have identified 61 different mutations in 102 families; 3 founder mutations occurred in over 70% of Ashkenazi LS families, where mutations in *MSH6* were more common than in *MLH1*. We identified founder mutations also among Jewish families from Georgia, Iran and Afghanistan. *MSH2* was mutated in 62% of the cases, one third of these mutations were large deletions. Constitutional mismatch repair deficiency (C-MMRD) was identified in 6 families. CONCLUSIONS: Mutation spectrum and gene distribution in the Israeli population is unique. Mutations in *MSH2* and *MSH6* cause the majority of cases. Six founder mutations contribute to LS in 4 different ethnic sub-groups. C-MMRD occurs either due to founder mutations or consanguinity. These features affect the phenotype, the diagnostic process, risk estimation, and genetic counseling.

P12.081-S
Genotype and Parent of Origin Effect on Colorectal and Endometrial Phenotypes in Patients with a PMS2 mutation

M. Suerink[1], H. M. Klift van der[1], S. W. Broeke ten[1], F. J. Hes[1], H. F. A. Vasen[2], C. M. Tops[1], J. T. Wijnen[1], O. M. Dekkers[3], **M. Nielsen**[1];
[1]Centre of Human and Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands, [2]Department of Gastroenterology, Leiden University Medical Centre, Leiden, Netherlands, [3]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands.

Introduction Mutations in the PMS2 gene are responsible for Lynch syndrome, a genetically inherited disorder with an increased risk of foremost colorectal cancer (CRC) and endometrial cancer (EC). Possibly, the reported variability in cancer prevalence and age of diagnosis between patients and families can partly be explained by genotype and/or parent of origin effects (POE). **Methods** The genotypes and clinical data of 383 European PMS2 mutation carriers were available for analysis. Mutations with loss of RNA expression (group 1) and retained RNA expression (group 2) were compared. A one-way Anova test and Cox regression were done to compare mean age of cancer diagnosis and calculate hazard ratios (HR). **Results** Mean age of CRC diagnosis was 50,99 years (CI 48,09-53,89) for group 1 and 60,00 years (CI 52,50-67,50) for group 2 (p=0,032). For EC no significant differences in mean age of diagnosis were found. Cox regression showed slightly higher non-significant HRs for both CRC (HR: 1,274, p=0,440) and EC (HR:1,216, p=0,722) when comparing group1 to group 2. No significant HR for CRC or EC depending on whether the mutation was inherited from father or mother was found. **Discussion** A higher mean age at CRC diagnosis and a non-significant higher CRC risk in the group with loss of RNA expression was identified. No significant evidence of a POE was found. Larger studies are needed to confirm findings. Possible information on genotype and other modifying risk factors might lead to individual risk stratification and surveillance programs in the future.

P12.082-M
Bi-allelic MSH6 mutations in a case of early onset multiple primary tumors resembling Lynch and Turcot syndrome

G. C. Casalis Cavalchini[1], *D. Giachino[2,3], G. Mandrile[2,3], I. Borelli[1,4], M. Micheletti[1], T. Venesio[5], M. De Marchi[2,3], B. Pasini[1,4];*
[1]Medical Genetics Unit, AO Città della Salute e della Scienza di Torino, Torino, Italy, [2]Medical Genetics Unit, San Luigi University Hospital, Orbassano, Italy, [3]Department of Clinical and Biological Sciences, University of Turin, Turin, Italy, [4]Department of Medical Sciences, University of Turin, Turin, Italy, [5]MedicalUnit of Pathology, Institute for Cancer Research and Treatment Genetics Unit, AO Città della Salute e della Scienza di Torino, Candiolo, Italy.

Multiple primary tumors of the gastrointestinal tract, uterus, ovaries, central nervous system and other organs are hallmarks of Lynch syndrome, caused by heterozygous germline mutations in the mismatch repair (MMR) genes MLH1, MSH2, MSH6 and PMS2. Bi-allelic mutations of the same genes have been associated with a rare childhood cancer syndrome characterized by hematological malignancies, sarcomas, brain and gastrointestinal tumors together with cafè-au-lait spots resembling Neurofibromatosis 1. Here we report on a female patient who developed multiple primary tumors between 21 and 27 years of age including two metachronous colorectal cancers, a fillodes tumour of the breast, a glioblastoma and a clear cell carcinoma of the ovaries. Genetic testing identified two germline heterozygote MSH6 mutations: a frameshift mutation (c.1610_1613delAGTA) inherited from the father and a suspected deleterious missense mutation (p.Arg1076His) inherited from the mother. No TP53, MLH1 or MSH2 mutations were found. Microsatellite analysis revealed instability of BAT26 and BAT40 in both the colon and the ovarian carcinomas. The MLH1, MSH2 and PMS2 proteins showed nuclear staining in all specimens while MSH6 was completely absent in tumor and normal cells, including the fillodes tumor of the breast and the normal mucosa of the colon. Germline mutations in the MMR genes, either mono-allelic or bi-allelic, can therefore underlie a wide spectrum of cancer syndromes characterized by variable age at onset and severity of the cancer risk. Development of multiple primary tumors in young adults appears to be suggestive for the presence of bi-allelic mutations of the MMR genes.

P12.083-S

Constitutional epimutation of *MLH1* gene coexisting with a genomic deletion in Lynch Syndrome

G. Cini[1], *M. G. Tibiletti*[2], *P. Sala*[3], *E. Giacomini*[1], *M. Quaia*[1], *A. Chiaravalli*[2], *I. Carnevali*[2], *A. Viel*[1];

[1]*CRO Aviano National Cancer Institute, Aviano, Italy,* [2]*Circolo Hospital-University of Insubria, Varese, Italy,* [3]*National Cancer Institute, Milano, Italy.*

A few Lynch Syndrome patients display constitutional epimutations of the *mismatch repair* genes. Two models of *MLH1* epimutations have been hypothesized: the "primary" type arises spontaneously and is reversible between generations; the "secondary" type is caused by an unknown cis-acting genetic-based alteration, with a classical Mendelian autosomal dominant inheritance pattern.

We report here a case with a heritable large genomic deletion of *MLH1* associated with constitutional promoter methylation of the same gene. Both aberrations were found by MLPA analyses in a patient with colorectal and endometrial cancers (30 and 40 years), displaying MSI-H and loss of the MLH1 protein. They were also detected in three other affected relatives and in tumors.

We have explored the link between *MLH1* deletion and methylation by different molecular approaches. The deletion of 997bp included the ATG codon, exon 1 and part of intron 1. Bisulfite sequencing demonstrated that CpG-methylation was present on the deleted allele and involved both flanking sequences. As expected, a lymphoblastoid cell line obtained from the proband expressed about half of the *MLH1* transcript levels, suggesting that the mutated/methylated allele was completely silenced. Treatments with the demethylating agent 5-AzaC was not able to revert the methylation status of the CpG analyzed and had only a little impact on *MLH1* expression.

In conclusion, in this family with a classical autosomal dominant pattern, we have obtained evidences that *MLH1* hypermethylation is not an independent event, but it is induced by a so far unknown mechanism related to the presence of the concurrent deletion.

P12.084-M

Appearances deceive twice. Lynch-like syndrome ends up being MUTYH-associated polyposis. Apparent homozygous MUTYH mutation ends up being compound heterozygous with a large deletion

A. Castillejo[1], *E. Hernández-Illán*[2], *S. Oltra*[3], *M. I. Castillejo*[1], *V. M. Barberá*[1], *A. B. Sanchez-Heras*[4], *J. L. Soto*[1];

[1]*Molecular Genetics Laboratory, Elche University Hospital, Elche, Spain,* [2]*Research Laboratory, Alicante University Hospital, Alicante, Spain,* [3]*Genetics Unit, La Fe University Hospital, Valencia, Spain,* [4]*Hereditary Cancer Unit, Elche University Hospital, Elche, Spain.*

Significant phenotypic similarities among Lynch syndrome (LS) and MUTYH-associated polyposis (MAP) has been reported.

We describe a family suspicious of having LS. A 69 years old female diagnosed of an endometrial cancer (T1N0M0) and right CRC (T3N0M0) with multiple polyps at ages 60 and 65, respectively. Endometrial tumor had loss of MLH1 and PMS2 expression, MSI, no BRAF_V600E mutation, absence of MLH1 methylation, and KRAS_G12C mutation. No pathogenic variant was found in the MLH1 mutation screening and MAP suspicion was considered. MUTYH testing was approached by Sanger sequencing screening of recurrent variants at exons 7 and 13. Patient did show homozygous pattern for c.1187G>A (p.G396D) variant and was diagnosed as MAP syndrome. Predictive test for relatives unveiled an unexpected finding, we found one of her sons with an apparent wild type sequence. Further analysis evidenced a large deletion comprising exon 4-16 in both mother and son. Breakpoint characterization of this deletion allowed us to precisely define this alteration as c.348+33_*64+146del4285insTA with a precise size deletion of 4,285 kb. The same deletion has been published in other two unrelated families from French and Portuguese origin suggesting a founder effect. Large rearrangements at MUTYH locus are rare although probably under-diagnosed. Based on these findings we recommend first, to include MUTYH gene in the testing strategy for LS and second, to test for MUTYH large rearrangements in heterozygous cases after whole gene sequencing, as well as in apparent homozygous cases.

P12.085-S

Male breast cancer in the Netherlands: uptake and outcome of BRCA testing. Results of study the Dutch Breast Cancer Research Group (BOOG 2009-04) in collaboration with the EORTC 10085 study.

C. J. van Asperen[1], *N. Dijkstra*[2], *P. J. M. van Hees*[1], *W. A. G. van Zelst-Stams*[3], *J. C. Oosterwijk*[4], *M. G. E. Ausems*[5], *R. A. Oldenburg*[6], *M. A. Adank*[7], *E. W. Blom*[8], *M. Ruijs*[9], *T. A. M. van Os*[10], *L. A. M. Janssen*[1], *C. van Deurzen*[11], *S. Roshani*[11], *J. W. M. Martens*[6], *C. P. Schroder*[4];

[1]*Dept. of Clinical Genetics, LUMC, Leiden, Netherlands,* [2]*BOOG Study Center, Amsterdam, Netherlands,* [3]*RadboudUMC, Nijmegen, Netherlands,* [4]*UMCG, Groningen, Netherlands,* [5]*UMCU, Utrecht, Netherlands,* [6]*ErasmusMC, Rotterdam, Netherlands,* [7]*VUMC, Amsterdam, Netherlands,* [8]*MUMC, Maastricht, Netherlands,* [9]*NKI, Amsterdam, Netherlands,* [10]*AMC, Amsterdam, Netherlands,* [11]*Dept. of Pathology, ErasmusMC, Rotterdam, Netherlands.*

Background: In male breast cancer (MBC) the prevalence of BRCA1/2 mutations varies considerably between countries. In the Netherlands data were collected of all MBC patients diagnosed in the last 20 years. The nationally agreed criteria for DNA testing are rather broad, implying that many MBC cases with or without a family history for breast cancer have been tested. Aim of this study is to get more insight in the percentage of BRCA1/2 mutations among an unselected cohort of MBC patients. **Methods:** All diagnosed MBC patients between 1989-2009 (n=1487) were linked to databases of all clinical genetic centers. Data of BRCA testing, family history and tumor characteristics were collected. **Results:** 334 (22%) of MBC patients were tested for BRCA1/2. Ten (3%) BRCA1, 51 (15%) BRCA2 mutations were identified and also 7 (2%) variants of uncertain significance (VUS). At least one first or second degree relative with breast cancer <50 yr was seen in 80% of BRCA1, 20% of BRCA2 and 6% of non-BRCA1/2 MBC patients. Preliminary studies did show that the majority (86%) of BRCA associated MBC were ductal carcinomas of no special type. **Conclusion:** Roughly one fifth of unselected MBC patients had undergone DNA testing, in 18% of these a BRCA mutation was found. Most striking family histories were seen in BRCA1 families, whereas the majority of BRCA2 MBC patients had no strong family history. Based on our results and previous studies genetic testing for BRCA1/2 should be recommended for any MBC case, regardless of family history for breast cancer.

P12.086-M

Role of MAP/Microtubule Affinity Regulating Kinase 4 in the regulation of cell cycle progression and cytoskeleton dynamics

D. Rovina[1], *L. Fontana*[1], *L. Monti*[1], *C. Novielli*[1], *N. Panini*[2], *S. M. Sirchia*[1], *E. Erba*[2], *I. Magnani*[1], *L. Larizza*[1];

[1]*Medical Genetics, Department of Health Sciences, Università degli Studi di Milano, Milano, Italy,* [2]*Flow Cytometry Unit, IRCCS, Istituto di Ricerche Farmacologiche Mario Negri, Milano, Italy.*

MAP/microtubule affinity regulating kinase 4 (MARK4) is a serine-threonine kinase that phosphorylates and regulates MAP proteins. MARK4 differs from the other members of the MARK protein family, for encoding two isoforms (MARK4L and MARK4S) differentially expressed in the nervous system, and for the peculiar sub-cellular localisation at the centrosome and the midbody. In order to better define the role of MARK4 in cell cycle and cytoskeleton dynamics, we performed cytofluorimetric analysis of fibroblasts and glioma cells, showing that MARK4 is expressed throughout the cell cycle and is preferentially activated during mitosis and cytokinesis. Using the same cell system we demonstrated the role of MARK4 in cell cycle progression and cytoskeleton regulation by knockdown and overexpression experiments. Upon MARK4S silencing, fibroblasts and glioma cells display altered morphology, matched with a reduction in proliferation rate and mitotic fraction. In addition, silenced cells show duplicated centrosomes positioned apically to the nucleus, a feature typical of the G1/S phase transition. Overexpression of MARK4L or MARK4S reduced the density of the microtubule network, confirming microtubules as the main target of MARK4. Furthermore in fibroblasts MARK4L was found to colocalise with vimentin and to reorganise

intermediate filaments. Overexpression of kinase-dead mutants indicated that the effects on both cytoskeleton compartments are due to MARK4 kinase activity. The overall data highlight MARK4 as a key component in the regulation of MT dynamics, demonstrate its role in cell cycle progression, particularly at the G1/S transition, and point to vimentin as a new plausible MARK4 interactor.

Multiple primary melanoma (MPM) as a valid criterion for genetic assessment : an Italian IMI multi-center study

W. Bruno[1], *P. Ghiorzo[1], L. Pastorino[1], F. Ayala[2], V. De Giorgi[3], F. Gensini[4], M. Mandalà[5], C. Menin[6], S. Osella Abate[7], G. Palmieri[8], M. Rodolfo[9], A. Ronco[10], G. Spadola[11], M. Tibiletti[12], P. Queirolo[13], G. Bianchi[14], IMI collaborators (Italian Melanoma Intergroup);*
[1]Department of Internal Medicine and Medical Specialties, Genoa University, Genoa, Italy, [2]Naples Cancer Institute, Naples, Italy, [3]Department of Dermatology, University of Florence, Florence, Italy, [4]Clinical Physiopathology Department , Florence University, Florence, Italy, [5]Ospedali Riuniti di Bergamo, Bergamo, Italy, [6]Veneto Oncology Institute - IRCCS, Padua, Italy, [7]Turin University, Turin, Italy, [8]Institute of Biomolecular Chemistry - National Research Council, Sassari, Italy, [9]Department of Experimental Oncology, National Cancer Institute, Milan, Italy, [10]Presidio Sanitario Gradenigo, Turin, Italy, [11]Melanoma and muscle-cutaneous sarcomas Division, European Oncology Institute, Milan, Italy, [12]Ospedale di Circolo-Università dell'Insubria, Varese, Italy, [13]Medical Oncology, IRCCS San Martino - National Cancer Research Institute, Genoa, Italy, [14]Department of Internal Medicine and Medical Specialties, Genoa University, IRCCS San Martino-National Cancer Institute, Genoa, Italy.

The prevalence of mutations in the CDKN2A melanoma candidate gene correlates with number of affected family members and number of MPM/neoplastic events. International referral guidelines for genetic counselling and testing (GenoMEL) indicate that in low melanoma incidence populations individuals developing two melanomas may be candidate for consideration for genetic testing, even in the absence of family history (FH). Aims of this multicenter case-control study performed within the Italian Melanoma Intergroup were to verify the likelihood to identify mutations carriers in MPM vs single primary melanoma (SPM) patients recruited, to update the current Italian shared protocol for hereditary melanoma (SIGU-ONC recommendations, Bianchi et al, 2004) and to include the presence of MPM, in the absence of family history, as a criterion. Despite regional differences (i.e. founder mutations), 118/587 (20,1%) of the recruited MPM patients (including those with melanoma FH) and 52/443 (11,7%) of sporadic MPM harbored CDKN2A mutations, suggesting that the development of MPM (2 or more events) even in the absence of FH can be considered a criterion for genetic testing on national basis. The presence of MPM cases in a family was confirmed as a strong mutation predictive parameter, while CDKN2A mutations in sporadic SPM was under 5%. The search for the MITF E318K mutation, recently identified as a novel intermediate risk allele, showed that the mutation was associated with the risk of sporadic MPM (3,7% of sporadic MPM compared to 0.8% of SPM), underscoring the importance of the MITF mutation to the burden of MPM susceptibility.

P12.088-M
Genetic variants in the interleukin locus at 1q32.1 as markers of melanoma survival

J. Rendleman, *C. Adaniel, E. Kern, N. Fleming, M. Krogsgaard, D. Polsky, R. Berman, R. Shapiro, A. Pavlick, Y. Shao, I. Osman, T. Kirchhoff;*
New York University, New York, NY, United States.

Interleukins play a critical role in immune regulation of tumor development. Because melanoma is a highly immunogenic cancer, and its progression often correlates with immune-related factors, in this study we have tested whether inherited genetic variants in interleukin pathways affect the clinical outcomes of melanoma patients. We performed a two-stage association analysis of 94 SNPs tagging 32 interleukin genes in 1,200 melanoma patients, ascertained at the New York University Medical Center between 2001-2013. The two stages (discovery and validation) were matched by tumor characteristics, age, and gender. Multivariate Cox regression models tested the associations with recurrence-free and overall survival (RFS and OS, respectively), including age, gender, stage, thickness, ulceration status, anatomic site, and histological subtypes as covariates. A region within 1q32.1 containing IL10, IL19, IL20, IL24 was significantly associated with melanoma OS. Specifically, two SNPs in IL10 (rs3024493 and rs2222202) showed the strongest associations with OS (HR=5.82, 95% CI=2.08-16.3, p=0.0009; HR=0.47, 95% CI=0.28-0.80, p=0.006 respectively). The association between rs3024493 and OS replicated among both stages (stage 1 p=0.028, stage 2 p=0.017). This study has identified novel associations of germline genetic risk variants in an interleukin locus at 1q32.1 with melanoma outcomes (rs3024493), and validated the associations from previous smaller studies that showed germline variants in IL10 (rs2222202) associate with worse OS. Pending multi-institutional meta-analysis and further genetic and functional investigations, this study strongly suggests that germline variants in the interleukin locus at 1q32.1 should be considered as novel prognostic markers with potential clinical utility.

P12.089-S
Germline variants and immunotherapy response in advanced melanoma

C. Adaniel, *J. Rendleman, D. Polsky, R. Berman, R. Shapiro, A. Heguy, Y. Shao, I. Osman, A. Pavlick, T. Kirchhoff;*
New York University Medical Center, New York, NY, United States.

BACKGROUND: Ipilimumab-based immunotherapy has substantially increased survival for patients with advanced melanoma, however, the benefit is observed only in a small portion of treated patients. It is highly plausible, yet completely unexplored, that germline genetic factors modulate immunotherapy outcome. In this study we performed whole-exome sequencing (WES) to discover novel germline determinants of response to ipilimumab. METHODS: Blood samples were collected from >60 metastatic melanoma patients treated with ipilimumab at the New York University Cancer Center. WES was performed on objective responders (OR) and non-responders (NR), defined by immune-related response criteria, using the Nextera platform (Illumina) at average 30x coverage. A novel method for testing the association between OR and NR by variant, gene and enrichment of molecular networks was implemented. Gene-Set Enrichment Analysis and Pathway Studio were used to test the pathway associations. RESULTS: The preliminary data comparing an initial subset of 30 ORs and 30 NRs identified significant associations with ipilimumab response for several loci including RPS6KB1 (p=0.001) and LNX2 (0.001). In addition, the pathway analysis showed significant associations for SMAD 3 (p=0.04) and interleukin 1 (p=0.04) related pathways. CONCLUSION: Preliminary findings provide promising evidence supporting the presence of germline genetic factors associated with response to ipilimumab therapy. The data suggest in part a role for immune-related pathways. As we continue to accrue patients, we anticipate an increase in the analytical power of the discovery phase and also an expanded validation of the current findings, suggesting for the first time that germline genetic factors modulate immunotherapy response.

P12.090-M
Functional consequences of cancer associated variants in six human microRNAs

I. Torruella-Loran, *A. Gallego, I. Balcells, E. Garcia-Ramallo, Y. Espinosa-Parrilla;*
Institut de Biologia Evolutiva (CSIC-Universitat Pompeu Fabra), Barcelona, Spain.

MicroRNAs are crucial post-transcriptional gene regulators whose strong sequence conservation leads to predict that nucleotide changes in these molecules may be related to disease. We analyzed human microRNA genetic variation and its possible involvement in cancer through a functional approach. From 284 common SNPs (MAF>0.05) located in 254 out of 1872 microRNAs (miRBase Release20.0), 191 were in the precursor microRNA (2.0 SNP/kb), 58 in the mature microRNA (1.5 SNP/kb) and 35 in the microRNA seed region (1.8 SNP/kb). Five of these SNPs, which were previously associated with cancer, were selected for further studies. Three of them (rs12416605, rs35770269 and rs2910164) were in the seed region of miR-938, miR-449c and miR-146a, respectively; one (rs11614913) in the mature miR-196a-2 and the last one (rs3746444) in the mature miR-499b and seed region of miR-499a. Target gene predictions using TargetScan for these microRNA variants revealed that major alleles had a larger number of predicted target genes than minor ones and very little overlap was observed between both alleles in all cases. Furthermore, morphological differences in HeLa cells were observed between the rs3746444 A and G alleles (miR-499a seed) after transfection experiments. Also different expression levels between the C and T rs11614913 alleles (mature miR-196a-2) were detected by RT-qPCR. We are currently investigating the effect of these variants in the spectrum of genes regulated by the studied microRNAs through transcriptome and functional experiments. Different alleles of common microRNA SNPs associated with cancer could lead to changes in microRNA expression and affect their gene regulatory networks.

P12.091-S
The expression of mature microRNAs let-7a, miR-155, miR-205 in non-small cell lung cancer and tumor-adjacent normal tissue

A. Shikeeva[1,2], *T. Kekeeva[1], L. Zavalishina[2], Y. Andreeva[2], G. Frank[2];*
[1]Research Center of Medical Genetics, Moscow, Russian Federation, [2]Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation.

Non-small cell lung cancer (NSCLC) is the major group of lung cancers. MicroRNAs (miRNAs) are a class of small non-coding RNAs that play a crucial role in the regulation of mRNA translation and degradation. miRNA expression is affected in many cancers. The expression levels of miRNAs let-7a, miR-155, miR-205 in tumor and adjacent normal tissue at 2 and 5 cm from

tumor were measured by real-time PCR with subsequent quantification using a 2-ddCT method. Obtained results were then analyzed for association with clinical-morphological parameters: age, cancer stage, and tumor cells differentiation. The expression of let-7a was significantly decreased in tumors comparing to adjacent tissue at both 2 and 5 cm. Let-7a and miR-155 levels in tumor were substantially lower than in adjacent tissue in patients under 63 years. The expression of let-7a and miR-155 in tumor was also suppressed in patients with III-IV stages of NSCLC. Besides that patients with poorly differentiated NSCLC had significantly lower let-7a level in tumor comparing to adjacent tissue. The levels of let-7a, miR-155, miR-205 were different even in adjacent tissue, in patients with differentiated tumors it was higher than in the group with poorly differentiated tumors. The study showed that let-7a expression is suppressed in tumors comparing to adjacent normal tissue at 2 and 5 cm from tumor. The decrease of let-7a and miR-155 is distinctive for younger patients, III-IV stages of NSCLC, and poor tumor cells differentiation. Altogether these findings consider miRNAs let-7a and miR-155 as markers of unfavorable prognosis for NSCLC patients.

P12.093-S

A germline mismatch repair mutation possibly leading to a de novo NF1 germline mutation

C. Bracco[1,2], *I. Borelli*[1,2], *M. Micheletti*[2], *D. Martorana*[3], *E. Grosso*[2], *B. Pasini*[1,2];
[1]*Department of Medical Sciences, University of Turin, Torino, Italy,* [2]*Medical Genetics Unit, AO Città della Salute e della Scienza di Torino, Torino, Italy,* [3]*3Molecular Genetics Unit, University-Hospital of Parma, Parma, Italy.*

We report on a female patient diagnosed with breast, colon, and endometrial cancer at the age of 38, 40, and 41 respectively, presenting with café au lait macules, multiple neurofibromas and axillary freckling.
With respect to the family history, her paternal grandmother died at the age of 63 for a colon cancer diagnosed when she was 35, whereas her father died at the age of 42 because of an accident.
As the proband met the criteria for Neurofibromatosis 1 (NF1), analysis of the NF1 gene was performed. A frameshift mutation (c.7096_7101delAACTTT) was identified confirming the clinical diagnosis.
The parents showed no clinical signs of NF1 nor did the two proband's siblings, which tested negative.
Because of the co-occurrence of endometrial and colon cancer in our patient, and the presence of an early-onset colon cancer in the paternal grandmother, expression of mismatch repair protein and Microsatellite Instability (MSI) were analyzed on endometrial and colon cancers.
Both tissue showed loss of staining for the MSH2-MSH6 heterodimer and high MSI, therefore analysis of MSH2 was performed, leading to the identification of a nonsense mutation of exon 2 (c.289C>T, p.Gln97*), consistent with the presence of the Lynch syndrome.
As women with NF1 have a fivefold risk of developing premenopausal breast cancer, no further analysis was performed.
Although it was not possible to analyze any member of the paternal family, an intriguing possibility is that the inherited germinal mutation affecting the mismatch repair system led to a de novo NF1 germinal mutation in our patient.

P12.094-M

Whole genome sequencing of mitochondrial DNA in low and high-risk neuroblastoma patients

F. M. Calabrese[1], *P. Pignataro*[1], *F. Totaro*[1], *G. Acierno*[1], *F. Cimmino*[1], *R. Gallesio*[2], *G. Tonini*[3], *L. Longo*[2], *A. Iolascon*[1], *G. Gasparre*[4], **M. Capasso**[1];
[1]*University of Naples Federico II, Napoli, Italy,* [2]*IRCCS AOU San Martino-IST, Genova, Italy,* [3]*Istituto di Ricerca Pediatrica (IRP), Padova, Italy,* [4]*Universitario S. Orsola-Malpighi, Bologna, Italy.*

Mitochondrial DNA (mtDNA) mutations may contribute to tumor initiation and progression. mtDNA mutations have never been considered as causative or secondary events for neuroblastoma progression. We sequenced 36 full-length mitochondrial genomes belonging to 16 low-risk (LR) and 20 high-risk (HR) Italian neuroblastomas by Sanger method.
Mutations were selected considering variability <0.01 (SiteVar algorithm) with respect to 14,144 mitochondrial genomes from healthy individuals. To determine whether the selected mutations were somatically acquired, we sequenced the matched germ-line DNAs.
We found 3 somatic missense mutations in CO1, CO2, CYTB genes in HR patients and 1 in (mt)-tRNA gene in LR patients. Moreover, we identified 47 germ-line mutations: 5 were novel (2 missense and 2 tRNA mutations in HR and 1 insertion in LR patients); 10 (83.3%) rare missense mutations occurred in HR and 2 (16.7%) in LR patients. Genes with higher germ-line mutation frequency in HR patients than in LR ones included CYTB (20.0% vs 6.2%), ND1 (10.0% vs 0.0%), and (mt)-tRNA (25.0% vs 12.5%). All CYTB and ND1 mutations in HR patients were missense. The highest rate of rare mutations was found in mt-tRNA gene (19.4% of cases). In HR patients, two mutations (one novel) in tRNA-thr altered (mt)-tRNA secondary structure and one novel mutation occurred in the anticodon loop of tRNA-gly.
In agreement with recent high-throughput screenings of nuclear DNAs, the rate of somatic mitochondrial mutations in neuroblastoma is low. Rare and novel germ-line variants in CYTB, ND1 and (mt)-tRNA loci might be important contributors to HR neuroblastoma development.

P12.095-S

A heterozygous deletion in *BUB1B* predisposing to pediatric cancer, outside the context of classic Mosaic Variegated Aneuploidy syndrome

M. Jongmans, *S. Bemelmans, J. Loonen, G. van de Zande, N. Hoogerbrugge, R. Kuiper, R. de Voer;*
Radboud university medical center, Nijmegen, Netherlands.

Biallelic mutations in *BUB1B* cause Mosaic Variegated Aneuploidy (MVA) syndrome, characterized by microcephaly, growth retardation, intellectual disability and cancer predisposition. *BUB1B* encodes a kinase involved in spindle assembly checkpoint (SAC) function. We describe a boy with PDD-NOS who developed acute lymphoblastic leukemia at age 9 years and primary diffuse leptomeningeal gliomatosis at age 17 years. His father, aged 54 years, had a head circumference at -2 SD and developed a brain tumor at the age of 19 years. They both were found to carry a monoallelic deletion of exons 9-23 of *BUB1B*. Karyotyping of EBV-transformed lymphoblastoid cell lines (LCL) from both father and son, revealed an enrichment of aneuploid cells (10% in both) and a significant increase in premature sister chromatid separation compared to controls. Since these two patients presented with features of the MVA syndrome, but did not present the full-blown phenotype, we hypothesized that this could be explained by BUBR1 protein expression levels below 50%. To study this hypothesis, *BUB1B* mRNA and BUBR1 protein expression levels were measured in EBV-transformed LCLs of the two cases. Expression levels were ~50% and, therefore, in concordance with a deletion of one *BUB1B* allele. Our findings suggest a role for heterozygous germline mutations in *BUB1B* in cancer predisposition, outside the context of classic MVA syndrome. An explanation might be found in digenic inheritance. To study this hypothesis, we will perform exome sequencing on germline DNA of the son and initially we will search for aberrations in SAC genes in particular.

P12.096-M

Somatic mosaicism and transmission of an MSH2 pathogenic variant in a parent of a Lynch Syndrome proband

S. A. M. Taylor[1,2], *M. J. Somerville*[1,2], *S. Tancredi*[2], *L. Vicen*[2], *C. Handford*[1], *D. Gilchrist*[1], *S. L. Hume*[1,2];
[1]*Medical Genetics, University of Alberta, Edmonton, AB, Canada,* [2]*Molecular Diagnostics Laboratory, Genetic Laboratory Services, Alberta Health Services, Edmonton, AB, Canada.*

We describe the finding of somatic mosaicism for a pathogenic variant of the MSH2 gene in the parent of a proband with Lynch Syndrome. The proband was diagnosed with a colorectal tumor at age 50 that was immunodeficient for MSH2 and MSH6. Sequencing and MLPA analysis of MSH2, MSH6 and MLH1 in a blood sample revealed the presence of a heterozygous pathogenic variant in the MSH2 gene, c.920_923delTCAG (p.Val307Glufs*23). The father was found to have a low level of mosaicism, <10%, for this variant in DNA from blood. This finding was confirmed on a buccal sample from him which showed a greater proportion of the pathogenic variant, ~20%. The father had been diagnosed with prostate cancer at age 70 and his family history is not suggestive of Lynch Syndrome. The mother's sample was negative and parentage was confirmed using microsatellite loci. BRCA1/2 analysis was negative in the proband's sister who was diagnosed with uterine and ovarian cancer at age 37. She was found to be a carrier of this MSH2 pathogenic variant. The results in this family suggest the pathogenic variant arose as an early postzygotic mutation in the father of the proband. Documented incidents of de novo mutation of the mismatch repair genes (MMR) in Lynch syndrome are rare. Our findings lend further support to the suggestion that HNPCC-like histopathological characteristics of tumours in addition to revised Bethesda criteria be used to improve ascertainment of individuals and families at risk of Lynch Syndrome.

P12.097-S

A study to investigate the genetic basis of multiple primary tumours

J. Whitworth[1,2], *J. Hoffman*[1], *C. Chapman*[1], *K. Ong*[1], *F. Lalloo*[3], *D. G. Evans*[3], *E. Maher*[4,1,2];
[1]*Birmingham Women's Hospital, Birmingham, United Kingdom,* [2]*University of Birmingham, Birmingham, United Kingdom,* [3]*Manchester Centre for Genomic Medicine, Manchester, United Kingdom,* [4]*University of Cambridge, Cambridge, United Kingdom.*

Multiple primary malignant tumours (MPMT) are frequently taken as an indicator of potential inherited cancer susceptibility and occur at appreciable frequency both among unselected cancer patients and referrals to cancer genetics services. Analysis of a referral based series of 212 MPMT cases sho-

wed that only around 40% of those who underwent genetic testing and 20% of referrals overall were identified as having a pathogenic germline mutation conferring predisposition to malignancy. Comparison of individuals who tested positive and negative revealed considerable overlap between the two groups with respect to clinical characteristics indicative of an inherited cancer syndrome, suggesting that many of the latter group also have a genetic basis. Analysis of PTEN and TP53, however, did not reveal any significant variants. Failure to detect a germline mutation may result from mosaicism for a mutation in a known inherited cancer gene, an unusual phenotype that leads to the relevant gene being overlooked or mutation in a novel inherited cancer gene. To address these possible explanations, further cases are being identified and next generation sequencing techniques applied to blood samples from the series. Initial analysis is being performed using the Ilumina TruSight cancer panel (of known inherited cancer genes) with subsequent whole exome or genome sequencing if no mutation is identified. Tumour samples will also be analysed for loss of heterozygosity at the relevant locus where putative mutations are found. Recruitment is currently open.

P12.098-M

Colorectal cancer susceptibility alleles as a possible explanation for phenotype variance in *MUTYH* associated polyposis (MAP) patients

S. W. ten Broeke[1], *L. Thomas*[2], *S. Horpaopan*[3], *I. Spier*[3], *T. van Wezel*[1], *F. J. Hes*[1], *C. Tops*[1], *H. F. A. Vasen*[1], *J. T. Wijnen*[1], *J. J. Houwing-Duistermaat*[1], *J. R. Sampson*[2], *S. Aretz*[3], *M. Nielsen*[1];

[1]*LUMC, Leiden, Netherlands,* [2]*Cardiff University, Cardiff, United Kingdom,* [3]*Bonn University, Bonn, Germany.*

Introduction. Biallelic *MUTYH* mutation carriers have a predisposition to colorectal carcinoma (CRC) and polyp development, but the severity of the phenotype is highly variable. We investigated whether this can be explained by the presence of single nucleotide polymorphisms (SNPs) which have previously been implicated in the susceptibility to CRC and polyps in genome-wide association studies (GWAS).

Method. 154 MAP patients from three countries (UK,NL and DE) were genotyped for 17 SNPs previously identified by GWAS. Data were analysed with ANOVA and cox regression analysis. Homozygotes for the non-risk allele were used as reference category.

Results. A CRC odds ratio (OR) was identified for rs10936599 of 5.101 (95% CI:0.761-34.206) for heterozygotes and 1.403 (CI:0.234-8.415) for homozygotes (p=0.022). The CRC OR for rs10795668 in this cohort is 5.470 (CI: 1.413-21.171) for heterozygotes and 4.684 (CI:1.200-18.289) for homozygotes (p=0.042). For rs961253 heterozygotes an OR for having more than 100 polyps of 2.887 (CI:1.274-6.541) was identified, this is 1.041 (CI:0.299-3.622) for homozygotes (p=0.021). For two SNPs (rs3802842 and rs16892766) previously associated with CRC risk in Lynch patients, a significant pair wise effect on difference in age of diagnosis (of 12 years) was identified between patients with zero and more than 1 risk alleles (p=0.015).

Discussion. There is evidence for an effect of GWAS SNPs in MAP patients. However, a larger cohort size is needed to truly determine this effect. Unravelling risk factors - like SNPs - in MAP patients might allow for individual risk stratification and personalised surveillance programs in the future.

P12.099-S

Identification by exome sequencing of a novel homozygous mutation in *NDRG4* in a family with infantile myofibromatosis

N. D. Linhares[1], *M. C. M. Freire*[2], *R. G. C. C. L. Cardenas*[1], *H. B. Pena*[3], *M. Bahia*[4], *S. D. J. Pena*[1,2,3];

[1]*Laboratório de Genômica Clínica, Faculdade de Medicina, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil,* [2]*Departamento de Bioquímica e Imunologia, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil,* [3]*Laboratório Gene – Núcleo de Genética Médica, Belo Horizonte, Brazil,* [4]*Divisão de Gastroenterologia Pediátrica, Hospital das Clínicas da UFMG, Belo Horizonte, Brazil.*

Infantile myofibromatosis (IM) is a rare disorder characterized by the development of benign tumors in the skin, muscle, bone, and viscera. The incidence is 1/150,000 live births and the disease is the most common cause of fibrous tumors in infancy. Although the identification of mutations in genes that may cause IM is the first step towards the possibility of targeted treatments, the molecular pathogenesis of IM is still poorly understood. Recently, mutations in *PDGFRB* and *NOTCH3* have been implicated in families with the autosomal dominant forms of IM. We have performed whole-exome sequencing of a family with a probably autosomal recessive visceral multicentric infantile myofibromatosis. We studied two brothers and their healthy consanguineous parents. In the two brothers we identified a c.511G>C (p.Val171Leu) novel homozygous mutation in *NDRG4* (N-myc downregulated gene family member 4). The healthy parents were heterozygous for the mutation. Consistent with the phenotype of IM, *NDRG4* is a tumor-related gene. Its expression has been shown to be decreased in numerous types of neoplasia and there have been proposed that it might be a tumor suppressor gene. Additionally, studies have demonstrated that *NDRG4* may have a role in cell survival, tumor invasion and angiogenesis in tumors. We believe that this homozygous mutation in *NDRG4* may be a good candidate for the causative variant of the autosomal recessive form of IM in the family studied and we propose that it should be investigated in other cases of autosomal recessive infantile myofibromatosis.

Next-generation panel based characterisation of breast/ovarian cancer genetic predisposition

R. Janavicius[1,2], *V. Rudaits*[3], *L. Griskevicius*[1];

[1]*Vilnius University Hospital Santariskiu Clinics Hematology, Oncology and Transfusion Medicine Center, Vilnius, Lithuania,* [2]*State Research Institute Innovative Medicine Center, Vilnius, Lithuania,* [3]*Vilnius University Hospital Santariskiu Clinics, Dept. of Oncogynecology, Vilnius, Lithuania.*

BACKGROUND. Genetic predisposition to breast and/or ovarian cancer is largerly confined to mutations in BRCA1/2 genes, although rarer mutations in other known genes (e.g. TP53, PTEN, STK11, CDH1, PALB2, BRIP1, CHEK2 etc.) are also important. Massivelly parralel (or next-generation, NGS) resequencing technology is attractive for identifing cancer predsposing mutations in known genes (panels) and discover new associations.

METHODS. We aimed to better characterize cancer predisposing landscape in clinicaly selected 96 breast and 96 ovarian cancer cases (with strong family history or early age at diagnosis and negative for previously tested BRCA1/2 genes mutations) by perfoming NGS based analysis of 94 genes previously associated with both common (e.g., breast, colorectal) and rare cancers (TruSight Cancer Nextera Custom hybridization-based target enrichment) on MiSeq (Illumina). VariantStudio software was used for anotation and filtering of genetic variants.

RESULTS. Of 192 tested subjects, 8% carried germline loss-of-function mutations (confirmed by Sanger sequencing) in 10 cancer predisposing genes, 3 of them were not previously implicated in hereditary breast/ovarian cancer predisposition.

CONCLUSION. NGS panel based resequencing is effective way for better characterising of cancer predisposition landscape.

P12.102-M

Role of inflammatory gene variants in oral cancer in an Indian population

M. Banerjee[1], *M. K. Gupta*[1], *M. Saxena*[1], *N. Sagar*[1], *R. Pant*[2];

[1]*Molecular & Human Genetics Lab, Department Of Zoology, University Of Lucknow, Lucknow, India,* [2]*Department Of Radiotherapy, Lucknow Cancer Institute, Lucknow, India.*

Oral squamous cell carcinoma (OSCC) is the eighth most common cancer worldwide. Alcohol, tobacco and smoking are well known risk factors for OSCC. During oral cancer development; inflammation, angiogenesis and thrombosis are involved which correlate with immune cells involved in the production of cytokines, growth factors and adhesion molecules. The study was to evaluate association of cytokine gene variants *viz. IL-1RN* Variable Number of Tandem Repeats (VNTR in intron 2), *IL-1β*-511C/T [rs16944], *IL-6*-597G/A [rs1800797] and *TNF-α*-308 G/A [rs1800629] with oral cancer in a north Indian population. Clinical and addiction details of healthy age/sex matched controls (n=140) and OSCC patients (n=77) were recorded after ethical clearance and consent. DNA was extracted and SNPs genotyped by polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP). Minor allele frequencies; genotype and allele frequencies were calculated by chi-square ($\chi 2$) analysis (SPSS v.15.0). Gene-gene interaction, pairwise linkage disequilibrium (LD) based on D' statistics and correlation coefficient (r2) of frequencies were analyzed using SHEsis (online version). Genotypic frequencies of *IL-1RN, IL-1β* and *IL-6* while allelic frequency of *IL-6* showed significant association with OSCC (P<0.001). *TNF-α* increases risk of OSCC upto 1.68 times in alcoholic subjects. GATI* and GGTII* haplotypes increased the risk up to 2.863 and 38.285 times respectively. This is the first report from India showing the effect of cytokine gene polymorphisms in OSCC to predict individuals at risk of oral cancer. The knowledge of risk alleles will enable individuals to take precautionary measures before hand and prevent or delay the onset of disease.

P12.103-S

Referral of ovarian cancer patients to genetic counselling by oncologists: room for improvement

M. T. Ricci[1], *S. Sciallero*[2], *S. Mammoliti*[2], *A. Pessino*[2], *V. Gismondi*[1], *M. Franiuk*[1], *L. Varesco*[1];

[1]*IRCCS AOU San Martino-IST, Unit of Hereditary Cancer, Genoa, Italy,* [2]*IRCCS AOU San Martino-IST, Medical Oncology Unit 1, Genoa, Italy.*

Aims and methods: *BRCA1/2* mutations occur in 10-15% of ovarian cancer (OC) patients, regardless of family history. In November 2012 a pilot protocol was developed by the Unit of Hereditary Cancer (UHC) and the Oncology Service (OS) caring most OC patients in our Institute, to assess the feasibility of offering genetic counselling (GC) to all OC women. Oncologists agreed to propose GC during their clinics and to refer all interested OC patients by directly arrange a contact with UHC. After the first year we evaluated oncologists' adherence to protocol, patients' compliance with GC and testing, and prevalence of *BRCA1/2* mutations.
Results: 104 OC women underwent an oncology visit from November 2012 to December 2013. Ten patients were excluded because they had GC in the past. Only 29 patients (29/94; 31%) were referred to GC; 22/29 attended GC (76%) and 21/22 had genetic testing (95%). Three pathogenic *BRCA* mutations were detected (3/21; 14%); among healthy female close relatives, seven were tested and three were mutation-positive. Referral was much higher for patients attending the first visit (14/26; 54%) than for follow up patients (15/68; 22%). The main differences in these two settings are the time schedule (one vs half an hour) and the checklist in the clinical record (including or not family history).
Conclusions: Patients' compliance to GC/testing was high, and *BRCA* mutation prevalence was as expected. However, oncologists' compliance was low, mainly because of practical barriers. Efforts are needed to integrate GC-focused tools and procedures in oncology practice.

P12.104-M
Targeted resequencing approach to investigate the mutational landscape associated to platinum resistance in EOC

M. Di Marino[1], *L. Beltrame*[1], *L. Paracchini*[1], *R. Fruscio*[2], *V. Fotia*[3], *T. Grassi*[2], *L. Clivio*[1], *M. D'Incalci*[1], *S. Marchini*[1];
[1]*IRCCS-Istituto di Ricerche Farmacologiche Mario Negri, Milano, Italy,* [2]*Clinic of Obstetrics and Gynecology, University of Milano-Bicocca, San Gerardo Hospital, Monza, Italy,* [3]*Medical Oncology Unit, IRCSS- Fondazione Salvatore Maugeri, Pavia, Italy.*

Introduction Despite initial response to first line platinum-based chemotherapy, more than 80% of high grade serous ovarian cancer patients relapse and develop resistance. The molecular and genetic features involved in drug resistance are still unknown. By gene expression profile in a cohort of patients from which matched biopsies were taken at primary surgery (PS-O) when tumor was sensitive to chemotherapy and at time of relapse (SCR) when the tumor was resistant, we identified EMT pathway as a key player in tumor relapse (Marchini et al., 2013). Here we investigate the genomic alterations driving drug resistance by performing targeted DNA resequencing on our cohort of SCR and PS-O samples.
Methods DNA libraries enriched in a selected panel of 30 genes encompassing key players of signal transduction, cell cycle and DNA repair were generated using TruSeq Custom Amplicon kit and sequenced on MiSeq (Illumina). Data were analyzed using a high performance cluster computing platform (Cloud4CARE project).
Results Analysis identified a total of 166 mutations (152 SNPs and 14 InDels), of which 51 affecting PS-O and 115 SCR. With a 500X coverage, we observed BRCA1, BRCA2 and TP53 mutated in the majority of cases. In addition, the PI3K pathway was found mutated in SCR samples only.
Conclusions Our preliminary results suggest two main conclusions:
1- genomic alterations (SNPs or InDels) were more frequent in SCR compared to PS-O;
2- most of the mutations affected genes belonging to DNA and PI3K pathway.

P12.105-S
Transcriptome and pathway analysis identifies IRF1 as a predictor of progression free and overall survival in ovarian carcinoma

J. Billaud[1], *J. A. Martignetti*[2], *S. Cohen*[3], *R. Mosig*[2], *R. Halpert*[1], *P. R. Dottino*[2];
[1]*Qiagen's Applications Team, Redwood City, CA, United States,* [2]*Icahn School of Medicine Mount Sinai, New-York, NY, United States,* [3]*Icahn School of Medicine Mount Sinai, New-York, CA, United States.*

Epithelial Ovarian Cancer (EOC) is the most lethal female reproductive tract malignancy. Most patients present with advanced stage disease and the cornerstone of treatment is surgical debulking followed by platinum-based chemotherapy. The major contributor to the high fatality-to-case ratio is chemoresistant disease. We sought to identify candidate biomarkers/pathways which could distinguish between platinum sensitivity and platinum resistance and test their prognostic ability. Ovarian tumor samples from patients with primary high-grade serous ovarian cancer were divided into two groups based on response to platinum status. Transcriptome analysis was performed using RNA-Seq and Ingenuity Pathway Analysis (IPA) was used to explore differences between these two sets of samples. Findings were validated using qRT-PCR. Survival analysis was performed in two independent sample sets: gene expression data (GEO); relapse-free/overall survival information, (EGA, TCGA).
IPA highlighted that Interferon regulatory factor 1 (IRF1) was differentially expressed between the two clinical groups and was upregulated in the platinum-sensitive group. Validation studies performed on 31 patient tumor samples demonstrated a significant difference in PFS between the low and high IRF1 groups (P = 0.027) as well as a distinct difference in the probability of recurrence. In conclusion, we have shown that high levels of IRF1 strongly correlated with increased overall survival in late-stage disease regardless of debulking status and grade in those patients who received platinum therapy.

P12.106-M
Role of p53 gene in the pathogenesis of Acinar Cell Carcinomas of the pancreas

B. Bernasconi[1], *N. Sahnane*[1], *D. Furlan*[1], *M. Frattini*[2], *F. Molinari*[2], *S. La Rosa*[3], *A. Vanoli*[4], *F. Sessa*[1], *M. Tibiletti*[3];
[1]*Department of Surgical Morphological Sciences, University of Insubria, Varese, Italy,* [2]*Laboratory of Molecular Diagnostic, Institute of Pathology, Locarno, Switzerland,* [3]*U.O. Anatomia Patologica, Ospedale di Circolo - Polo Universitario, Varese, Italy,* [4]*Department of Pathology, University of Pavia, Pavia, Italy.*

Introduction: The role of p53 (17p13.1) in the pathogenesis of pancreatic acinar cell carcinomas (ACCs) has not been fully clarified yet. Few studies, mainly using immunohistochemistry (IHC), suggested that p53 is not involved in ACCs but molecular data are controversial. Recently, p53 mutation and a significant (>50% of cells) p53 nuclear immunoreactivity (IR) have been reported in 20% and 27% of ACCs, respectively. Aim: To clarify the role of p53 in the pathogenesis of ACCs we investigate p53 alterations (mutation, methylation, loss and nuclear protein expression) in 44 ACCs using different approaches: direct sequencing of exons 5-8, MS-MLPA, FISH and IHC. Results: p53 mutations were found in 8/44 (18%) cases, correlated with higher tumor stage (5 cases were at stage IV). In one case, p53 mutation was observed only in the metastasis of a primary p53 wild-type ACC. Methylation of p53 was observed in only one case. Loss of p53 gene, including 17p13.1 deletion and monosomy of chromosome 17, was found in 50% of ACCs and in 4 cases a concomitant mutation was identified. The simultaneous presence of both p53 mutation and loss correlated with worse prognosis (p=0.001). Conclusions: p53 alterations including mutations and cytogenetic loss are frequent in ACCs. p53 mutation and loss are correlated with higher tumor stage and with worse prognosis. Our results suggest that p53 is not an early event in ACC tumorigenesis, but it is involved in late phases of cancer progression.

P12.107-S
Do pancreatic cancer patients diagnosed with BRCA1/2 Ashkenazi mutations have less clinical risk factors?

R. Gershoni-Baruch[1], *R. Epelbaum*[2], *A. Kurolap*[3], *E. Dagan*[4];
[1]*Institute of Human Genetics, Rambam HealthCare Campus, Haifa, Israel,* [2]*Institute of Oncology, Rambam HealthCare Campus, Haifa, Israel,* [3]*The Ruth and Bruce Rappaport Faculty of Medicine, Technion Israel Institute of Technology, Haifa, Israel,* [4]*Department of Nursing, University of Haifa, Haifa, Israel.*

Aim: This study investigated the clinical background of Ashkenazi pancreatic cancer patients, either carriers or non-carriers of any of the three founder Ashkenazi mutation in BRCA1/2 genes namely, 185delAG, 5382insC and 6174delT.
Methods: Clinical characteristics including age at onset, smoking behaviour, physical activity, BMI, and chronic diseases e.g., hypertension and hyperlipidemia was available for 90 pancreatic cancer patients, consecutively referred to our oncogenetic clinic.
Results: Fifteen (16.7%) carried a founder Ashkenazi mutation in either BRCA1or BRCA2: of these, nine (60%) carried the 6174delT mutation in BRCA2; five (33.3%) and one (6.7%) harbored the 185delAG and the 5382insC mutations in BRCA1, respectively. Carriers compared to non-carriers were diagnosed at 61±7.5 and 63.0±11.3 years of age, respectively (p=0.520); and have higher BMI levels (28.9±7.3 compared to 25.1±4.9; p=0.112). Although, not significant, *carriers* smoked less than *non-carriers* (3, 20% compared to 28, 37.3%; p=0.197), were less physically active (3, 20% compared to 34, 45%; p=0.092), suffered less from the chronic diseases, hypertension (3, 20% compared to 31, 41%; p=0.072); and hyperlipidemia (0 compared to 11, 14.7%; p=0.080).
Conclusion: Our observation revealed that although not significant, non-carriers tend to have more known risk factors for the development of pancreatic cancer compared to BRCA1/2 mutation carriers.

P12.108-M
Germline FH mutations presenting with Phaeochromocytoma

G. R. Clark[1], *M. Sciacovelli*[2], *E. Gaude*[2], *D. M. Walsh*[3], *G. Kirby*[4,3], *M. A. Simpson*[5], *R. C. Trembath*[5], *E. R. Woodward*[3], *C. Frezza*[2], *E. R. Maher*[1];

[1]University of Cambridge, Dept. of Medical Genetics, Cambridge, United Kingdom, [2]University of Cambridge, MRC Cancer Unit, Cambridge, United Kingdom, [3]University of Birmingham, Centre for Rare Diseases, Birmingham, United Kingdom, [4]West Midlands Regional Genetics Service, Birmingham Women's Hospital, Birmingham, United Kingdom, [5]Division of Genetics and Molecular Medicine, Kings' College London, London, United Kingdom.

At least a third of patients with phaeochromocytoma (PCC) or paraganglioma (PGL) harbour an underlying germline mutation in a known PCC/PGL gene. Mutations in SDHx genes (SDHB, SDHD, SDHD and SDHA) encoding a component of the TCA cycle, succinate dehydrogenase (SDH), are a major cause of inherited PCC/PGL. SDHB mutations are also associated with inherited renal cell carcinoma (RCC). Inactivation of SDH in tumour cells results in abnormalities of cellular metabolism associated with activation of hypoxic gene response pathways and epigenetic alterations (e.g. DNA methylation). Similar findings have recently been reported in cases with mutations the FH gene, which encodes the TCA cycle component directly downstream of SDH, fumarate hydratase. However, the clinical phenotype of germline mutations in SDHx genes and FH is usually distinct with FH mutations classically associated with hereditary cutaneous and uterine leiomyomatosis and renal cell carcinoma. In order to identify potential novel PCC/PGL predisposition genes we undertook an exome resequencing study in a case of childhood PCC. After identifying a candidate FH missense mutation (p.Cys434Tyr) we sequenced FH in a further 71 patients with PCC, PGL or head and neck paraganglioma (HNPGL) and identified a further candidate missense mutation (p.Glu53Lys). We then performed In vitro analyses and demonstrated that both missense mutations were associated with elevated intracellular fumarate levels compared to a wild-type rescue construct. These findings (a) confirm that germline FH mutations may present, albeit rarely, with PCC or PGL and (b) extend the clinical phenotype associated with FH mutations to paediatric PCC.

P12.109-S

Molecular analysis of somatic mutations in Phaeochromocytoma and Paraganglioma

A. Luchetti[1,2], *D. Walsh*[3], *H. Martin*[2], *G. Clark*[1], *T. Martin*[4], *R. Irving*[4], *E. R. Woodward*[3], *F. Latif*[3], *M. Robledo*[5], *E. R. Maher*[1,2,3];
[1]Department of Medical Genetics, University of Cambridge, Cambridge, United Kingdom, [2]Cambridge NIHR Biomedical Research Centre, Cambridge, United Kingdom, [3]Centre for Rare Diseases and Personalised Medicine, University of Birmingham, Birmingham, United Kingdom, [4]Queen Elizabeth Hospital, Birmingham, United Kingdom, [5]CNIO, Madrid, Spain.

At least a third of patients with phaeochromocytoma (PCC) or paraganglioma (PGL) harbour an underlying germline mutation in a known PCC/PGL gene. Identification of germline mutations and key somatic mutations is important for the application of personalised medicine. To investigate the molecular pathogenesis in PCC, PGL and head and neck paraganglioma (HNPGL) we analysed PCC/PGL/HNPGL by next generation (NGS) and Sanger sequencing strategies. For the NGS studies, 55 tumours were analysed with the Ion Torrent AmpliSeq Cancer Hotspot Panel v2 which targets 54kb of mutational hotspots in 50 oncogenes and tumour suppressor genes and exome resequencing was performed in 12 tumours. Confirmed somatic missense mutations occurring in a single tumour were detected in CDH1, APC and JAK3. Activating mutations in HRAS (p.Gln61Arg and p.Gly13Arg) and HIF2A (p.Pro531Thr) were detected in 9.3% and 2% of tumours analysed. HRAS and HIF2A oncogenic mutations were detected in 6/30 PCC, 0/21 HNPGL and 0/4 PGL (frequency in PCC vs HNPGL P=0.69). Ten tumours harboured mutations in inherited PCC/PGL/HNPGL genes and no HRAS or HIF2A mutations occurred in this group. Combining our data with a previous report of HRAS mutations in PCC/PGL (JCEM 2013;98:E1266-71) we find that the mean frequency of HRAS mutations (7/9 at codon 61) in sporadic PCC/PGL is 10.8% (9/83; 95% CI = 6.3 to 17.9%) and in PCC/PGL with an inherited gene mutation 0% (0/29; 95% CI 0 to 13.9%) suggesting that HRAS and inherited PCC/PGL gene mutations might be mutually exclusive.

P12.110-M

Germline mutations in SDHB, SDHD, VHL, RET and TMEM genes in patients with nonsyndromic pheochromocytoma/paraganglioma in Serbian population

J. Bankovic, *B. Ilic, B. Beleslin Cokic, J. Antic, G. Rodic, I. Milicevic, M. Petakov, S. Damjanovic;*
Clinic for endocrinology, Clinical Center of Serbia, Belgrade, Serbia.

Background: Several susceptibility genes have been found to be associated with development of pheochromocytoma PHEO/ paraganglioma PGL : RET, VHL, SDHB, SDHD and TMEM. We investigated the frequency of germline mutations in these genes in patients with apparently sporadic PHEO/PGL.
Material and methods: Two hundred patients (F/M 112/88) with apparently sporadic PHEO /PGL were screened.Germline mutations were investigated by using direct sequencing for point mutations in RET, VHL, SDHB, SDHD and TMEM, and multiplex ligation - dependent probe amplification for gross deletions in VHL gene.
Results: In 30/200 (15%) probands, germ-line variants were identified: 12 heterozygous germline mutations (7 novel nonsense: W218X; frameshift: c.661delG, p.Asp221ThrfsX27; splicing:c.424-12delTCTT; missense: R116M; frameshift: c. 636_637 ins A, p. Met 213Asn fsX8 and missense: H132R; splicing: c. 424-1insG -7 delA) of the SDHB gene, 10 in VHL1 novel, V84M, in 3 families , 6 variants in SDHD, 1 in RET and 1 in TMEM gene. Familiy members were also tested. Most of the patients with mutation in SDHB gene were found to have malignant PHEO/PGL. Patients with mutations in VHL, RET and TMEM genes developed PHEO.
Conclusion:The most commonly mutated gene was SDHB, which carries the highest risk of malignancy. Our patients with extra-adrenal disease needs careful follow-up, since they are in higher risk for the development of metastases or novel adrenal/extra-adrenal PHEO. The patients with VHL mutation (V84M) is apparently classified as 2C. These patients may develop some other tumors than PHEO.

P12.111-S

Post-transcriptional regulation of *PHOX2B* gene expression

T. Bachetti[1], *E. Di Zanni*[1], *R. Ravazzolo*[1,2], *I. Ceccherini*[1];
[1]Laboratory of Molecular Genetics, Giannina Gaslini Institute, Genova, Italy, [2]Department of Neurosciences, Rehabilitation, Ophthalmogy, Genetics, Maternal and Child Health and CEBR, Università degli Studi di Genova, Genova, Italy.

Neuroblastoma (NB) is one of the most frequent and severe solid tumors in childhood.
Mutations in the genes coding for the transcription factor *PHOX2B* and for its transcriptional target *ALK* have been detected in sporadic and familial cases of NB and over-expression of the two genes have been identified in NB samples and cell lines.
In this work, in order to investigate the mechanisms underlying *PHOX2B* overexpression in NB, we report *in silico* and *in vitro* characterization of the *PHOX2B* 3' untranslated region (3'UTR).
First, the *in silico* search for elements known to regulate the mRNA stability allowed us to identify three AU-RICH elements (AREs) in the more distal region of the 3'UTR, in addition to several putative miRNAs binding sites. Regions of the distal *PHOX2B* portion likely responsible for mRNA regulation were eventually defined by combining the above predictions with results from the phylogenic conservation of the PHOX2B 3'UTR.
In vitro experiments in IMR32 NB cells have shown that *PHOX2B* mRNA is not stable, thus suggesting it as target of post-transcriptional regulation mechanisms. The successive cloning of the 3'UTR *PHOX2B* downstream the *Luciferase* gene in the pmiRGlo vector allowed us to confirm such a hypothesis and, following the generation of constructs containing progressively shorter deletions of the 3'UTR, to map position and extent of the regions responsible for the *PHOX2B* mRNA stability.
As a consequence of all the above described observations, we suggest that regulation and modulation of *PHOX2B* post-transcriptional stability may be considered a pharmaceutical target in NB.

P12.112-M

In vitro drug screening approaches targeting PHOX2B over-expression in neuroblastoma

E. Di Zanni[1], *D. Fornasari*[2], *R. Ravazzolo*[3,1], *I. Ceccherini*[1], *T. Bachetti*[1];
[1]U.O.C. Genetica Medica, Istituto G.Gaslini, Genova, Italy, [2]Università degli Studi di Milano, Dept. of Medical Biotechnology and Translational Medicine, Milano, Italy, [3]Dipartimento di Neuroscienze, Oftalmologia, Genetica e Materno Infantile (DINOGMI), Università di Genova, Genova, Italy.

PHOX2B is a transcription factor involved in the regulation of neurogenesis and in the correct differentiation of autonomic nervous system. Several evidence report a pathogenetic role of PHOX2B in neuroblastoma (NB): (i) somatic and germline gain of function mutations in familial, sporadic and syndromic cases of NB; (ii) the finding of *ALK*, a transcriptional target of PHOX2B, as major familial NB predisposition gene; and (iii) the observation of *ALK* and *PHOX2*B over-expression in tumor samples and NB cell lines. Starting from these observations, we have performed an *in vitro* drug screening targeting PHOX2B over-expression as a potential pharmacological means in NB. First, we have evaluated the effects of a (i) small subset of molecules and an (ii) epigenetic library in a IMR-32 cell line stably expressing *Luciferase gene* under the control of *PHOX2B promoter* to identify molecules able in down-regulating PHOX2B expression. Curcumin, SAHA and trichostatin A showed a down-regulation of *PHOX2B* promoter activity and a decrease of both protein and mRNA expression. To deepen into curcumin mechanisms of action, we have investigated the role of transcription factors (TF) predicted by *in silico* analysis to bind the PHOX2B promoter.

Among these TF, we have demonstrated that treatments with 8 or 20 μM curcumin led to a decrease of *PBX1/MEIS1* expression and modulated the activity of NFκB and AP-1. Moreover, combined drug treatments showed successful effects of down-regulation of the expression of both PHOX2B and its target *ALK*, thus supporting the notion of the effectiveness of molecule combination in tumor therapy.

P12.113-S

PIK3CA mutations in non-small cell lung cancer

S. Ekinci[1], H. Ilgin-Ruhi[1], M. Doğan[2], S. Gursoy[3], S. Dizbay-Sak[4], A. Demirkazık[5], **F. Tukun**[1,3];
[1]Ankara University Faculty of Medicine Department of Medical Genetics, Ankara, Turkey, [2]Ankara Numune Training and Research Hospital, Medical Oncology Clinic, Ankara, Turkey, [3]Duzen Laboratories Group, Division of Medical Genetics, Ankara, Turkey, [4]Ankara University Faculty of Medicine Department of Medical Pathology, Ankara, Turkey, [5]Ankara University Faculty of Medicine Department of Medical Oncology, Ankara, Turkey.

Background: Most of the proteins that are encoded by oncogenes which play a role in molecular pathogenesis of cancer, function as protein kinases. Acquired constitutional activity of these proteins leads to the activation of signaling pathways which are involved in cell proliferation, apoptosis, protein synthesis, cell migration and many other cellular processes. One of the most important signaling pathways that plays role in the pathogenesis of cancer is phosphatidyl inositol 3 kinase (PI3K) signaling pathway. Especially class IA PI3Ks are known to play a role in the pathogenesis of cancer. Basically, p110α isoform of catalytic domain accounts for the enzymatic function of class IA PI3Ks. It is encoded by *PIK3CA* gene. *PIK3CA* mutations has been previously reported in many cancers.

Methods: All exons of the *PIK3CA gene* were sequenced in 40 NSCLC tumor samples. All individuals provided informed consent, and the study was performed in accordance with ethical guidelines.

Results: The 1634A>C mutation which has already been identified in many cancers and NSCLC was determined in 7,5% of the tumor tissue samples. This mutation rate is higher than reported in the literature. Interestingly a second mutation (1658_1659delGTinsC) was identified in these patients. The concurrence of these two mutations has been reported as Cowden syndrome in the literature which is known to be a cancer predisposition syndrome. **Conclusion:** This finding is quite important since it can be an indication of underlying cancer predisposition syndrome in NSCLC patients. Besides previously reported PIK3CA mutations some novel mutations have been defined.

P12.114-M

Development of Acquired Resistance to Anti-EGFR Therapy in Colorectal Cancer Identified by Whole-Genome Plasma DNA Sequencing

S. Mohan[1], *E. Heitzer[1], P. Ulz[1], I. Lafer[1], S. Lax[2], M. Auer[1], M. Pichler[3], A. Gerger[3], F. Eisner[3], G. Hoefler[4], T. Bauernhofer[3], J. B. Geigl[1], M. R. Speicher[1];*
[1]Institute of Human Genetics, Medical University of Graz, Graz, Austria, [2]Department of Pathology,General Hospital Graz West, Graz, Austria, [3]Division of Oncology, Medical University of Graz, Graz, Austria, [4]Institute of Pathology, Medical University of Graz, Graz, Austria.

Introduction: EGFR-targeting monoclonal antibodies, cetuximab and panitumumab, are important therapeutic options in *KRAS* wild-type metastatic colorectal cancer (mCRC) patients. However, secondary resistance inevitably ensues in all patients within 3-12 months from the start of therapy. The mechanism and timing of emergence of resistance which limit the efficacy of these drugs, is highly relevant for designing therapeutic strategies. **Methods:** We examined the plasma DNA of 10 *KRAS* wild-type mCRC patients who received anti-EGFR therapy, using a high-throughput whole genome sequencing (Plasma-Seq) and ultra-deep sequencing of genes associated with resistance to anti-EGFR therapy such as *KRAS*, *BRAF*, *PIK3CA* and *EGFR* with Illumina's MiSeq. **Results:** Genome-wide characterisation of the plasma DNA and corresponding primary tumor revealed several tumor specific aberrations such as over-representation of chromosomes 8q, 13 and 20q, and losses of 8p, 4 and 18. The development of resistance to anti-EGFR therapy was observed to be associated with novel focal amplification of *KRAS* (n=3), *MET* (n=2) and *ERBB2* (n=1) or high level polysomy of 12p which includes *KRAS* (n=1). Overrepresentation of *EGFR* gene was associated with initial good response to therapy. However, ultra-deep sequencing of *KRAS, BRAF, PIK3CA* and *EGFR* did not reveal any novel mutations. **Conclusion:** Overall, predictive biomarkers associated with the anti-EGFR therapy efficacy, correlating well with treatment response was identified in 70% of our patients. The tumor genome is prone to continuous changes and plasma-Seq, a fast and affordable tool enables identification of novel clones and guide real-time modification of treatment regimen to delay or prevent disease progression.

P12.115-S

PMS2 mutation detection and PMS2 mutation spectrum in the Netherlands

H. M. van der Klift[1], *A. R. Mensenkamp[2], Y. J. Vos[3], J. J. P. Gille[4], E. J. W. Redeker[5], E. Bik[1], A. Wagner[6], E. Gomez Garcia[7], M. J. W. Olderode-Berends[3], F. H. Menko[4], T. A. van Os[5], S. Verhoef[8], M. Nielsen[1], F. J. Hes[1], P. Devilee[1], M. Ligtenberg[2], J. T. Wijnen[1], C. M. J. Tops[1];*
[1]Leiden University Medical Centre, Leiden, Netherlands, [2]Radboud University Medical Centre, Nijmegen, Netherlands, [3]University Medical Centre Groningen, Groningen, Netherlands, [4]VU University Medical Centre, Amsterdam, Netherlands, [5]Academic Medical Centre, Amsterdam, Netherlands, [6]Erasmus Medical Centre, Rotterdam, Netherlands, [7]Maastricht University Medical Centre, Maastricht, Netherlands, [8]Netherlands Cancer Institute, Amsterdam, Netherlands.

Heterozygous mutations in the mismatch repair (MMR) gene *PMS2* cause Lynch syndrome (LS), an autosomal dominant predisposition for colorectal, endometrial and other cancers. Biallelic mutations lead to constitutional MMR-deficiency syndrome (CMMR-D) in which various types of malignancy occur early in life. Isolated loss of PMS2, detected by immunohistochemistry in tumours directs mutation scanning to *PMS2* to diagnose LS and CMMR-D. Mutation scanning of this gene has been notoriously difficult due to the presence of highly homologous pseudogene sequences and frequent gene conversion events. Here we present results of recently improved DNA-based and RNA-based mutation detection strategies for *PMS2* as obtained in the five Dutch accredited diagnostic laboratories that offer *PMS2* genetic testing. Altogether, 53 different deleterious *PMS2* mutations were discovered in 126 LS and 8 CMMRD index patients. Recurrent *PMS2* mutations, probably of founder origin, appear to be common in the Dutch cohort: 15 mutations found in at least 3 probands represent 68% (96/142) of mutated alleles. Notably, one such recurrent mutation, detected in 3 probands in our cohort, is the recently described retrotranspositional insertion of an SVA repeat, that is missed by current DNA-based protocols. Pathogenic *PMS2* mutations were found in 78% (57/73) of patients with isolated PMS2 loss, and another 10% (n=7) could be explained by an *MLH1* mutation (data from 2 labs with complete data set). Based on an estimated number of 700 Dutch proven LS families, 18% (126/700) is explained by a *PMS2* mutation. Our data substantially expand knowledge on the spectrum of disease-causing *PMS2* mutations.

P12.116-M

A new POLD1 germline mutation as cause of Familial Colorectal Cancer Type X

E. Hernández-Illán[1], *A. Castillejo[2], M. I. Castillejo[2], A. Segura[3], M. J. Juan[4], M. Juarez[1], R. Jover[5], J. L. Soto[2];*
[1]Research Laboratory, Alicante University Hospital, Alicante, Spain, [2]Molecular Genetics Laboratory, Elche University Hospital, Elche, Spain, [3]Hereditary Cancer Unit, La Fe University Hospital, Valencia, Spain, [4]Hereditary Cancer Unit, Valencian Institute of Oncology, Valencia, Spain, Valencia, Spain, [5]Research Laboratory, Gastroenterology Service, Alicante University Hospital, Alicante, Spain.

The genetic basis for Familial Colorectal Cancer Type-X (fCRC-X) is unknown. Mutations at the proof-reading domains of DNA polymerase ε (POLE) and δ (POLD1) have been recently identified in families with multiple colorectal adenomas and CRC.

We aimed to assess the prevalence of POLE and POLD1 mutations in fCRC-X.

A total of 63 index cases fulfilling Amsterdam II criteria with normal expression of mismatch repair proteins and microsatellite stable tumors were included. Sanger sequencing of POLE-exon13 and POLD1-exon11 was performed.

None of the cases carried mutations in POLE. We found one case with a new POLD1 variant in heterozygosis: c.1421T>C (p.Leu474Pro). The patient was a woman who underwent a synchronous CRC and large bowel gastrointestinal stromal tumor at age 36. Her maternal aunt had metachronous CRC (dx33y) and endometrial cancer (dx56y) and was a carrier of this variant. Therefore, the index case's mother, who underwent endometrial cancer (dx52y), was an obligate variant carrier. It has been described that the homologous residue of POLD1 p.Leu479Pro mutation in S. cerevisiae causes a mutator phenotype. Furthermore, this is the paralogous residue of the hot spot at POLE (p.Leu424). In silico prediction analysis strongly suggests a pathogenic nature for this variant. Integration of all these evidences drove us to classify this new variant as probably damaging.

POLD1 mutations might explain about 1.6% of fCRC-X. POLD1 testing should be included in the diagnostic strategy for unexplained familial CRC.

P12.117-S

Polymerase Proofreading - Associated Polyposis (PPAP): an unusual family with the highly penetrant POLE p.Leu424Val mutation with colorectal cancer, polyposis, duodenal cancer and diabetes

S. M. A. Goodman[1], *C. M. Brewer*[2], *I. Tomlinson*[3], *K. Ong*[4], *A. Considine*[4], *M. M. J. Bradford*[1];

[1]*Peninsula Clinical Genetics Service, RD&E NHS Foundation Trust, Plymouth, United Kingdom,* [2]*Peninsula Clinical Genetics Service, RD&E NHS Foundation Trust, Exeter, United Kingdom,* [3]*Molecular & Population Genetics Laboratory, Welcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom,* [4]*West Midlands Regional Genetics Service, Birmingham, United Kingdom.*

Mutations in the exonuclease domain of the polymerase E (POLE) gene have recently been identified as causing a rare but highly penetrant predisposition to colorectal cancer and colorectal polyps. Palles et al employed whole-genome sequencing and detected the p.Leu424Val (L424V) mutation in 12 families, with no evidence of a shared common ancestor. The phenotypes of these families were consistent with an autosomal dominant predisposition to colorectal adenomas and carcinomas, with some individuals having multiple tumours. Tumours from these subjects were all microsatellite stable (MSI-S) and did not show any preponderance of site within the colon or particular morphology. There were no extra-colonic tumours described in any affected individuals in these families. Following the identification POLE L424V in our family through the CORGI study, subsequent testing identified the familial mutation in an individual with an MSI unstable (MSI-H) tumour and synchronous duodenal adenocarcinoma, rectal carcinoma and adenomas. It was also noted that all the individuals affected with colorectal cancer in this family also have diabetes, consistent across 3 generations. The co-segregation of diabetes and colorectal cancer requires formal confirmation in some relatives. This association warrants further study. An increased risk of CRC in patients with diabetes mellitus has been recognised for some years. Emerging evidence that polymerase D (POLD1) gene has an important function in adipose tissue homeostasis lends weight to the association. This family provides evidence of a broader phenotype of malignancy in POLE, and opportunity for new investigations into the possible mechanism linking diabetes and colorectal cancer.

P12.118-M

Association of variant -765G>C in the PTGS2 gene promoter with melanoma in Italian patients and its relation to gene expression in dermal fibroblasts

M. Gomez Lira[1], *S. Ferronato*[1], **G. Malerba**[1], *M. Santinami*[2], *A. Maurichi*[2], *A. Sangalli*[1], *A. Turco*[1], *P. Perego*[3], *M. Rodolfo*[4];

[1]*Department of Life and Reproduction Sciences, Section of Biology and Genetics, University of Verona, Verona, Verona, Italy,* [2]*Unit of Melanoma and Sarcoma, Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy,* [3]*Molecular Pharmacology Unit, Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy,* [4]*Unit of Immunotherapy, Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy.*

Aim: The production of prostaglandins, especially prostaglandin E synthetase (PGE2) is hypothesized to influence carcinogenesis by promoting cell proliferation, inhibiting apoptosis, stimulating angiogenesis, and mediating immune suppression. Cyclooxygenase-2 (Cox-2), the inducible isoform of cyclooxygenase coded by the PTGS2 gene, is the key enzyme in the production of prostaglandins involved in inflammatory processes including cancer. In melanoma skin cancer, Cox-2 is overexpressed in primary malignant melanoma and in their corresponding metastases. Aim of this study was to investigate if polymorphisms -765G>C (rs20417), and -1195A>G (rs689466) in the PTGS2 gene impact on its expression in dermal fibroblasts and are associated with individual susceptibility to malignant cutaneous melanoma.
Methods: Two hundred forty patients presenting melanoma and 342 control individuals were genotyped for polymorphisms -765G>C (rs20417) and -1195A>G (rs689466) by restriction fragment length polymorphism (PCR-RFLP) analysis. PTGS2 gene expression was performed by Real Time PCR using Sybr Green.
Results: The allele -765C was associated with an increased prevalence of melanoma. No association of -1195A>G polymorphism was observed. Haplotype analysis of both variations showed that the haplotypes carrying the minor alleles were associated to a higher risk of melanoma (p=0.02). Expression analysis indicated that allele -765C is associated to a higher gene expression and thus could represent a risk allele by affecting the functionality of the promoter.
Conclusion: In conclusion, variant -765G>C may be associated to malignant cutaneous melanoma with a low penetrance effect and this effect could be a consequence of altered gene expression.

P12.119-S

DNA methylation profiles of PDGFB and FGF2 are potential biomarkers of disease progression in primary myelofibrosis

C. Augello[1], **R. Falcone**[2], *F. Savi*[3], *S. Tabano*[1,2], *C. Pesenti*[2], *N. Fracchiolla*[4], *A. Iurlo*[4], *U. Gianelli*[2], *M. Miozzo*[2,1], *S. Sirchia*[5];

[1]*Department of Pathophysiology and Transplantation; Università degli Studi di Milano, Milano, Italy,* [2]*Division of Pathology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, Milano, Italy,* [3]*Division of Pathology, San Paolo Hospital, Milano, Italy,* [4]*Department of Hematology-Oncology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, Milano, Italy,* [5]*Department of Health Sciences, Università degli Studi di Milano, Milano, Italy.*

The primary myelofibrosis (PMF) is characterized by clonal proliferation of the hematopoietic precursors, fibrosis, osteosclerosis and angiogenesis. Bone marrow fibrosis is a reactive process, where the fibroblast proliferation is in response to cytokines, such as platelet derived growth factor (PDGF) and the basic fibroblastic growth factor (FGF2), produced by malignant megakaryocytes or monocytes. No specific prognostic markers are today available to refine the clinical classification and the risk to develop fibrosis. The purpose of this study is to investigate DNA methylation of PDGFB and FGF2, to verify possible associations among the epigenetic profile fibrosis progression and prognosis of PMF. The methylation is evaluated by pyrosequencing in a cohort of 58 PMF cases and 20 controls. The methylation percentages of PDGFB and FGF2 in PMF ranged from a complete demethylation to hypermethylation (PDGFB range: 3-95, mean value: 39; FGF2 range: 1-96%, mean value: 40), in controls the methylation values of both genes are clustered in more restricted intervals (PDGFB: 28-46% mean value: 35; FGF2: 16-43% mean value: 28). The methylation values of PDGFB and FGF2 are significantly increased in the prefibrotic cases compared to controls (PDGFB: 71 vs. 33, $p < 0.0005$ and FGF2: 56 vs. 27.5, $p < 0.0005$). Interestingly hypomethylated PDGFB was an indicator of better prognosis for fibrosis, International Prognostic Scoring System (IPPS) and Dynamic International Prognostic Scoring System (DIPPS) progression (p=0.03, p=0.02 and p=0.01 respectively).

Synergistic effect and VEGF/HSP70-hom haplotype analysis: relationship to prostate cancer risk and clinical outcome

S. Sfar[1], *H. Saad*[2], *F. Mosbah*[3], *L. Chouchane*[1];

[1]*Department of Molecular Immuno-Oncology Faculty of Medicine, Monastir, Tunisia,* [2]*2Depatment of Urology, EPS Fattouma Bourguiba, Monastir, Tunisia, Monastir, Tunisia,* [3]*Depatment of Urology, EPS Sahloul, Sousse, Tunisia, Sousse, Tunisia.*

Prostate cancer is a complex disorder resulting from the combined effects of multiple environmental and genetic factors. Our previous single locus analysis showed that *VEGF* and *HSP70-hom* polymorphisms were significantly associated with prostate cancer susceptibility and prognosis. Both genes encoding these proteins were located on chromosome 6p21, and combining the neighboring SNPs into haplotypes may increase the association with the disease. Three tagging polymorphisms, the *HSP70-hom* 2437 T/C, the *VEGF*-1154 G/A and the *VEGF*-634 G/C SNPs were genotyped in 101 cases and 80 controls. For the combined analysis of *VEGF* and *HSP70-hom*, we found a positive gradient in the ORs related to the number of high risk genotypes with a 3.53-fold increase of prostate carcinoma risk (OR= 3.53; *P*= 0.015). Furthermore, The TAG and CAG haplotypes at positions *HSP70-hom*, *VEGF* -1154 and *VEGF* -634 exhibited a twofold (OR= 0.46; P= 0.014) and a sevenfold (OR= 0.14; P= 0.00005) reduction in prostate cancer risk, respectively. Regarding prostate cancer prognosis, the TAG haplotype had a negative association with the aggressive phenotype as defined by the histopathological grade (OR= 0.28; P= 0.006). Our findings confirm the role of at-risk haplotype across the *HSP70-hom/VEGF* gene cluster in determining susceptibility to prostate cancer.

P12.121-S

Frequency and clinical implication of rare *BRAF* variants other than *BRAF* V600E mutation in a large cohort of consecutive thyroid fine needle aspiration cytology samples

G. Hong[1], *K. Park*[1], *C. Ki*[1], *S. Kim*[2], *J. Chung*[2], *J. Shin*[3], *Y. Oh*[4], *J. Kim*[1];

[1]*Departments of Laboratory Medicine & Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,* [2]*Division of Endocrinology and Metabolism, Department of Medicine, Thyroid Center, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,* [3]*Department of Radiology and Center for Imaging Science, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,* [4]*Department of Pathology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of.*

Background: *BRAF* mutation analysis is a useful adjunctive tool in diagnosing thyroid nodules. The *BRAF* V600E (c.1799T>A) mutation comprises over 95% of all *BRAF* gene mutations in papillary thyroid carcinoma (PTC). The clinicopathological association of rare *BRAF* variants other than V600E

mutation is still obscure.
Methods: We evaluated a total of 1067 consecutive patients with malignant or indeterminate thyroid nodules by ultrasonography. All fine needle aspiration cytology (FNAC) samples were tested for *BRAF* mutation using mutant enrichment with 3'-modified oligonucleotide (MEMO) sequencing with real-time PCR concurrently. Rare *BRAF* variants were evaluated with regard to cytology and/or histology results.
Results: *BRAF* mutations were detected in 37.9% (404/1067) of all samples. The V600E mutation was detected in 98.3% (397/404), and six rare variants were detected by MEMO sequencing. Three types of variants were identified: c.1799_1801del (p.Val600_Lys601delinsGlu), c.1794_1795insGTT (p.Ala598_Thr599insVal), and c.1801A>T (p.Lys601*). The former two are known mutations to be associated with PTC and three patients with these mutations were diagnosed as PTC histologically. The third variant was novel. The case with c.1801A>T was diagnosed as a benign follicular nodule.
Conclusions: Out of 1067 thyroid nodule cytology samples, six (0.56%) had rare *BRAF* variants. A novel variant was identified in a cytologically benign thyroid nodule. Targeted testing for detecting only the V600E mutation may be good enough to increase the diagnostic value of FNAC, however, identification of other variants in *BRAF* gene may provide additional valuable information on the nature of thyroid nodules in the future.

P12.122-M
Association between the cytogenetic profile of tumor cells and response to preoperative radiochemotherapy in locally advanced rectal cancer

M. González-González[1], *J. García*[2], *J. Alcazar*[2], *L. Gónzalez*[2], *O. Bengoechea*[3], *M. Abad*[3], *M. Gutiérrez*[1], *A. Santos-Briz*[3], *O. Blanco*[3], *M. Martín*[4], *E. Fonseca*[5], *A. Rodríguez*[6], *M. Fuentes*[1], *L. Muñoz-Bellvis*[2], *A. Orfao*[1], *J. Sayagués*[1];
[1]*Servicio General de Citometría, Departamento de Medicina and Centro de Investigación del Cáncer (IBM, Salamanca, Spain,* [2]*Service of General Surgery and Digestive Apparatus, University Hospital of Salamanca-IBSALnvestigación del Cáncer (IBMCC-CSIC/USAL), Universidad de Salamanca, Salamanca, Spain,* [3]*Departament of Pathology, University Hospital of Salamanca-IBSAL, Salamanca, Spain,* [4]*Servicio de Radio-diagnóstico, Hospital Universitario de Salamanca-IBSAL, Salamanca, Spain,* [5]*Service of Medical Oncology, University Hospital of Salamanca-IBSAL, Salamanca, Spain,* [6]*Servicio de Oncología Radioterápica, Hospital Universitario de Salamanca, Salamanca, Spain.*

Neoadjuvant radiochemotherapy to locally advanced rectal carcinoma patients has proven efficient in a high percentage of cases. Despite this, some patients show non-response or even disease progression. Recent studies suggest that different genetic alterations may be associated with sensitivity vs. resistance of rectal cancer tumor cells to neoadjuvant therapy. We investigated the relationship between intratumoral pathways of clonal evolution as assessed by iFISH (51 different probes) and response to neoadjuvant radiochemotherapy, evaluated by Dworak criteria in 45 rectal cancer tumors before (n=45) and after (n=31) treatment. Losses of chromosomes 1p (44%), 8p (53%), 17p (47%), 18q (38%) and gains of 1q (49%), 13q (75%) as well as amplification of 8q (38%) and 20q (47%) chromosomal regions were those specific alterations found at higher frequencies. Significant association ($p<0.05$) was found between alteration of 1p, 1q, 11p, 12p and 17p chromosomal regions and degree of response to neoadjuvant therapy. A clear association was observed between cytogenetic profile of the ancestral tumor cell clone and response to radiochemotherapy; cases presenting with del(17p) showed a poor response to neoadjuvant treatment (p=0.03), while presence of del(1p) was more frequently observed in responder patients (p=0.0002). Moreover, a significantly higher number of copies of chromosomes 8q (p=0.004), 13q (p=0.003) and 20q (p=0.002) were found after therapy vs. paired pre-treatment rectal cancer samples. Our results point out the existence of an association between tumor cytogenetics and response to neoadjuvant therapy in locally advanced rectal cancer. Further studies in larger series of patients are necessary to confirm our results.

P12.123-S
Epigenetic Profile of Early Relapsed Childhood ALL

Y. Erbilgin[1], *O. Hatirnaz Ng*[1], *S. Firtina*[1], *T. T. Celkan*[2], *S. Anak*[3], *Z. Karakas*[3], *N. Sarper*[4], *E. Zengin*[4], *E. Turkkan*[5], *D. Atay*[5], *Y. Ng*[1,6], *O. Dogru*[7,8], *E. Dayıoglu*[9], *M. Sayitoglu*[1], *U. Ozbek*[1];
[1]*Institute for Experimental Medicine, Istanbul University, Istanbul, Turkey,* [2]*Department of Pediatric Hematology-Oncology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey,* [3]*Department of Pediatric Hematology, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey,* [4]*Pediatric Hematology Division, Kocaeli Medical Faculty, Kocaeli University, Kocaeli, Turkey,* [5]*Pediatric Hematology Division, Istanbul Okmeydani Education and Research Hospital, Istanbul, Turkey,* [6]*Faculty of Engineering, Bilgi University, Istanbul, Turkey,* [7]*Medical Park Hospital, Istanbul, Turkey,* [8]*Akdeniz University, Medical Faculty, Antalya, Turkey,* [9]*Department of Thoracic and Cardiovascular Surgery, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey.*

Relapsed acute lymphoblastic leukemia (ALL) is one of the leading causes of death among children with cancer. The prognosis for early relapse children remains poor. To discover the underlying epigenetic pathways that may play a role in drug resistance and relapse, we performed Infinium HumanMethylation450K BeadChip arrays and to characterize the molecular evolution of relapsed childhood ALL, we used Illumina HumanCytoSNP-12 arrays to identify somatic copy number alterations (CNAs) in 16 diagnosis/relapse pairs. Flow-sorted normal B-cell progenitor subpopulations and CD4+CD8+ T-cell purified from thymus were used as controls.
Analysis variant CpG sites in an unsupervised manner, we identified three distinct DNA methylation profiles in samples according to their structural variations. ALL cases did not show significant differences between paired diagnose/ relapse samples though they had hyper DNA methylation than control samples. Aberrant DNA methylation had been detected in negative regulator of cell cycle genes and DNA damage repair genes in ALL. Copy number analysis of patients revealed varying numbers of genetic lesions ranging from 0 to 45 CNAs per sample. The vast majority of CNAs observed were shared between diagnosis and relapse in the same patients. One of the most frequent CNAs involved deletions of CDKN2A/B , occurring in 8 patients, 2 of 8 patients lost the CDKN2A/B at relapse time. Integration of methylation and genotyping data revealed high concordance.
Early relapse samples were more likely to be similar to their respective diagnostic sample that suggests early-relapse results from the emergence of a related clone.

P12.124-M
Genome-wide methylation analysis of tubulocystic and papillary renal cell carcinomas

M. Korabecna[1], *A. Horinek*[1], *O. Seda*[1], *Z. Halbhuber*[2], *R. Blatny*[2], *O. Hes*[3], *V. Tesar*[1];
[1]*First Faculty of Medicine of Charles University and General Faculty Hospital in Prague, Prague, Czech Republic,* [2]*Central European Biosystems, Prague, Czech Republic,* [3]*Faculty of Medicine in Pilsen, Charles University, Pilsen, Czech Republic.*

This study was undertaken to characterize and compare molecular signatures associated with tubulocystic renal cell carcinoma (TRCC) and papillary renal cell carcinoma (PRCC).
We performed methylated DNA immunoprecipitation (MeDIP) coupled with genome wide microarray analysis (Roche NimbleGen) in 6 PRCC and 2 TRCC together with analysis of control tissues of normal histological appearance adjacent to each examined tumor sample.
All examined tumors and their control tissues of histological normal appearance share alteration in regulation of specific pathways. In TRCC we found higher number (48) of methylated tumor suppressor genes (TSG) than in PRCC (35). Only TSG DPH1 and VHL were found to be distinctively methylated in all PRCC. The methylation of gene sequences SPIB, PLAT, PCDHB1 and FAF2 was found exclusively in TRCC tumor samples, the methylation in genes KIFC3, MDH2, PAG1, BICD1, PLG and CTRL was limited to all PRCC tumor samples only.
Using bioinformatics tools (DAVID and GSEA), we found the pathways and genes which are altered by differential methylation and which may be responsible for developmental divergence of both tumors from precancerous renal tissue. The genes involved in transmembrane transport of small molecules, lipoprotein metabolism and transmission across chemical synapsis are significantly overrepresented among genes methylated preferentially in TRCC, PRCC is characterized by overrepresentation of genes playing roles in RNA metabolism and processing.
Supported by grants no. PRVOUK P25/LF1/2 of the Ministry of Education, Youth and Sport of the Czech Republic and no.RVO-VFN 64165 of the Ministry of Health of the Czech Republic.

P12.125-S
Identification of mosaicism in patients with sporadic retinoblastoma using NGS

G. Gómez-Mariano[1], *C. Rodriguez-Martín*[1], *L. de la Vega*[1], *Á. Zaballos*[2], *C. Sabado*[3], *T. Vendrell*[3], *J. C. Ferreres*[3], *N. Martín*[3], *P. García-Miguel*[4], *A. Sastre*[4], *J. Abelairas*[4], **J. Alonso**[1];
[1]*Instituto de Investigación de Enfermedades Raras, Majadahonda, Spain,* [2]*Centro Nacional de Microbiología, Majadahonda, Spain,* [3]*Hospital Vall d'Hebron, Barcelona, Spain,* [4]*Hospital Infantil La Paz, Madrid, Spain.*

Objectives: Retinoblastoma is the paradigm of hereditary cancer. Approximately, 40% of patients carry germline mutations in the retinoblastoma gene RB1 that predispose to develop retinoblastoma. These mutations can be detectable in blood DNA using standard techniques. However, these techniques are not sensitive enough to detect mosaicism in sporadic cases of the disease (without family history). This study was thus designed to determine the frequency of mosaicism in patients with sporadic retinoblastoma by using next generation sequencing (NGS) technologies.
Methods: We selected for this study 22 patients with sporadic retinoblastoma in which we had previously identified two inactivating mutations in the RB1 gene in tumor DNA, but in which none of those mutations were detected in blood DNA using Sanger sequencing. Blood DNA of these patients was analyzed by NGS (Roche/454) in order to identify in low proportion

(mosaicism) one of the mutations identified in the tumor.
Results: Roche/454 sequencing was able to detect mutations present at <1% in blood DNA. In our series, NGS was able to detect, in 5 out of 22 patients (22.7%), one of the mutation identified in the tumor in the blood DNA. The frequency of the mutations in blood DNA ranged between 0.8 and 16.8%.
Conclusion: Roche/454 sequencing is very sensitive allowing the identification of mosaicism in patients with sporadic retinoblastoma. The existence of mosaicism can modify the risk of retinoblastoma and the probability of transmitting the mutation to offspring. Therefore, the identification of mosaicism in these patients improves genetic diagnosis.

P12.126-M
BRCA1 and TP53 germline mutations are associated with gynecologic sarcomas

D. E. Nowakowska[1], *A. Niwińska, A. Kluska, M. Dąbrowska, A.D. Czapczak, E. Kwiatkowska, A. Nasierowska-Guttmejer*[2];
[1]*The Maria Sklodowska -Curie Cancer Center & Institute in Warsaw, Warsaw, Poland,* [2]*Central Clinical Hospital Ministry of Interior in Warsaw, Warsaw, Poland.*

Introduction: gynecologic sarcomas comprise less than 1% of all gynecologic malignancies and represent very heterogeneous group. Very little is known about etiology of these malignancies, the only documented etiologic factor in less then 25% of these tumors is previous pelvic irradiation and some have been linked to tamoxifen treatment. We report that BRCA1 & TP53 germline mutations are associated with gynecologic sarcomas.
Methods:
During the last ten years 16 patients diagnosed with gynecologic sarcoma were seen at Genetic Counseling Unit at Cancer Center & Institute of Oncology in Warsaw. All the patients were offered genetic testing, after genetic counseling and after obtaining the written informed consent. The consent protocol was accepted by the local ethical committee. BRCA1 analysis was performed on DNA from the peripheral blood leukocytes. The mutations in BRCA1 were detected using DHPLC and sequencing of exons 2, 5, 11 and 20, where the Polish founder mutations are found most frequently. TP53 gene was sequenced from exon 2 to 10.
Results:
Among 16 patients with gynecologic sarcomas, we found 6 (37%) BRCA1 germline mutation carriers.
We have found only one TP53 mutation carrier, who had been diagnosed with vulvar angiosarcoma at exceptionally young age.
Conclusions:
In women diagnosed with gynecologic sarcoma screening for the germline mutations in the BRCA1 gene is important strategy. In pediatric patients gynecologic sarcoma should prompt Li-Fraumeni syndrome diagnosis.

Table 1

patient ID number	diagnosis	age at diagnosis (years)	mutation in BRCA1	mutation in TP53

P12.127-S
Glutathione S-transferase P1 gene in secondary Acute Myeloid Leukemia

A. Daraki[1,2], *F. Rosmaraki*[1,2], *S. Zachaki*[1], *K. Kakosaiou*[1], *C. Panagiotopoulou*[1], *C. Sambani*[1], *P. Kollia*[2], *V. Aleporou-Marinou*[2], *K. Manola*[1];
[1]*NCSR Demokritos, Athens, Greece,* [2]*National and Kapodistrian University of Athens, Athens, Greece.*

Interactions between genetic, epigenetic and genotoxic factors play a pivotal role in secondary acute myeloid leukemia (s-AML) development. The GSTP1 is a well-known housekeeping gene engaged in the detoxification of a variety of carcinogens. We hypothesized that genetic and epigenetic mechanisms resulting in reduction or inactivation of GSTP1 expression may be implicated in s-AML pathogenesis. Thus, we investigated the possible implication of the A313G germline polymorphism in s-AML development and/or its specific chromosomal abnormalities. Moreover, we studied the possible contribution of GSTP1 promoter hypermethylation in s-AML development and the methylation status in respect to patients' genotype. Concerning GSTP1 genotyping, a case-control study in 75 s-AML patients and 185 controls was performed by Real-Time PCR. The GSTP1 hypermethylation was studied by methylation-specific PCR in 40 of the above cases and 15 controls. The genotypic distribution between cases and controls revealed a statistically higher frequency of the variant genotypes (A/G, G/G) in s-AML compared to the controls (p=0.001). Allele frequency distribution analysis showed that s-AML patients exhibited an almost 2-fold increased risk of carrying at least one variant G allele compared to the controls. Stratification of patients according to the karyotype revealed a significantly increased frequency of A/G heterozygotes in patients carrying -7/del(7q) (89.5%). The GSTP1 promoter was hypermethylated in a large proportion of s-AML patients (32.5%), but in none of the controls. No statistically significant associations were found between the methylation status and GSTP1 genotype. Our findings provide evidence for an important role of the GSTP1 gene in AML pathogenesis.

P12.128-M
TP53 gene mutation analysis in breast cancer: Our experience of six years

T. Dabir[1], *S. Liew*[2];
[1]*Medical Genetics Dept., Belfast City Hospital, Belfast, United Kingdom,* [2]*Queen's University, Belfast, United Kingdom.*

Hereditary breast cancers account for 5-10 % cases and are predominantly due to BRCA1/2 genes and less commonly due to other high penetrant (TP53, STK11, PTEN) and less penetrant (CHEK2,ATM,PALB2, BRIP1) genes. Breast cancer is an important component of Li-Fraumeni Syndrome (LFS) cancer spectrum related to TP53 gene mutation. Genetic testing for BRC1/2 is generally not offered in young breast cancer women (<30 years) alone unless they meet the testing criterion (Manchester score etc). However TP53 testing is suggested for young breast cancer alone cases without family history of LFs tumours
We analysed our data of past 6 years (2008-2013) of TP53 gene testing in women with breast cancer. Information was obtained regarding family history of cancers, age of onset, receptor pathology and BRCA1/2 testing. No TP53 mutation was found in our breast cancer alone cohort. The solitary TP53 mutation was detected in a woman with family history suggestive of LFS. The TP53 gene mutation detection rate in our cohort was only 4.5 %. (1/22).
Although our sample size is small TP53 gene mutation rate is likely to be better in breast cancer cases with LFS family history and may be influenced by receptor pathology as published previously. Genetic centres with limited resources need to consider these factors before requesting expensive send away genetic tests. Availability of affordable NGS panel testing for breast cancer genes may address this issue in future and would also help in understanding the contribution of the above mentioned genes to hereditary breast cancer.

P12.129-S
Expression analysis of TNF related apoptosis inducing ligand and its receptors in gastrointestinal tumors

I. Chatziandreou[1], *S. Tsikalakis*[1], *S. Sakellariou*[1], *N. V. Michalopoulos*[2], *G. Theodoropoulos*[2], *P. Kontogianni*[2], *D. Theodorou*[2], *P. Korkolopoulou*[1], *E. Patsouris*[1], *A. A. Saetta*[1];
[1]*1st Department of Pathology, University of Athens, Athens, Greece,* [2]*1st Department of Propaedeutic Surgery Hippokrateion Hospital, Athens, Greece.*

TRAIL (TNF related apoptosis inducing ligand) is a member of the tumor necrosis factor superfamily. Due to its ability to selectively induce apoptotic death in transformed cells, TRAIL pathway has been considered as a promising drug target for cancer therapy. Our purpose was to examine TRAIL pathway components expression in gastrointestinal tumors.
mRNA relative expression levels in 45 colon, 11 esophageal, and 11 gastric cancers (37 RCL2-fixed, 30 fresh frozen,43 male and 24 female, median age 67 years) along with matching normal tissues were analysed using RT-PCR for TRAIL pathway genes, namely TRAIL, DR4, DR5, DcR1, DcR2, OPG. Colon cancer samples displayed elevated mRNA levels in 20% (9 of 45), 42% (19 of 45), 47% (21of 45), 64 % (29 of 45), 44% (20 of 45), 31% (14 of 45) of the cases for TRAIL, DR4, DR5, DcR1, DcR2, OPG genes respectively. Furthermore, TRAIL receptors were found simultaneously overexpressed in a subset of colon tumors. TRAIL overexpression was correlated with low stage tumors (p=0.03) in our cohort. Esophageal cancers overexpressed TRAIL and its receptors DR4, DR5, DcR1, DcR2 at 18%, 54.5%, 27%, 45.5% and 45.5% of the cases, respectively. Finally, in gastric cancer samples overexpression was found in 45% of the cases for Dcr2 and 36% for DR4/5, DcR1 and TRAIL.
TRAIL receptor mRNA levels were found elevated in a significant percentage of gastrointestinal tumors. In addition, TRAIL expression emerged as an early event, which may delay disease progression.

Discordant molecular breakpoints in an apparent recurrent translocation (3;12)(q13;p13)

D. Costa[1], *C. Muñoz*[1], *A. Carrió*[1], *A. Arias*[1], *C. Gómez*[1], *F. Solé*[2], *B. Espinet*[3], *G. Azaceta*[4], *M. Calasanz*[5], *E. Campo*[1], *B. Nomdedeu*[6];
[1]*Unitat d'Hematopatologia. Hospital Clínic, Barcelona, Spain,* [2]*Institut de Recerca contra la Leucèmia Josep Carreras, Badalona, Spain,* [3]*Laboratori de Citogenética Molecular. Hospital del Mar., Barcelona, Spain,* [4]*Hospital Clinico Universitario de Zaragoza, Barcelona, Spain,* [5]*Universidad de Navarra, Barcelona, Spain,* [6]*Departament d'Hematologia. Hospital Clínic, Barcelona, Spain.*

Background: The identification of recurrent translocations in neoplasia has been used to identify the genes involved in the neoplastic process in order to develop new therapies.The objective of our study was to determine if the breakpoints determined by conventional cytogenetics in two apparently recurrent translocations (3;12)(q13;p13) were the same at the molecular level. Material and Methods. Two patients with myelodysplastic syndrome had a complex karyotype including a translocation (3;12)(q13;p13). In addition to the translocation, both karyotypes shared a deletion of chromosome 5 and a trisomy of the chromosome 8. A set of 35 Bacterial Artificial Chromosomes (BACs) were used to cover the 3p11.1-q13.32 region and a set of 12 BACs were used to cover the 12 p11.21-p13.31 region.Results. The breakpoints were precisely established only for the translocation t(3;12)(q13;p13) in patient 1, within the BAC RP11-491D12 at the 3p11.2 region and within the BAC RP11-705C15 at the 12p13.31 region. A region of 22.458 kbp was deleted including the 12p13.2 - 12p11.21 region. In patient 2 the breakpoints on chromosomes 3 and 12 were not found, but based on the BACs study they should be more centromeric than the breakpoints determined in patient 1. A deleted region of 23.163,9 kbp including the 12p13.2 - 12p11.21 region was found in patient 2. Conclusion: BACs studies revealed that the breakpoints in two apparently recurrent translocations were different at the molecular level. Both translocations showed a deletion of 22.458 kbp - 23.163,9 kbp near the breakpoint, including the 12p13.2 - 12p11.21 region.

P12.131-M
Prevalence of BRCA1 and BRCA2 germline mutations in triple-negative breast cancer

M. W. Wong-Brown, *K. A. Avery-Kiejda, N. A. Bowden, C. J. Meldrum, R. J. Scott; University of Newcastle, Hunter Medical Research Institute, New Lambton Heights, Australia.*

Triple-negative breast cancer (TNBC) is a subtype of breast cancer that lacks ER, PR and HER2 expression. TNBCs have a gene expression profile similar to breast tumours BRCA mutations. However, despite this correlation, there have not been many studies showing the prevalence of BRCA mutations in TNBC patients. It has been proposed that women with TNBCs may be candidates for genetic screening due to their shared phenotype with breast tumours of BRCA mutation carriers.
The aim of this study was to investigate the prevalence of germline BRCA mutations in TNBC cases unselected for family history of the disease. This knowledge could aid in the selection of women who could be candidates for genetic testing.
The study cohort comprised of 347 TNBC patients. BRCA genes were amplified by Fluidigm Access Array. The amplicons were sequenced on Illumina MiSeq. The sequencing data were analysed with NextGENe 2nd Generation Sequencing Software. MLPA was also performed and the peaks heights were analysed on GeneMarker® software.
39 (11.2%) pathogenic mutations were detected in our cohort of 347 TNBC patients. 22 of these patients (56.4%) did not have a recorded family histories of breast and/or ovarian cancers.
Our study shows that in a large cohort of TNBC patients unselected for family history of breast cancer, approximately 11.2% of the patients harbour a BRCA mutation. This suggests that there may be an underestimation of BRCA mutations in a breast cancer population using current screening criteria, and TNBCs should be considered as an inclusion criterion for genetic testing.

P12.132-M
Align-GVGD, SIFT, PolyPhen, MAPP-MMR, Grantham Analysis and Condel are weak predictors of the clinical significance for missense variants

I. Kerr, *J. M. Eggington, K. Moyes, B. C. Burdett, A. Van Kan, H. McElroy, P. J. Vail, D. B. Sumampong, N. J. Monteferrante, K. L. Hardman, A. Theisen, E. Rosenthal, R. J. Wenstrup; Myriad Genetic Laboratories, Inc., Salt Lake City, UT, United States.*

Non-synonymous missense changes that result in amino acid substitutions represent the majority of variants of uncertain clinical significance (VUSs) identified by genetic testing. We sought to analyze whether commonly used in silico tools, which assess the phylogenetic conservation of specific amino acids throughout evolution, can accurately characterize the possible disease association of missense mutations. We compared the accuracy of six commonly used algorithms (Align-GVGD, SIFT, PolyPhen-2, MAPP-MMR, SIFT, Grantham Analysis and Condel) using a dataset of 1,118 BRCA1, BRCA2, MLH1 and MSH2 variants previously classified as clinically deleterious or benign by our laboratory's variant classification program. For all algorithms (except Align-GVGD), the false-positive (FP) rate compared to our laboratory's variant classification program was higher than traditionally accepted thresholds for clinical confidence, with a range from 30.6% - 58.5% for BRCA1, 27.1% - 40.1% for BRCA2, 17.9% - 67.9% for MLH1 and 17.1% - 56.1% for MSH2. Although the FP rates using Align-GVGD for all four genes were lower, including values of 2.2% for BRCA1 and 7.9% for BRCA2, the sample size was too small to provide a robust analysis. The high FP rates for Condel, which classifies variants based on a weighted average of scores from five in silico tools, suggests that the use of multiple models is not significantly more accurate than any of the individual models in isolation. The results of our study suggest that none of the commonly used in silico tools achieve the traditionally accepted minimum threshold of specificity for the clinical use of predictive tools.

P12.133-S
Comparison between splicing reporter minigene assays and patient blood RNA analyses used for the assessment of splicing defects caused by variants in the DNA mismatch repair genes

A. M. L. Jansen, *H. M. van der Klift, N. van der Steenstraten, E. Bik, C. M. J. Tops, J. T. Wijnen, P. Devilee;
Leiden University Medical Centre, Leiden, Netherlands.*

A fraction of sequence variants found in disease-causing genes induce aberrant splicing. At the moment, reliable splice-prediction tools are only available for variants in the consensus splice site regions, and even these cannot predict the exact molecular nature of the aberrant transcription. Wet-lab splicing assays, either RT-PCR analyses of patient RNA or functional splicing reporter minigene tests, have to be performed to confirm aberrant splicing. Here, we present results of splicing reporter minigene assays performed for 37 disease-gene variants of unknown significance (VUS), mainly found in the four DNA mismatch-repair genes *MLH1*, *MSH2*, *MSH6* and *PMS2* that are associated with Lynch syndrome. Twenty variants are located in the consensus splice site regions, 13 are exonic and 4 are deep-intronic variants. We used a previously described minigene vector, and transfected HEK293 and/or Hela cells with wildtype and variant constructs. For 32 variants also results from patient RNA analyses were available, either performed by our laboratory or presented in literature. For comparison with minigene assay splicing data, we especially included variants that showed multiple aberrant transcripts in patient RNA analysis, or another splice effect than the prevalent exon skip. We found 100% concordance between patient RNA analyses and minigene assays in terms of showing an effect on splicing or not. However, for 6 variants discrepancies in the molecular nature of aberrant transcription were observed. Possible explanations for these discrepancies, and implications for the assessment of pathogenicity of the variant are discussed.

P12.134-M
Genetic risk factors in a vulvar cancer cluster among young Indigenous women in Arnhem Land, Australia

R. McWhirter[1,2], *A. Rumbold*[3], *J. Marthick*[1], *J. Dickinson*[1,2], *J. Condon*[2];
[1]*Menzies Research Institute Tasmania, Hobart, Australia,* [2]*Menzies School of Health Research, Darwin, Australia,* [3]*University of Adelaide, Adelaide, Australia.*

Vulvar cancer is usually rare, and occurs most often in postmenopausal women. Among young (<50 years) Indigenous women living in remote Aboriginal communities in Arnhem Land, however, the incidence of this malignancy is more than 70 times the national Australian rate for the same age group. Previously, we found that neither excess human papillomavirus (HPV) incidence nor a particularly virulent strain of HPV could explain the very high incidence of vulvar cancer in this population. Reports from the Gynaecology Outreach Service that cases appeared to cluster in family groups suggested that a genetic susceptibility, either to the effects of HPV or another cause of vulvar cancer, may be involved in this cluster. To investigate the role of genetic risk factors, 30 cases and 61 controls, matched on age and community of residence, were recruited to the study. DNA was extracted from saliva samples, and genotyped to provide information on approximately 2.5 million variants. These data were analysed using both genome-wide association and identity-by-descent techniques. We found clear evidence for the involvement of a genetic risk factor predisposing this population to vulvar cancer, and identified three genomic regions of interest. Bioinformatic analysis prioritised biologically plausible candidate genes within these regions and functional studies to further elucidate the role of genetic variants in the aetiology of vulvar cancer are currently underway. This is the first genetic

study of this population, and these findings continue to inform health care delivery in Arnhem Land, especially vaccination policy and screening strategies.

P12.135-S
Whole exome sequencing identifies novel mutations from DNA repair pathways in familial esophageal squamous cell carcinoma

M. R. Abbaszadegan[1,2], *M. Nasiri Aghdam[2], A. Baranova[3], S. Bruskin[4], A. Aarabi[1];*
[1]Division of Human Genetics, Immunology Research Center, Avicenna Research Institute, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran, [2]Medical Genetics Research Center, Department of Medical Genetics, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran, [3]School of System Biology, George Mason University, Fairfax, VA, United States, [4]Vavilov Institute of General Genetics, Russian Academy of Sciences, Moscow, Russian Federation.

Introduction: Esophageal cancer (EC) is the fifth leading cause of cancer death in Iran and esophageal squamous cell carcinoma (ESCC) is an aggressive subtype comprises 95% of all Iranian EC cases. High existence of familial aggregation among ESCC cases necessitates the identification of new germline mutations for the purpose of surveillance and personalized medicine. **Methods:** We analyzed the mutation spectra from 100X whole exome sequencing (WES) of peripheral blood mononuclear cell's DNA extracted from 10 affected probands of familial ESCC using SureSelect target enrichment system capture process (Agilent, U.S). All family members directly sequenced for confirmation of targeted mutations in patients.
Result: We identified 9 mutated genes from DNA repair pathways including ATM, BRCA1, SLX4, FANCA, FANCB, FANCE, RAD51AP1, RAD51AP2, RECQL5 with the allele frequencies below 0.01 according to 1000 Genome project (Oct 2011). Novel non-synonymous substitution found in FANCE causing glutamate to aspartate amino acid change. All mutations identified as damaging variants using SIFT and PolyPhen softwares. **Conclusion:** The use of WES identified that familial cases of ESCC harbor mutations from DNA repair, especially homologous recombination and Fanconi anemia pathways. These findings have potential implications on the surveillance and treatment of ESCC patients. Particularly, these patients may benefit from treatment with DNA cross-linking chemotherapeutic drugs, such as cis-platin and mitomycin C, or from a PARP [poly (ADP-ribose) polymerase] inhibitor. Additionally, genetic consoling and mutational analysis of the proband's relatives will considerably benefit these individuals for their surveillance and early diagnosis leading to an improved disease management.

P12.136-M
Whole transcriptome analysis of testicular germ cell tumors

L. Degoricija[1], *K. Y. Lee[1], S. Patel[1], A. J. M. Gillis[2], M. Rijlaarsdam[2], L. C. J. Dorssers[2], L. Looijenga[2];*
[1]Thermo Fisher Scientific, South San Francisco, CA, United States, [2]Erasmus MC-University Medical Center, Rotterdam, Netherlands.

Next generation sequencing of the whole transcriptome enables high resolution measurement of gene expression activity in different tissue and cell types. This methodology provides an in depth study of known transcripts and depending on the data analysis, allows identification of additional transcript types such as transcript variants, fusion transcripts, and small and long ncRNAs. In this study we performed RNA-Seq using the Ion Torrent Proton platform to compare the expression profile of testicular germ cell tumors (seminoma type, n=3) and normal testis (n=3). Using Partek Flow and Star or TopHat aligners, we aligned the reads to the human genome and mapped sequences to the RefSeq database. We identified a large number of genes that were up and down regulated with high degree of significance p<0.01, >2X FC). These included genes related to testicular tissue type, stem cell pleuripotency (NANOG; POU5F1) and proliferation (KRAS, CCND2). In addition, a number of differentially expressed noncoding RNAs were identified (SNORD12B, XIST). The method was validated on a small set of genes (>20) using qPCR (TaqMan Assays). We used the Open Array platform to quantitatively screen a larger number of differentially expressed genes (224) across a number of different testicular germ cell tumor types (non-seminoma).

P12.137-S
Upregulation of key wnt signaling molecules in human astrocytic brain tumors

N. Pecina-Slaus, *A. Kafka, D. Tomas, B. Kruslin;*
Medical School University of Zagreb, Zagreb, Croatia.

The knowledge on molecular profiles of astrocytic brain tumors still needs elucidation. In the present study key players of wnt signaling, beta-catenin (CTNNB1), TCF1 and LEF1, adenomatous polyposis coli (APC) and axin (AXIN1) were investigated in the set of human astrocytic brain tumors.
The investigation of beta-catenin demonstrated 10% of samples with potential activating mutations. The results on protein levels demonstrated that 50% of glioblastomas (WHO grade IV) and 56% of astrocytomas (WHO grades II and III) showed upregulation of beta-catenin and nuclear localization was found in 52.1% of glioblastomas. Transcription factors of the wnt pathway were also upregulated. Strong TCF1 and LEF1 expression was observed in 51.6% and 71% of glioblastomas. Analysis of variances performed on the total sample indicated significant differences in the values of TCF1 weak expression (F=2.804; p=0.045), LEF1 weak (F=4.255; p=0.008) and LEF1 strong expression (F=5.498; p=0.002) with regard to malignancy grade. The F-ratios for two variables (LEF1 strong and LEF1 weak) indicated that differences between astrocytomas (II, III) and glioblastomas were statistically significant (p<0.02).
Allelic losses of APC gene were frequent with glioblastomas showing 60% and diffuse astocytomas (grade II) 20%. Allelic losses of AXIN1 were found in 10% of glioblastomas. In 31% of glioblastomas and 22% of astrocytomas downregulation of axin proteins was detected. In 31% of glioblastomas axin was localized in the nucleus.
Our findings contribute to understanding of human astrocytic brain tumor genetic profile and suggest that molecular changes of wnt signaling play important roles in astrocytic tumor etiology.

P12.138-M
Exome sequencing and deep sequencing reveals „mutational storm" in xeroderma pigmentosum (XP) patients

P. Bauer[1], *Y. Kamenisch[2], C. Bauer[1], M. Sturm[1], C. Schroeder[1], O. Riess[1], M. Berneburg[3];*
[1]Institute of Medical Genetics and Applied Genomics, Tübingen, Germany, [2]Department of Dermatology, Tübingen, Germany, [3]Department of Dermatology, Regensburg, Germany.

Xeroderma pigmentosum (XP) is a rare genetic disorder with molecular defects in the DNA repair machinery. Clinically, patients suffer from increased UV-sensitivity and a skin cancer risk that is increased more than 1000-fold. It has been postulated that due to the repair defect patients show a mutator phenotype with indicative UV-signature mutations. We have sequenced exomes from sun-exposed and sun-protected tissues from three patients with XPC. Moreover, two long-range amplicons covering the whole mitochondrial genome and a comparable nuclear DNA fragment have been sequenced at >1.000 x coverage. These three XP-C patients have been compared to young and old healthy controls. The bioinformatics analysis was tailored towards detection of exposition-specific variants with high sensitivity. A representative subset of identified exposure-specific variants has been validated by a subsequent deep-sequencing approach. The number of exposure-specific variants was very high in the XP-C patients (610, 2.088, and 6528, respectively compared to 95%), the third XPC patient had relatively low numbers of exposure-specific variants and no predominance for UV signatures (~75% in 610 variants). Interestingly, all three samples displayed increase variation in the nuclear DNA but not the mitochondrial DNA as expressed by the count of non-consensus bases in amplicon deep sequencing. As expected, XPC hypermutation arises in the nuclear DNA predominantly with typical signature mutations. Interestingly, not all XPC patients seem to share the signature phenotype although the hypermutation is a common feature. In contrast, mitochondrial DNA does not show any differences as compared with young and old controls.

P12.139-S
YAP1 acts as oncogenic target of 11q22 amplification in multiple cancer subtypes.

E. Lorenzetto[1], M. Brenca[1], M. Boeri[2], C. Verri[2], E. Piccinin[3], P. Gasparini[2], F. Facchinetti[4], S. Rossi[5], G. Salvatore[6], M. Massimino[7], G. Sozzi[2], R. Maestro[1], **P. Modena**[8];
[1]CRO National Cancer Institute, Aviano, Italy, [2]Milan National Cancer Institute, Milano, Italy, [3]Mario Negri Sud, Santa Maria Imbaro, Italy, [4]INT National Cancer Institute, Milano, Italy, [5]Treviso General Hospital, Treviso, Italy, [6]University Federico II, Napoli, Italy, [7]Milan Narional Cancer Institute, Milano, Italy, [8]Sant' Anna General Hospital, Como, Italy.

The transcriptional coactivator YAP1 is a critical effector of the human Salvador-Warts-Hippo-pathway. Literature data report apparently discrepant results on the carcinogenic role of YAP1, which acts as oncogene or tumor suppressor in different in-vitro and in-vivo models. Furthermore, amplification events of 11q22 locus-encompassing YAP1 gene-have been detected in multiple tumor types but there is limited direct evidence about the oncogenic role of endogenous YAP1 within in the amplicon.
We screened a panel of human tumor samples and cancer cell lines and identified that the YAP1 amplification event is actually present in up to 23% of the cases. We exploited EKVX, CaSki and RO82 cell lines harboring both genomic YAP1 amplification and YAP1 protein overexpression, in order to study the effects of downregulation of endogenous YAP1 by RNA-interference strategies. Gene expression profiling data identified 707 statistically significantly modulated genes (p-value =0.002) that were functionally annotated for cell proliferation and cellular movement ontologies. Mechanistic studies of the identified perturbed pathways revealed that YAP1 silencing

significantly decreased cell proliferation and cell cycle perturbation associated with upregulation of p21 and p27 cell-cycle inhibitors, reduced cell migration (p<0.048) and anchorage-independent growth (p<0.02). In CaSki cell line, YAP1 silencing induced significantly increased sensitivity and cell-death response to cisplatin treatment (p=0.011) as well as reduction of in-vivo tumorigenic potential (p=0.027).
Overall, these results establish that YAP1 is a direct oncogenic target of the 11q22 amplicon in previously unreported cancer types and support the relevance of such genetic aberration in carcinogenesis in a fraction of multiple tumor types.

P12.140-M
No change in the rate of bilateral mammographies after BRCA1/2 testing among true non-carriers

G. Larouche[1,2], J. Chiquette[1,2,3], J. Simard[1,2,4], **M. Dorval**[1,2,3];
[1]Université Laval, Québec, QC, Canada, [2]Centre de recherche du CHU de Québec, Québec, QC, Canada, [3]Centre des maladies du sein Deschênes-Fabia, Québec, QC, Canada, [4]Chaire de recherche du Canada en Oncogénétique, Québec, QC, Canada.

The majority of women who are true non-carriers of the BRCA1/2 familial mutation may be reassured that they are no longer considered at high risk for breast and ovarian cancer. For this reason, most should be encouraged to adopt the same cancer screening practices as those recommended to women of the same age in the general population. The aim of this study is to compare the rate of bilateral mammographies after BRCA1/2 testing to that prior among true non-carriers of BRCA1/2 mutation. Information from the Quebec Health Insurance Board was used to identify all registered bilateral mammographies done between May 1, 1998 and March 31, 2012 among a cohort of 143 French Canadian unaffected true non-carriers. The Cox proportional hazards model for repeated events, with women's age as the time scale, was used to obtain hazard ratios of bilateral mammographies. The rate of mammographies did not change after BRCA1/2 testing, neither globally (HR=0.93, p=0.22), nor by age (<50 years HR=0.81, p=0.13; ≥50 years HR=1.01, p=0.84). Although women <50 years had a lower rate of mammographies than women ≥50 years (HR=0.55; 95% CI = 0.43-0.70) after genetic testing, 74% still continued to be screened, which is not generally recommended to women of the same age group in the general population. In conclusion, genetic testing information did not have a significant effect on mammography screening in our cohort of true non-carriers of BRCA1/2 mutation. Clear-cut recommendations for the follow-up of true non-carriers of BRCA1/2 mutation are needed.

P12.141-S
EGFR and ALK genes mutation screening in Non-small-cell lung carcinoma (NSCLC) specimens

J. Kasnauskiene[1,2], *A. Laurinavičiene[2], E. Žurauskas[1,2], A. Šimbelytė[2], A. Laurinavičius[1,2];*
[1]Vilnius University, Vilnius, Lithuania, [2]National Centre of Pathology, Vilnius, Lithuania.

BACKGROUND: Testing for genetic abnormalities in epithelial growth factor receptor (EGFR) and anaplastic lymphoma receptor tyrosine kinase (ALK) is a critical tool in the care of advanced NSCLC. We investigated the incidence of epidermal growth factor receptor (EGFR) mutations and anaplastic lymphoma kinase (ALK) rearrangements in Lithuanian patients with non-small cell lung cancer (NSCLC). MATERIALS AND METHODS: 326 NSCLC paraffin-embedded, formalin-fixed (FFPE) specimens were collected, DNA extracted, and using real time mutations analysis in EGFR gene and translocation in AKL gene by IHC following confirmation positive test by FISH analysis. RESULTS: We screened 326 consecutive patients with NSCLC for the presence of concomitant EGFR mutations and ALK rearrangements Mutations in EGFR gene appeared mutated in 17%; ALK translocation was found in 4% of NSCLC cases.

P12.142-M
miR-106b-5p may act as tumor suppressor by down-regulation C1orf24 expression in human thyroid carcinoma.

G. M. G. Carvalheira, *B. H. N. Nozima, J. M. Cerutti;*
UNIFESP, São Paulo, Brazil.

We have previously shown that the C1orf24 gene is highly expressed in follicular thyroid carcinomas while is not expressed in benign thyroid lesions. However, little is known about the molecular mechanism involved in C1orf24 expression. It is widely demonstrated that microRNAs (miRs) are potent regulators of gene expression. The miRs expression varies in according of tissue, development stage, and tumor types. We therefore, investigated whether miRs could modulate C1orf24 expression in thyroid cancer. In this study, we show that the miR-106b expression is lower in thyroid carcinomas, than in benign thyroid lesions (p<0,01). Functional analysis was performed in follicular thyroid carcinoma cell line (WRO), which highly express C1orf24 gene. The ectopic expression of miR106b into WRO resulted in down-regulation of C1orf24 at both mRNA and protein levels, when compared to negative control. Mutations made at miR-106-5p binding sites in the C1orf24 mRNA 3' UTR showed that miR-106b directly interacts with C1orf24. Additionally, miR-106b overexpression significantly decreased the migration capabilities of cells whilst increased apoptosis rate. Our findings indicate that miR-106-5p may play a role in thyroid carcinogenesis by negatively regulating C1orf24 expression and, therefore, by acting as tumor suppressor. However, further analyses are needed to fully demonstrate the role of miR-106b-5p in thyroid carcinogenesis.

SOX2 gene expression and copy number variation in squamous cell lung cancer

E. Sodja, *M. Rijavec, A. Koren, I. Kern, P. Korošec, T. Čufer;*
University Clinic Golnik, Golnik, Slovenia.

Transcription factor SOX2 might have an important oncogenic role in development and progression of lung cancer. The aim of our study was to estimate copy number variation (CNV) of SOX2 in primary tumours and to analyse SOX2 expression in primary tumour tissue and in blood samples in relation to CNV status in squamous cell lung cancer patients. 28 patients with metastatic squamous cell lung cancer were prospectively included between years 2010 and 2013. Total RNA was isolated from whole blood collected in PAXgene Blood RNA Tube before any systemic treatment. For 10 patients primary tumour tissue was available from the same time points; for those patients RNA and DNA were extracted from FFPE tumours. SOX2 expression levels and CNV status were determined by quantitative RT-PCR. Copy number analysis revealed high copy number of SOX2 in 3/10 (30%) tumours and gain of function in another 3/10 (30%) tumours. Median SOX2 expression in FFPE tumour tissue was 3.9 (0.1-29.1) and in blood samples 5.4 (0.4-17.9). Elevated copy number of SOX2 correlated with higher SOX2 expression in tumours (ρ=0.92). Moreover, correlation between SOX2 expression in blood samples and FFPE tumour tissue was observed (ρ =0.60); patients with high SOX2 expression in blood tended to have high SOX2 expression in tumour tissue. According to our observation genetic alterations in SOX2 seem to be common event in squamous cell lung cancer. Furthermore, good correlation between SOX2 expression in blood and tumour samples supports the idea of liquid biopsy in lung cancer.

The phenotype of the 22q11.2 deletion syndrome (22q11DS) is higly variable with a wide spectrum of abnormalities. About 90% of patients have a 3Mb deletion spanning LCR22-A to LCR22-D in the 22q11 region containing four low copy repeats (LCR22).
Methods : On behalf of the ACLF, 27 French Cytogenetics laboratories collaborated to collect data of 731 patients with 22q11DS diagnosed between 1996 to 2013.
Results :
Clinical data: On average over the years 2010-2012, at least 70 patients were annually diagnosed postnatally. The symptomatology that led to genetic analysis changes with patient's age, eg :
Heart defect, facial dysmorphism, hypocalcemia and thymus hypoplasia or agenesis in newborns
Developmental and speech delay with facial dysmorphism and velopharyngeal insufficiency in children

Variable phenotype in adults : some had intellectual disability with typical gestalt, some had psychiatric disorders, and a minority was almost asymptomatic parents when the diagnosis was first made in their children.
Molecular data: Thirteen cases were diagnosed with array-CGH. The majority of these patients were referred for intellectual disability (n=10/13) and only 3 had heart defect. The size of the deletion was variable: 745 - 2904 kb and surprisingly only 46,2% had deletion between LCR22-A and LCR22-D. The 22q11 deletion was inherited in 22.2% of cases and mainly maternally (86.7%).
Conclusion : We report the largest series of 22q11DS postnatal diagnosis. We plan to study more patients using array-CGH to investigate whether the size of the deletion or the presence of other CNV may explain the phenotype variability.

Transgenerational inheritance of 22q11.2 atypical deletion: instability of LCRs in a family with discordant clinical phenotype

R. L. Dutra[1,2], *É. A. Zanardo*[3], *G. M. Novo-Filho*[3], *A. T. Dias*[4], *M. M. Montenegro*[4], *F. A. S. L. Souza*[4], *A. M. Nascimento*[3], *C. O. Santos*[4], *T. V. M. M. Costa*[4], *F. B. Piazzon*[4], *J. B. de Melo*[5], *L. D. Kulikowski*[4], *C. A. Kim*[3];
[1]*University of Sao Paulo, Sao Paulo, Brazil,* [2]*Genetics Unit, Department of Pediatrics/ LIM 36, HC-FMUSP, São Paulo, Brazil,* [3]*Genetics Unit, Department of Pediatrics/ LIM 36, HC-FMUSP, Sao Paulo, Brazil,* [4]*Department of Pathology, Cytogenomics Laboratory/ LIM 03, HC-FMUSP, Sao Paulo, Brazil,* [5]*Cytogenetics and Genomics Laboratory, Faculty of Medicine, University of Coimbra,, Coimbra, Portugal.*

Genomic rearrangements in 22q11.2 region are caused mainly by LCRs elements or repetitive sequences, leading to different clinical phenotypes including velocardiofacial or DiGeorge syndrome. Most of the deletions encompass the ~3 (LCR A and D) or ~1.5 Mb (LCR A and B), however atypical deletions have been described in a few cases. Patients with genomic alterations in 22q11.2 region present a spectrum of phenotypic manifestations and this condition can be more severe compared with the relatives. We report on a family, including the maternal grandfather, the mother and daughter, with discordant clinical phenotype and 22q11.2 atypical deletion using SNP-array (Illumina 850K) in order to better delineate the size of deletion. In three generations we found a difference in the deletion size in the 22q11.2 region, range of approximately 0.1 Kb to 0.5 Kb, encompassing the A and B LCRs for mother and daughter, and also the A and C LCRs in the grandfather.
Although there are rare, atypical variant deletion endpoints could provides important insights related to the role of genomic architecture in chromosomal rearrangements, chromosome evolution, and in human disease.

P13.03-S
A catalog of hemizygous variation in 127 22q11 deletion patients

M. S. Hestand[1], *B. A. Nowakowska*[1,2], *J. K. J. Van Houdt*[1,3], *L. Dehaspe*[3], *A. Swillen*[1], *K. Devriendt*[1], *D. McDonald-McGinn*[4], *B. S. Emanuel*[5], *S. T. Warren*[6], *J. R. Vermeesch*[1];
[1]*Department of Human Genetics, KU Leuven, Leuven, Belgium,* [2]*Institute of Mother and Child, Warsaw, Poland,* [3]*Genomics Core, UZ Leuven, Leuven, Belgium,* [4]*Clinical Genetics, The Children's Hospital of Philadelphia, Philadelphia, PA, United States,* [5]*Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States,* [6]*Department of Human Genetics, Emory University School of Medicine, Atlanta, GA, United States.*

The 22q11.2 deletion syndrome (22q11.2DS) is the most common chromosomal deletion syndrome in humans with an incidence of 1 in 2-4000 live births. The clinical presentation of 22q11.2DS is extremely variable, but the underlying reason for this variation remains unknown. Individuals with 22q11.2DS most often have a classically associated 3 MB or 1.5 MB deletion. However, nested deletions as well as atypical deletions also occur that can contribute to the broad spectrum of phenotypic abnormalities. It is also hypothesized that variations in the remaining allele could underly the phenotypic variability.
To investigate variation within the non-deleted allele we performed targeted resequencing of the 22q11.2 region for 127 patients, identifying multiple deletion sizes, including two atypical deletions. We cataloged over 18 thousand hemizygous variant positions, of which sixty percent were previously annotated. As expected, in this gene dense region more variants were intronic (52%) than intergenic (36%). Within the coding regions we identified 213 non-synonymous variants, 6 stop gains, and 5 frameshift insertions. In addition, the observed number of variants per gene was higher or lower than expected for some genes in both our data and 1000 genomes data, indicating some genes may tolerate variation more or less than others. This extensive catalog of hemizygous varaints will serve as a blueprint for future experiments to correlate 22q11DS variation with phenotype and serve as an analysis model as we extend to whole genome sequencing of 22q11DS patients.

Instituto de Salud Carlos III, Majadahonda, Madrid, Spain,* [8]*Instituto de Investigación en Enferemdades Raras (IIER). Instituto de Salud Carlos III, Majadahonda, Madrid, Spain.*

Alpha1-antitrypsin (AAT) deficiency is a common hereditary disorder associated with reduced AAT serum level, predisposing to pulmonary emphysema or liver disease. It is caused by inheritance of mutations in the AAT gene (SERPINA1). Most of the deficiency alleles occur in the coding sequence of the gene due to aminoacid substitution or deletion resulting in reduced protein level or altered functionality. Rarely mutations affecting RNA splicing in the AAT gene have been described so far.
We have identified a new null allele, QOmadrid in two siblings with significantly reduced serum levels of AAT. QOmadrid allele results from a duplication of a timine in the position +2 of the donor splice site of exon 1C (+2dupT). In these patients QOmadrid occurred in combination with another previously described rare null variant, QOporto. These two variants correspond to splicing mutations in a regulatory region of the gene, both causing disruption of the normal splicing of intron 1C. Analysis of transcripts in patients' samples and in vitro assays using minigenes revealed abnormal splicing leading to absence of transcription from exon 1C, where the hepatocytes transcription start site is located. Thus, in these patients no normally spliced RNA products are expected to be produced in the liver, causing the AAT deficiency. This mutation constitutes a new null allele, QOmadrid, contributing to explain the disease.

P13.05-S
Upstream open reading frames regulate cannabinoid receptor 1 expression under baseline conditions and during cellular stress

M. Eggert[1], *M. Pfob*[1], *G. Schelling*[2], *O. K. Steinlein*[1];
[1]*Institute of Human Genetics, University Hospital, Ludwig-Maximilians-University, Munich, Germany,* [2]*Department of Anesthesiology, University Hospital, Ludwig-Maximilians-University, Munich, Germany.*

The endocannabinoid system (ECS) plays a crucial role in the regulation of a variety of physiological functions, such as learning and memory processing, vegetative control, energy homeostasis, immunity and stress response. It acts through different endogenous endocannabinoids which are able to bind to the cannabinoid receptor subtypes 1 and 2 (CNR1 and CNR2). The CNR1 is not only associated with phenotypes such as cognitive performance, addiction and anxiety, but is also known to be crucially involved in cellular responses to acute and chronic stress conditions. The molecular mechanisms leading to altered CNR1 expression under acute or chronic stress exposure are not completely understood so far. It is known that the 5'- and 3'untranslated regions (UTRs) of genes can harbor regulatory elements, such as upstream open reading frames (uORFs) that are capable of influencing the expression pattern of the main protein coding region.
In our study, we investigated the influence of putatively functional uORFs present in the five known mRNA variants of the human CNR1 gene on transcription and translation under baseline conditions and various stress conditions in vitro. The functional analysis performed with reporter gene assay and quantitative realtime PCR revealed that two of these variants contain upstream open reading frames that modulate gene expression both under baseline condition and conditions of cellular stress. Thus our findings suggest that the functionally relevant uORFs found in the 5'UTR variants of CNR1 are part of the cellular stress response mechanisms.

P13.06-M
Clinical, cytogenetic and molecular analyses in seven patients with a constitutive autosomal ring chromosome.

A. Cervantes[1,2], *C. García-Delgado*[3], *F. Fernández-Ramírez*[1], *A. Reyes de la Rosa*[3], *P. Núñez Martínez*[3], *K. Nieto Martínez*[2], *L. Gómez Laguna*[1], *A. Morales Jimenez*[3], *C. Arias Villegas*[3], *L. Muñoz Martínez*[3], *J. Berumen*[1], *S. Kofman*[1], *V. F. Morán-Barroso*[3];
[1]*Hospital General de Mexico Dr. Eduardo Liceaga, Mexico, D.F., Mexico,* [2]*Facultad de Medicina, UNAM, Mexico, D.F., Mexico,* [3]*Hospital Infantil de Mexico Federico Gómez, Mexico, D.F., Mexico.*

Autosomal ring chromosomes have a frequency of 1/30,000 to 1/60,000

births. We report 7 patients identified from the cytogenetic registers of the HIMFG, who attended during the last 8 years. They corresponded to r(4)(p16q35), r(5)(p15.3q35.3), r(9)(q24.3q34.3), r(14)(p11?q32.33), r(19)(p13.3q13.4), r(21)(p11q22.3) and idic r(21)(p11.2q22.3) (cases1-7, respectively). Additional chromosomal analyses with GTG banding were performed in all cases, FISH with subtelomeric probes were applied to 4 cases and molecular karyotyping with SNP array were carried out in 2. As cases 2 and 5 are mosaic with a normal cell line, they should have been originated postzygotically. A dynamic mosaicism was present in all the cases. All the rings were originated by breaks on both arms with loss of subtelomeric material and subsequent reunion of free ends with the exception of cases 2 and 5. The r(14) was probably generated by an inv-dup-del mechanism as there are a deletion and a duplication of 14q. The large dicentric r(21) may have been formed by breakage and reunion of long arms of an isochromosome. The phenotypes described included short height, microcephaly, variable facial dysmorphism and psychomotor developmental delay, corresponding to autosomal ring syndrome. Some patients showed hirsutism, renal abnormalities and hypoacusia, data corresponding to monosomy of the specific chromosomal region implicated. Cases 1 and 7 presented characteristics of Wolf-Hirschhorn and Down syndromes, respectively. Patients 2 and 4 had difficult control seizures. We consider that the variable clinical data reported in these patients are due to the specific chromosomal region involved and to the ring chromosome instability.

P13.07-S

A new translocation involving 4 and 11 chromosomes in a adult man

S. Barati, *A. Giuffrida, E. Ferro, M. Santagati, C. D. Salpietro, R. Civa;*
Genetic and Immunology Pediatric Department, AOU Policlinic G.Martino, Messina, Italy.

Chromosomal translocations occurring between the chromosome 11 (region q12) and other chromosomes are the most recurrent chromosomal aberrations observed in some subtypes of leukemia, lymphoma and sarcomas. In many cases, identification of these chromosome abnormalities is crucial to select appropriate treatment protocols.
To our knowledge we are the first group to describe a new translocation, involving 11q12 and 4q21 regions, in a 35 years old man.
The proband came to our observation to perform cytogenetic analysis because of a suspected infertility and we found 46,XY t (4;11) (q21;q12) karyotype. The man had a cortical dysplasia and seizures from birth.
We extended the cytogenetic analysis to the parents and sister of the proband and the same translocation was found only in the father.
It is known that some types of dysplasia are linked to the presence of genetic alteration but so far it has not been described any association between dysplasia and chromosomal aberration.
The region 11q12 is involved in many chromosomal translocations such as t(2;11) (q31; q12), t(11; 17) (q12; p11.2), and t(6; 11) (p21; q12) which are all related to tumor development . The common breakpoint region (11q12) has been delineated by FISH and contains the FOSL1 gene which has been associated with fibroblast growth or cancer development, such as colorectal, breast, prostate and lung cancer, head and neck squamous cell carcinoma. Since the region 11q12 seems to be linked to tumor development, would be appropriate to perform a follow-up to monitor the subject at risk.

P13.09-S

Stable segregation of apparently benign chromothripsis in three generations

L. Nazaryan*[1], *B. Bertelsen**[1], *W. Sun**[2], *M. Bak*[3], *G. Xie*[2], *W. Chen*[2], *L. E. Hjermind*[4,5], *J. T. d. Dunnen*[6], *P. E. M. Taschner*[6], *Z. Tumer*[1];
[1]Applied Human Molecular Genetics, Kennedy Center, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark, [2]Max Delbrück Center for Molecular Medicine, Berlin Institute for Medical Systems Biology, Berlin, Germany, [3]Wilhelm Johannsen Centre for Functional Genome Research, Department of Cellular and Molecular Medicine, Faculty of Health Science, University of Copenhagen, Copenhagen, Denmark, [4]Memory Disorders Research Group, Neurogenetics Clinic, Department of Neurology, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [5]Department of Cellular and Molecular Medicine, Section of Neurogenetics, Panum Institute, University of Copenhagen, Copenhagen, Denmark, [6]Department of Human Genetics, Center for Human and Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands.

Chromothripsis (CTH) is a newly described phenomenon of chromosome shattering where multiple localized breakpoints result in catastrophic genomic rearrangements. CTH is found both as a somatic (cancer) and germline rearrangement (G-CTH). The limited G-CTH cases (n=16) described so far have all been associated with abnormal phenotype. In this study we present a familial G-CTH with 7 breakpoints and a deletion, stably segregating in three generations (10 individuals) without an apparent association with a disorder. Initial cytogenetic analysis suggested an apparently balanced translocation t(3;5)(q22.3;q23.1). Using chromosome array and next generation mate-pair sequencing followed by Sanger sequencing we discovered a G-CTH involving six breakpoints and a ~108kb deletion within a ~6,4Mb region on 3q22.3-q23. Although six protein-coding genes were affected by the breakpoints the 10 carriers of the G-CTH do apparently not have common associated disorders. However, there are several spontaneous miscarriages in the family records presumably resulting from unbalanced rearrangements due to G-CTH. Our study is the first report suggesting that G-CTH may not always be associated with an abnormal phenotype but may also have a neutral effect. It is therefore possible that G-CTH may be found not only among individuals with apparently balanced rearrangements but also karyotypically normal asymptomatic individuals. We describe CTH on the cytogenetic level based on recommendations of ISCN-2013 (International System for Human Cytogenetic Nomenclature) as: 46,XX,t(3;5)(q22.3;q23.1).arr ngs[hg19] 3q23.3(137735949-137845370)x1.ngs 3q22.3q23(135827611-142218722)cth fam. We suggest combining this with a molecular description following HGVS (Human Genome Variation Society) nomenclature (see ESHG abstract by Taschner P. et al.). *Shared first-authors

Background: In South America four cleft lip with or without cleft palate (CL±P) high prevalence regions was detected, one of them being the Patagonia (Argentina). We aim the identification of independent autosomal segments containing polymorphic markers that may contribute to CL±P with a family-based design for genome-wide association scan.
Methods: The study sample included 26 families with isolated CL±P (27 affected and 99 total individuals).They were genotyped on the Affymetrix Genome-Wide 6.0 array. Only „independent" SNPs were included in the association analysis. We calculated linkage disequilibrium (LD) between each pair of SNPs into a window of 50 SNPs, shifting the window 5 SNPs forward and repeating the procedure to scan all autosomes. Then we pruned the data removing one SNP of each pair that was in strong LD (r >0.8). We perform the transmission disequilibrium test (TDT). We identified segments of a maximum length of 250Kb with more than one SNP significantly associated with CL±P.
Results: A total of 88 genomic segments with two or more independent SNPs significantly associated with CL±P were identified. An intergenic region of 33Kb on 10q25.2 showed the most significant association with CL±P ($p< 0.00007$). Furthermore, we found other significant association with 6p21.2 including the marker rs4153154 ($p<0.00009$). Besides, others genomic segments including the genes TGFB2 (1.4Kb on 1q41) and CRISPDL2 (61.3Kb on 16q24.1) deserve our attention because they have previously been associated with oral cleft in others populations.
Conclusion: Our results suggest 10q25.2 and some genes spread across autosomes as candidate loci to CL±P.

P13.11-S

The FRA14B common fragile site maps to a region of frequent somatic and germ-line rearrangements within the GPHN gene

D. Zheglo[1], *L. Brueckner*[2], *L. Savelyeva*[2];
[1]Research Centre for Medical Genetics, Moscow, Russian Federation, [2]German Cancer Research Center (DKFZ), Heidelberg, Germany.

Common fragile sites (cFS) are heritable chromosomal loci that exhibit non-random breaks on metaphase chromosomes in response to replication stress. Chromosome breakage at cFSs contributes to cancer genome evolution and de novo pathogenic germ-line alterations. Approximately 90 cFSs have been identified at cytogenetic band resolution, but just few of them have been molecularly characterized. Precise mapping of cFSs can reveal new rearrangement-prone candidate genes critical for the development of cancer and hereditary conditions.
We performed FRA14B mapping in cultured lymphocytes treated with a replication inhibitor, aphidicoline, using six-color FISH with contiguous BAC probes on metaphase chromosomes. FRA14B was restricted to a 765 kb region within 14q23.3, overlapping with a major part of the GPHN gene.

GPHN encodes a protein involved in molybdenum cofactor biosynthesis and clustering of postsynaptic neurotransmitter receptors. Computational analysis of the FRA14B sequence revealed a large hairpin-prone motif. Targeted oligonucleotide array CGH in 160 cancer cell lines and primary tumors detected 13 copy number alterations at FRA14B. Sequence analysis of cancer breakpoint junctions indicated an involvement of microhomology-mediated repair. In 2 cell lines, exonic deletions resulted in the expression of abberant GPHN transcripts. A survey of publicly available copy number profiles revealed that FRA14B is a hotspot of focal losses in cancer cell lines, loss-in-size rare CNVs, and rare and de-novo deletions in patients with neurodevelopmental diseases.
In summary, intrinsic chromosome instability at FRA14B may account for pathogenic germ-line and somatic GPHN alterations, providing new insight into the role of cFSs in cancer and neurological disorders.

P13.12-M
Signature of germline chromothripsis in a 14-break complex rearrangement associated with deletions at 7q33-q35/11p13 and CNTNAP2 gene disruption

A. C. S. Fonseca[1,2], *S. Antonini*[2], *A. Bonaldi*[2], *M. Mehrjouy*[1], *M. Bak*[1], *N. Tommerup*[1], *A. M. Vianna-Morgante*[2];
[1]*Wilhelm Johannsen Centre for Functional Genome Research, Department of Cellular and Molecular Medicine, University of Copenhagen, Copenhagen, Denmark,* [2]*Department of Genetics and Evolutionary Biology, University of São Paulo, São Paulo, Brazil.*

We report an apparently balanced complex chromosome rearrangement (CCR) t(7;10)(q35;p12.1)ins(7;11)(q35;p14.1p12) associated with intellectual disability, developmental delay, absent speech and aniridia. The breakpoints were mapped by FISH. The *CNTNAP2* gene was truncated by the breakpoint at 7q35 (chr7:146,808,760-146,922,794; hg 19). The breakpoint interval at 10p12.1 (chr10:27,897,058-28,081,590) contains the *MKX* gene. The distal insertion breakpoint interval at 11p14.1 includes the *BDNF* gene (chr11:27,718,086-27,929,856), whilst the proximal breakpoint was mapped to a segment devoid of genes at 11p12 (chr11:37,068,735-38,957,367). Array-CGH (180K; Agilent) detected four deletions of 2.3Mb, 1.6Mb, 724Kb and 610kb at 7q33-q35 (chr7:135,994,754-138,315,026; chr7:138,522,186-140,134,404; chr7:140,258,006-140,982,607; chr7:144,738,971-145-,349,495), encompassing 28 genes. The inserted fragment of chromosome 11 contains a 2.9Mb deletion (chr11:28,964,028-31,926,058), spanning *PAX6* and other nine genes. To characterize this CCR at the nucleotide level mate-paired sequencing is in progress. The der(7) nine breakpoints and der(11) four breakpoints are, respectively, within 10.9Mb (7q33-q35) and 11.2Mb (11p14.1-p12) segments. Considering the breakpoint clustering and chromosome reorganization, we speculate that chromothripsis underlies this CCR formation. Twelve germline chromothripsis were previously reported, most of them balanced (Kloosterman et al. Curr Opin Cell Biol 2013;25:341). Our case illustrates that localized shattering of chromosomes and assembly of resulting fragments, signature of chromothripsis, may result in several fragment losses. Therefore the balanced state of most germline cases might not be a feature of constitutional chromothripsis, but reflect embryonic viability. Among the deleted/disrupted genes likely contributing to the patient's clinical features are *PAX6* explaining aniridia, and *CNTNAP2*, implicated in neurodevelopment, and particularly language abilities.

Saturation of the human genome with chromosomal breakpoints

N. Tommerup[1], *M. B. Rasmussen*[1], *C. L. Schlechter*[2], *M. M. Mehrjouy*[1], *I. Bache*[1,3], *A. Lind-Thomsen*[1], *A. Silahtaroglu*[1], *C. Hansen*[1], *S. Kjaergaard*[3], *K. Brøndum-Nielsen*[4], *P. K. A. Jensen*[5], *C. Fagerberg*[6], *L. N. Krogh*[7], *J. Hansen*[5,8], *A. C. D. S. Fonseca*[1,9], *A. M. V. Morgante*[9], *K. T. Abe*[10], *C. Halgren*[1], *P. Jacky*[11], *M. Bak*[1];
[1]*University of Copenhagen, Copenhagen, Denmark,* [2]*Oregon Health & Science University, Portland, OR, United States,* [3]*Rigshospitalet, Copenhagen, Denmark,* [4]*Kennedy Center, Glostrup, Denmark,* [5]*Aarhus University Hospital, Aarhus, Denmark,* [6]*Vejle Hospital, Vejle, Denmark,* [7]*Odense University Hospital, Odense, Denmark,* [8]*Danish Cytogenetic Central Registry, Aarhus, Denmark,* [9]*Universidade de São Paulo, São Paulo, Brazil,* [10]*Rede Sarah de Hospitais de Reabilitação, Brasília, Brazil,* [11]*Northwest Permanente, PC, Emeritus, Portland, OR, United States.*

Even in the era of exome and full genome sequencing, it will take decades and tremendous resources to saturate the human genome with mutations linked to abnormal and normal phenotypes.
As a supplement to exome and full genome sequencing strategies, we will use already identified balanced chromosomal rearrangements (BCR) to establish a first, detailed map of mutations covering a significant fraction of the human genome. In the first reexamination of *unselected de novo* BCRs (BCRdn) detected by 40 years of prenatal diagnosis in Denmark, we have shown that BCRs truncate protein coding genes, ncRNA genes, unannotated transcripts detected by deep sequencing, as well as developmental regulatory genomic landscapes, mimicing random mutagenesis. In addition, our study revealed a ~20% long-term disease-risk of unselected BCRdn, 2-3 fold higher than previously assumed, suggesting that a genotype-phenotype relationship can be obtained for a significant number of the human genes by mapping of BCRs.
We have initiated clinical reexamination/mapping of all known BCRs in Denmark. Based on a population of just 5.5 mill, this will provide data on >1.200 breakpoints. By international expansion, we will extend this at least 10-fold to reach a proposed first goal of ~10.000 breakpoints. Unlike other large scale genomic efforts, all countries including undeveloped and developing countries can participate. The breakpoint-map will identify and confirm numerous genotype-phenotype associations, saturate the regulatory landscapes around evo-devo genes that specify the vertebrate body plan, reveal novel genetic mechanisms, and define genomic regions which can be mutated without any direct phenotypic consequence.

P13.14-M
Insight into the mutational mechanism of the recurrent CREBBP c.3832G>A p.(Glu1278Lys) mutation in patients with Rubinstein-Taybi syndrome

M. J. van Belzen, *C. A. C. van der Lans, D. J. M. Peters, C. L. Harteveld;*
Leiden University Medical Center, Leiden, Netherlands.

Rubinstein-Taybi syndrome (RTS) is a rare disorder affecting approximately 1/100,000 newborns. The syndrome is characterized by mental and growth retardation and a particular dysmorphology mainly concerning the face, hands and feet. The most frequent cause of RSTS are de novo mutations in the CREBBP gene, leading to haplo-insufficiency and found in 30-50% of patients. Furthermore, micro-deletions involving the CREBBP gene have been found in ~10% of patients.
Mutations are distributed throughout the gene and most mutations are unique. The c.3832G>A p.(Glu1278Lys) mutation in exon 21 is one of the most frequent pathogenic sequence variants in the CREBBP gene. We have identified this mutation in six independent patients out of a group of 101 RTS patients with a CREBBP mutation. Five of these patients were from the Netherlands, and another was from Spain. The molecular mechanism underlying most Guanine to Adenine substitutions is deamination of Cytosine to Uracil and the subsequent replacement of the complementary Guanine for an Adenine during DNA replication. However, recurring disease mutations in totally independent individuals at the same position within the gene suggests a shared mutation mechanism. By the systematic analysis of known DNA mutation mechanisms such as gene conversion, homologous recombination and DNA replication faults involving loop formation one may get insight in more general disease causing mutation mechanisms and find an explanation for recurrent mutations. This may have implications for counseling when hotspots are predictable based on knowledge about mechanisms leading to disease causing mutations.

P13.15-S
In vivo and *in silico* analyses of impact of the p.Val322Ala mutation on *CFTR* protein in a Brittany family

R. Farhat[1], *A. El Seedy*[1,2], *A. Sari*[1], *M. Pasquet*[1,3], *C. Adolphe*[4], *A. Kitzis*[1,3], **V. Ladeveze**[1];
[1]*Université de Poitiers Pôle Biologie Santé, Génétique Moléculaire de Maladies Rares, Poitiers, France,* [2]*Department of Genetics, Alexandria University, Alexandria, Egypt,* [3]*CHU de Poitiers, Poitiers, France,* [4]*Université de Poitiers, Poitiers, France.*

Background: Cystic Fibrosis (CF) is an autosomal recessive severe genetic disease. Mutations on CFTR (Cystic Fibrosis Transmembrane conductance Regulator) gene could induce CF or CFTR-RD (related disorder). A missense mutation detected in a Brittany family (c.965T>C or p.Val322Ala) was studied since this mutation is present in a family owning a risk ¼ to have a child carrying this mutation and another severe mutation in trans (p.Phe508del). To provide a wise genetic counseling to this family, *in silico* and biological studies of the impact of the p.Val322Ala on CFTR protein were realized. **Aim:** This mutation was studied to elucidate its impact on CFTR process *in cellulo* (maturation and localization), and in silico (protein structure) as the prediction of the severity of this mutation is evaluated as "high" by Polyphen-2. **Methods:** pTCF plasmids containing CFTR-WT, or CFTR-p.Phe508del, or CFTR-p.Val322Ala are transfected in eukaryotic cells for western blot and confocal microscopy. Polyphen 2 and swiss prot were used to *in silico* studies. **Results:** The p.Val322Ala leads to a normal processing and correct membrane localization. Both mutated protein and the WT-CFTR structures are similar, suggesting that this mutation is a mild mutation. **Conclusions:** These results emphasise the importance of molecular studies in elucidating the impact of mutations on clinical phenotypes and therapeutic strategies.

P13.16-M
High frequency of chromosomal anomalies and a novel chromosomal insertion associated with infertility and recurrent miscarriages(Reproductive Failure) in west Turkey

*F. Silan[1], S. Yalcintepe[1], D. Uysal[1], M. Urfali[1], **E. SIK**[1], A. Uludag[1], E. Cosar[2], A. N. Cakir Gungor[2], O. Ozdemir[1];*
[1]Canakkale Onsekiz Mart Universty, Faculty of Medicine Department of Medical Genetics, Canakkale, Turkey, [2]Canakkale Onsekiz Mart University Faculty of Medicine Department of Gynecology and Obstetrics, Canakkale, Turkey.

Numerical and/or structural chromosomal abnormalities may be a reason of high infertility rates and recurrent pregnancy losses (RPLs) in humans. Karyotype and karyogram profiles of patients with RPLs are presented in current results. A total of 722 patients; 161(44.5%) infertile and 200(55.5%) RPL couples were included in the study.
Karyotype and structural chromosome analyses of both patient groups in Canakkale population were made between May 2011-December 2013, using peripheral lymphocyte cell culture and GTG banding technique.
High frequency of chromosomal abnormalities(%7.45) were detected in 24 patients of the infertility group(n:322). 10 patients(42%) of this group(n:24) had numerical and 14 patients(58%) had balanced structural choromosomal abnormalities. A novel choromosomal insertion was found in an infertile male, one of the 22th choromosome was totally inserted in 9th choromosome [ins(9;22)(9pter-q12::22q11.1-q13.33::9q12-9qter)]. This is the first report of germline total inserion of a chromosome. Interestingly, this insertion was inherited from father. Balanced structural chromosomal abnormalities was also detected in 17 patients (4.25%) of RPL group without any numerical abnormalities.
Current results constitute the first report on the high incidence of structural chromosomal aberrations in RPLs and infertile couples in Canakkale district.

P13.17-S
Combination of molecular techniques in evaluation of de novo chromosome rearrangements involving terminal regions

A. Pavel[1], *L. Dimos[1], V. Plaiasu[1,2], O. Mantescu[1], F. Nedelea[1,3], R. Simion[1], D. Stambouli[1];*
[1]Cytogenomic Medical Laboratory, Bucharest, Romania, [2]Mother and Child Care Institute "Alfred Rusescu", Bucharest, Romania, [3]Filantropia Clinic Hospital, Bucharest, Romania.

Structural aberrations make a significant contribution to genetic disease. Balanced or unbalanced structural abnormalities may be inherited from a carrier parent or may occur as de novo rearrangements. When the abnormality occurs as a de novo event, the risk for genetic disease or phenotypic effects is increased, even when the rearrangement appears balanced. This may result from either submicroscopic deletions or duplications at the breakpoints.
We report three cases with structural chromosomal abnormalities that were detected using a combination of different techniques. Conventional karyotype revealed the presence of de novo chromosomal rearrangements in all three cases. The investigation continued with targeted array CGH (Comparative Genomic Hybridization) technique, using BAC (Bacterial Artificial Chromosome) clones for the identification of chromosome imbalances. Since the results obtained using cytogenetic analysis and targeted array CGH revealed the implication of terminal regions of abnormal chromosomes, we also applied MLPA (Multiplex ligation-dependent probe amplification) for subtelomeric regions, as an additional detection technique. In two cases additional information regarding the chromosome constitution was provided by MLPA.
Knowing the advantages and limits of each technique, complementary investigations were necessary to detect the architecture of chromosomal imbalances.
Further investigations for a specific case, although it means additional costs, are required by a low genotype-phenotype correlation. Any discrepancy between the clinical picture and the results of genetic testing imposes supplementary tests for an accurate diagnosis and a proper genetic counseling.

P13.18-M
Somatic mosaicism for deletion at 8p21.3p23.1: some new twists on generation of terminal 8p rearrangements

A. D. Kolotii[1,2], *S. G. Vorsanova[1,2,3], Y. B. Yurov[1,2,3], V. Y. Voinova[1,2,3], I. Y. Iourov[1,2,4];*
[1]National Research Center of Mental Health, RAMS, Moscow, Russian Federation, [2]Institute of Paediatrics and Paediatric Surgery, Ministry of Health, Moscow, Russian Federation, [3]Moscow City University of Psychology and Education, Moscow, Russian Federation, [4]Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.

Somatic mosaicism for terminal 8p deletions is rare. Here, we report on a case of a deletion at 8p21.3p23.1 affecting about 50% of cells addressed by SNP/oligonucleotide CGH. An 8 year old girl presented with intellectual disability, autistic features, microcephaly, large upper incisors, small lower jaw, hypertrichosis, and pectus excavatum. Cytogenetic analysis has indicated the presence of a deletion at the short arm of chromosome 8 in about 60% of cells. SNP/oligonucleotide CGH has confirmed the presence of mosaic terminal deletion at 8p21.3p23.1 spanning about 11.152 Mb affecting 178 genes. Molecular cytogenetic analysis showed that 48% of cells are affected by this deletion. Clinically, the index case resembles non-mosaic deletions of 8p23. Nevertheless, milder manifestations of intellectual disability, microcephaly and facial dismorphisms were noticed, whereas autistic features were found to be more prominent. Interestingly, genomic loci flanking the breakpoint of mosaic deletion were regularly deleted. The regular deletion spanned three olfactory receptor (OR) genes (OR7E158P, OR7E161P, OR7E160P) and three beta-defensin (DEFB) genes (DEFB137, DEFB136, DEFB134). Since OR gene clusters are known to be involved in generation of 8p chromosome rearrangements, we have hypothesized that at least in the present case DEFB gene cluster is also involved in chromosome abnormality formation. Finally, to our knowledge this is the first case of a mosaic 8p deletion addressed by SNP/oligonucleotide CGH and mediated by OR gene recombination. Supported by the Russian Federation President Grant (MD-4401.2013.7).

Differential allelic expression of the SOS1 c.755C activating variant in a Noonan syndrome family

*S. Moncini[1], M. T. Bonati[2], I. Morella[3], L. Ferrari[1], R. Brambilla[3], **P. Riva**[1];*
[1]Dipartimento di Biotecnologie Mediche e Medicina Traslazionale - Università degli Studi di Milano, Milano, Italy, [2]IRCCS Istituto Auxologico Italiano, Milano, Italy, [3]Istituto Scientifico San Raffaele, Milano, Italy.

Noonan Syndrome (NS) is a genetic condition characterized by congenital heart defects, short stature and characteristic facial features. We analyzed a girl with moderate learning disabilities, delayed language development, craniofacial features and skin anomalies reminiscent of NS. After a mutation screening of the known NS genes PTPN11, SOS1, RAF1, KRAS, GRB2, BRAF and SHOC2 we found the heterozygous c.755T/C variation in SOS1 causing the I252T substitution, which was considered possibly pathogenetic by bioinformatic predictions. The same mutation was present in the proband's mother and maternal grandfather, both displaying some NS features, but also by a healthy subject on 1000 genomes analyzed. The functional analysis revealed that the SOS1 c.755T/C activated the Ras effector Erk1, confirming the predicted pathogenetic substitution. To explain the incomplete penetrance of the reported mutation we hypothesized that SOS1 may be subjected to a differential allelic expression (DAE). Interestingly, after sequencing the cDNA from peripheral blood compared to genomic DNA, we showed a DAE of some known SOS1 SNSs in healthy individuals and observed the mutated allele C 50% more expressed than the normal allele T in all our NS familial carriers. The similar level of SOS1 mRNA, between mutated and control individuals, suggests that the mutation here described does not affect SOS1 expression. We are now evaluating the SOS1 promoter polymorphisms. This study, providing the first evidence of allelic imbalance of SOS1, pinpoint DAE as a possible mechanism underlying a different penetrance of some SOS1 mutated alleles in unrelated carriers.

P13.20-M
Association of genetic factors involved in folate metabolism and the occurrence of congenital heart defects in individuals with Down syndrome

*C. C. Mendes, I. G. Forte, J. A. Setino, J. M. Biselli-Périco, B. L. Zampieri, D. B. Victorino, E. M. Goloni-Bertollo, **É. C. Pavarino**;*
Faculdade de Medicina de São José do Rio Preto - FAMERP, São José do Rio Preto, Brazil.

Down syndrome (DS) individuals with polymorphisms in genes involved in folate metabolism can have increased risk for developing congenital heart defects, which are the leading cause of death in the first years of life. Moreover, these polymorphisms in mothers may also be associated with the risk for congenital heart disease in DS offspring. This study investigated whether the presence of the *MTHFR* C677T, *MTHFR* A1298C, *MTHFR* T1317C, *MTR* A2756G, *RFC1* A80G, *MTRR* A66G, *TC2* C776G, *TC2* A67G, *CBS* 844ins68, *CBS* T833C, *BHMT* G742A, *MTHFD1* G1958A, *DHFR* del 19 bp and *SHMT* C1420T polymorphisms in DS individuals and their mothers is associated with congenital heart defects. We evaluated 86 individuals with free trisomy 21 and their mothers, attended by Genetics Service at Faculdade de Medicina de São José do Rio Preto at the period 2005-2008. The investigation of polymorphisms was performed by Polymerase Chain Reaction (PCR), Real time PCR and PCR followed by digestion. The *RFC1* 80G polymorphic allele increased the risk for interatrial communication (IAC) (OR=7.92, CI=1.21-51.84, P=0.03) when in DS individuals. The *BHMT* 742A maternal polymorphic allele increased the risk of atrioventricular septal defect (AVSD) (OR=10.50; C=1.36-81.06; P=0.02) and interventricular communication

(IVC) (OR=18.00; CI=2.0-159.09; P=0.009) in DS offspring. We conclude that the *RFC1* A80G polymorphism in DS individuals is associated with the risk for IAC and *BHMT* G742A maternal polymorphism is associated with risk for AVSD and IVC in DS offspring.

P13.21-S
Protective action of NADPH oxidase inhibitors and the role of NADPH oxidase in the pathogenesis of colon inflammation in mice

V. Salteniene, *R. Ramonaite, S. Juzenas, J. Kupcinskas, J. Skieceviciene, L. Kupcinskas; Lithuanian University of Health Sciences Institute for Digestive Research, Kaunas, Lithuania.*

AIM: To investigate the role of NADPH oxidase in colon epithelial cells in pathogenesis of acute and chronic colon inflammation using mice dextran sulphate sodium (DSS) colitis model.
METHODS: BALB/c mice were divided into three groups: 8 mice with acute DSS colitis, 8 mice with chronic DSS colitis and 12 mice without DSS supplementation as control group. The primary colonic epithelial cells were isolated using chelation method. The cells were cultivated in the presence of mediators (lipopolysaccharide (LPS), apocynin or diphenyleneiodonium). Viability of cells was assessed by fluorescent microscopy. Production of reactive oxygen species (ROS) by the cells was measured fluorimetrically using Amplex Red. Production of tumour necrosis factor- alpha (TNF- α) by the colonic epithelial cells was analysed by ELISA. Nox1 gene expression was assessed by real-time (RT) PCR.
RESULTS: Our study showed that TNF-α level was increased in unstimulated primary colonic cells both in the acute and chronic DSS colitis groups, whereas decreased viability, increased ROS production, and expression of Nox1 was characteristic only for chronic DSS colitis mice when compared to the controls. The stimulation by LPS increased ROS generation via NADPH oxidase and decreased cell viability in mice with acute DSS colitis. Treatment with NADPH oxidase inhibitors increased cell viability decreased the levels of ROS and TNF- α in the LPS-treated cells isolated from mice of both acute and chronic DSS colitis groups.
CONCLUSION: Our study revealed the importance of NADPH oxidase in pathogenesis of both acute and chronic inflammation of the colon.

P13.22-M
Centromere of chromosome 9 presents unusual behavior in rearrangements leading to complete 9p duplication

R. S. Guilherme[1], *A. B. A. Perez*[1], *V. A. Meloni*[1], *A. L. Pilla*[1], *M. A. P. Ramos*[1], *A. G. Dantas*[1], *S. S. Takeno*[1], *L. D. Kulikowski*[2], *M. I. Melaragno*[1];
[1]*University Federal of São Paulo, São Paulo, Brazil,* [2]*University of São Paulo, São Paulo, Brazil.*

Trisomy 9p is one of the most common partial trisomies found in newborn, possibly because this region is relatively poor in genes resulting in a high survival rate. We report four different chromosome rearrangements resulting in complete 9p duplication, three of them involving 9p centromere alterations. The rearrangements in the patients were characterized by G-banding, SNP-array and FISH (Fluorescent *in situ* Hybridization) with different probes. One presents 9p duplication concomitant to 18p deletion due to an inherited der(18)t(9;18)(p11.2;p11.31)mat. Two patients present de novo dicentric chromosomes: der(9;15)t(9;15)(p11.2;p13) and der(9;21)t(9;21)(p13.1;p13.1), respectively. Another patient presents two rearranged chromosomes: a der(12)t(9;12)(q21.13;p13.33) and concomitant i(9)(p10) which showed a FISH centromeric signal smaller than its homologous. Besides the duplication 9p24.3p13.1, array revealed deletion in 9q13q21.13 (7.3 Mb). This rearrangement may have been originated by a misdivision centric fission resulting in a smaller centromere in i(9p) and part of the 9q long arm being translocated to the distal 12p. The deletion 9q may have been caused during the rearrangement with the chromosome 12. The chromosome 9 is rich in segmental duplications, especially in pericentromeric region, with high degree of sequence identity to sequences in 15p, 18p and 21p, chromosomes involved in our rearrangements. In two patients the dicentric chromosomes formed may have been converted into stable functional monocentric chromosomes by epigenetic centromere inactivation followed by heterochromatinization. Thus, we suggest that chromosome 9 is prone to illegal recombination, either intra or interchromosomal, that predispose it to rearrangements, frequently involving pericentromeric regions (Financial support FAPESP, Brazil).

Multiprobe FISH method for enhanced detection of chromosome 9 heterochromatin rearrangements

A. Sipek jr.[1], *A. Panczak*[1], *R. Mihalova*[1], *L. Hrckova*[1], *E. Suttrova*[1], *M. Janashia*[1], *P. Lonsky*[2], *A. Sipek*[2,3], *M. Kohoutova*[1];
[1]*Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University, Prague, Czech Republic,* [2]*Department of Medical Genetics, Pronatal Sanatorium, Prague, Czech Republic,* [3]*Department of Medical Genetics, Thomayer Hospital, Prague, Czech Republic.*

Heterochromatin rearrangements are believed to be clinically insignificant variants of the human karyotype. However, several authors have studied the possible association of heterochromatin variants with certain clinical diagnoses, especially with reproduction failure. Variants of heterochromatin area of chromosome 9 are the most common. They involve enlargement (qh+) or shortening (qh-) of the heterochromatin block as well as the pericentric inversion - inv(9)(p12q13). More complex variants of this area may include duplication and/or combination of above mentioned rearrangements.
Distinguishing between benign and pathological rearrangement in this area can be challenging. The classical G and/or C-banding are not very specific and array methods like SNP-array/array-CGH are usually not able to analyse precisely this pericentric region, which is composed mainly of satellite DNA.
For enhanced analysis of heterochromatin area of chromosome 9 we implemented a special molecular cytogenetic method using three different FISH probes - centromeric alpha-satellite, centromeric III-DNA satellite and a specific BAC probe (hybridizing on 9p12 and 9q13 homologous sequences). The outcomes of this examination in 20 patients with different clinical indications are demonstrated.
Although believed to be benign, the heterochomatin variants of chromosome 9 have been repeatedly mentioned as potentially associated with reproduction failure. Since the majority of these variants are undoubtedly truly benign, presented molecular cytogenetic examination is able to analyse this region more precisely than standard banding methods and distinguish among different (sub)variants of chromosome 9 much better than karyotyping and point out these potentially harmful.
This study was supported by the GAUK 523456 grant project.

P13.25-S
De novo case of a mosaic small supernumerary marker chromosome leading to proximal partial trisomy 5p

I. Škrlec[1], *S. Pušeljić*[2], *M. Heffer*[1], *T. Liehr*[3], *J. Wagner*[1];
[1]*Cytogenetics Laboratory, Department of Medical Biology, School of Medicine, J. J. Strossmayer University in Osijek, Osijek, Croatia,* [2]*Pediatric Clinics, Clinical Hospital Center Osijek, Osijek, Croatia,* [3]*Institute of Human Genetics, Jena University Hospital, Jena, Germany.*

Small supernumerary marker chromosomes (sSMC) are structurally abnormal parts of the karyotype with unknown origin that may arise de novo or be inherited from parents. ~70% of people with sSMC grow and develop normally, while 30% show different clinical signs and symptoms. Here we present the clinical and cytogenetic findings in a 1-year-old female referred for genetic evaluation because of dysmorphic features, including hypotonia, umbilical hernia, hypertelorism, broad nasal bridge, microretrognathia, low set ears, and wide spaced nipples. Cytogenetic examination of GTG banded metaphases showed a female karyotype with mosaicism of an sSMC. Additional molecular cytogenetics analysis (cenM-FISH and subcenM-FISH) characterized the sSMC to be derived from chromosome 5 including heterochromatic and euchromatic material. The shape of sSMC was not clearly to define; either it is a ring or centric minute. The karyotype can be reported as : mos 47,XX,1qh+pat,+der(5)?r(5)(::p1?4→q11.1::)[3]/der(5)?min(5)(:p1?4→q11.1:)[1]dn[38]/46,XX,1qh+pat[62]. Proband's twin sister and parents have normal karyotypes with respect to the sSMC. According to the literature, there are several cytogenetically similar cases described but with different clinical features. The most cases of proximal partial trisomy 5p arose in connection with familial translocations, while just five cases are due to a pure sSMC(5). The critical region for trisomy 5p syndrome seems to be located in the distal part of the short arm as the symptoms are similar to those seen in cases with pure trisomy 5pter to 5p13. The most common features are mental retardation, facial dysmorphism and hypotonia according to webpage "Small supernumerary marker chromosomes" (http://ssmc-tl.com/sSMC.html).

P13.26-M
Defining the role of CGGBP1 protein in FMR1 gene expression

M. Goracci, *S. Lanni, G. Mancano, F. Palumbo, P. Chiurazzi, E. Tabolacci, G. Neri; Institute of Medical Genetics-Catholic University, Rome, Italy.*

Fragile X syndrome (FXS) is the most common heritable form of cognitive impairment and is caused by the expansion over 200 repeats and subsequent methylation of the CGG triplets at the 5' UTR of the FMR1 gene, leading to gene silencing. The epigenetic and molecular mechanisms responsible for FMR1 gene silencing are still unclear. To outline structure-specific proteins that could recruit components of the silencing machinery we investigated the role of CGGBP1 in FMR1 gene transcription. CGGBP1 is a highly conser-

ved protein which binds specifically unmethylated CGG tracts. The role of CGGBP1 on FMR1 transcription is yet to be defined. Sequencing analysis and expression studies through quantitative PCR of CGGBP1 were performed in cell lines with different allele expansions (wild-type WT, premutation, methylated full mutations FXS and unmethylated full mutation UFM), demonstrating no differences between them. ChIP assays showed that CGGBP1 binds unmethylated CGG triplets of the FMR1 gene proportionally to the length of the repeats. We also observed that CGGBP1 binding to the FMR1 locus was restored after pharmacological demethylation with 5-azadC of FXS alleles, suggesting a possible role for CGGBP1 in FMR1 expression. CGGBP1 silencing with siRNA (reaching ~ 85% of CGGBP1-mRNA depletion) did not affect FMR1 transcription in WT and UFM fibroblasts. Although the strong binding to the CGG tract could suggest a relevant role of CGGBP1 on FMR1 gene expression, our results demonstrate that CGGBP1 is not a direct regulator of FMR1 transcription.

G6PD-Meyer: a new mutation causing compensated chronic haemolysis

A. Citana[1], *D. Leone*[1], *F. Moruzzi*[1], *G. Ivaldi*[1], *T. Casini*[2], *C. Cecchi*[2], *R. Notaro*[3], *M. Berardi*[3], *D. A. Coviello*[1], *L. Luzzatto*[3];
[1]*E.O. Ospedali Galliera, Laboratorio di Genetica Umana, Genoa, Italy,* [2]*A.O.U. Meyer, U.O. Oncoematologia, Florence, Italy,* [3]*Istututo Toscano Tumori, Florence, Italy.*

An updated database reports 186 different G6PD mutations. Many of these are polymorphic in various populations; many are sporadic, having been discovered because they cause chronic non-spherocytic haemolytic anemia (CNSHA) associated with severe enzyme deficiency (WHO class I).
A little boy with a history of neonatal jaundice treated with phototherapy, and of anemia (Hb 80-90 G/L) during his first semester, was seen at age 3.4 years. He is clinically well, with no significant physical findings; Hb 110 G/L, MCV 95, MCH 31, MCHC 33, reticulocytes 271x109/L, bilirubin 22 µmol/L: indicating a well compensated haemolytic condition. G6PD activity was 0.89 IU/GHb (ref values 7-10 IU/GHb). Sequencing the G6PD gene revealed an A->G change in exon 7 at nucleotide 655, predicting an Arg->Gly change at codon 219. The mother was shown to be heterozygous for the same mutation: her G6PD assay was normal. This mutation is not present in the database and therefore it is a new sporadic class I mutation. We interpret the CNSHA phenotype as related to the fact that Arg->Gly is a rather drastic amino acid change, since it entails a charge change as well as a steric change: such changes are likely to cause decreased stability of the G6PD protein and enzyme deficiency. It is interesting that Arg219 is not a conserved residue: we have previously reported that in terms of clinical phenotype the consequences in such cases would not be so drastic, and this may explain why this child does have haemolysis but only mild anemia.

P13.28-M

Large duplication implicating only exon 1 of F8 gene in mild hemophilia A phenotype

N. Lannoy[1], *C. Bandelier*[1], *B. Grisart*[2], *H. Antoine-Poirel*[1], *C. Hermans*[3];
[1]*Center of Human Genetics, Brussels, Belgium,* [2]*Center of Human Genetics, Charleroi (Gosselies), Belgium,* [3]*Hemostasis and Thrombosis Unit, Brussels, Belgium.*

In 98% of mild hemophilia A (HA) patients, a missense mutation spread throughout the Factor 8 (F8) gene's 26 exons can be identified using complete gene sequencing. In this study, 12 French-speaking Belgian with mild HA to whom any mutation could be identified by complete sequencing, multiplex ligation-dependent probe amplification (MLPA) analysis was performed as a second step. This gene dosage technique allowed for the detection of exon 1 duplication of the F8 gene in three apparently unrelated subjects. Using array-comparative genomic hybridization, breakpoint analysis delimited the duplication extent to 210 kb in the F8 gene intron 1 and in the VBP1 gene intragenic position. We postulated that the rearrangement responsible for this duplication could have arisen due to symmetrical tandem inversion duplication resulting in resulting in a large rearrangement of F8 gene intron 1 of 233 kb. This intron revised should allow the production of small number of normal mRNA transcripts in relation with mild HA phenotype. Indeed, the F8 gene mRNA from Patient 1 unexpectedly exhibited normal amplification of the segment containing exons 1 to 9 and reduced cross-reacting material (CRM), compatible with the patient's mild disease severity. All patients displayed an identical F8 haplotype, despite not being related, which suggests a possible founder effect of a 210 kb-large duplication involving the F8 gene exon 1.
The present study will need to be confirmed on a larger cohort of same genetic origin/background to evaluate for prevalence of the duplication as a cause genotype in mild HA patients.

P13.29-S

Subtelomeric chromosomal breakages characterization in patients with intellectual Disabilities/Congenital Anomalies and mechanisms for formation

G. M. Novo-Filho[1,2], *E. A. Zanardo*[1,2], *R. L. Dutra*[1,2], *A. T. Dias*[1], *M. M. Montenegro*[1], *F. A. S. L. Souza*[1], *A. M. Nascimento*[1], *N. A. Fernandes*[2], *C. O. Santos*[1], *T. V. M. M. Moura*[1], *F. B. Piazzon*[1], *C. A. Kim*[2], **L. D. Kulikowski**[1];
[1]*Department of Pathology, Cytogenomics Laboratory/ LIM 03, HC-FMUSP, São Paulo, Brazil, São Paulo, Brazil,* [2]*Genetics Unit, Department of Pediatrics/ LIM 36, HC-FMUSP, São Paulo, Brazil, São Paulo, Brazil.*

Abnormal CNVs are frequently found in subtelomeres of patients with intellectual disabilities (ID) and congenital anomalies (CA). The subtelomeric rearrangements do not usually present recurrent breakpoints (BPs) and involve several different chromosomes ends. Although these regions encompass approximately 30% of pathogenic CNVs, the causes of subtelomeric breakages and repair have not yet been investigated comprehensively. We investigated 105 unrelated patients with ID/CA using MLPA, FISH and arrays (BeadChip-Illumina/CGH-array-Agilent) in order to characterize the subtelomeric BP. Within the set of subtelomeric rearrangement studied, the deleted regions ranged from 137 kb to 29 Mb, and the duplicated regions from 155 kb to 32 Mb. We identified 38 BPs, from 19 different regions. Our analysis showed repetitive elements in 31 BPs encompassing SINEs (Alu; MIR), LINEs (L1; L2), and LTRs. We also found six BPs presenting simple tandem repeats and two BPs with interstitial telomeric sequences (ITs). Rearrangements with exclusively deletions are suggested to be caused by non-homologous end joining (NHEJ) or microhomology-mediated end joining (MMEJ) mechanisms. Complex rearrangements are likely caused by fork stalling and template switching (FoSTeS) or microhomology-mediated break-induced replication (MMBIR). Misalignments during replication due the repetitive sequences in these loci can lead to MMBIR and generate the complex dup/del rearrangements observed in 7 of our patients. Furthermore, genomic architectural features, like sequence motifs, non-B DNA conformations, and repetitive elements may increase the susceptibility for DNA breakage or promote FoSTeS in these regions. Mapping subtelomeric BPs should help to clarify the mutational mechanisms involved in these genomic rearrangements.

P13.30-M

Two cryptic duplications detected in an apparently balanced inversion posing a diagnostic challenge

P. C. Evangelidou, *E. Constantinou, A. Alexandrou, N. Salameh, L. Kokkinou, I. Papaevripidou, G. Tanteles, C. Sismani;*
The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

Balanced rearrangements in patients with abnormal phenotype are often associated with cryptic copy number changes (CNCs). These CNCs might not always be the cause of the phenotype and one must be careful prior to interpretation especially in aberrations involving the X chromosome. A 22-year old female patient was referred for cytogenetic analysis because of certain non-specific unusual facial features, a history of hypothyroidism and bilateral hearing loss. Chromosomal analysis revealed a small paracentric inversion on chromosome X with breakpoints at Xq21.1 and Xq23 delineated by FISH using several BACs. Surprisingly, array CGH analysis with a high resolution exon specific X-chromosome array (OGT) revealed two cryptic duplications, 116kb and 184kb in size, on each breakpoint. Cryptic duplications associated with apparently balanced inversions are very rare events. The duplications include coding genes such as *POF1B, ZNF711, SATL1, APOOL* and *LHFPL1.* Therefore the duplication was suspected to be causative for the phenotype as some of these genes included in the duplicated regions might partially explain the phenotype of the patient, e.g *LHFPL1* which has been previously found to be associated with hearing loss. Family studies revealed the same duplication in the father and grandmother of the patient. The father and grandmother have no remarkable clinical features with the exception of hypothyroidism in the father, rendering the duplication as coincidental rather than pathogenic. This case highlights the need for extended family studies and careful detailed clinical evaluation of other family members carrying the same aberration prior to interpretation and genetic counselling.

P13.31-S

Oncogenic splicing switch to the L isoform of the MAP/Microtubule Affinity-Regulating Kinase 4 (MARK4) gene in glioma through PTB (Polypyrimidine Tract-Binding protein)-driven pre-mRNA alternative splicing

L. Fontana[1], *D. Rovina*[1], *C. Novielli*[1], *E. Maffioli*[1,2], *G. Tedeschi*[1,2], *I. Magnani*[1], *L. Larizza*[1];
[1]*Università degli Studi di Milano, Milan, Italy,* [2]*Fondazione Filarete, Milan, Italy.*

MARK4, a centrosomal serine-threonine kinase that phosphorylates microtubule associated proteins, takes part in cell cycle regulation and proliferation. In glioma we pointed out an imbalance between MARK4 isoforms, proportional to cellular de-differentiation and tumor grade. This imbalance

is triggered by decreased expression of MARK4S, the canonical isoform, associated with overexpression of MARK4L, the alternative isoform with skipping of exon 16.
Having ruled out mutations, CNVs and transcription defects as cause of deregulated MARK4 expression, we searched alterations in alternative splicing at the origin of the observed isoforms imbalance.
Bioinformatic analysis of MARK4 genomic sequence revealed three binding sites for the splicing factor PTB in introns flanking MARK4 alternative exon 16. A functional role for these sites is suggested by the conservation in mouse and the surrounding polypyrimidine rich context. Since in glioma PTB overexpression drives an oncogenic splicing switch favoring exon skipped-isoforms, we performed Western blot on glioma and glioblastoma-derived cancer stem cell samples and found a significant overexpression of PTB, correlating with MARK4L expression. Splicing assay of the designed and differently deleted minigenes revealed that IVS15 contains a functional intronic splicing silencer (ISS). However, mutagenesis of the PTB binding site in this region does not affect minigene splicing, suggesting PTB binds to a non-canonical ISS. Electrophoretic mobility shift coupled to mass spectrometry confirmed the PTB binding to MARK4 IVS15 and its involvement in MARK4 alternative splicing.
Alternative splicing thus emerges as an oncogenic mechanism that through the PTB-mediated regulation of MARK4 isoforms expression fosters proliferation and de-differentiation in glioma.

P13.32-M
Normal and oncogenic proliferation under control of microRNAs: a functional high content screening

D. Sastre[1,2], *I. M. Lima*[2], *J. F. Guerreiro*[1], *D. T. Covas*[2], *M. A. Zago*[2], *R. A. Panepucci*[2];
[1]Federal University of Pará, Belém/PA, Brazil, [2]University of São Paulo, Ribeirão Preto, Brazil.

Cancer cells share several characteristics with normal stem cells especially those concerning cell cycle regulation. Therefore it is believed that cancer cells might arise from stem cells possessing self-renewal capabilities. MicroRNAs (miRs) are small RNA molecules that act regulating gene expression post-transcriptionally by targeting hundreds of mRNAs simultaneously. With this in mind, we hypothesized that significant changes in the cell cycle could be a good indicator for miRs capable of regulating normal and oncogenic proliferation. To test this hypothesis, 2.000 BJ foreskin fibroblasts were transfected with 50nM of 28 microRNAs mimics (pre-miR) and inhibitors (anti-miR) in 96-well microplates. After 5 days, proliferation was measured by XTT assay. Cell cycle classification (EdU assay) and viability (Sytox Green staining) following miR transfection were performed in a High-Content Screening platform. Nineteen treatments significantly altered the cell proliferation. Interestingly, while transfection of pre-miR of miR-20b, miR-101 and miR-181d decreased the proliferation, the corresponding anti-miRs had the opposite effect. Pre-miR-181d, pre-miR-20b and pre-miR-101 had the most cytotoxic effect. Pre-miR-181d and pre-miR-101 induced a significant reduction in the percentage of cells in S phase. Cyclin D1 expression was elevated by anti-miR-101 and by pre-miR-24, indicating that this cell cycle regulator might be the mediator of these miR's effects. These results indicate that these miRs can be good candidates for inducing alterations of interest in the cell cycle, such as speeding it up or slowing it down as desired. Also miR-101 acts as tumor suppressor in colorectal cancer and this role is under evaluation in our lab.

P13.33-S
The evaluation of apoptotic gene expressions, telomerase activity and the effects of insulin like growth factor-I and erythropoietin on apoptosis in an experimental necrotizing enterocolitis mice model

O. Altun Koroglu[1], **B. Durmaz**[2], *M. Akisu*[1], *S. Unlubay*[2], *M. Yalaz*[1], *M. Baka*[3], *O. Cogulu*[2], *H. Akin*[2], *U. Ates*[3], *N. Kultursay*[1];
[1]Ege University, Faculty of Medicine, Department of Pediatrics, Izmir, Turkey, [2]Ege University, Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey, [3]Ege University, Faculty of Medicine, Department of Histology and Embryology, Izmir, Turkey.

Necrotizing enterocolitis (NEC) is a major cause of mortality among premature infants. Apoptosis, which occurs after hypoxia/reoxygenation (H/R), has an important role in the pathogenesis of NEC. Telomerase activity may also be important in the recovery process. The aim of this study is to evaluate the apoptotic gene expressions and telomerase activity in the H/R-induced intestinal mucosa and to investigate whether pre-treatment with insulin-like growth factor-I (IGF-I) and erythropoietin (EPO) could protect the intestinal cells from apoptosis or intestinal injury.
The study set was divided into 4 groups, each containing 10 young Balb/c mice. Group 1 mice were exposed to H/R. Group 2 and group 3 mice were pre-treated with IGF-1 and EPO for 7 days respectively before H/R. Group 4 served as a control group. Intestinal injury was evaluated by histological scoring. TUNEL test and caspase-3 activity was perfromed to asses apoptosis. Pro-apoptotic (p53, Casp3, Tnf, Bax, Fas, Bad) and anti-apoptotic (Bcl2, Bcl-W, Bcl-XL, NF-kB) gene expressions and telomerase activity were studied by Real-Time RT PCR.
IGF-1 and EPO treated animals showed decreased histological damage and decreased apoptosis which was confirmed by TUNEL test and caspase-3 activity. Telomerase activity increased in these groups in addition to increased expression of anti-apoptotic genes ($p< 0.01$). However pro-apoptotic gene expressions were not statistically different ($p>0.05$). In conclusion, the protective effects of IGF-1 and EPO in H/R damage may be due to increased expressions of anti-apoptotic genes.

P13.34-M
Phenotype variability in Slovak NF1 patients related to some mutation characteristics

M. Nemethova[1,2], *A. Bolcekova*[2], *Z. Pysova*[2], *D. Ilencikova*[2], *S. Pozgayova*[2], *L. Kadasi*[1,3], *L. Kovacs*[2], *A. Zatkova*[1];
[1]Institute of Molecular Physiology and Genetics,Slovak Academy of Sciences, Bratislava, Slovakia, [2]2nd Department of Pediatrics, Comenius University Medical School University and Children´s Hospital, Bratislava, Slovakia, [3]Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia.

One of the most frequent autosomal dominant disorders is neurofibromatosis type 1 (NF1). In NF1 patients are usually found at least two of seven consensus clinical features: "café au lait" macules, freckling, Lish nodules, bone dysplasia, glioma of optical pathway, different types of neurofibromas and the first degree relative with confirmed NF1. Our cohort included 108 unrelated Slovak NF1 patients and we identified in 39% (42/108) patients frameshift, in 13% (14/108) missense, in 18.5% (20/108) splicing, in 17% (18/108) nonsense mutations, moreover in 4,5% (5/108) deletion of entire gene type I, in 6% (7/108) large deletions and in 2% (2/108) small in frame deletions. 23% (25/108) of mutations were located in Ras-GRD (Ras GAP related) domain and 21% (23/108) in CSRD (cystein serine rich) domain. "Café au lait" macules were present in all patients, freckling in 87%, Lish nodules in 28%, glioma of optical pathway in 31%, neurofibromas in 56%, and bone dysplasia in 6% of patients. Patients with nonsense mutations show the lowest occurrence of Lish nodules (11%) and the highest incidence of neurofibromas (72%). There are no significant differences between clinical features of patient with mutations in Ras-GRD and CSRD domains. Complete mutation analysis in the first-degree relatives was performed in 51 families. Interestingly, we showed that 63% (32) of the patients from these families carry de novo NF1 mutation. Age of the patients was from 2 to 69 years, 41% patients were younger than 18 years.

P13.35-S
In vitro analysis of alternative splicing of OLR1, a gene involved in atherogenesis and tumorigenesis

E. Morini[1], *J. Tejedor*[2], *B. Rizzacasa*[3], *M. Bellocchi*[4], *F. Ferrè*[5], *A. Botta*[3], *D. Caporossi*[1], *J. Valcárcel*[2], *G. Novelli*[3], *F. Amati*[3];
[1]Dept. of Movement, Humanities and Health Sciences, Foro Italico University, Rome, Italy, [2]Centre de Regulació Genòmica and Universitat Pompeu Fabra, Barcelona, Spain, [3]Dept. of Biomedicine and Prevention, Tor Vergata University, Rome, Italy, [4]Dept. of Sperimental Medicine and Surgery, Tor Vergata University, Rome, Italy, [5]Dept. of Biology, Tor Vergata University, Rome, Italy.

Lectin-like oxidized low-density lipoprotein receptor-1 (LOX-1), encoded by OLR1 gene, is the major endothelial ox-LDL receptor and plays a role in the pathogenesis of atherosclerosis and tumorigenesis.
OLR1 is subjected to a physiological alternative splicing. Two different isoforms are known: Loxin (NM_001172633.1) lacks exon-5 and encodes for a putative truncated receptor (LOXIN) with impaired binding activity; OLR1D4 (NM_001172632.1) lacks exon-4 and the putative protein has a different C-terminus domain. Functional role of OLR1D4 is unknown, while LOXIN is a natural inhibitor of LOX-1-mediated signalling and its up-regulation may have a potential therapeutic effect.
We transfected HeLa cells with minigenes (HIGH/LOW-risk) carrying two different haplotypes of the six SNPs regulating OLR1/Loxin splicing. A dose-curve PMA treatment shows that 10nM PMA at 3h up-regulates Loxin expression (FC10nM=+1.6, $p<0.05$) in HeLa transfected with H-risk haplotype (Hela-H). Loxin increase was not followed by OLR1 up-regulation and the OLR1/Loxin ratio after 10 nM of PMA was lowered to 28.1% than HeLa-H. These results suggest a role of PMA in modulating OLR1 splicing in vitro, leading to an increase of Loxin isoform. Moreover, we performed a computational analysis from different databases (TargetScan, miRanda, Pita) that predicted two microRNAs that bind the 3'UTR of OLR1 gene in nucleotide region in which are located SNPs. So these miRNAs may act as regulators of OLR1 expression and alternative splicing.
These are the first evidences of a regulation of OLR1 splicing, and provide new data addressing a future more selective and personalized therapy for diseases caused by OLR1 over-expression.

P13.36-M
Exploring the role of a ceRNA-based regulatory network, involving GBA and GBAP1, in the pathogenesis of familial Parkinson disease

V. Rimoldi[1], *N. Tonsi*[1], *L. Straniero*[1], *M. Aureli*[1], *S. Goldwurm*[2], *S. Duga*[1], *G. Soldà*[1], *R. Asselta*[1];
[1]*1Dipartimento di Biotecnologie Mediche e Medicina Traslazionale, Università degli Studi di Milano, Milan, Italy,* [2]*Parkinson Institute, Istituti Clinici di Perfezionamento, Milan, Italy.*

Parkinson disease (PD) is a complex neurodegenerative disorder characterized by the loss of dopaminergic neurons of the substantia nigra, which causes motor impairment and resting tremor. To date, mutations in the glucocerebrosidase (GBA) gene represent the most frequent cause of genetic PD. A widespread deficiency of GBA activity was recently demonstrated in the brains of PD patients carrying GBA mutations. Most interestingly, also PD patients without GBA mutations had lower levels of GBA activity in the brain, suggesting that dysregulated GBA expression could contribute to PD susceptibility. Possible mechanisms modulating GBA expression include post-transcriptional networks involving microRNA (miRNAs) and competing-endogenous RNAs (ceRNAs). ceRNAs are a class of regulators that titrate away miRNAs from their targets, thus influencing mRNA expression. The highly-homologous and expressed GBA pseudogene (GBAP1), located 16 kb downstream of GBA, is particularly suited to act as a GBA ceRNA. To verify this hypothesis, we first bioinformatically selected five miRNAs potentially targeting both transcripts, and demonstrated that one of them is significantly overexpressed in whole blood from PD cases vs. controls (2-fold increase, P=0.0028). Then, the miRNA precursor was overexpressed in HeLa/Hek293/HepG2 cells; in all cases, both GBA and GBAP1 endogenous mRNA levels were significant decreased (up to 70%). The specific interaction between the miRNA and its targets was demonstrated by luciferase-based reporter assays. Finally, preliminary overexpression experiments showed that the GBAP1 3'-untranslated region is able to act as a molecular "sponge" of the identified miRNA, thus suggesting the actual existence of a ceRNA-based regulatory network modulating GBA expression.

P13.37-S
Non-coding PAH gene alterations act as new transcription regulators

M. Stojiljkovic, *K. Klaassen, B. Zukic, M. Ugrin, V. Spasovski, N. Novcic, N. Kotur, S. Srzentic, G. Nikcevic, S. Pavlovic;*
IMGGE, University of Belgrade, Belgrade, Serbia.

Phenylketonuria (PKU) is rare metabolic disease caused by mutations in phenylalanine hydroxylase gene (*PAH*). Mutations that abolish structure and function of PAH are main determinant of PKU phenotype. However, phenotype couldn't be always predicted precisely. Previously, we found a transcription enhancer in *PAH* intron 8 that could affect genotype-phenotype correlation. In this study, we functionally analyzed additional non-coding *PAH* gene alterations to propose new transcription regulatory elements.
In silico prediction for transcription factor binding sites pointed to a population-specific promoter alteration (*PAH*: c.-170delC) and VNTR alterations in 3' region, that have never been analyzed before. We transiently transfected HepG2 cell line with various CAT reporter constructs to determine the effect of a *PAH* gene non-coding sequences on transcription. We found that a construct with additional binding site in promoter and constructs with VNTR3, VNTR7 and VNTR8 alterations had a 50-60% reduction of CAT activity in comparison to pBLCAT5. EMSA supershift showed binding of KLF1 transcription factor to the analyzed promoter sequence, while the full structure of VNTR3 was needed to obtain binding of C/EBPalfa.
Our study pointed to two new elements in promoter and 3' region of *PAH* gene that could act as transcription silencers and thus influence genotype-based prediction of PKU severity. Given that these non-coding alterations are population specific, further validation of their relevance should be studied in different populations. New transcription regulators in non-coding regions, like these ones, will contribute to better understanding of PKU phenotype complexity and may become important for optimization of PKU treatment.

P13.38-M
Apparent chromothripsis in a child with a complex chromosome rearrangement resulting in an 11p11.2 microdeletion within the Potocki-Shaffer syndrome region

B. Argiropoulos[1,2], *O. Caluseriu*[3], *K. Bowser*[2], *J. E. Chernos*[1,2];
[1]*University of Calgary, Calgary, AB, Canada,* [2]*Alberta Children's Hospital, Calgary, AB, Canada,* [3]*University of Alberta, Edmonton, AB, Canada.*

Chromothripsis is a phenomenon of genomic rearrangement arising during a single genome-shattering event resulting in multiple chromosome breaks involving one or more chromosomes, followed by imprecise reassembly. We report a case of a 21 month old female presenting with global developmental delay, hypotonia, minor dysmorphic features, nystagmus and multiple café-au-lait spots. Array-CGH analysis identified a 1.15 Mb interstitial deletion within chromosome 11p11.2 that partially overlaps the proximal interval of the Potocki-Schaffer syndrome (PSS) critical region. This deletion does not overlap the EXT2 and ALX4 genes which are associated with the multiple exostoses and parietal foramina phenotypes, respectively, frequently observed in individuals with this syndrome. This deletion does, however, overlap a 137 kb region previously identified as the critical region sufficient to cause hypotonia in PSS. Furthermore, haploinsufficiency of PHF21A, which is deleted in this patient, has been implicated in the intellectual disability and craniofacial anomalies associated with PSS. Chromosome and FISH analyses revealed an unanticipated de novo complex rearrangement involving chromosomes 9, 10 and 11 with at least 8 chromosome breaks: 46,XX,der(9)(10qter->10q24.3::11p11.2->11p13::9p23->9qter),der(10)(10pter->10q24.3::11p13->11p14::9p23->9p24::11p14->11pter),der(11)(9pter->9p24::11q13.5->11p11.22::11q13.5->11qter)dn. Although the deletion within chromosome 11p11.22 was the only clinically significant copy number imbalance, it is unclear if the other chromosome breaks and possible gene disruptions contribute to the patient's phenotype. Similar to other reported instances of apparent germline chromothripsis, this case showed minimal DNA loss presumably reflecting a selection against massive copy number imbalances. This case highlights the importance of performing both array-CGH and conventional cytogenetic methods as either investigation alone would have provided partial information.

P13.39-S
'Unexpected' finding with QF-PCR.

K. Huijsdens-van Amsterdam, *A. van der Kevie-Kersemaekers, A. C. Glas, P. Lakeman, E. Pajkrt, A. C. Knegt;*
Academic Medical Center, Amsterdam, Netherlands.

At 11^{+5} weeks of pregnancy, chorionic villus sampling was performed with referral reason 'DNA analysis for sickle cell anaemia'. The HbS mutation was not identified. As is standard in our laboratory a rapid test for aneuploidy detection, quantitative fluorescence (QF)-PCR. was performed. The QF-PCR pattern of multiple X/Y specific markers was consistent with the presence of two X chromosomes, as well as Y-specific sequence (SRY). This suggested that the fetus could have a XX male genotype. FISH showed that SRY was located on the derivative X chromosome. Additional karyotyping (46, XX.ish der(X) t(X;Y)(p22.3;p11.2)(SRY+)) confirmed the presence of a 46,XX, SRY+ disorder of sexual development. After karyotyping and FISH analysis of both parents, the abberation turned out to be *de novo*. Thus, additional aneuploidy testing resulted in an unexpected finding which complicated the prenatal counselling.
Approximately 1 in 20,000 individuals with a male appearance have a 46,XX testicular disorder. The SRY gene, normally located on the Y chromosome, provides instructions for making the sex-determining region Y protein, which causes a fetus to develop as a male. Ultrasound at 18 weeks of gestation and postnatal inspection and ultrasound showed normal male genitalia. There were no signs of ambiguous genitalia. Parents felt confused by knowing prenatally that their unborn male child will be infertile, because of absence of the Y-chromosomal AZF regions. It is likely that at puberty hormone treatment is necessary to induce development of male secondary sex characteristics with testosterone and to prevent development of gynaecomasty.

P13.40-M
Post-transcriptional control of RET gene expression: implications in Hirschsprung Disease and Thyroid Cancer

A. Lo Sardo, *P. Griseri, M. Rusmini, F. Caroli, A. Grossi, R. Ravazzolo, I. Ceccherini;*
U.O.C. Genetica Medica, Istituto G.Gaslini, Genova, Italy.

Control of mRNA half-life plays a central role in normal development and disease. mRNA stability depends not only on *cis*-acting sequences, but also on *trans*-acting elements able to promote mRNA degradation.
Though the RET gene is the major known gene involved in Hirschsprung disease (HSCR), a congenital defect of gut innervation, and in Medullary Thyroid Carcinoma (MTC), its role in these disorders has not fully been explored yet. To this end, we sought to characterize molecular events leading to post-transcriptional regulation and to identify genetic variants of RET 3'UTR predisposing to HSCR and MTC development. Starting from a large set of DNA samples from patients affected with either HSCR or sporadic MTC, we focused on RET variants lying in candidate regulatory regions or miRNAs target sequences of the distal gene portion. To this end, a next generation sequencing approach for the whole RET gene has been undertaken. Alleles of variants located in proximity of Poly-Adenylation cleavage sites and putative regulatory elements have turned out differently distributed among HSCR, MTC and control samples. Moreover, linkage disequilibrium is apparently stronger in cases than in controls, thus further suggesting that functional

3'UTR variants may be responsible for variable susceptibility to RET-related pathologies. Furthermore, to identify AU-rich regions, microRNAs and binding factors involved in the post-transcriptional control, the RET 3'UTR was fragmented in three parts and cloned into a luciferase vector. Preliminary results show different effects on mRNA stability for these fragments both in RET-positive and RET-negative cell lines.

Mosaic ring chomosome 17 : a new case

A. Receveur[1], E. Bourel[2], J. Andrieux[3], M. Barathon[4], G. Morin[5], F. Amram[5], T. Dery[1], F. Jobic[5], G. Jedraszak[5], M. Mathieu-Dramard[5], H. Copin[1], **B. Demeer**[5];
[1]Cytogenetics department, University hospital, amiens, France, [2]neuropediatrics department, University hospital, amiens, France, [3]Medical genetics department, Jeanne de Flandre Hospital, lille, France, [4]pediatrics department, Creil hospital, creil, France, [5]Genetics department, University hospital, amiens, France.

Ring 17 syndrome is a rare disorder and only 19 cases have been reported so far. Severity of the associated phenotype is influenced by the presence or deletion of the Miller-Dieker critical region (MDCR) with presence of the MDCR being associated with milder phenotypes, including growth delay , intellectual disability, epilepsy, café au lait skin spots and minor facial dysmorphism. We report a patient born at 41 gestation weeks after an uneventful pregnancy, with normal birth parameters - weight : 3kg350, length : 49 cm-. The Initial psychomotor development was normal. When he was 3 years old the patient developed fronto-parietal epilepsy. Cytogenetic investigations from peripheral blood cells showed a mosaic ring chromosome 17 karyotype :mos 46,XY,r(17)(p13;q25)[42]/45,XY,-17[5]/46,XY[3]. At 6 years of age, he had generalised epilepsy, developmental delay, school difficulties, and attention deficit disorder. Clinical examination showed no facial dysmorphism and no growth delay. Skin changes showed sparse café au lait spots but no axillary or inguinal freckling, and 2 small achromic spots. Cerebral MRI, cardiac ultrasound and ophtalmological fundus were normal. Molecular cytogenetic investigations confirmed that no terminal deletion had occurred, and an array-CGH (Agilent 44K) did not detect any submicroscopic deletion or duplication. Chromosome analysis were also obtained on café au lait skin spot and normal skin, and are currently being studied. Data from the patient will be compared to the literature, including the recent reports which raised the hypothesis of telomere shortening and telomere position effect in mild ring 17 syndrome.

P13.42-M
Somatic structural genome variations (chromosome rearrangements) are common in children with intellectual disability, congenital malformations and autism

S. G. Vorsanova[1,2,3], *Y. B. Yurov[1,2,3], M. A. Zelenova[1,2], O. S. Kurinnaia[1,2,3], T. Liehr[4], A. D. Kolotii[1,2], I. A. Demidova[1,2,3], V. S. Kravets[1,2,3], S. A. Korostelev[5], I. Y. Iourov[1,2,6];*
[1]National Research Center of Mental Health, RAMS, Moscow, Russian Federation, [2]Institute of Paediatrics and Paediatric Surgery, Ministry of Health, Moscow, Russian Federation, [3]Moscow City University of Psychology and Education, Moscow, Russian Federation, [4]Institute of Human Genetics, Jena, Germany, [5]The State Educational Institution of Professional Training under the Federal Agency of Health Care and Social Development, Moscow, Russian Federation, [6]Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.

Classically, common pathogenic somatic genome variations are attributed to mosaic aneuploidy or polyploidy. However, recent reports on somatic mosaicism have demonstrated that mosaic structural genomic rearrangements (chromosome abnormalities) are likely to underlie intellectual disability, congenital malformations and autism as low-level mosaic aneuploidy does. To get further insight into possible role of somatic structural genome variations in disease, we have analyzed 202 patients with intellectual disability, congenital malformations and autism using SNP/oligonucleotide array CGH (two array CGH platforms with a resolution of 1 and 15 kb). Low-level mosaic aneuploidy (additional chromosome Y in about 5% of cells) was found in 2 cases (1%). Mosaic structural genomic rearrangements associated with a phenotypic outcome (according to an original bioinformatic technology) were detected in 14 cases (6.9%). These were mosaic duplications at 1q21.1q21.2 (1.9Mb), 11p15.5 (1.3Mb), 11p14.3 (8.4Mb) and mosaic deletions at 1p36.33p36.23 (7Mb), 2q22.1q23.3 (10.2Mb), 2q23.3q24.2 (10.7Mb), 5q14.3q15 (6.3Mb), 7q35q36.3 (14.6Mb), 8p23.3p23.1 (11.1Mb), 11q23.3 (0.1Mb), 21q11.1q21.2 (11.4Mb) and Xq28 (MECP2) (0.09Mb). Moreover, two cases have demonstrated low-level mosaicsim for isochromosome 12p and small supernumerary chromosome, which represented min(17)(:p11.2->q11.1:) (8Mb). These rearrangements were further confirmed by FISH and/or multicolor banding. Additionally, two benign mosaic subchromosomal aberrations (deletion at 14q11.2 in 7 cases; duplication at Xq28 in 2 cases) were observed. To our knowledge, such somatic genome variations (recurrent and benign) were not reported. Our data evidence that somatic genome variations manifesting as structural rearrangements are relatively common among children with intellectual disability, congenital malformations and autism. Supported by the Russian Federation President Grant (MD-4401.2013.7).

P13.43-S
Assessing the impact of exonic variants on splicing regulation by functional analysis and bioinformatics predictions: BRCA2 exon 18 as a model system

P. Gaildrat[1], G. Castelain[1], O. Soukarieh[1], S. Krieger[2], S. Caputo[3], J. Abdat[1], S. Aklil[1], D. Di Giacomo[1], A. Drouet[1], C. Houdayer[3], M. Guillaud-Bataille[4], C. Delnatte[5], F. Revillion[6], F. Bonnet[7], C. Delvincourt[8], F. Vaz[9], O. Sinilnikova[10], M. Leone[10], E. Rouleau[3], M. Tosi[1], T. Frebourg[11], **A. Martins**[1];
[1]Inserm U1079 and Rouen University, Rouen, France, [2]Centre François Baclesse, Caen, France, [3]Institut Curie, Paris, France, [4]Institut Gustave Roussy, Villejuif, France, [5]CHU, Institut de Biologie, Hôtel Dieu, Nantes, France, [6]Centre Oscar Lambret, Lille, France, [7]Institut Bergonié, Bordeaux, France, [8]CHU, Institut Jean Godinot, Reims, France, [9]Instituto Portugues de Oncologia, Lisbon, Portugal, [10]Hospices civils de Lyon and Centre Léon Bérard, Lyon, France, [11]Inserm U1079 and Rouen University Hospital, Rouen, France.

Sequence changes in exons can alter pre-mRNA splicing either by changing splice sites or by modifying exonic splicing regulatory elements (ESR). The effects on ESR are especially difficult to predict by using currently available bioinformatics tools. Here, we used as a model system the exon 18 of BRCA2 gene involved in breast-ovarian cancer predisposition, and tested the impact on splicing of 36 variants identified in patients or reported in public databases. By using a splicing minigene assay, we found that 13 (7 missense, 4 synonymous, 1 nonsense and 1 in frame deletion variants) out of these 36 variations induce an increase in exon 18 skipping, by potentially modifying ESR. When patient blood RNA was available (n=4), the effects of the variants were confirmed. Recently, we demonstrated the predictive value of ESR hexamers' scores established by Ke et al. (2011) in identifying splicing regulatory mutations within BRCA2 exon 7 (Di Giacomo et al, 2013). Here, we show that this approach is also able to predict the effect on splicing regulation of BRCA2 exon 18 variants. Together with segregation data, these results should contribute to the classification of variants of unknown significance in BRCA2 exon 18. In addition, this study extends the validation of a new in silico tool for predicting the impact of exonic variants on ESR. This tool may have important applications in the filtering strategy allowing the discovery of pathogenic mutations among the large fraction of variants detected by high throughput sequencing.

P13.44-M
„Stress Entropic Load" as a Transgenerational Epigenetic Response Trigger

J. Bienertova-Vasku, *I. Necesanek, F. Zlamal, A. Vasku;*
Department of Pathological Physiology, Masaryk University, Brno, Czech Republic.

Epigenetic changes are generally based on the switching of alternative functional or structural states and result in the adaptation of cellular expression patterns during proliferation, differentiation or plastic changes in the adult organism, whereas some epigenetic information can be passed on other generations while other is not. Hence, the principal question is: why is some information reset or resolved during the meiosis process and other is passed from one generation to anohter, or, in other words: what "adaptation trigger" level initiates transgenerationally transmitted epigenome change? Hereto, we propose a theory which states that stress, or, more specifically, the energy cost of an individual's adaptation to stress, represents a viable candidate for the transgenerational transmission trigger of a given acquired trait. It has been reported recently that the higher lifetime entropy generation of a unit's body mass, the higher the entropy stress level (which is a measure of energy released by a unit's organ mass where k = heat) and the irreversibility within the organ, resulting in faster organ degradation and consequent health problems for the entire biological system.
We therefore suggest a new variable: "stress entropic load" actually reflecting the energetic cost of an individual's adaptation that may be used to estimate the probability of inducing transgenerational response and propose methods for its estimation

P13.45-S
Prenatal diagnosis of partial trisomy 14 and partial trisomy 18 due to a 3:1 segregation of maternal reciprocal translocation t(14;18)(q13;q12.2)

I. Tonkovic Djurisevic, *K. Crkvenac Gornik, M. Miklos, S. Huljev Frkovic, L. Letica, R. Lasan, D. Begovic;*
Division of Genetics, Department of Pediatrics, University Hospital Centre Zagreb, Zagreb, Croatia.

A 30-year-old woman was a known carrier of a balanced translocation 46,XX, t(14;18)(q13;q12.2), ascertained prenatally 30 years ago, when her

mother performed amniocentesis because of advanced maternal age. Karyotyping was confirmed by FISH five years ago. The woman with a known balanced translocation between chromosomal bands 14q13 and 18q12.2 was referred for prenatal diagnosis by amniocentesis at 17 weeks of gestation. Cytogenetic analysis of the father's lymphocytes showed a normal male karyotype 46,XY. Their first baby had normal karyotype 46,XX, also prenatally observed. We present the case of prenatally diagnosed tertiary trisomy with supernumerary derivative chromosome 14, due to a 3:1 segregation of maternal reciprocal translocation. The fetal karyotype was 47,XX,+der(14)t(14;18)(q13;q12.2)mat, resulting in partial trisomy 14(pter-q13) and partial trisomy 18 (q12.2-qter). There was no evidence of fetal malformations by ultrasound examination. After the amniocentesis procedure, amniotic fluid has leaked and the mother miscarried. In reciprocal translocation carriers these chromosomes can arise in different segregation modes, such as alternate, adjacent-1, adjacent-2, 3:1 or 4:0, resulting in the formation of 32 possible zygotes with different chromosome complements. This case supports the thesis that the incidence of 3:1 segregation is higher in female than in male carriers, more often occurs when one of the derivative chromosomes is relatively small, and also suggests that translocation with acrocentric chromosomes tends to produced 3:1 segregation.

P13.46-M
Mosaic Uniparental Isodisomy (UPD) of 11p, presenting as a regular beta-thalassemia carrier.

C. L. Harteveld, *M. J. v. Belzen, C. A. L. Ruivenkamp, M. J. V. Hoffer, M. Phylipsen;*
Leiden University Medical Center, Leiden, Netherlands.

Recently we discovered three independent cases of "severe late onset β-thalassemia", all presenting with the mild phenotype of beta thalassemia minor up to adult age and developing a severe transfusion dependent phenotype in the third and fourth decade of life when a presumed homozygosity for the beta-thalassemia mutation is observed. Affymetrix and/or Illumina SNP-array analysis revealed incomplete homozygosity for SNP's along almost the entire short arm of chromosome 11 containing the beta-globin gene, indicating mosaicism for a partial uniparental isodisomy of chromosome 11p. Three patients were born asymptomatic as beta-thal carriers and developed a severe blood-transfusion dependent beta-thalassemia major at different ages and with different percentages of mosaicism. Recently we discovered another case showing a similar mosaic UPD of 11p, presenting as a regular beta-thalassemia carrier. The fourth patient however did not develop the clinical severity despite of an almost 50% mosaicism determined from the DNA isolated from leucocytes. The most probable mechanism seems clonal selection for hematopoietic stem cells containing the uniparental isodisomy for the mutant beta-globin gene during life, this may account for the progressive development of the disease. However, there seems to be no correlation between the percentage of mosaicism measured in the DNA isolated from the white cells and the severity of the clinical phenotype related to the expression in red cells, which strongly suggests hematopoietic tissue heterogeneity for the observed UPD containing cell lineages. This may have serious consequences for disease prediction and counseling, as this is largely dependent upon DNA isolated from leucocytes.

P13.47-S
Cryptic genomic imbalances and developmental delay and/or congenital defects in apparently balanced rearrangement carriers

B. Hernández-Charro, *M. Moreno Igoa, A. Bengoa, A. Pérez-Juana, C. Catalli, M. Ramos-Arroyo;*
Complejo Hospitalario de Navarra, Pamplona, Spain.

Apparently balanced chromosomal rearrangements (ABCRs) are associated with an abnormal phenotype in 6% of cases. It has been described that in over 40% of cases thie phenotype may be caused by cryptic genomic imbalances, both at the breakpoints (25%) and elsewhere in the genome (15%). However, cryptic genomic imbalances detectable by array-CGH have also been postulated as the underlying cause of developmental delay and/or congenital abnormalities (DD/MCA) in 10-15% of patients with normal karyotype. The aim of this study is to determine if copy number variants are in fact a major genetic defect associated with DD/MCA in ABCRs carriers,
We performed CGH-array studies in three groups of patients: G1.1: 21 ABCR carriers with DD/MCA; G1.2: 22 ABCR carriers with normal phenotype and G2: 45 cases with normal karyotype and DD/MCA. Similar number of pathogenic imbalances were detected in both groups of patients with DD/MCA, independently of their karyotype (5/21 of cases in G1.1 (24%) and 9/45 in G2 (20%)). Only one of the ABCR carriers (5% of cases) had an imbalance at the breakpoints.
Conclusion: Simple ABCR do not seem to confer an independent and significantly higher risk for DD/MCA associated with genomic imbalances,

P13.48-M
Patterns of X inactivation in abnormal X chromosome

P. S. Fahmy;
National Research Center, Cairo, Egypt.

Background: X inactivation is a dose compensation mechanism which results in silencing majority of genes on one of the two X chromosomes in every somatic cell of human females. Early in embryonic development, cells inactivate all their X chromosomes except one. Once an X is chosen, it is stably inherited through subsequent somatic mitotic divisions. The process of X inactivation is under the control of X inactivation center. Purpose: Study of X inactivation patterns in cases with abnormal X chromosome and its correlation with patients phenotype. Methods: 15 selected patients having abnormalities of the X chromosome were subjected to Clinical examination, GTG banding, FISH technique to detect origin of some structural X abnormalities and Detection of X chromosome replication pattern (Late Replicating Chromatin) technique. Results: Cases were classified according to their karyotypes into three groups: Cases with numerical X abnormalities, Cases with iso X chromosome and Cases with other structural X abnormalities. In most of X aneuploidies, each cell has only one active early replicating X, while other extra or abnormal X chromosomes are inactivated late replicating. Regarding the balanced X;autosome translocation, there was a mosaic pattern; in majority of cells translocated X was late replicating inactive, while in few cells translocated X was early replicating active X chromosome. Conclusion: It has been found that at least 30 X-linked genes are expressed on the inactivated X chromosome. The varying degree of phenotypes within each syndrome occurs because the genes that escape X inactivation are expressed at varying degrees.

P13.49-S
Uncovering the oligomeric structure of the y+LAT1/4F2hc amino acid transporter

M. Tringham[1], *J. Kurko*[1], *O. Simell*[2], *J. Mykkänen*[2];
[1]*Department of Medical Biochemistry and Genetics, University of Turku, Turku, Finland,* [2]*Department of Paediatrics, University of Turku and Turku University Hospital, Turku, Finland.*

y+LAT1 and 4F2hc are protein subunits that form a transporter complex for cationic amino acids in the basolateral membrane of epithelial cells, mainly in the small intestine and proximal kidney tubules. Mutations of y+LAT1, 56 of which are currently known, cause lysinuric protein intolerance (LPI, OMIM #222700), a rare metabolic disorder characterised by diminished intestinal absorption of the cationic amino acids lysine, arginine and ornithine and by severe loss of these amino acids into the urine. The more detailed structure of this transport complex has so far been unclear - it has remained unelucidated whether the complex is formed as a dimer or a tetramer of the subunits. What has been known, however, is that the y+LAT1 subunits cannot reach the plasma membrane without forming a complex with 4F2hc. We previously established fluorescence resonance energy transfer (FRET) microscopy and FRET-FACS as tools in studying the interactions of y+LAT1 and 4F2hc. We have now applied these techniques together with immunohistochemistry to the exploration of the heteromerisation status of the y+LAT1/4F2hc transporter complex. We discovered that when fused into fluorescent vectors and transfected into the HEK293 cells, the y+LAT1 proteins interact together in the presence as well as absence of 4F2hc. Our initial results therefore suggest that the holotransporter is a multimer of y+LAT1 and 4F2hc subunits.

Technical aspects of ALK FISH test to improve therapy selection of lung cancer patients

V. Martin[1], *B. Bernasconi*[2], *P. Balzarini*[3], *W. Vermi*[3], *F. Sessa*[2], *L. Mazzucchelli*[1], *M. G. Tibiletti*[4];
[1]*Institute of Pathology, Locarno, Switzerland,* [2]*Department of Surgical and Morphological Sciences, University of Insubria, Varese, Italy,* [3]*Department of Pathology, University of Brescia, Brescia, Italy,* [4]*U.O. Anatomia Patologica, Ospedale di Circolo – Polo Universitario, Varese, Italy.*

Introduction. ALK gene (2p23) rearrangement characterizes a subgroup of patients affected by lung adenocarcinoma who may benefit from the ALK-inhibitor crizotinib. ALK translocation is principally related to a small paracentric inversion. FISH with break-apart strategy is considered the gold standard to investigate ALK. Evidence based studies settled the presence of ≥15% cells with rearrangements as cut-off to classify patients as positive (ALK_FISH+). Recently, same Authors identified a subset of borderline patients that might benefit from therapy, wondering whether this cut-off could reflect a real biologic distinction between ALK-positive and ALK-negative tumors.
Materials & Methods. We investigated ALK gene status by FISH, using ALK LSI Dual-Color Break-Apart (Abbott) and ALK Split-Signal (DAKO) probes, in

243 lung adenocarcinomas collected in three Institutions. A series of standardized ALK-negative lung cancer cell lines (Abbott) were used as negative controls. A specific scoring system considering not only the splitting of the signals but also their distance was developed.
Results. We identified 12% ALK_FISH+ patients, with similar rate among the three Institution (13%, 12%, 9%). ALK_FISH+ cases showed: 53% inversion/translocation, 28% deletion and 18% both patterns. Concordance was observed between the different operators and between the two probes, both on patients and on the panel of negative controls. In this last, the cut-off obtained (by calculating M+3SD) was 14.9%.
Conclusions. Difficulties in interpretation of ALK FISH signals pattern might be bypassed using our detailed scoring system, that is reproducible among different operators, probes, and provide experimental evidence that 15% is a reasonable cut-off for patients selection.

P14.02-M
Allelic drop-out in large Iranian Brugada syndrome family revealed by new generation sequencing

A. Bukaeva[1], M. Polyak[1], **O. Glazova**[1]*, S. Saber[2], E. Zaklyazminskaya[1];*
[1]Petrovsky Russian Research Centre of Surgery, Moscow, Russian Federation, [2]Sechenov Moscow State Medical Univercity, Moscow, Russian Federation.

Background: Sanger sequencing is a gold standard of DNA diagnostic currently used for NGS validation. Nevertheless, it has its own limitations producing false results. The well-known mechanism of allelic dropout is the presence of SNPs in 3'-region of PCR primers. The early recognition of allelic dropout prevents diagnostic errors.
Materials and Methods: The DNA samples from Brugada syndrome Iranian family were extracted from peripheral blood. Sanger sequencing of SCN5A gene coding areas was performed for proband and relatives. Control re-sequencing via semiconductor PGM IonTorrent platform using Ampliseq primer pool encompassing coding area of 10 genes including SCN5A was performed for family members.
The control group comprised 100 ethnically matched healthy donors.
Results: Sanger sequencing has revealed a novel heterozygous genetic variant p.P1506S in exon 26 of SCN5A gene in proband. Surprisingly, his son carried p.P1506S variant in homozygous state. Carriage of p. P1506S variant in mother had been excluded by Sanger sequencing and PCR-RFLP analysis. We performed control re-sequencing via semiconductor PGM IonTorrent platform for proband and his son. NGS results showed a discrepancy with primary Sanger sequencing results, proving heterozygousity of p.P1506S variant in proband's son. Sanger re-sequencing using alternative oligonucleotide primers for exon 26 confirmed NGS outcome. Thus, SNP rs41315501 was identified in 3'-region of previously used forward primer. Prevalence of rs41315501 was assessed by PCR-RFLP in 200 chromosomes cohort and MAF (minor allele frequency) accounted 9,4%. SNP was detected in proband's wife and son in heterozygous state.
Conclusion: Currently Sanger sequencing is used for validation of NGS techniques. But vice versa, NGS technology can be applied for capillary sequencing quality control.

P14.03-S
Scanning Alpha Haemoglobin-Stabilizing Protein (AHSP) gene by High Resolution Melting Analysis

S. Pappa[1], G. Kellaris[1], E. Voskaridou[1], P. Kollia[2], A. Balassopoulou[1], **E. Boutou**[1]*;*
[1]Laiko Hospital, Athens, Greece, [2]Athens University, Athens, Greece.

Alpha-Haemoglobin Stabilizing Protein (AHSP) is involved in the stability, folding and binding of alpha globin to the hemoglobin complex, regulates the free alpha globin pool and has been associated with heterogeneity of thalassaemia phenotypes. AHSP is encoded by a relatively small gene and is a good candidate for High Resolution Melting Analysis (HRMA). The aim of this study was to develop a rapid, specific and sensitive HRMA approach for scanning AHSP gene. Alpha thalassaemia heterozygotes with the same underlying mutation (αPA1α/αα) but heterogeneity in haematological indices MCV and MCH and no iron deficiency were selected and divided in three subgroups. Ten normal samples were used as controls. AHSP gene was divided in small sized overlapping amplicons and PCR conditions were optimized prior to HRMA. Samples presenting distinct derivative plots were Sanger sequenced. Two variations were detected. The variation 12895 G>T (exon III) was detected in samples regardless group and may represent a neutral polymorphism as reported previously. The second variation detected, 12391 G>A, is located in an Oct-1 binding site and was also detected in samples from different sub-groups. These results indicate that HRM analysis can be used as a fast, cost effective, relatively simple and high-throughput amenable method for scanning AHSP gene. This approach can be incorporated in order to analyze higher number of samples and strengthen the characterisation of these changes as neutral or not polymorphisms in the Hellenic population. Moreover, detection of other variations may associate them with heterogeneity of alpha / beta thalassaemia phenotypes.

P14.04-M
NGS network for diagnostic of autoinflammatory diseases (AID)

M. Van Gijn[1], I. Ceccherini[2], **I. Touitou**[3]*;*
[1]Universitair Medisch Centrum, Utrecht, Netherlands, [2]Gaslini Hospital Center, Genova, Italy, [3]UMAI laboratoire de génétique des maladies rares et autoinflammatoires, Montpellier, France.

Hereditary autoinflammatory diseases (AID) are characterized by recurrent bouts of systemic inflammation caused by dysregulation of proteins of the innate immunity system. Identification of about 25 genes over the last 17 years rendered possible genetic diagnosis, a major tool to discriminate patients with close phenotype. This genetic heterogeneity and the rarity of these conditions motivated an International concerted action for the use of next generation sequencing for diagnosis of AID.
A survey among AID experts was conducted in 2013. Twenty laboratories declared willing to participate in this network and filled out a questionnaire. Results were as follows:
• Sequencing equipments varied across the laboratories. Illumina MiSeq was the major device (29%), followed by Lifetech PGM (25%), Illumina HiSeq (18%), Roche Junior (14%), other (14%).
• Sequencing results were analyzed with either a software from the platform, an in house pipeline, a collaboration (21% each), or a combination (37%).
• The number of AID genes included in the panels varied from the five most frequent to all published genes.
• Clinical expectations included ethics: develop new informed consent (53%) and guidelines (47%), and collaboration: sharing experience for variant interpretation (31%), access to patients and database (28%), harmonization of technology and reports (17%).
Through a close collaboration with clinicians, we could connect this project with two existing dedicated patient (Eurofever) and mutation (Infevers) registries. Integration of clinical and genetic data will help 1) elaborate a consensus for classification criteria and 2) identify new AID genes in orphan patients.

P14.05-S
Next Generation Sequencing approach to molecular diagnosis of autoinflammatory diseases: from gene panel design to variant call

M. Rusmini[1]*, F. Caroli[1], A. Grossi[1], L. Tattini[2], A. Magi[3], R. Ravazzolo[1,4], A. Martini[4,5], M. Gattorno[5], I. Ceccherini[1];*
[1]U.O.C. Genetica Medica, Istituto G Gaslini, Genova, Italy, [2]Dipartimento di Neuroscienze, Psicologia, Area del Farmaco e Salute del Bambino, Ospedale Pediatrico Meyer, Firenze, Italy, [3]Dipartimento medicina sperimentale e clinica, Università degli Studi di Firenze, Firenze, Italy, [4]Dipartimento di Neuroscienze, Oftalmologia, Genetica e Materno Infantile (DINOGMI), Università di Genova, Genova, Italy, [5]Pediatria II, Reumatologia, Istituto G Gaslini, Genova, Italy.

Auto-Inflammatory Disorders (AIDs) are monogenic diseases caused by primary dysfunctions of the innate immune system. However, molecular diagnosis performed by Sanger sequencing of known genes fails to detect mutations in around 86% of patients recruited to our Unit. Clinical misdiagnosis, mutations in untested gene regions, genetic heterogeneity and/or a complex mode of inheritance are all possible explanations.
The Next Generation Sequencing approach has been undertaken to improve mutations detection in AIDs. By using the Ion Ampliseq™ Designer (LifeTech) online tool, we designed a panel of 203 amplicons including the 121 exons of 11 genes already known to be involved in AID, for a total of 22Kbs. Eight samples can be sequenced in one Ion PGM™ 314-chip. The mean coverage has turned out to be 225X, with 93.4% of the target region covered >20X and 76,5% >100X. The analysis from FastQ to VCFs was carried out using three different workflows: i) Ion Torrent Alignment and Ion Reporter™ 4.0, specific for data generated by PGM ii) in-house pipeline based on free-tools like BWA and GATK, iii) CLC Bio software.
Focusing on three representative DNA samples already genotyped for the respective causative genes, Ion Reporter and CLC allowed to detect all the three expected mutations, while GATK did miss one of these. In order to maximize sensitivity and specificity for routinely use of the procedure in AIDs diagnosis, we will present data from 50 additional DNA samples carrying mutations at least at one of the 11 genes in the present panel.

P14.06-M
A robust approach for blind detection of balanced chromosomal rearrangements with whole-genome low-coverage sequencing

Z. Dong, *W. Wang, H. Jiang, F. Chen, S. Cao;*
BGI-Shenzhen, Shenzhen, China.

Balanced chromosomal rearrangement (or balanced chromosome abnor-

mality, BCA) is a common chromosomal structural variation. Next-generation sequencing has been reported to detect BCA-associated breakpoints with the aid of karyotyping. However, the complications associated with this approach and the requirement for cytogenetics information has limited its application. Here, we provide a whole-genome low-coverage sequencing approach to detect BCA events independent of knowing the affected regions and with low false positives. First, six samples containing BCAs were used to establish a detection protocol and assess the efficacy of different library construction approaches. By clustering anomalous read pairs and filtering out the false-positive results with a control cohort and the concomitant mapping information, we could directly detect BCA events for each sample. Through optimizing the read depth, BCAs in all samples could be blindly detected with only 120 million read pairs per sample for data from a small-insert library and 30 million per sample for data from non-size-selected mate-pair library. This approach was further validated using another 13 samples that contained BCAs. Our approach advances the application of high-throughput whole-genome low-coverage analysis for robust BCA detection, especially for clinical samples, without the need for karyotyping.

Using biotin-streptavidin interaction for binding plasmid to a cell-penetrating peptide

D. S. Polyakov;
Institute of Experimental Medicine of the NorthWest Branch of the Russian Academy of Medical Science, St.Petersburg, Russian Federation.

Gene therapy strategies based on plasmid DNA are more preferable than viral-based gene delivery. Plasmids are more stable in vivo and known to be less immunogenic. Retroviral-based vectors integrate in actively transcribed genes that can lead to disruption of tumor suppressor genes. Gene delivery methods based on plasmid DNA do not cause mutagenesis and they do not integrate in chromosomes providing increased safety. Despite the potential advantages of using plasmid DNA, delivery issues with plasmid vectors exist. One of the ways of plasmid delivery into a cell can be biotin-streptavidin interaction of the plasmid to a cell-penetrating peptide (CPP). Streptavidin binds the small molecule biotin with femtomolar affinity. We have created a biotinylated pEGFP-N3 circular plasmid DNA to further its binding to the streptavidin-CPP fusion protein. Few thymines were replaced by biotinylated uracils in the plasmid. The presence of biotinylated uracils in purified plasmid was verified in restriction analysis followed by dot blot procedure. Streptavidin-conjugated alkaline phosphatase was used to detect the biotin-uracils. The ability to express green fluorescent protein was tested in Hela cell culture. We have created a genetic construct for synthesis of monovalent tetrameric streptavidin, which consists of one WT streptavidin and three inactive streptavidins. Each inactive streptavidin is fused to chain of four HIV TAT-peptides. The resulting chimeric protein binds one biotinylated circular plasmid DNA due to the biotin-streptavidin interaction. This structure can be used for gene therapy.

Methyl-DNA detection: a performance comparison of four commercial kits

C. A. Leontiou, *M. D. Hadjidaniel, M. Ioannides, S. P. Stylianou, K. Tsangaras, P. Antoniou, P. C. Patsalis;*
The Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus.

Epigenetic alterations, including DNA methylation, play an important role in the regulation of gene expression. Several methods exist for evaluating DNA methylation, but bisulfite sequencing remains the gold standard by which base-pair resolution of CpG methylation is achieved. The main limitation of this method is its harshness to DNA and several commercial kits try to find a balance between reagent harshness and conversion efficiency. Our study compares four popular kits (Diagenode, Promega, Epigentek, Qiagen) regarding their conversion efficiency and degradation effect. We used in-vitro methylated and unmethylated forms of two λ-phage PCR products to create various DNA mixtures (spikes), including ratios 1:0, 1:1, 1:3 and 0:1 methylated to unmethylated DNA. These were bisulfite converted with all 4 kits and then PCR amplified producing templates for Sanger sequencing and NGS. Our Sanger sequencing results showed 100% conversion efficiency of cytosines across all kits and there was a correct trend of methylation status at CpG sites which reflected the expected ratios of the spikes. However, the method was limiting in displaying accurately the extent of methylation in each case. DNA degradation was compared between kits based on the efficiency of PCR amplification and it was shown that the Diagenode and Promega kits had the least degrading effect.
Our NGS results offered higher resolving power as expected, allowing accurate assessment of methylation ratios lower than 1:3. Our results indicate bisulfite-NGS applications are applicable for detecting small variations in methylation while our comparison shows which kit is the least harsh and the most efficient.

P14.09-S
Molecular testing of BRCA1&2 genes with NGS technology: a three-step approach

A. Martayan, *A. Antenucci, C. Del Carlo, F. De Bellis, L. Conti;*
Istituto NazionaleTumori Regina Elena Roma, Rome, Italy.

The aim of our study was to enhance the throughput of mutation detection analysis in order to supply high sensitivity, fast and accurate data on BRCA1/2 genes' mutational status of selected breast and/or ovary cancer patients. Starting from June 2012 a panel of 8 selected BRCA1/2 pathogenic mutation–prone cases have been analysed on a GS 454 Junior platform (Roche) and 6 out of 8 pathogenic variants were successfully identified. One of the two unidentified variants was a single nucleotide insertion just adjacent to a homopolymer stretch of 8 Adenines in the coding region of BRCA2. The second unidentified variant was a deletion of the whole exon 14 of BRCA1 gene. The latter two unidentified pathogenic variants were revealed subsequently using the BRCA Homopolymer (BRCA HP) kit from MULTIPLICOM and MLPA analysis. We then decided to adopt a Three-step mutational screening approach. As a first step BRCA1 &2 amplicon libraries were generated with BRCA MASTR™ assay from Multiplicon, and sequenced on our GS 454 junior platform. Sequencing data are then analysed with Amplicon Variant Analyzer (AVA) software (Roche). The samples with no pathogenic variants identified are then involved in the second step which is the processing with BRCA HP kit in order to uncover insertions or deletions in homopolymeric coding regions of both genes. The third step is MLPA analysis to uncover large genomic rearrangements. So far 181 samples were analysed in our laboratory and 29 pathogenic variants were identified with our three step testing approach.

P14.10-M
Efficient sharing of BRCA1 and BRCA2 variant and phenotype data between diagnostic labs

J. T. den Dunnen[1], *P. E. M. Taschner*[1], *F. B. V. Hogervorst*[2], *M. P. G. Vreeswijk*[1], *Dutch and Belgian working group for Breast CancerDNA Diagnostics (LOB);*
[1]*Human and Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands,*
[2]*Netherlands Cancer Institute, Amsterdam, Netherlands.*

The Dutch and Belgian working group for Breast Cancer DNA Diagnostics (LOB) has decided to share over 7500 variants detected in the BRCA1 and BRCA2 genes in breast cancer families since 1997. For this, the data, almost evenly split among both genes, have been submitted to the LOVD 3 shared gene variant database installation (1,2). Previously, variants identified in Dutch and Flemish (Belgian) DNA diagnostic labs were collected yearly and stored in an Excel data file. Advantages of the LOVD system include: simple submission of new data in a standardized way, instant updates after curation, easy maintenance and automatic backups. Although most data are publicly accessible online, some data are shared by members only. Others can see whether such information is available (password protected file links), giving them the option to contact the submitter for further details. Members can contribute their opinions about variant classification, increasing its consistency, but being aware of potential misinterpretation they have reservations sharing this information. Data are stored variant-by-variant and connected to each individual patient and submitting diagnostic lab. Using existing LOVD functionality, users can perform queries per gene or individual, use other linked resources of interest, get genome browser views of the data and use web services to access variants stored in other gene variant databases. In addition, LOVD3 has a new access level, designated "collaborator", allowing submitters to share otherwise non-public data with other submitters, e.g., to share detailed phenotype information with other diagnostic labs only.

2) http://databases.lovd.nl/shared/genes/BRCA2

P14.11-S
Validation of a Next Generation Sequencing assay for BRCA1 and BRCA2

C. J. Meldrum, *M. Hipwell, S. Dooley, M. McPhillips, D. Mossman, C. Smith, R. J. Scott;*
Hunter Area Pathology Service, New Lambton, Australia.

Next Generation sequencing (NGS) is rapidly finding a place in routine diagnostics although, extensive validation of such platforms and the associated bioinformatics is urgently required before they reach equivalent confidence as Sanger sequencing. Routine testing of BRCA1 and BRCA2 for Breast Cancer predisposition has resulted in numerous positive and negative controls for the rigorous assessment of NGS. A further consideration when implementing a new technology for routine testing is it's suitability to the diagno-

stic laboratory which will be discussed.
This study examines approximately 400 samples referred for BRCA1 and BRCA2 testing in the context of familial breast cancer and compares the performance of NGS to Sanger sequencing. The approach used involved microfluidic PCR (Fluidigm Access Array), followed by NGS on an Illumina MiSeq instrument and subsequent bioinformatic analysis with NEXTGENe (SoftGenetics). A single assay is capable of performing 42 BRCA1 and BRCA2 screens in less than 5 days. The failure rate for the assay was 4% (17/399), primarily contributed by the initial two assays (N=94) with subsequent assays providing a 1.6% failure rate (5/305). The sensitivity of the assay compared to Sanger sequencing was estimated at 99.7%. Overlapping amplicon design was the most significant problem encountered with bioinformatic analysis, requiring several rounds of optimisation. Validation of the workflow consisted of ~400 samples distributed across retrospective (including a reproducibility component) and prospective arms as well as a blinded/inter laboratory sample assessment and a concurrent testing period. The validated assay has been accredited to international standards and is now in routine use.

P14.12-M
Initial evaluation of the cardiomyopathy-specific content of Illumina's TruSight ONE next generation sequencing assay

S. Waldmueller, *K. Imbrich, S. Junker, M. Sturm, P. Bauer, O. Riess, M. Bonin;*
University Hospital Tuebingen, Tuebingen, Germany.

Introduction: The recently launched TruSight ONE panel comprises 4812 genes and is meant to enable a one-for-all-mendelian-diseases test. Objective: To determine whether the cardiomyopathy-specific genes are covered sufficiently good enough to justify the use of TruSight ONE in clinical genetic testing. Subjects, Materials and Methods: In order to initially analyze control samples, DNA was obtained from three individuals presenting with conditions other than cardiomyopathy (CM). TruSight ONE DNA enrichment and next generation sequencing (NGS) was conducted according to the manufacturer's instructions using a MiSeq instrument. A proprietary NGS data processing and filtering pipeline was used. Results: A) Performance characteristics for 46 core CM genes: The fraction of bases covered with less than 20 reads varied between 2.3 and 5.4% (mean: 3.7%). The average read depth varied in the range of 84- to 147-fold (mean: 120-fold). A mean of 4 relevant variants (i.e. missense, nonsense or splicing) was observed (range: 2-8). B) Performance characteristics for a set of 288 genes annotated for cardiomyopathy by NCBI's Entrez Gene (including the 46 core CM genes): A mean fraction of low coverage bases of 4.7% was observed (range: 3.7-6.6%). The mean average read depth was 118-fold (range: 81-148-fold) and 15-30 (mean: 22) relevant variants were detected. Conclusions: The cardiomyopathy-specific genes could efficiently be analyzed using TruSight ONE and a MiSeq instrument. The sensitivity and specificity of the test will be determined and compared to that of Illumina's separate 46 gene cardiomyopathy assay.

P14.13-S
Computer-aided facial recognition of Cornelia de Lange Syndrome (CdLS): a follow-up study

L. Wolf[1,2], *C. Gervasini*[3], *M. Orin1*[1], *L. Basel-Vanagaite*[1,2,4];
[1]*1 FDNA Ltd., Herzlyia, Israel, Tel-Aviv, Israel,* [2]*Tel Aviv University, Tel Aviv, Israel,* [3]*University of Milano, Department of, Health Sciences, Milano, Italy,, Milano, Italy,* [4]*Schneider Children's Medical Center of Israel, Rabin Medical Center, and Felsenstein Medical Research Center, Petach Tikwa, Israel.*

CdLS is a genetically heterogeneous disorder, exhibiting a wide phenotypic spectrum. Approximately 70% of the clinically diagnosed CdLS patients are confirmed for a cohesin-related gene mutation.
In "*Computer-aided facial recognition of Cornelia de Lange syndrome: a comparison to the recognition by human experts*" presented at the 2012 DSW workshop, the *FDNA*® technology successfully recognized facial dysmorphology associated with CdLS from 2D photos, producing results comparable with those of human experts.
In this study, we collected and tested blindly 18 photos of probands with a molecularly-confirmed or clinical diagnosis of CdLS and 10 with confirmed diagnosis of various non-CdLS syndromes (e.g., *kabuki, Aarskog, dubowitz, etc.*). For each photo, the system produced a score above (positive) or below (negative) a threshold, determined from the results of the original study.
4/5 probands with the NIPBL mutation (including 1 mosaic mutation), 3/4 with the SMC1L1 mutation and 5/9 clinically diagnosed by geneticists as CdLS-like, but carrying various genomic imbalances, received positive scores. 10/10 non-CdLS probands received a negative score. The 6 false-negatives were reported to have a mild phenotype or not to meet the clinical diagnostic criteria, of which 3 received a score well below the threshold and 3 a score immediately below the threshold, suggesting that the threshold may be skewed upwards and requires further adjustment to increase system's sensitivity from 67% to 83%, while maintaining specificity of 100%.
Results show consistency with experts' evaluation of the "classic" CdLS facial morphology, validating the system's ability to discern between CdLS's and other syndromes' phenotype.

Profiling circulating miRNAs in plasma samples of celiac disease patients

R. C. Almeida[1], *S. Vriezinga*[2], *V. Kumar*[1], *A. Stachurska*[1], *R. Modderman*[1], *U. Võsa*[3,4], *L. Mearin*[2], *C. Wijmenga*[1], *S. Withoff*[1];
[1]*University of Groningen, University Medical Center Groningen, Dept. of Genetics, Groningen, Netherlands,* [2]*Leiden University Medical Center, Leiden, Netherlands,* [3]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [4]*Department of Biotechnology, Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia.*

Celiac Disease (CeD; "gluten intolerance") is diagnosed by symptoms, detecting CeD-specific antibodies, and biopsy results. The only available therapy is a life-long gluten-free diet. Despite the availability of diagnostic tools, as many as 7 out of 8 adult CeD patients are either not or incorrectly diagnosed, highlighting the need for novel biomarkers.
Circulating miRNA profiles have been shown to be disease-specific, even disease-stage-specific, in patients with cancer or gastro-intestinal disease. We examined whether circulating miRNAs in plasma samples of CeD patients can be used as CeD biomarkers. By next generation sequencing we profiled miRNAs in 95 plasma samples from 12 CeD patients, 5 patients positive for CeD-associated antibodies and 5 control subjects from the Prevent CD cohort. In this cohort, newborns at risk for CeD were challenged with low levels of gluten between 4-6 months of age to induce gluten tolerance, and plasma samples were taken every 3 months until diagnosis. Comparing data from samples taken at diagnosis to samples taken at 3 months of age (first available sample), we found 62 miRNAs significantly differently expressed (FDR<0.05). Of those, 4 miRNAs were previously reported to be associated with CeD, 12 were implicated in other autoimmune diseases and 7 miRNAs have been implicated in immune signaling. One of these immune related miRNAs is miR-23b, which appears to be downregulated 2-fold in CeD patients at time of diagnosis. This miRNA is known to limit tissue inflammation. A downregulation of this miRNA would therefore contribute to the pro-inflammatory state in active CeD.

P14.15-S
Northern Lights Assay of cfDNA damage in body fluids

J. J. Jonsson[1,2], *B. Gudmundsson*[1,2,3], *H. G. Thormar*[1,3], *A. S. Sigurdsson*[1], *D. Olafsson*[1], *A. M. Halldorsdottir*[2], *S. Thongthip*[4], *M. Steinarsdottir*[2], *A. Smogorzewska*[4];
[1]*Univ. of Iceland, Reykjavik, Iceland,* [2]*Landspitali - National University Hospital, Reykjavik, Iceland,* [3]*Lifeind/BioCule Inc, Reykjavik, Iceland,* [4]*Rockefeller University, New York, NY, United States.*

Structural damage in cfDNA molecules in body fluids has been little studied. Such damage may reflect normal and abnormal cell turnover, genome instablity or exporsure to genotoxic agents. We analyzed cfDNA damage in plasma, urine and saliva. Standard methods of isolation of cfDNA in plasma and urine are based on inducing ssDNA with a chaotropic agent and selective cordination binding of lone pair electrons on guanine to silica. These methods were not usable. In contrast, we found that selective ion exchange chromatography allowed gentle isolation of DNA without inducing damage. Damage in isolated DNA was assessed with the Northern Lights Assay. This assay is based on Two-Dimensional Strandness-Dependent Electrophoresis (2D-SDE) in premade microgels. Each sample was run in duplicate i.e. uncut and cut with Mbo I, an enzyme which cuts both single- and double-stranded DNA. Single-stranded breaks, either nicks or gaps, were detected as horizontal streaks from uncut DNA molecules. Double-stranded breaks generated an arc in the gel. DNA molecules with interstrand crosslinks (ICL) migrated as an arc behind normal dsDNA molecules. DNA with intrastrand crosslinks and bulky adducts were bent and migrated in front of that arc. Single-stranded DNA molecules, too damaged for complementary strand binding, formed a diagonal line. Patterns of cfDNA in plasma of normal subjects showed an apoptosis pattern with single- and double-stranded breaks of nuclesomal fragments. cfDNA in urine showed composite patterns of apoptosis and nonspecifc degradation. The most extensive damage and variable patterns were seen in saliva including prominent single-stranded breaks.

P14.16-M
A retrospective view on External Quality Assessment of Charcot-Marie Tooth disease over 16 years

B. W. Rautenstrauss[1], *U. Schoen*[1], *A. Benet-Pages*[1], **J. M. Hertz**[2];
[1]*Medizinisch Genetisches Zentrum, Munich, Germany,* [2]*Odense Universitetshospital, Odense, Denmark.*

Charcot-Marie-Tooth disease (CMT) is a clinically and genetically heterogeneous disorder of the peripheral nervous system. CMT1A is the most frequent autosomal dominantly inherited form caused by a 1.4-Mb tandem duplication in chromosome 17p12. In 1997 the first annual German external quality assessment (EQA) was performed for CMT1A. At this time the molecular genetic analysis was mainly based on 5 methods: RFLP Southern blotting, STR markers, PCR for junction fragments within the CMT1A-REP elements, PFGE and FISH. 10 laboratories in Germany participated. In the year 2000 the scheme was offered to a wider audience with 22 participating laboratories. Only one genotyping error occurred. Since 2008 the European Molecular Genetics Quality Network (EMQN) has organised the EQA scheme. In 2012 the number of participating laboratories increased to 66 from 22 countries (198 reports) representing countries from around the globe.
Methods like FISH, PFGE and Southern blotting have disapeared; PCR, qPCR and MLPA are now used. Next generation sequencing (NGS) allowing simultaneous sequence analysis as well as gene dosage determination is a future perspective.
Currently at least 60 genes are associated with disorders of the peripheral nervous system. Consequently the scheme scope has been extended to sequence analysis of GJB1 (CX32) (CMTX1). In 2012 again only 1 genotyping error occured. The efforts that have been made for an EQA in molecular genetic diagnosis for Charcot-Marie-Tooth disease demonstrate very good laboratory analytical performance. Nevertheless national laws affecting human genetics are different, thus harmonization in political terms (e. g. predictive testing) remains as important task.

P14.17-S
Comparative-High Resolution Melting - a novel method of simultaneous screening for small mutations and copy number variations

P. Borun, *A. Plawski;*
Institute of Human Genetics, Poznan, Poland.

Efficient and cost-effective screening for DNA sequence changes, both small mutations and copy number variations (CNVs), is a crucial aspect for routine genetic diagnostics as well as for basic research. In this study we present a development and evaluation of comparative high resolution melting (C-HRM), a new approach for the simultaneous screening of small DNA changes and gene CNVs. In contrast to other methods, relative quantification in C-HRM is based on the results obtained during the melting process and calculations of the melting peak height ratio in the multiplex reaction. Validation of the method was conducted on DNA samples from 50 individuals from Duchenne muscular dystrophy (DMD) families, 50 probands diagnosed with familial adenomatous polyposis and a control group of 36 women and 36 men. The results of analyses conducted on fragments of the DMD and APC genes correspond completely (100%) with the results of previous studies. C-HRM sensitivity in CNV detection was assessed through the analysis of mixed DNA samples with different proportions of a deletion carrier and wild type control. The results are presented as a linear regression with R2 of 0.9974 and imply the capability of the method to detect mosaics. C-HRM is an attractive and powerful alternative to other methods of point mutations and CNV detection with 100% accuracy in our studied group.

Chronic myeloid leukemia (CML) is a clonal myeloproliferative disorder characterized by the Philadelphia chromosome (Ph), resulting from the t(9;22)(q34;q11) balanced reciprocal translocation that generates the BCR-ABL1 fusion protein. The first line therapy of CML is Imatinib Mesylate, which targets BCR-ABL1 protein, inhibiting proliferation pathway. Residual leukemia is assessed by a sensitive molecular quantitative manner evaluating levels of BCR-ABL1 transcripts by real-time reverse transcriptase PCR (qRT-PCR). Undetectable levels of chimeric transcript, however, can reflect either an effective elimination of leukemia cells, or the presence of a quiescent leukemic stem cells transcriptionally silent. We developed a novel highly sensitive method to identify quiescent leukemic cells and possible candidates for discontinuation of therapy through quantitative real-time PCR (Q-PCR) based on the DNA. Detection of BCR-ABL1 fusion gene is critical for the diagnosis of chronic myeloid leukemia and to follow the disease progress in patients under therapy. We applied targeted next-generation sequencing (NGS) to resolve sequence breakpoints in BCR-ABL1 fusion gene in CML patients and K562 cell line. In conclusion, DNA genomic Q-PCR is a very sensitive and direct technique to identify quiescent leukemic cells and patients that could be possible candidates to stop Imatinib therapy. We identified junction sequences in all samples using Agilent SureSelect enrichment and Illumina paired-end sequencing.

Rapid Serial PCR Instrument with High Speed Melting (HSM) Analysis

J. Huuskonen[1], *S. Sundberg*[1], *R. Pryor*[2], *J. Farrar*[2], *C. Wittwer*[2], *R. Palais*[2], *H. Stiles*[1], *L. Xu*[1], *R. M. Howell*[1];
[1]*Canon U.S. Life Sciences, Inc., Rockville, MD, United States,* [2]*University of Utah, Salt Lake City, UT, United States.*

We have developed a prototype instrument capable of rapid serial PCR/HSM, enabling multiple targets to be tested sequentially. The current system processes eight samples simultaneously and has a liquid handling system that delivers PCR reagents to a cartridge with microfluidic channels used for rapid PCR and HSM. A unique feature is that once PCR/HSM is completed (<12min per test), reagents for the next assay are then delivered, tested and analyzed.
We tested 100 blinded clinical blood samples (obtained from ARUP Laboratories) for *F2* (c.*97G>A), *F5* (c.1601G>A), and *MTHFR* (c.665C>T and 1286A>C) genotype using this instrument. The samples were also tested on a LightScanner®32 (Biofire™) using high resolution melting analysis (HRMA) assays designed by the University of Utah. Data from both instruments was interpreted using custom Melting Wizard software. Results show that all four tests with all 100 samples were genotyped accurately. Follow-up testing was required on 1.4% of the assays for a definitive genotype.
The prototype instrument described allows for extremely rapid PCR (each thermal cycle < 15 seconds) and HSM (melting rate up to 2°C/s) due to unique design of the microfluidic chip. The onboard liquid handling system allows multiple tests to be performed sequentially, and adding tests during the run. This method facilitates reflex testing, such as exon scanning followed by a reflexive genotyping assay, or a second reflexive genotyping assay. These features are better aligned with a workflow that requires multiple tests run on a single sample adding flexibility compared to current batch PCR workflows.

Challenges in the interpretation of variants identified in autosomal dominant familial nonsyndromic congenital heart defects by targeted next-generation sequencing

Y. Jia[1], *J. Louw*[1,2], *J. Breckpot*[1,3], *B. Callewaert*[4], *Y. Snajer*[5], *M. Gewillig*[2], *E. Souche*[1], *L. Dehaspe*[1], *J. R. Vermeesch*[1], *K. Devriendt*[1], *A. Corveleyn*[1];
[1]*Center for Human Genetics, University Hospitals Leuven, Leuven, Belgium,* [2]*Department of Congenital and Pediatric Cardiology, University Hospitals Leuven, Leuven, Belgium,* [3]*Department of Pediatrics, University Hospitals Leuven, Leuven, Belgium,* [4]*Center for Medical Genetics, University of Ghent, Ghent, Belgium,* [5]*Center for Human Genetics, Université Catholique de Louvain, Brussels, Belgium.*

High throughput sequencing technologies enable efficient large-scale genetic analysis, dramatically accelerating the genetic research and diagnostics. Our study aims to determine the proportion of familial nonsyndromic congenital heart defects (CHD) that can be explained by pathogenic mutations in currently known CHD associated genes, by implementing next-generation sequencing technologies in genetic diagnosis for familial nonsyndromic CHD. Targeted resequencing of known cardiac genes was performed in 36 patients from 13 nonsyndromic CHD families, using either array-based or solution-based method to capture the coding regions of 57 genes associated with CHD. Following variant analysis and Sanger validation, we identified 6 functional deleterious mutations in 3 genes, explaining the defects in 6 families. The genetic heterogeneity of CHD and remarkable variability of expression make it challenging to interpret the large number of identified variants in patients. Thus, setting up a well-defined analysis pipeline is necessary to identify causative mutations. In conclusion, by targeted resequencing of known CHD associated genes in well selected nonsyndromic CHD families and cautious variant interpretation, likely causative mutations were identified in 6/13 (46%) families. Reduced penetrance and possibility of phenocopies complicate the interpretation. Targeted next-generation sequencing is a powerful tool in genetic testing of familial nonsyndromic CHD, however, variant interpretation remains a major challenge for the diagnostic application.

P14.21-S
Whole exome sequencing in congenital myopathies: two case reports

A. Armaroli[1], *C. Scotton*[1], *J. Sigurðsson*[2], *C. Passarelli*[3], *M. Neri*[1], *F. Di Raimo*[1], *F. Gualandi*[1], *E. Mercuri*[4], *M. Pane*[4], *A. Ferlini*[1];
[1]*Dept. of Medical Science, Medical Genetic Section, Ferrara, Italy,* [2]*deCODE Genetics, Reykjavik, Iceland,* [3]*Unit of Neuromuscular and Neurodegenerative Diseases, Dept. of Neurosciences, Bambino Gesù Children Hospital, IRCCS, Rome, Italy,* [4]*Dept. of Pediatric Neurology, Catholic University, Rome, Italy.*

Congenital myopathies are a heterogeneous group of genetic diseases characterized by hypotonia and muscle weakness. Many causative genes have been identified in the last decade, underlining the high genetic heterogeneity in these pathologies. Sanger molecular diagnosis is an expensive and time consuming step-by-step process. In addition some genes involved are very large and high demanding in terms of molecular diagnostics. Here we report on two "families-of-four" with congenital myopathy in which we performed whole exome sequencing approach (WES). The analysis was performed by deCODE Genetics and we analyzed the families applying candidate genes interrogation and autosomal recessive inheritance; identified variations were prioritized for the pathogenic prediction and the rare allele frequency under 1% of the population.
In the first family, with one affected child, we found a known pathogenic in-frame deletion of the isoprenoid synthase domain-containing protein gene (ISPD). Mutations in this gene are known to be associated to congenital muscular dystrophy phenotypes. In the other family, with two affected sibs, we identified a mutation in RYR1 gene. In both families a previous partial molecular diagnosis by Sanger, and not exploring all exons, was performed.
In these two cases WES identified mutations in two known genes "correcting" a non-exhaustive diagnostic approach. This is an example confirming the usefulness of next generation sequencing as an accurate molecular diagnostic approach for pathologies with high genetic heterogeneity and/or large genes.
The Neuromics EU project is acknowledged.

P14.22-M
Detection of Copy Number Variation by PCR under Limiting Conditions

L. Zhou[1], *R. Palais*[2], *C. Wittwer*[1];
[1]*Department of Pathology, University of Utah School of Medicine, Salt lake City, UT, United States,* [2]*Department of Mathematics, University of Utah, Salt lake City, UT, United States.*

DNA copy number variation (CNV) is associated with genetic disorders, chromosomal rearrangements, and cancer. We present a simple closed-tube method based on high-resolution melting that is accurate enough to reliably determine all common CNV ratios. Target and reference regions of genomic DNA were PCR amplified together using a variety of reagent and cycling protocols. We found that the ratios of reference and copy number variants were maintained either by limiting PCR cycles, or by limiting quantities of dNTPs or Taq polymerase and allowing PCR to plateau. High-resolution melting analysis with the DNA binding dye LCGreen Plus was used to determine CNV ratios from the relative heights of the target melting peak after reference melting peaks were equalized. All common CNV ratios may be detected using any of the PCR limiting protocols. The most robust and simplest method uses limiting dNTP concentrations. CNV ratios differing by 10% could be distinguished when dNTPs were limited to 3.25 uM. Trisomy was easily and accurately typed using duplex PCR, and chromosome X and Y copy number variants were identified using triplex PCR. The method also identified large CFTR exon 2 and exon 3 heterozygous deletions that are difficult to detect using other approaches. This protocol is simple, closed-tube, fast, economical, and is more accurate and less susceptible to contamination than other methods. Assays are easy to design, limiting dNTPs is simple, and the results are stable and reliable. It may also have application to the analysis of gene expression via relative template quantification.

P14.23-S
Study of the molecular basis of cystic fibrosis by Next-Generation Sequencing

L. Straniero[1], *G. Soldà*[1], *L. Costantino*[2], *D. Rusconi*[2], *M. Seia*[2], *C. Colombo*[3], *R. Asselta*[1], *S. Duga*[1];
[1]*Dipartimento di Biotecnologie Mediche e Medicina Traslazionale, Università degli Studi di Milano, Milan, Italy,* [2]*Laboratory of Medical Genetics, Molecular Genetic Sector, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy,* [3]*Cystic Fibrosis Center of Milan, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milano, Milan, Italy.*

Despite extensive genetic screening, 1-5% of cystic fibrosis (CF) patients still lack a definite molecular diagnosis. Today, next-generation sequencing (NGS), combined with target enrichment and multiplexing, is making increasingly affordable a sequencing-based approach to mutation detection in extended genomic regions. In this frame, we analyzed 24 selected CF patients by full CFTR gene resequencing (8 with known CFTR genotype, 11 with only one mutation identified, and 5 with no mutations after conventional screening). A custom capture SeqCapEZ Library (Roche) and an HiSeq 2000 platform (Illumina) were used. Multiplexing 6 samples in the capture phase and 12 in the sequencing step, we obtained a mean depth >1,000X, with a 98% coverage. An in-house developed pipeline was used for variant detection and annotation, which allowed the identification of all 14 previously known mutations. Moreover, 4 genetic lesions undetected by genetic screenings were found, including a large heterozygous deletion. Additionally, we found new intronic variants, whose possible role on RNA splicing was excluded by a combination of in-vivo and in-vitro analyses. In conclusion, NGS increased the percentage of genetically diagnosed patients, being able to disclose mutations escaped to "standard" mutational screening. Moreover, read alignment also allowed an immediate definition of large deletion breakpoints at the nucleotide level. Finally, even after this extensive sequencing strategy, 5 probands did not show any mutation in CFTR (nor in the SCNN1A, SCNN1B, and SCNN1G coding regions), suggesting the intriguing possibility of an additional locus for CF. These subjects are currently being processed for whole-exome sequencing analysis.

P14.24-M
Performance of the Luminex xTAG Cystic Fibrosis kit (EU)

V. Ritchie, *C. Dey, L. Lan, D. Himsworth, J. Liu;*
Luminex Molecular Diagnostics, Toronto, ON, Canada.

The xTAG® Cystic Fibrosis Kit (EU) [herein termed xTAG CFE] is a qualitative genotyping device used to simultaneously detect and identify a panel of mutations and variants in the Cystic Fibrosis transmembrane conductance regulator (CFTR) gene in human blood specimens and blood spots. The assay identifies the recommended ACMG/ACOG mutations and variations, as well as some of the world's most prevalent mutations. Additionally, xTAG CFE identifies mutations specific to Europe, such as 4016insT, L1065P and L1077P in the French and Italian populations, 2184insA in Central Europe, T338I in the Italian (Sardinia) population, 712-1G>T in the Spanish population, and E585X, R1066H, Q552X and G1244E in Southern Europe. DNA samples can be screened for 5 variants and up to 75 CFTR mutations, out of a total pool of 85 available mutations, allowing the user to customize CF testing to a particular region. The assay is comprised of a single multiplex polymerase chain reaction which is then used in three separate Allele Specific Primer Extension (ASPE) reactions (A, B, and C). The limit of detection of the assay is 2 ng/µL with an input genomic DNA range of 10 ng to 1.5 µg. Diagnostic accuracy was assessed for the xTAG CFE assay using the xTAG Cystic Fibrosis and bidirectional dideoxy-sequencing as comparator methods. Over four hundred samples were analyzed that included genomic DNA extracted from whole-blood specimens, dried bloodspots and Coriell samples. Sensitivity and specificity for the xTAG CFE assay across all mutations was 100%.

Missing the forest for the trees: integrating traditional and molecular cytogenetics technology in hematological neoplasia

S. Shetty[1], *K. McDonnell*[1], *R. Smith*[1], *K. S. Theil*[2], *J. Cook*[2], *E. D. Hsi*[3], *G. W. Procop*[1], *J. P. Maciejewski*[4], *M. A. Sekeres*[4], *R. V. Tiu*[4], *H. J. Rogers*[2];
[1]*Department of Molecular Pathology, RT-PLMI, Cleveland Clinic, Cleveland, OH, United States,* [2]*Department of Clinical Pathology and Molecular Pathology, RT-PLMI, Cleveland Clinic, Cleveland, OH, United States,* [3]*Department of Clinical Pathology, RT-PLMI, Cleveland Clinic, Cleveland, OH, United States,* [4]*Department of Translational Hematology and Oncology Research and Leukemia Program/ Hematologic Oncology & Blood Disorders (HOBD), Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH, United States.*

This retrospective study investigates appropriate utilization of technology for cost effectiveness without compromising patient care in hematological malignancies. Bone marrow aspirates from 409 cases submitted for cytogenetics workup of myeloid disease were reviewed. 163 (40%: median age 60 years; M/F=1.6) had a combination of cytogenetics, FISH and SNP array testing. Based on morphology, they were classified as non-diagnostic (60), MDS (55), MPN (9), MDS/MPN (13) and AML (26). The mean turnaround time (day) was 17.4 (range 6-24) for cytogenetics, 7.0 (4-13) for FISH, and 15.0 (7-29) for array. Overall discrepancy between cytogenetics and FISH results was 14.1% (abnormal(+) cytogenetics/normal(-) FISH in 14/99 cases; P<0.0001). Discrepancy between cytogenetics and array results was 32.3% (+cytogenetics/-array in 8/65 cases; -cytogenetics/+array in 10/65 cases; +cytogenetics/+array in 3/65 cases; P=0.0020). There was 96% concordance for clinically relevant copy number changes between cytogenetics and array. Array detected cryptic deletion in 4% not seen by cytogenetics. However, low-level mosaicism for copy number changes was missed by array in 11% and 13% showed LOH/-cytogenetics; of these 5% were clinically

relevant. Therapy was initiated before release of results in 27%, after cytogenetics in 9%, after FISH in 3%, after array in 1% and supportive care in 60%. The preliminary data suggests a tier testing approach does not compromise patient care if tier testing is completed within 3-4 weeks of initial diagnosis. In presence of unfavorable prognostic abnormalities by cytogenetics, array testing may not be warranted. Based on this data, we would like to propose the optimal genetic testing algorithm.

P14.26-M
Real-time and Droplet PCR quantification for non-invasive determination of RHD incompatibility between mother and foetus

I. Svobodova, *S. Pospisilova, E. Pazourkova, A. Horinek, M. Korabecna;*
General faculty hospital in Prague, Prague 2, Czech Republic.

The aim of this study was to compare two strategies of DNA quantification: Real-Time PCR (qPCR) and Droplet PCR (dPCR). The benefit of dPCR against qPCR is represented by absolute quantification of target nucleic acid molecules without the requirement of calibration curves. The methods were compared by quantification of standard nuclear DNA of known concentration. DNA was eightfold diluted (2-0.015 ng/ul) and twelve replicates were realized for each dilution. Concentrations were then measured as levels of amplicons of two genes, housekeeping gene GAPDH and human RHD gene (exon 10). The same genes were analyzed in plasma cell-free DNA and also in cell-free fetal DNA isolated from maternal plasma. Evaluation of these two methods' performance was based on several parameters, such as degree of linearity (R^2), accuracy, detection limit, etc. In case of standard nuclear DNA, both methods showed high accuracy and low detection limit, both genes were detected even in most diluted samples. High linearity degree (R^2 > 0.99) has been reached by both methods. The correct RHD status of tested women was immunologically verified. Regarding analysis of cell-free fetal DNA in RHD negative maternal plasma, dPCR failed against the qPCR to convincingly distinguish RHD positive samples from the negative ones. For the purpose of prenatal screening, the qPCR method would be probably the preferable alternative due to very low fetal DNA concentrations (about 0.002 ng/ul) in maternal plasma, which is under the detection limit of dPCR.

Development and evaluation of a gene panel for the diagnosis of monogenic epilepsies

A. Labalme[1], S. Dimassi[1,2], A. Campan-Fournier[1,2], C. Bardel[3], N. Boutry-Kryza[4], M. Elsensohn[3], P. Roy[3], R. Lamy[4], P. Edery[1,2], A. Calender[4], D. Sanlaville[1,2], **G. LESCA**[1,2,4]*;*
[1]Department of Medical Genetics, Groupement Hospitalier Est, Lyon University Hospital, Lyon, France, [2]CRNL, CNRS UMR 5292, INSERM U1028, Université Claude Bernard Lyon I, Lyon, France, [3]Department of Biostatistics, UMR 5558 CNRS UCBL, Centre Hospitalier Lyon Sud, Lyon University Hospital, Lyon, France, [4]Department of molecular Genetics, Edouard Herriot Hospital, Lyon University Hospital, Lyon, France.

Next Generation Sequencing (NGS) is a great advance in the field of molecular genetics, especially for diseases with high genetic heterogeneity, allowing parallel testing of many disease-causing genes. It will lead to a better access of a larger number of patients to molecular diagnosis. In order to improve the diagnostic yield of genetic testing in patients with epileptic diseases, we developed a panel including 41 genes causing monogenic form of epilepsy or neurodevelopmental disorders frequently associated with seizures. Until now, only 13 of these genes have been currently screened by Sanger sequencing, on a sequentially basis. In the present study we compared two methods: the Haloplex technology (Agilent) and the SeqCap (Roche) technology. Sequencing was performed using an Ion Torrent PGM sequencer (Life Technologies). We performed NGS sequencing on DNA samples from 44 patients, including 38 patients in whom a (probably) causative mutation had been previously found by sequential Sanger sequencing in our routine practice, and 6 novel patients who had not been screened. DNA samples were anonymized and the first steps of the analysis were performed following a blind protocol. DNA from all the patients was analyzed with the Haloplex technology and only 24 of them were also analyzed with the SeqCap technology (they were sorted among the 44 patients). Data analysis will be performed with the NextGene Software (Softgenetics) and also with specific BWA-GATK pipeline based on the recommendations of BroadInsitute. Our analysis will include coverage, sensitivity and false positive rate as well as a cost evaluation.

P14.28-M
Scaling up whole-exome sequencing on Ion Proton using AmpliSeq

I. M. Jonasson, *C. Lindau, U. Gyllensten, A. Ameur;*
Uppsala University / IGP, Uppsala, Sweden.

The Ion Proton[a] and Ion PGM[a] (Life Technologies) technologies are used in the National Genomics Infrastructure - Sweden (NGI) to handle the different requests and needs for rapid massively parallel sequencing, (MPS).
Ion Proton[a] enables a rapid workflow for human whole exome sequencing. The PCR based whole exome capture (Ion Ampliseq Exome Kit) provides consistent high coverage across annotated exonic regions, with the PI[a] chip yielding 50-60.000 SNPs per sample, with ~98% of these overlapping variants reported in dbSNP. Sample preparation and sequencing is performed in less than two days. We are exploring the possibility to scale-up the throughput by loading two PI chips on one initialization and to combine 3 exomes per PI chip. With this set up it will be possible sequence up to 30 exomes per week on one Ion Proton[a].
The bioinformatics analysis has been streamlined using an in-house database system, based on R and MySQL, where all detected variants from all in house exome-sequencing runs are stored. This system allows for very efficient and fast filtering of SNPs or indels between any groups of samples and we currently have a success rate of almost 80% of finding disease-causing variants in small families or trios with rare Mendelian disorders.
Ion Proton[a] is also being used for clinical applications such as identification of fusion transcripts from cancer samples, mutation screening using panels of candidate genes. The sample preparation will be simplified and faster when the automated system, Ion Chef[a] is introduced and established in the workflow.

P14.29-S
Evaluation of three sequence capture platforms for whole exome sequencing

K. Zerjavic[1], J. Meienberg[1], M. Okoniewski[2,3], A. Patrignani[2], K. Ludin[4], S. Gysi[1], B. Steinmann[5], T. Carrel[6], B. Roethlisberger[4], R. Schlapbach[2], **G. Matyas**[1]*;*

Whole exome sequencing (WES) can be effective for identifying sequence variants. Here, we present a comprehensive comparison of the most recent next generation sequencing (NGS) exome enrichment methods of Agilent (SureSelect V5+UTR), NimbleGen (SeqCap V3+UTR), and Illumina (Nextera Expanded Exome). Exomes of six human DNAs were captured by these methods and sequenced at 100x depth of coverage on an Illumina HiSeq 2000 platform by four vendors. Read depth, % of coverage, GC bias, and number of detected single nucleotide variations (SNVs) and small indels were compared. To examine the methods' ability to identify SNVs and small indels, we analyzed heterozygous positions and small indels previously detected by Sanger sequencing (SS). For two DNAs, WES data were also compared to whole genome sequencing (WGS). SureSelect and NimbleGen demonstrated highest average read depth in target region. Considering ≥20x for read depth, SureSelect covered the largest proportion of its targeted bases. SureSelect and NimbleGen showed the highest average read depth as well as detected the highest number of SNVs and small indels in RefSeq. However, all SNVs identified by SS were accurately called by all three methods. Less consistent was the detection of small indels, where a substantial difference among the platforms and vendors was observed. In addition, all three methods showed high GC bias which was not seen in WGS. Our analysis indicated a considerable variability among exome enrichment methods, DNA sequencing laboratories, and even among DNA samples. Our data revealed that both SureSelect and NimbleGen performed better than Nextera.

The importance of root cause analysis following an external quality assessment (EQA) to improve the quality and accuracy of a diagnostic service

R. J. Hastings[1], *J. C. Cigudosa[2], N. Foot[3], C. Guiver[1], N. de Leeuw[4], E. Maher[5], S. O'Connor[6], C. Pescucci[7], B. Quellhorst-Pawley[1], E. van den Berg-de Ruiter[8];*
[1]John Radcliffe Hospital, Oxford University Hospitals NHS Trust, Oxford, United Kingdom, [2]Molecular Cytogenetics Group Centro Nacional de Investigaciones Oncológicas, Madrid, Spain, [3]GSTS Pathology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [4]Radboud University, Nijmegan, Netherlands, [5]Lothian NHS Trust, Edinburgh, United Kingdom, [6]St James's Institute of Oncology, Leeds, United Kingdom, [7]University Hospital of Careggi, Florence, Italy, [8]Academisch Ziekenhuis Groningen, Groningen, Netherlands.

EQA is essential to verify the quality and accuracy of the diagnostic service. When new technologies emerge, EQAs need to be developed to verify the laboratory diagnostic validation process and enable benchmarking of their performance. When laboratories introduce new technologies diagnostically, most critical errors in EQAs are analytical. As laboratories gain more experience in the new technologies, the critical errors usually become limited to the interpretation of results.

EQA is intended to be educational so if a laboratory receives a poor performance, they are asked to review their results and perform an audit so they can identify the root cause of the error. If required, repeat EQA samples are made available to exclude the rare instances of a problem with a manufacturer's kit. In 2013, a thorough root cause analysis by one participating laboratory identified a potential problem with one manufacturer's probe. An independent verification by CEQAS using multiple FISH probes and arrays confirmed a 967kb deletion of 13q14.2q14.3. There is a discordant result between the microarray and FISH probes for one of the deletion breakpoints. As a consequence the manufacturer immediately withdrew the probe and replaced it with a new product to eliminate the likelihood of future false negative results. A second laboratory identified an internal problem with their fluorescent microscope filters which they replaced and then verified gave the correct results using validated EQA material.
This presentation will give examples of how different approaches to investigating a poor performance can result in different outcomes including changes to practice.

Gaslini Children's Hospital, Genova, Italy,* [4]*Department of Life Sciences, University of Trieste, Trieste, Italy,* [5]*Department of Mathematics and Geosciences, University of Trieste, Trieste, Italy.*

Fanconi Anemia (FA) is a bone marrow failure disorder characterized by high clinical and genetic heterogeneity (at least 16 genes), which makes diagnosis complex and time-consuming. Next-generation sequencing technologies, such as the Ion PGM™ System (IPGM; Life Technologies), could improve the molecular genetic testing in FA. To test IPGM, we sequenced 30 DNA samples: 2 from controls and 28 from FA patients, whose mutations were previously identified by Sanger sequencing in 18 of them. According to the Ampliseq Designer software, the molecular target has a size of 74.2 kb covering 96% of the FA coding exons and their flanking regions. After exclusion of one sample for low coverage, we found that the coverage was higher than expected (>100X in 97% of reads per run) except for one sample that was excluded from the analysis. Then, comparing the IPGM and Sanger sequencing data, we asses sensitivity (100%), specificity (99%) and accuracy (100%). In addition to confirming all the mutations (31 alleles) identified by Sanger sequencing, this study allowed us to characterize another 18 out of the 54 FA alleles in our cohort. The remaining 5 are likely to be localized in genomic region not covered by the sequencing analyses. Moreover, quantitative analysis aimed at detecting copy number variations (CNVs) detected complete (n=1) and partial (n=7) deletions of FANCA, or entire removal (n=1) of FANCD2.All the CNVs were confirmed by SNP array or MLPA analysis. Our data suggest that IPGM is suitable for detection of point mutations and large deletion in FA.

Genetic testing of Fragile X disorders is now performed with PCR-based methods which sensitivity and precision allow detection and accurate sizing of FMR1 alleles in the entire spectrum of the CGG repeat amplifications. These molecular tools, designed to analyze a region of DNA with intrinsic characteristics of instability, could lead to new observations that were out of reach of previous methods. We report the detection of a smaller and less represented fragment in PCR amplifications of the FMR1 repeat region in independent samples of unrelated individuals, three males with intellectual disability and one normal female, with otherwise normal Fragile X alleles and karyotype. A smaller fragment present in PCR reactions from different DNA extractions and samples of each identified individual, has been detected by three different Italian laboratories with different settings (primers, amplification, electrophoresis). In one of the cases both parents of the proband resulted to not carry the smaller fragment, thereby excluding a rare X-chromosome or autosomal polymorphism as a possible cause. The possibility of random somatic instability as a cause of such finding in our cases is challenged by the similar size (286-293 bp) and quantitative representation of the peak. The fact that the same result has been found in four unrelated subjects (three Italian and one Israeli) out of 2000 tested, suggests a frequency of about 1/500 individuals. Further characterization of the extra peak is underway to establish its sequence origin and better understand the nature of what could give new information on the Fragile X region.

P14.33-S
Development of a Next-Generation-Sequencing based framework for comprehensive genetic analysis of Neurogenetic disorders

R. Chen[1,2], *J. Duan*[3], **T. Liu**[1], *X. Wei*[4], *X. Yi*[5], *H. Zhang*[1,2];
[1]*Beijing Genomics Institute, Tianjin, China,* [2]*Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, Beijing, China,* [3]*Shenzhen Children's Hospital, Shenzhen, China,* [4]*Beijing Genomics Institute, Wuhan, China,* [5]*Beijing Genomics Institute, Shenzhen, China.*

With the advance of sequencing technologies, the capacity to generate accurate genotype data greatly outpaces our ability to analyse it. To facilitate data intrepretation, a framework were developed for estimating the relative pathogenicity of variants. We used Tuberous Sclerosis, an autosomal dominant Neurogenetic disorder caused by mutations in either TSC1 or TSC2, to test our famework. As all kinds of mutations, including single nucleotide variants (SNVs), small insertions/deletions (indels), and large deletion/duplication mutations have been reproted in TSC1 and TSC2 scattering almost all along the 65 exons of the two genes without any obvious hotspot, the Neurogenetic disorders panel including 399 genes, in addition to TSC1 and TSC2, was used for the genetic analysis of 276 referred TSC, or probably-TSC patients. All identified variants of potential clinical interest were verified by Sanger sequencing or MLPA in probands and family members whenever available. 137 patients (49.6%) were found to carry known disease-causing mutations, 98 (35.5%) patients carried 93 unique highly-likely pathogenic variants. Accumulatively, this assay were able to identify the causative mutation in 85.1% (237/276) TSC patients. Of note, 23 large structural variants and 2 cases of somatic mosaicism were identified in our patients which might otherwise be neglected in sanger-sequencing based genetic testing. In conclusion, our framework can be readily used to analyze the gene variant profiles of TSC with high sensitivity, fidelity, throughput and speed. This framework lay the basis for the genetic testing of other complex Neurogenetic disorders.

P14.34-M
EGFR screening using Gold nanoprobes

S. Figueiredo[1], *P. Pedrosa*[1], *C. Clemente*[2], *W. Fritzsche*[3], *J. Greenman*[4], *S. Haswell*[4], *P. Baptista*[1];
[1]*Nanotheranostics@CIGMH, DCV, Faculdade de Ciências e Tecnologia, Universidade Nova de Lisboa, Caparica, Portugal, Almada, Portugal,* [2]*STABVIDA, Lda, Caparica, Portugal, Almada, Portugal,* [3]*IPHT - Institut für Photonische Technologien, Jena, Germany,* [4]*School of Biological, Biomedical and Environmental Sciences, University of Hull, Hull, United Kingdom.*

Targeted chemotherapy directed at epidermal growth factor receptor for treatment of non-small cell lung carcinoma patients has been put forward as an alternative to standard chemotherapy. However, the application of EGFR inhibitors therapy is only effective in cancers with mutated and overactive EGFR, requiring preliminary screening to detect EGFR mutations.
Typically, diagnostics procedures examine the profile of genetic alterations in tumours removed for biopsy in search for mutations that make them susceptible to treatment. Usually, DNA mutations are detected by PCR and confirmed by sequencing, which are quite expensive and time-consuming. Thus, the trend in molecular analysis is directed at increasing sensitivity rather the multi-loci analysis. Therefore, multiplexing and multiparallel strategies may become an alternative to directed analysis of whole spectra of mutations.
The LungCARD project aims the development and optimisation of a low cost microfluidic chip to assess EGFR mutations directly from immune-captured circulating tumour cells (CTCs). Here, we present the optimisation of a protocol for PCR amplification of EGFR exon 19 and 21 directly from single cells and the subsequent identification of mutations present via a gold nanoparticle based assay. This colorimetric assay is based on the non-cross-linking approach using a set of gold nanoprobes (thiol-functionalised gold nanoparticles) that are capable to specifically detect the EGFR variants. Furthermore, preliminary results from Ferguson plot analysis revealed that wild-type and mutated samples present distinct rfs and can be discriminated. The assay is optimised for reduced reaction volumes and short time, in order to be compatible with a microfluidic device.

Development of a next generation sequencing panel to assess hereditary cancer risk that includes clinical diagnostic analysis of the BRCA1 and BRCA2 genes

K. R. Bowles[1], *B. Roa*[1], *S. Bhatnagar*[2], *N. Gutin*[1], *A. Murray*[1], *B. Wardell*[2], *M. Bastian*[2], *J. Mitchell*[2], *J. Chen*[2], *T. Tran*[2], *D. Williams*[2], *J. Potter*[2], *S. Jammulapati*[2], *M. Perry*[2], *B. Morris*[2], *K. Timms*[2];
[1]*Myriad Genetic Laboratories, Inc., Salt Lake City, UT, United States,* [2]*Myriad Genetics, Inc., Salt Lake City, UT, United States.*

Assessment of hereditary breast and ovarian cancer risk should include germline sequencing of BRCA1 and BRCA2 as well as additional genes with known associations in breast/ovarian cancer patients. Sanger DNA sequencing has been the gold standard for molecular genetic analysis but next generation sequencing (NGS) platforms could provide another sequencing alternative. However, optimized assay design and validation are critical to maximize the analytical sensitivity and specificity of NGS assays and to ensure high quality interpretation for clinical decision making. We developed a 25-gene NGS hereditary cancer panel that uses RainDance PCR technology for high-throughput sample preparation, Illumina HiSeq and MiSeq NGS technologies, and commercially available and lab-developed informatic tools. Initial assessment of analytical sensitivity and specificity was performed by comparing BRCA1 and BRCA2. NGS was performed on 1864 anonymized patient samples, which had previously undergone BRCA1 and BRCA2 Sanger sequencing. Sanger sequencing identified 15,878 variants, of which 681 were unique and 482 were classified as disease-associated mutations. We identified 15,877 variants at an initial sensitivity of >99.99% for BRCA1 and BRCA2. One polymorphic variant was missed due to a variant under the primer. Sensitivity was subsequently optimized through process improvements. No additional variants were found by NGS, yielding a specificity of 100%. This preliminary analysis facilitated assay optimization and validation of all 25 genes in the NGS panel. This analysis indicates that a NGS gene panel designed to meet rigorous quality standards can be used to provide clinical sequencing results equivalent to those obtained from Sanger DNA sequencing analysis.

P14.36-M
In silico analysis of the effect on splicing of single nucleotide changes at exon-intron junctions is predictive of pathogenicity. A study on *MYBPC3* mutations.

J. B. A. van de Meerakker, *M. P. Lombardi, K. van der Lip, M. Alders, M. A. M. M. Mannens;*
Dept. Clinical Genetics, Laboratory for DNA-Diagnostics, Amsterdam, Netherlands.

Hypertrophic cardiomyopathy (HCM) is one of the most common inherited cardiovascular disorder with an estimated prevalence of 1/500. About half of the cases are familial and mutations in *MYBPC3* are among the most frequent cause of HCM.
Here we report on 14 patients with HCM in which single nucleotide substitutions potentially affect splicing of the MYBPC3 gene. Twelve mutations are located either on the last nucleotide of an exon or within the consensus 3'- and 5'- splice site sequences, while two are situated outside these regions. Mutations at the exon-intron junctions can potentially affect splicing. However, only changes affecting the invariant AG-GT nucleotides are considered to be certainly pathogenic, while the rest require functional studies. Mutations were first analysed *in silico,* using a combination of 5 splice site prediction algorithms, integrated in the Alamut 2.0 Splicing prediction module. For 12 mutations splicing prediction analysis indicated an effect on splicing and for 2 there were no alterations. Subsequently, all mutations were analysed by cDNA sequence analysis and these results were compared to the prediction models. In all patients the results of sequence analysis were consistent with the predicted effect, namely exon skipping, intron inclusion, partial exon deletions and insertions of intronic sequences or no altered splicing at all. In conclusion, this study indicates that *in silico* splicing analysis can accurately and reliably predict the effect on splicing of mutations occurring at exon/intron junctions representing a helpful tool in DNA diagnostics for the assessment of the pathogenicity of a sequence variant.

P14.37-S
Genetic diagnosis of familial colorectal cancer: Detection of large rearrangements in the MMR genes by molecular combing

A. Petit[1], *H. van der Klift*[2], *J. Abscheidt*[1], *D. El Mahli*[1], *A. Thomas*[1], *A. Bensimon*[1], *J. Wijnen*[3], **S. Barradeau**[1];
[1]*Genomic Vision, Bagneux, France,* [2]*Department of Human and Department of Clinical Genetics, Leiden University Medical Centre, Leiden, Netherlands,* [3]*Department of Human and Department of Clinical Genetics, Leiden University Medical Centre, Leiden, the Netherlands, Leiden, Netherlands.*

Hereditary Non Polyposis Hereditary Colorectal Cancer (HNPCC) or Lynch syndrome is an autosomal dominantly inherited cancer susceptibility caused by germline mutations in one of the DNA mismatch repair (MMR) genes (MSH2, MLH1, PMS2 and MSH6). Although most of the mutations reported in these genes are point mutations, large genomic rearrangements in one of the MMR genes occur with a frequency varying from 5 to 20% depending on the population. Effective methods to identify these types of mutation should be integrated in current diagnostic procedure to obtain a more comprehensive genetic screening strategy. Molecular Combing is a powerful FISH-based technique for the direct visualization of single DNA molecules which allows exploration of the genome at high resolution in a single analysis. We are developing a novel HNPCC genetic test based on molecular combing, for which specific "genomic Morse codes" (GMC) have been designed for each MMR genes. These GMC have been validated on combed genomic DNA extracted from the cancer-derived cell lines LoVo and Sk-OV-3, which harbor MSH2 and MLH1 large deletion respectively, and from HNPCC patients. From these patients, large rearrangements corresponding to either deletions of one to several exons in one of the MMR genes and with sizes ranging from 4 kb to 53 kb or the paracentric inversion in the MSH2 gene have been detected. Importantly, the mutations identified by Molecular Combing confirm the results previously obtained by Southern Blot analysis on the same patients, with a resolution in the 1-2 kb range.

When an allele drops out of amplification: whole exome sequencing unmasks a case of false-negative genetic diagnosis

C. Kotta[1,2], *A. Ghidoni*[1,2], *R. Insolia*[2], *E. Mastantuono*[3], *P. Lichtner*[3], *T. Wieland*[3], *T. Strom*[3], *T. Meitinger*[3,4,5], *P. J. Schwartz*[1], *L. Crotti*[1,2,3];
[1]*IRCCS Istituto Auxologico Italiano, Center for Cardiac Arrhythmias of Genetic Origin and Laboratory of Cardiovascular Genetics, Milan, Italy,* [2]*Department of Molecular Medicine, University of Pavia, Pavia, Italy,* [3]*Institute of Human Genetics, Helmholtz Zentrum München, Munich, Germany,* [4]*Munich Heart Alliance, Munich, Germany,* [5]*Institute of Human Genetics, Technische Universität München, Munich, Germany.*

Introduction: Sudden cardiac death without an attributable cause after clinical diagnostic work-up, is defined as idiopathic ventricular fibrillation (IVF). Mutations in genes primarily involved in inherited arrhythmia syndromes underlie some cases of IVF.
Methods: An IVF patient underwent routine mutational analysis of 6 arrhythmia-susceptibility genes (*KCNQ1*, *KCNH2*, *SCN5A*, *KCNE1*, *KCNE2* and *RYR2*) through direct sequencing. Afterwards, exome sequencing (Agilent SureSelect) was performed on the proband and his non-affected parents on an Illumina HiSeq2000 (minimum coverage 20x for 90% of bases, genotype quality score≥40). Identified variants were subjected to a 3-step filtering strategy (*de novo*, nonsynonymous, absent from dbSNP-1000Genomes).
Results: Traditional mutation scanning failed to identify a pathogenic variant. When exome sequencing was performed, a *RYR2* candidate variant was identified (c.12006G>T, p.M4002I) that however could not be validated by Sanger sequencing. This prompted further investigation and all factors contributing to either a stochastic sampling or a systematic error were evaluated. Previously published primer sequences were inspected. A SNP near the primer's 3' site (rs790889, MAF=0.426) was identified and hypothesized to cause the mutant allele to drop out. Targeted screening with redesigned primers confirmed the presence of the variant.
Conclusion: In routine diagnostics often laboratories use screening conditions reported through literature dated at a time when genetic variation information was not widely available. Allelic dropout or, more precisely, the occurrence of a null/false allele due to primer-target mismatch, constitutes an avoidable laboratory error. Our report highlights the need to periodically reevaluate even previously well established screening conditions.

Pyrosequencing Assay Panel For Imatinib Resistance Mutations

S. Acunalp Erdogan[1], *G. Inan*[2], *F. Narz*[3], *B. Torun*[1], **D. Ciglidag Dungul**[1];
[1]*ATQ Biotechnology, Ankara, Turkey,* [2]*METU Department of Statistics, Ankara, Turkey,* [3]*Qiagen GmbH, Hilden, Germany.*

Background: Chronic myeloid leukemia (CML) is characterized by the presence of the Philadelphia (Ph) chromosome. Ph chromosome results from the translocation of *ABL* protoonkogene from chromosome 9 and *BCR* gene on chromosome 22, which leads to the formation of BCR-ABL chimeric gene with constitutive tyrosine kinase activity. Imatinib (Gleevec) is the first BCR-ABL tyrosine kinase inhibitor used in the treatment of CML. Second generation drugs such as nilotinib and dasatinib, are now considered as alternative treatments to imatinib. Point mutations the kinase domain of the BCR-ABL were detected from 40% to 90% of the Gleevec-resistance cases. These mutations disrupt the binding site of imatinib on the tyrosine kinase, resulting in a loss of sensitivity to the drugs. **Method:** We performed a pyrosequencing assay panel for the detection of eleven important mutations in BCR-ABL kinase domain, which are Y253H, Y253F, E255K, E255V, V299L, T315A, T315I, F317L, F317V, F359C, F359V. Plasmids coding for respective vari-

ants were used to study assay performance and precision. Totally 25 RNA samples of BCR-ABL positive patients were analyzed by pyrosequencing and samples, which had mutation were also analyzed with sanger sequencing. **Results:** Our assay allows flexible, fast and reliable detection of mutations in cDNA from both blood and bone marrow with high concordance to Sanger sequencing. **Conclusion:** Our pyrosequencing assay for imatinib-resistant mutations provides a reliable method for the detection of the mutant BCR-ABL transcripts and also provides a significant value for the follow up of CML patients on imatinib.

P14.40-M
Next generation tissue profiling

O. Söderberg;
Uppsala University, Uppsala, Sweden.

Cancer develops as a consequence of genetic mutations, which results in deregulation of gene expression and/or proteins with aberrant functions. These changes often interfere with cellular processes such as survival and proliferation. The cancer cells evolve and are subjected to natural selection through interplay with its microenvironment. As is the case with other ecosystems, also the tissue microenvironment changes and responds to the populations in its niche and to external interference. Communication with other cells in the microenvironment will provide input signals that are interpreted by the malignant cells, and responded to, based on their altered genetic programs. Hence, the consequence of a mutation has to be viewed in the environmental context of each individual cell. The activity status of a protein or signaling pathway can be visualized with in situ Proximity Ligation Assays (in situ PLA) using a pair of antibodies equipped with DNA oligonucleotides (proximity probes) to target interacting proteins. Proximal binding of such probes template the creation of a circular DNA molecule, which is a surrogate marker for the interaction. We recently developed a multiplexed version of in situ PLA by introducing unique tags as identifiers in each different proximity probe. The combinatorial events generating an in situ PLA signal will harbor a set of identifier tags that will be unique for each protein interaction. By combining in situ PLA with padlock probes, analysis of signaling activity can be achieved together with genotyping expressed mRNA in fixed tissue sections, retaining the architectural information while providing single-molecule resolution.

P14.41-S
Quantification of donor/recipient chimerism in leukemia samples by digital PCR

K. Hayashibara[1], *A. Jiménez-Velasco*[2];
[1]*Thermo Fisher Scientific, South San Francisco, CA, United States,* [2]*Carlos Haya Hospital, Malaga, Spain.*

During leukemia treatment mixed chimerism occurs in which both recipient and donor cells are present in the bone marrow or peripheral blood after transplantation. Chimerism analysis is performed to monitor peripheral blood or bone marrow in the recipient after allogenic stem cell transplantation to monitor for leukemic relapse. Observation of increasing mixed chimerism after transplantation is associated with a higher risk of relapse in acute leukemia. Previously, a quantitative PCR (qPCR) technique, using insertion/deletion polymorphisms, was found to predict relapse in 88.2% vs. 44.4% of individuals analyzed by VNTR markers with a median anticipation period of 58 days and a sensitivity of 0.01% vs. 3%. Here we present results from research experiments performed to determine if a digital PCR (dPCR) method is able to predict relapse earlier and with greater accuracy than the qPCR method using retrospective leukemia samples. Research results showed that dPCR using the QuantStudio™ 3D Digital PCR System and the qPCR method yielded similar percent recipient chimerism values when recipient DNA was present above the 1% level. Furthermore, dPCR using the system was found to be more sensitive than the qPCR method based on the ability to detect the recipient DNA in a relapsed individual about 2 months earlier where the percent recipient chimerism was 0.2% or less. The false positive rate was close to the complete chimerism value of 0.01% for peripheral blood samples.

P14.42-M
Hotspot mutation and fusion transcript detection from the same non-small lung adenocarcinoma sample

A. Cheng, V. Bagai, N. Hernandez, M. Li, C. San Jose, J. Schageman, **R. Petraroli**, *A. Vlassov, S. Magdaleno;*
Thermo Fisher Scientific, Austin, TX, United States.

The presence of certain chromosomal rearrangements and the subsequent fusion gene derived from translocations has been implicated in a number of cancers. Hundreds of translocations have been described in the literature recently but the need to efficiently detect and further characterize these chromosomal translocations is growing exponentially. The two main methods to identify and monitor translocations, fluorescent *in situ* hybridization (FISH) and comparative genomic hybridization (CGH) are challenging, labor intensive, the information obtained is limited, and sensitivity is rather low. Common sample types for these analyses are biopsies or small tumors, which are very limited in material making the downstream measurement of more than one analyte rather difficult; obtaining another biopsy, using a different section or splitting the sample can raise issues of tumor heterogeneity. The ability to study mutation status (DNA) as well as measuring fusion transcript expression (RNA) from the same sample is powerful because you're maximizing the information obtained from a single precious sample and eliminating any sample to sample variation. We isolated DNA and RNA from the same non-small lung adenocarcinoma sample without splitting or dividing the sample, and both mutation analysis, as well as fusion transcript detection was performed using the Ion Torrent PGM™ platform on the same Ion 318™ chip. Using 10ng of DNA and 10ng of RNA input, we applied the Ion AmpliSeq™ Colon and Lung Cancer panel to analyze over 500 COSMIC mutations in 22 genes and the Ion AmpliSeq™ RNA Lung Fusion panel to detect 40 different fusion transcripts.

P14.43-S
Development and verification of an Ion Ampliseq RNA gene fusion panel for lung cancer: an OncoNetwork collaborative research study

Chromosomal translocations and corresponding gene fusions play an important role in carcinogenesis. The recent establishment of ALK, ROS1, RET and NTRK1 fusion transcripts as predictive biomarkers for lung cancer therapy has increased the need for a technology that could detect these biomarkers starting from very limited amounts of material. Here we describe the development and verification of an Ion AmpliSeq RNA fusion panel that can simultaneously detect ALK, RET, ROS1 and NTRK1 fusion transcripts in a single reaction. For the development of the panel we used previously characterized samples comprising 6 cancer cell lines and 62 FFPE lung tumor samples. Upon RNA isolation and amplification using the panel, samples were sequenced on the Ion PGM system. Initially, using serial dilutions of RNA from cell lines in normal RNA a limit of detection of 1% was established. Next, using the FFPE samples a fusion transcript was detected in 21 of the 24 known positive samples. Two of the non-concordant results were due to lack of representative tumor material. For the third, although no specific fusion transcript was identified, the internal control for ALK expression revealed the presence of an unknown ALK fusion transcript. Additionally, two new RET fusions were detected in samples not previously tested for RET translocations. These preliminary results are highly encouraging regarding the possibility of a reliable experimental protocol for the detection of fusion transcripts in the biological material routinely obtained for the diagnosis of lung cancer. An extensive verification is under way within the OncoNetwork.

P14.46-M
MicroRNA detection by real-time TaqMan® assays for translational research

L. Wong, *T. Gulham, P. Tsang, B. Moy, C. Liu, F. Hu, S. Dong, C. Chen, J. Stevens;*
Thermo Fisher Scientific, South San Francisco, CA, United States.

MicroRNAs (miRNAs) are small non-coding RNAs involved in the multilevel regulation of gene expression targeting a battery of mRNA genes. Researchers have discovered that miRNAs are efficacious biomarkers for the classification of tumors and prediction of outcome for many diseases because of their evolutionary conservation, unique expression signatures, relative stability, and abundance. There has been an increased interest in recent years for the identification of circulating miRNAs in serum, plasma, and other body fluids because it holds great promise for a non-invasive approach to molecular diagnostic and therapeutics. However, detection of miRNAs in these clinically relevant samples has been difficult, often requiring greater sensitivity. We have developed a new method for the detection and quantification of miRNAs that is highly specific and sensitive. The highly efficient

upstream chemistry allows synthesis of miRNA template library that is used in the downstream real-time TaqMan qPCR for miRNA-specific detection. The universality of template synthesis simplifies the workflow and provides the flexibility for scalable content (miRNA coverage). Whether applied to basic or translational research, profiling, screening, or validation, this new and robust method allows detection and quantification of miRNAs to address the unmet needs in workflow and sensitivity that exists today with next generation sequencing and other qPCR technologies, especially with clinical samples. Results show miRNA-specific amplification with a 7-log linear dynamic range and sensitivity of 60 copies input to meet the needs of translational research and clinical/diagnostic application.

P14.47-S
A new strategy for genetic testing of neurodegeneration with brain iron accumulation (NBIA) using amplicon multiplexing and next generation sequencing

S. Moutton[1,2], *A. De Pindray*[1], *N. Houcinat*[1], *C. Plaisant*[1], *J. Deforges*[1], *D. Lacombe*[1,2], *B. Arveiler*[1,2], *C. Goizet*[1,2], *P. Fergelot*[1,2];
[1]*Service de génétique médicale - CHU de Bordeaux, Bordeaux, France,* [2]*Laboratoire MRGM : Maladies Rares, Génétique et Métabolisme, Université de Bordeaux, Bordeaux, France, Bordeaux, France.*

In the expanding field of neurodegeneration with brain iron accumulation (NBIA), the development of sensitive brain imaging played a major role to characterize iron-related damages in patients. In parallel, new genes have been identified allowing genotype-phenotype correlations. However, overlapping phenotypes and non-informative pedigrees are still sources of delayed diagnosis. For these reasons, it would be more rapid and cost-effective to propose a simultaneous analysis of the nine genes identified so far.
Here, we propose a Next Generation Sequencing solution, tested in our series. NBIA genes (ATP13A2, CP, C19orf12, DCAF17; FA2H, FTL, PANK2, PLA2G6 and WDR45) were included in a custom panel of 35 genes dedicated to our routine molecular diagnosis platform. Two librairies of amplicons were designed and built with the AmpliSeqTM technology. Sequencing was performed according to the semi-conductor technology on a PGM. The Torrent Suite (Life Technologies) and AlamutTM interface (Interactive Biosoftware) were used for the mapping of reads, the variant calling and the interpretation. Workflow analysis was validated on known FTL and PANK2 mutations previously identified using Sanger sequencing. DNA samples irrelevant for NBIA were used as control to avoid considering recurrent artefacts. In silico AmpliSeq design covered 99% of NBIA genes targeted regions, of which 98% were sequenced at least 40X. Preliminary results obtained from 3 patients showed a perfect match between NGS and Sanger sequencing results. Thirty patients with compatible symptoms and MRI signs of NBIA who were referred to our laboratory for genetic testing are currently screened.

New generation sequencing dedicated to *CFTR* genotyping: comparison of two kits for multiplexed amplicons resequencing

M. Reboul[1], *E. Lasseaux*[1], *F. Salin*[2], *M. Déalbert*[1], *S. Labatut*[1], *C. Plaisant*[1], *D. Lacombe*[3,1], *B. Arveiler*[3,1], *P. Fergelot*[1,3];
[1]*CHU de Bordeaux, Bordeaux, France,* [2]*UMR1202 BIOGECO,INRA, Universite de Bordeaux, Bordeaux, France,* [3]*EA4576 MRGM Université de Bordeaux, Bordeaux, France.*

NGS is predicted to become the method of choice for fast screening of known mutations as well as resequencing of the *CFTR* gene. Our diagnosis laboratory, involved in cystic fibrosis testing, is currently developing this new strategy using a PGM (Life Technologies). The aim of this study was to define a NGS workflow for specific resequencing of the coding and flanking intron regions of the *CFTR* gene. We studied the feasability and analytical performance of two kits designed for amplicon library building and sequencing on PGM: the AmpliSeq™ CFTR kit from Life Technologies and the CFTR MASTR v2 assay (multiplicom). The latter was used according two different PGM protocols, 200 and 400 bp sequencing, due to the length of amplicons. These two kits and two protocols were compared using 20 patients DNA samples that have been previously sequenced by capillary electrophoresis using a 3500xL Dx Genetic Analyzer for CFTR genotyping (27 exons and exon-intron junctions). Gene rearrangements were searched using SALSA® MLPA® kit (MRC- Holland) or custom array CGH. Mutations were deletions, duplications, splicing variants and different combinations of T and TG tracts in intron 9. All expected mutations were identified by the two kits while it remained difficult to characterize intron 9 homopolymers. We discuss about the reliability of these protocols and of dedicated analysis pipeline in the context of cystic fibrosis diagnosis. Further improvements of software analysis pipelines would help to allow for automated CFTR mutation detection, particularly in repetitive and homopolymer sequence regions.

P14.49-S
The road to next generation molecular diagnostics, when NGS takes over Sanger sequencing

K. De Leeneer[1], *J. Hellemans*[2], *W. Steyaert*[1], *I. Vereecke*[1], *E. Debals*[1], *B. Crombez*[1], *M. Baetens*[1], *M. Van Heetvelde*[1], *F. Coppieters*[1], *A. Dejaegher*[1], *S. Lefever*[1], *E. De Baere*[1], *P. Coucke*[1], **K. Claes**[1];
[1]*Center for Medical Genetics Ghent, Ghent University, Ghent, Belgium,* [2]*Biogazelle, Zwijnaarde, Belgium.*

In diagnostics, next generation sequencing (NGS) of fixed sequence panels of captured genes/exomes is being introduced. Here it was our aim to develop a flexible, cost-efficient and easily expandable NGS-based workflow.
For target enrichment, we opted for PCR. Primer design is performed using an in-house developed primer design software program (Primer XL), allowing uniform PCR conditions for >3000 amplicons of >200 different genes. The library preparation is done with a modified version of the Nextera XT Sample Prep (Illumina) protocol. Our approach allows pooling of up to 15000 amplicons from different genes and patients in a single MiSeq run (2x250bp), resulting in an average coverage of 500x, and guaranteeing a minimal coverage of >36x for 99% of the samples.
The sensitivity of the data analysis pipeline was evaluated with 387 different positive controls. For substitutions and indels < 15 bp, an overall sensitivity of 99,99% was obtained, comparable to Sanger sequencing. A lower sensitivity was observed for the identification of indels > 15 bp, a known shortcoming of short read sequencing. Detection of these seems dependent on the sequence context and can be performed with capillary electrophoresis. For analysis of the specificity, the variants detected in 61 patients in 8 different genes (n= 327) were investigated with Sanger sequencing. A positive predictive value of 98% was obtained.
This ISO15189 accredited flexible workflow allows a strong reduction of cost and turnaround time compared to Sanger sequencing. The hands-on time will be further reduced by automation of the upstream PCR set-up.

P14.50-M
Validation of a next generation sequencing approach for rapid and accurate CFTR mutations screening

A. Telese[1], *V. D'Argenio*[1,2], *I. Postiglione*[1,2], *P. Nardiello*[1], *G. Castaldo*[1,2], *F. Salvatore*[1,2,3];
[1]*CEINGE Biotecnologie Avanzate, Naples, Italy,* [2]*Department of Molecular Medicine and Medical Biotechnologies, University of Naples Federico II, Naples, Italy,* [3]*IRCCS-Fondazione SDN, Naples, Italy.*

Cystic Fibrosis (CF) is one of the most frequent autosomal recessive disease among Caucasians (prevalence 1:2500); it depends on mutations in the Cystic Fibrosis Transmembrane Regulator (CFTR) gene that encodes a chloride exchanger. More than 1500 causative CFTR mutations have been identified, including missense, frameshift, splice site, nonsense and deletion mutations. Their accurate detection is important to improve the clinical management of CF patients and to correctly identify all CFTR carriers. Here, we report the use of a next generation sequencing screening for the identification of CFTR germline mutations. The study was performed on 60 subjects, including CF patients, CFTR carriers and controls, previously analyzed by traditional methods (reverse dot blot and Sanger sequencing). CFTR coding regions (including their flanking sites) were amplified using the CFTR MASTR Assay kit (Multiplicom) to obtain a library/sample. The subsequent sequencing reactions were performed with both the GS Junior System (Roche) and the MiSeq System (Illumina) allowing the simultaneous analysis respectively of 10 and 60 patients/run. Finally, the downstream data analysis was carried out through the SeqNext tool (JSI Medical Systems). All the features and performances of the Next Generation Sequencing technologies are discussed in the light of results obtained with the two used systems. Comparative sequence analysis highlighted that the proposed method is reliable, since all mutations previously identified were confirmed and the time of analysis is also markedly reduced. Our results assess the feasibility of a next generation sequencing approach for CFTR mutation detection to be included in a routine diagnostic workflow.

P14.51-S
Molecular analysis of mutations in the CFTR gene by Next Generation Sequencing

S. Chamayou[1], *M. Sicali*[1], *A. Covone*[2], *S. Ferrari*[3], *M. D'apice*[4], *A. Rosatelli*[5], *A. Coiana*[6], *C. Mazza*[7], *G. Savoldi*[7], *B. Sobrino Rey*[8], *F. Barros*[8], *S. Fernandez*[9];

Cystic fibrosis (CF) is the most common autosomal recessive disease in Cau-

casians, with an Cystic fibrosis (CF) is the most common autosomal recessive disease in Caucasians, with an incidence of approximately 1 in 2500 and a carrier frequency of 1 in 25. The gene responsible for CF, named the Cystic Fibrosis Transmembrane Conductance Regulator (CFTR), encodes the cyclic adenosine monophosphate (cAMP)-dependent chloride channel found in the apical membrane of secretory epithelial cells. The known mutations of the CFTR gene are 1965 (Cystic Fibrosis Mutation Database). The massive sequencing for mutation analysis and copy number variations (CNVs) by Next Generation Sequencing (NGS) allows investigating at the second and third level with the scanning of all exons, the flanking regions and the search for deletions and/or insertions in a single diagnostic test.
To check the reliability of massive sequencing by NGS as many as 100 control cases provided by an European network, were analyzed. All of the mutations previously obtained by Sanger Sequencing were confirmed by NGS that was shown to be highly sensitivity and specific.
The massive sequencing offers the possibility to carry out a reliable and comprehensive analysis for all genetic variants in reduced time (16h) testing up to 20 cases-samples in a single run. The costs of genetic analysis are substantially decreased.

P14.52-M
Enabling high-throughput discovery of the RNA transcription landscape using a directional RNA workflow and a combinatorial multiplexing approach

D. B. Munafo[1], P. Liu[1], C. J. Sumner[1], **B. Textor**[2]*, B. W. Langhorst[1], F. J. Stewart[1], E. T. Dimalanta[1], T. B. Davis[1];*
[1]New England Biolabs, Ipswich, MA, United States, [2]New England Biolabs, Frankfurt, Germany.

Massively parallel next generation cDNA sequencing (RNA-Seq), has allowed many advances in the characterization and quantification of transcriptomes, including the detection of non-canonical transcription start sites and termination sites, and identification of alternative splice isoforms, transcript mutations and edits. Additionally, the ability to obtain information on the originating strand is useful for reasons including for example: identification of antisense transcripts, determination of the transcribed strand of noncoding RNAs, and determination of expression levels of coding or noncoding overlapping transcripts. However, standard methods for sequencing RNA do not provide information on the DNA strand from which the RNA strand was transcribed, and methods for strand-specific library preparation can be inefficient and time-consuming. To address this challenge we developed a streamlined, low input method for Directional RNA-Sequencing that highly retains strand orientation information while maintaining even coverage of transcript expression. This method is based on second strand labeling and excision after adaptor ligation; allowing differential tagging of the first strand cDNA ends. We have also extended the utility of this method by developing additional adaptor and primers, including a dual barcoding approach for multiplexing up to 96 samples. As a result, we have enabled highly multiplexed, strand-specific mRNA sequencing, as well as whole transcriptome sequencing (Total RNA-seq) from ribosomal-depleted samples, enabling the discovery of a much broader picture of expression dynamics including discovery of antisense transcripts. This work presents a streamlined, fast solution for complete RNA sequencing, with high quality data that illustrates the complexity and diversity of the RNA transcription landscape.

P14.53-S
Highly efficient diagnostic testing in patients with hereditary hearing loss using Panel-based Next Generation Sequencing

K. Peters, *S. Fehr, M. Menzel, T. Scheurenbrand, A. Sprecher, S. Biskup, K. Hoertnagel; CeGaT GmbH, Tübingen, Germany.*

Genetic heterogeneity complicates the molecular diagnosis of hereditary hearing loss (HHL). Although a multitude of genes are attributed to HHL, patients are routinely tested only for mutations in GJB2, GJB3 and GJB6 (~5-10% of HHL). Thus, screening of all known hearing loss genes in parallel by high-throughput sequencing methods (next generation sequencing technology) is the most promising tool for a comprehensive detection of causative mutations, especially after negative testing for GJB2. Here we present the methodology of the 'hearing loss' diagnostic panel comprising 110 genes associated with non-syndromic and syndromic HL (Target enrichment, NGS library preparation and sequencing on the Illumina HiSeq2500 platform, bioinformatic analysis and medical evaluation). A group of 200 patients with profound hearing loss were analyzed in a clinical setting. Multiplexed samples were sequenced with high coverage per base and combined with bioinformatic analyses, single base substitutions, small deletions, and insertions in known genes of genetic hearing loss can reliably be detected. In conclusion, we have established a panel-based NGS pipeline which is a highly sensitive, fast and cost efficient tool for the genetic diagnostics of HHL. NGS-based mutation analysis allows us to detect causative mutations in >55% of HHL patients. These results imply consequences for counseling of patients and families and can also be the foundation for novel gene- or even mutation-specific treatment options in hearing loss.

P14.54-M
Technical challenges towards extended blood group genotyping by next-generation sequencing (NGS)

Y. Fichou[1,2]*, M. Audrézet[1,3], P. Guéguen[1,3], C. Le Maréchal[1,2,3], C. Férec[1,2,3];*
[1]Inserm, U1078, Brest, France, [2]EFS - Bretagne, Brest, France, [3]Laboratoire de Génétique Moléculaire et d'Histocompatibilité, CHRU Morvan, and Faculté de Médecine et des Sciences de la Santé, UBO, Brest, France.

Generating libraries by using the AmpliSeq™ strategy (Ion Torrent) for next-generation sequencing (NGS) is very convenient in terms of technical handling and time. By these means we designed primers and generated libraries to investigate exons, flanking introns and UTRs of 18 genes involved in 15 human blood systems, for a total of ~57 kilobases. After normalization by two different approaches, libraries were sequenced by the Ion PGM™ Sequencer (Ion Torrent). While all coding DNA sequences, except in *ABO*, exhibited a significant ~90% coverage, data analysis of genotypes in homologous genes (i.e., *RHD* and *RHCE*; *GYPA*, *GYPB*, and *GYPE*) resulted in discrepancy with what expected due to misassignment of sequencing data to target genes by analysis softwares. That prompted us to specifically PCR-amplify the exons in our genes of interest with gene-specific primers. PCR products were subsequently fragmented and sequences from homologous genes were labeled with different barcodes. All products were mixed with the AmpliSeq™-generated products before sequencing. Sequencing data were finally found to be in accordance with known genotypes. This work actually made the proof of principle that 1/ libraries generated by two different means can be combined and sequenced together, and 2/ gene-specific primers are required to accurately investigate genotypes in homologous pairs of genes. Meanwhile we also define conditions to reduce both intra- and intersample variability. Overall this study illustrates that NGS is applicable for blood group genotyping, and may be used in a near future for molecular diagnosis at the laboratory level.

P14.55-S
Cardiovascular NGS-Panel testing: design and first experiences

I. Lafer, *A. Gamillscheg, B. Pieske, M. R. Speicher, C. Windpassinger, T. Schwarzbraun; Medical University Graz, Graz, Austria.*

Syndromes resulting in primary structural heart disease or arrhythmia are characterized by a large clinical variability and a significant genetic heterogeneity. In fact, in a diagnostic setting it is not uncommon to have more than 40 genes as potential targets for an individual patient. For patient care, this situation is often not satisfactory because a precise diagnosis of the underlying cause of the disease directly affects patient treatment and allows counseling on risks for relatives.
To address these issues we designed an enrichment panel covering 97 genes, including all genes currently associated with LQT, SQT, BrS, IVFA, ARVC, HCM, DCM, RCM and SUDS/SIDS. After targeted enrichment, the DNA is sequenced on an Illumina MiSeq and subjected to analysis employing our analysis pipeline. Our strategy includes an indication specific analysis with an in depth evaluation for highly penetrant genes with a prevalence of >5% where we complement regions with a coverage below 50x by Sanger sequencing. For the remaining genes we generate a screening report and usually achieve coverage above 50x for more than 95% of bases. Up to date we applied our cardiovascular NGS panel to more than 25 patients, which allowed us to establish a definite diagnosis in many of these cases. For example, we detected mutations in *MYBPC3* in 5 out of our 8 patients with suspected HCM. We will present a summary of interesting cases and our experiences with this interesting diagnostic tool.

P14.56-M
Is exome sequencing of single patients with intellectual disability an effective diagnostic strategy?

C. A. L. Ruivenkamp, *M. J. V. Hoffer, M. Kriek, E. Aten, E. K. Bijlsma, A. van Haeringen, M. H. Breuning, S. A. Kant, W. Arindrarto, M. Losekoot, G. W. E. Santen; Leiden University Medical Center, Leiden, Netherlands.*

Trio-sequencing can be used in all disorders, and has particularly proven its value in finding causes of intellectual disability (ID) or multiple congenital anomalies. In contrast, we investigated whether sequencing only the affected patient without parents is sufficient to find the causative mutation, leading to a considerable reduce in costs. In this study, we enrolled 36 patients with unexplained ID, and sequenced the exome. The exome sequences were analysed with a stringent post-sequencing annotation pipeline including an

ID gene panel of ~500 genes for filtering of the data. All remaining variants with a potential clinical consequence were validated by Sanger sequencing and tested in the parents for inheritance.
After variant filtering we noticed an average of 13 variants per patient (range 2 to 27) requiring further clinical interpretation. The majority of these variants were inherited from one of the parents. Hitherto, we identified 5 de novo mutations in 36 patients (14%).
Without exome sequencing the parents, a relatively high amount of potentially pathogenic variants remain. All these variants require clinical interpretation which is very time-consuming, while most of these variants were likely benign because they are inherited from one of the parents. With trio-analysis inherited variants can be filtered out suggesting that this strategy, at this moment, is more efficient in identifying the causative variant. In the future when databases are filled with more and more exome data and consequently with more rare benign variants, exome sequencing single patients will become a more realistic diagnostic approach.

P14.57-S
Detection of large rearrangements in the CFTR gene: Comparison between custom CGH array and NGS

M. Audrezet, *P. Gueguen, S. Redon, A. Despres, C. Le Maréchal, C. Férec;*
CHRU BREST, Brest, France.

24 years after the discovery of the CFTR gene, more than 1900 anomalies are described, mainly single base-pair substitutions or micro-insertions/deletions, but many large rearrangements are also described.
Identification of mutations has important implications for genetic counselling, prenatal diagnosis, cascade screening in families, and for understanding the genotype-phenotype relationship.
Classical approaches for gene analysis aim either to look for point mutations or to identify large deletions or duplications, but no strategy allows, to date, to identify both types of mutations.
Since a few years, NGS technologies enable us to overcome the classical approaches of whole coding sequence sequencing at single nucleotide resolution.
The aim of this study is to validate NGS data analysis to detect large rearrangements in the CFTR gene.
23 DNA carrying known large deletions (n=20) or duplications (n=3) previously identified by CGH-array or qFM-PCR and two control samples, one complete deletion, and the other corresponding to the wild-type sequence of the gene were included in this study.
Analysis was conducted by SeqNext and Nextgene sofwares and by a simple spreadsheet by comparing the average depths obtained for each amplicon.
This method allowed us to confirm all the large deletions/duplications affecting more than one exon. Only one short deletion of 1 kb affecting exon 17b alone was not detected by both methods.
In conclusion, NGS technology should be the first technique that allows in a single step both the identification of point mutations and large rearrangement in a gene.

P14.58-M
The impact of NGS on gentic services: prioritization criteria and accountability

L. Pennese[1,2], *M. Castagnetta*[1], *M. Cecconi*[1], *E. Gennaro*[1], *F. Zara*[2], *D. A. Coviello*[1];
[1]*E.O. Ospedali Galliera, Laboratorio di Genetica Umana, Genoa, Italy,* [2]*IRCCS G. Gaslini, Unità di Malattie Muscolari e Neurodegenerative, Genoa, Italy.*

Clinical use of Next Generation Sequences (NGS) technologies is appealing, but requires high accuracy, simple assays, small inexpensive instruments, flexible throughput, short run times and most importantly, robust data analysis as well as tools for biological interpretation of results.
We have launched a pilot project to assess the clinical value of NGS technology according to the following criteria: 1) phenotypes characterized by genetic heterogeneity; 2) accurate selection of patients in collaboration with a clinical team; 3) the informed consent of the patient to perform the test. We performed targeted NGS analysis on 38 selected patients with Hypertrophic cardiomyopathy (HCM) and Epileptic Encephalopathies (EE) using custom panels of candidate genes on PGM (Life Technologies).
Our study highlight important issues which have to be considered for the accountability of management and transmission of the results: 1) increased identification of new variants with uncertain pathogenic value affecting the expectance of patients, especially in predictive or presymptomatic testing; 2) incomplete representation and coverage of target regions lead to missing clinically relevant mutations. Accordingly, Sanger sequencing seems to be required to analyse specific genomic segment. 3) Our experience indicates that most of identified nonsynonymous missense coding variants are validated by standard sequencing techniques. On the other hand small indels are more frequently false positives or miscalled.
The study confirms the potential of NGS techniques, indicates caution in interpretation and validation of data and suggests a soft transition between classical methods and NGS approach in clinical application.

P14.59-S
Application of NextGeneDx, a validated NGS based procedure, in the clinical practice

J. Garcia-Planells[1], *C. Ruiz Lafora*[1], *L. Rausell*[1], *M. Bermejo*[1], *E. Ramirez*[1], *M. Molero*[1], *M. Lazaro*[1], *L. Rausell*[1], *M. Garcia-Hoyos*[1], *M. Perez-Alonso*[2];
[1]*Instituto de Medicina Genomica (IMEGEN), Paterna (Valencia), Spain,* [2]*Department of Genetics. University of Valencia, Paterna (Valencia), Spain.*

c We have developed a NGS based procedure, called NextGeneDx, with the main objective that it can be used for genetic diagnosis, by using specific designs targeted at specific clinical problems. High coverage and representativity (100%) guaranties a sensitivity and specificity comparable to Sanger sequencing. Validation has been performed by an extensive comparison between the results obtained with NextGeneDx and Sanger sequencing. Versatility and robustness of NextGeneDx allows to increasing gradually the number of genes and diseases analysed. Nine months after the validation of the whole procedure we have developed more than 46 NextGeneDx services for multigenic or genetically heterogeneous diseases including more than 180 genes. The application of this technology in the clinical practice shows a significant reduction of the global costs of sequencing, making accessible the diagnosis of multigenic and heterogeneous diseases, bringing to an increase in the detection of disease-causing mutations and, definitely, a higher number of patients with a genetic diagnosis. Cost effectiveness analyses, from DNA extraction to obtain the final report, bear an important reduction of the costs, especially that related with hands-on and turnaround time, without compromising the diagnostic accuracy of the analysis. In conclusion, NextGeneDx provides an analytical accuracy comparable to Sanger sequencing and permits the analysis of all of the coding region and adjacent intronic sequences including those refractory to other types of sequencing. Therefore, NextGeneDx is a cost effective approach for the genetic diagnosis of multigenic and genetically heterogeneous illnesses, with a negligible number of incidental findings or unsolicited genomic information.

P14.60-M
Noninvasive prenatal testing for fetal trisomies: a validation study using the SOLiD Wildfire platform

M. G. Elferink[1], *E. de Bruijn*[2], *P. van Zon*[1], *O. Akkermans*[1], *K. A. Kusters*[1], *W. van Haren-van 't Woudt*[1], *G. C. M. L. Page-Christiaens*[1], *K. D. Lichtenbelt*[1], *M. J. A. van Kempen*[1], *I. J. Nijman*[1], *G. van Haaften*[1], *B. van der Zwaag*[1], *E. Cuppen*[1,2], *J. K. Ploos van Amstel*[1], *G. H. Schuring-Blom*[1];
[1]*UMC Utrecht, Utrecht, Netherlands,* [2]*Hubrecht Institute, Utrecht, Netherlands.*

Next-generation sequencing of cell-free DNA, isolated from plasma of pregnant women, is widely used for noninvasive prenatal testing (NIPT) for fetal trisomies. Recently, a new upgrade for the SOliD platform was released: the SOLiD Wildfire. The Wildfire has a simplified sample preparation protocol removing the laborious and expensive emulsion PCR step, an increased sequencing throughput, and the capability to use individual lanes and reuse unused flowchip lanes. Consequently, run time and costs are reduced significantly whilst obtaining equal numbers of mapped reads for statistical analysis. In this study, we aimed to validate the use of the SOLiD Wildfire for NIPT. In total, 154 samples were tested (between 11-20th weeks of gestation) including sixteen T21, ten T18 and four T13 (validated by karyotyping or QF-PCR in chorion villi or amniocytes). Cell-free DNA was extracted from 1 ml plasma and processed using a NIPT optimized library preparation and multiplexed (up to 16-plex). Libraries were sequenced on the Wildfire (35bp) targeting > 10 million uniquely mapped reads without mismatches per sample. The in-house developed pipeline CHROMATE (CHROMosomal Aneuploidy TEster) was used for GC-correction, read filtering, and statistical analysis to calculate Z-scores.To conclude, we demonstrate that the Wildfire can be used to reliably detect fetal trisomies and that results are robust between runs and under suboptimal conditions. Low costs, ease of use, decreased run time, and robustness underline the suitability of the Wildfire for cost-effective and rapid NIPT in clinical practice.

P14.61-S
Epigenetic strategies for non-invasive prenatal diagnosis: The power of the fetal methylome

E. A. Papageorgiou[1,2], *G. Koumbaris*[1,2], *E. Kypri*[1], *M. Hadjidaniel*[2], *P. C. Patsalis*[2];
[1]*NIPD Genetics Ltd, Nicosia, Cyprus,* [2]*The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.*

Epigenetic modifications have proven to play a significant role in cancer development as well as fetal development. Taking advantage of the knowledge acquired during the last decade, great interest has been shown worldwide in deciphering the fetal epigenome towards the development of methylation

based non-invasive prenatal diagnostic (NIPD) assays. We hereby highlight the different approaches implemented such as sodium bisulphite conversion, restriction enzyme digestion and methylated DNA immunoprecipitation, for the identification of differentially methylated regions (DMRs) between free fetal DNA found in maternal blood and DNA from maternal blood cells. Furthermore, we evaluate the use of selected DMRs identified towards the development of NIPD for fetal chromosomal aneuploidies. In addition, we perform a comparison analysis; we evaluate the performance of each assay and provide a comprehensive discussion on the potential use of different methylation-based technologies in retrieving the fetal methylome, with the aim to further expand the development of NIPD assays.

P14.62-M
Next-generation variant effect predictions and data integration

B. Vroling, *T. van den Bergh, T. te Beek, R. Kuipers, H. Joosten;*
Bio-Prodict, Nijmegen, Netherlands.

The interpretation of variants flowing out of next-generation sequencing experiments is one of the largest bottlenecks for DNA diagnostics. Frequently used tools like PolyPhen and SIFT are not up to this task, and consequently there is an enormous need within the community for novel tools to reliably interpret the effects of polymorphisms. In response to the growing demand for high-quality variant effect predictions we present 3DM; a data integration & mutation prediction platform for protein families.
3DM relieves many of the burdens that researchers face in dealing with the growing amounts and complexity of biomedical data. For each protein family a large amount of information that is extracted from protein structures, alignments and scientific literature, among others, is available. All this information is integrated and validated, and can be analysed via a number of different methods and tools.
By intelligently combining all this heterogeneous information 3DM is able to provide state-of-the-art predictions about the effects of genetic variations.
Collaborative work with a number of the largest hospitals in the Netherlands has shown that our solutions represent a major step forward in helping researchers and clinicians making accurate assessments of the pathogenicity of their variants, both by providing predictions, as well as enabling them to quickly navigate to literature and other relevant data.

P14.63-S
The Israeli experience of the first 300 Panorama™ tests that use 19,488 single nucleotide polymorphisms (SNPs) followed by high-throughput sequencing for common trisomies risk assessment

H. N. Baris[1], *Z. Weiner*[2], *I. Solt*[2], *M. Shohat*[3], *D. M. Behar*[4];
[1]*The Genetic Institute, Rambam Health Campus, Haifa, Israel,* [2]*The Obstetrics and Gynecology department, Rambam Health Care Campus, Haifa, Israel,* [3]*The Recanati Genetic Institute, Rabin Medical Center, Petach Tikva, Israel,* [4]*The Genetic Institute, Rambam Health Care Campus, Haifa, Israel.*

Background Cell free DNA (cfDNA) has emerged over the last year as an alternative for amniocenthesis for diagnosis of the common aneuploidies looking at trisomy 21, 13, 18, sex chromosomes and triploidy. **Methods** We present our experience of the first 300 Panorama™ tests sent from Israel. This method is based on massively multiplexed PCR amplification of cfDNA isolated from maternal plasma, targeting 19,488 SNPs, followed by high-throughput sequencing. The fetal fraction is determined. The SNP pattern of maternal DNA (from buffy coat) is compared to the SNP pattern of free DNA from maternal plasma, which contains maternal and fetal DNA. Paternal genomic samples, when available, were included in the analysis; in the absence of a paternal sample, the algorithm considers population allele frequencies. Combining the maximum likelihood ratio with a priori risk generates a risk score. **Results** The results of the first 300 sequential tests performed in Israel were analyzed. Fifteen samples necessitated redraw, two samples failed analysis. Four samples yielded high risk scores: two cases for trisomy 21, one for Kleifelter syndrome (KS) (47,XXY) and one for trisomy 18. Confirmation of both trisomy 21 and one KS were done by CVS or amniocenthesis. The suspected trisomy 18 is in the process of confirmation. There are no known false negative results. **Discussion** Panorama™ test is a reliable tool for identification of pregnancies at high risk for fetuses with the common aneuploidies with a high success rate. We recommend confirmation of the diagnosis for high risk scores pregnancies using invasive tests.

P14.64-M
Quality control procedure for assessing good manufacturing of a molecular diagnostics test in freeze-dried format

A. Moiana, *L. Ventura, L. Turner, M. Incandela, M. Gramegna;*
Sentinel CH. SpA, Milan, Italy.

Quality Control (QC) procedures are crucial in manufacturing of molecular diagnostics tests. The aim of this work is to describe QC procedures used to check properties of a freeze-dried PCR master mix for molecular diagnostics (STAT-NAT®, Sentinel CH. SpA).
A liquid bulk was prepared as follows: reaction buffer, dNTPs, $MgCl_2$, DNA polymerase, primers and probe for detection of human beta-globin gene, preservatives and stabilizers. Prior to freeze-dry, a PCR was performed with an aliquot of this mix to assure the functionality (Pre-Lyophilization control, Pre-Lyo). The mix bulk was then dispensed in aliquots of 25µL using a Freedom EVO 100 liquid handler (Tecan) and freeze-dried using an Epsilon 2-12D freeze-dryer (Martin Christ). A PCR was performed with lyophilized mix to check the functionality (Post-Lyophilization control, Post-Lyo). PCR performances were evaluated on a 7500 Real-time PCR System (Applied Biosystems). Moreover, to inspect the residual moisture in the lyophilized mix, an analysis using C20 Compact Karl Fischer Coulometer (Mettler Toledo) was performed.
Test performances were checked using as template different concentrations of human genomic DNA (hu gDNA; Roche). Similar threshold cycles in Pre- and Post-Lyo controls were obtained with a concentration ranging from 0.1 to 10 ng of hu gDNA. Moreover, Karl Fischer analysis after freeze-drying showed residual moisture content less than 5%.
The described QC procedure assures to control in an effective way the manufacturing of a freeze-dried molecular biology test in terms of performance evaluation and residual moisture content.

P14.65-S
Phenotype ontology driven gene panel construction in diagnostic next generation sequencing

A. Maver, *B. Peterlin;*
Clinical institute of Medical Genetics, Ljubljana, Slovenia.

Technological advances in determination of human genetic sequence have significantly facilitated genetic diagnostics in human disorders at progressively diminishing costs. Due to interpretative and ethical challenges faced in medical reporting of findings in whole exome sequencing (WES), sequencing of arbitrarily defined gene panels is commonly endorsed in clinical practice. Such selection of clinical sequencing target, however, narrows the diagnostic survey to genes directly associated with proposed diagnosis, is not resistant to ambiguity in determination of patients' diagnosis and suffers from large disparity in definitions of gene panels between diagnostic centres.
The systematization of human phenotype annotation, notably with the Human Phenotype Ontology (HPO) project now offers a possibility for formalized dissection of human phenotypic traits and offers a possibility for straightforward, systematic and individualised definition of clinical sequencing target based on distinct patients phenotypic features. We therefore propose a novel approach to outlining the clinical sequencing target for diagnostic next generation sequencing, where patient's phenotype is first defined according to HPO nomenclature and according gene panel is then dynamically constructed based on known phenotype-gene associations. Proposed algorithm automatically scores genes based on their phenotypic compatibility with disease under evaluation and defines a tailored sequencing target based on specific phenotypic characterization of disease.
We demonstrate that such an approach allows for judicious extension of currently established sequencing panels while assuring comparable power to establish genetic etiology and controlling for issues in either WES or targeted panel sequencing approaches.

P14.66-M
A new paradigm for prenatal chromosome microarray testing: increased resolution without equivocal findings

C. Ogilvie[1], *S. Bint*[2], *S. Mohammed*[1], *J. Ahn*[1];
[1]*Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom,* [2]*GSTS Pathology, London, United Kingdom.*

A novel prenatal chromosome microarray testing strategy has been developed, that moves away from size-based detection thresholds, towards a more clinically relevant analysis, providing higher resolution than G-banded chromosomes but avoiding the detection of imbalances of unclear prognosis that cause parental anxiety. All prenatal samples fulfilling our criteria for karyotype analysis (n=353) were tested by chromosome microarray; only copy number variants of established deletion/duplication syndrome regions and any other imbalance >3Mb were detected and reported. A retrospective full-resolution analysis of 249 of these samples was carried out to ascertain the performance of this testing strategy. Using our prenatal analysis, 28/353 (7.9%) samples were found to be abnormal. Of the remaining samples, 249 were anonymized and reanalyzed at full postnatal resolution; a further 46 regions of imbalance were detected in 44 of these traces (17.7%). None of these additional imbalances was of clear clinical significance. This prenatal chromosome microarray strategy therefore detected all CNVs of clear prognostic value. This strategy avoids the problems associated with interpre-

ting imbalances of uncertain prognosis and the parental anxiety that are a result of such findings.

P14.67-S
Determining the sensitivity of diagnostic methods to maternal cell contamination (MCC) in prenatal diagnosis (PND)

M. Ho, *E. Pontikinas, M. Vo, N. Lerda, M. Attwell, A. Simsek, C. Nicholls;*
SA Pathology, Adelaide, Australia.

Background: MCC is a potential risk factor for misdiagnosis in PND. The purpose of this study was to quantify the percentage of MCC that can be present in a fetal sample without compromising the fetal genotyping result in each of the different assays used for PND in this laboratory.
Method: Maternal DNA carrying X-linked and autosomal recessive disease was mixed with unaffected fetal DNA (prepared from dissected chorionic villi) in known proportions. Diagnostic methods examined included primer-extension assays with detection by MALDI-TOF mass spectrometry, gap-PCR, MLPA, long range PCR and Sanger sequencing. STR analysis (AmpFlSTR Identifiler kit, Life Technologies) is routinely used in our laboratory to assess MCC and was run in parallel with each assay to assess the theoretical versus the detectable MCC.
Results and discussion: An unacceptable level of MCC was defined as the percentage of MCC that results in an equivocal or incorrect genotype in the fetus. This percentage of detectable MCC was assay dependent, ranging from 1.0% with the gap-PCR, 10-15% for long range PCR, 15-20 % for Sanger Sequencing and 50% for MLPA. A correct genotyping result was obtained with the primer extension assay up to 20% MCC. STR analysis had a limit of detection of 1.0%, providing a useful tool for quantifying MCC. Results of this study have provided a basis for interpreting a PND result when MCC is present and advising requesting clinicians when repeat invasive procedure is warranted.

Mutation screening in patients with PCD by a multi-gene panel and next generation sequencing technology

F. Boaretto[1], *A. Spalletta*[1], *A. Barbato*[2], *D. Snijders*[2], *S. Quartesan*[2], *M. L. Mostacciuolo*[1], *G. Vazza*[1];
[1]*Department of Biology, University of Padova, Padova, Italy,* [2]*Department of Pediatrics, Medical Hospital, University of Padova, Padova, Italy.*

Primary ciliary dyskinesia (PCD) is a rare, autosomal recessive genetic disorder characterized by defect in the action of the cilia lining the respiratory tract, fallopian tube and also of the flagella of sperm in males. The impaired ciliary function results in neonatal respiratory distress, chronic oto-sino-pulmonary disease, infertility, and organ laterality defects in approximately 50% of cases. Currently, the diagnosis of PCD involves the study of cilia morphology, motility and ultrastructure, nasal nitric oxide measurement and, more rarely, genetic analysis. This is mainly due to the high genetic heterogeneity of the disease which has been associated to mutations in 26 different genes.
This study aims to improve the genetic diagnosis of PCD that it is routinely limited to a subset of the most frequently mutated genes. This approach is expensive, time consuming and ineffective leaving many patients without a molecular diagnosis. Using the AmpliSeq technology we developed a panel which allows comprehensive, rapid and cheap analysis of the 26 PCD-causative genes. A total of 160Kb genomic sequence including all the protein coding sequences, splice sites and 5'-3'UTRs will be amplified in 1151 amplicons using two primer pools and sequenced in the Ion Torrent platform. Twenty PCD patients diagnosed according to the protocol of the European Respiratory Society Consensus Statement have been selected for a test study. Technical details, results and cost-effectiveness analysis will be presented.

Public Health Genomic and genetic tests. Cost evaluation analysis and quality standards as relevant factors in health care planning

D. A. Coviello[1], *C. Lanza*[1], *A. Seri*[1], *M. I. Parodi*[1], *S. Casati*[2], *M. Baldi*[1], *P. Casale*[3], *A. Fabbri*[3], *M. Esposto*[3], *P. Giunciuglio*[3];
[1]*E.O. Ospedali Galliera, Laboratory of Human Genetics, Genoa, Italy,* [2]*UNIAMO, Italian Patient Federation on Rare Diseases, Venice, Italy,* [3]*E.O. Ospedali Galliera, Management Control Unit, Genoa, Italy.*

Genomic era has improved a lot molecular diagnosis, but in the last five years the new revolution of next generation sequencing has open a new window not only on research but also on diagnostic testing.
The scientific framework and the laboratory activities are completely changed: the number of known disease genes has increased exponentially, automation is now applied, certification and accreditation procedures are in place in a growing number of laboratories.
Both public National Health systems and private laboratories or companies are facing with an increasing demand of genomic tests for the most common diseases. Correct information and awareness among public and all stakeholders are crucial.
Since it has not been clearly defined how many genomic tests have enough clinical utility, the investigation of their costs could be a way to establish a correct public health policy.
Activity-Based Costing is the methodology used to assigns the cost of each activity.
The systematic analysis of activities needed to perform genetics tests has identified a number of indicators to assess the workload for every professional who participates in the process of diagnosis and the proportion of material used for each activity. All these parameters have been incorporated into a software able to split all the lab costs (personnel, material and general costs) for each test provided in order to compare costs among different laboratories, to compare the performance of the same laboratory in subsequent years and to make a priority list of genetic/genomic tests to provide, taking into account costs/benefits data.

P14.70-M
Testing homopolymers in pyrosequencing-based next generation sequencing chemistry

G. Ivady[1], *L. Madar*[1], *E. Dzsudzsak*[1], *J. Kappelmayer*[1], *V. Krulisova*[2], *M. Macek*[2], **I. Balogh**[1];
[1]*University of Debrecen, Debrecen, Hungary,* [2]*Charles University, Prague, Czech Republic.*

In the human exome, approximately 1.43 million homopolymers exist with the size of 4-mer and up. Majority (97%) of them are in the range of 4-mer to 6-mer. To detect indel mutations in homopolymers is of great importance in order to implement the corresponding sequencing system into the routine clinical practice. To test the analytical performance of the pyrosequencing-based GS Junior system in assessing homopolymer sequences, a series of plasmid vectors were generated using pcDNA3.1 as template. Altogether 12 clones were produced, 4-mer, 5-mer, and 6-mer homopolymers with all four nucleotides using site-directed mutagenesis. Mutations were confirmed using Sanger sequencing. For the test system, each homopolymer tract was tested using three pairs of PCR/sequencing primers to test the hypothesis whether the beginning of the sequencing reaction might provide the necessary signal-to-noise ratio to accurately test the size of the homopolymers. In the first, the forward, in the second, the reverse primer was located (i.e. the primer's 3' end) just next to the homopolymer to be analyzed, respectively. In the third, the homopolymer was in the middle of the sequenced product. Average of the correct genotypings were 95.8% in 4-mers, 87.4% in 5-mers, and 70.0% in 6-mers, respectively. Contrary to the low genotyping accuracy in 5-mers and 6-mers, acceptable settings could be found in both with a minimum of 97% in 5-mer and 91% in 6-mer tracts. In conclusion, we have developed a test system that can be used for the assessment of genotyping accuracy of next generation sequencing systems.

P14.71-S
Target Enrichment and Next-Generation Sequencing for Diagnostic Testing of RASopathies

S. Ekvall[1], *E. Falk Sörqvist*[1], *B. Baskin*[1], *B. Jonsson*[1], *O. Karlberg*[1], *M. Zenker*[2], *G. Anneren*[1], **M. Bondeson**[1];
[1]*Uppsala University, Uppsala, Sweden,* [2]*Humangenetisches Institut, Erlangen, Germany.*

RASopathies are a group of clinically and genetically related disorders, including Noonan, LEOPARD CFC, Costello, Legius and neurofibromatosis-Noonan syndrome as well as NF1. These disorders result from mutations affecting the RAS-MAPK signaling pathway, which explains the clinical overlap within this group of syndromes. In routine diagnostics, RASopathy-associated genes are usually tested sequentially using Sanger sequencing until a likely causative mutation is identified, which is laborious, time consuming and expensive.
We have developed a cost-effective multi-gene sequencing panel for RASopathies using HaloPlex target enrichment, sample barcoding and sequencing with MiSeq. The panel targets approximately 40kb of the coding sequences of NF1, PTPN11, SOS1, CBL, BRAF, RAF1, SHOC2, MAP2K2, MAP2K1 , SPRED1, NRAS, HRAS and KRAS. Eleven RASopathy-individuals with previously Sanger-validated variants were sequenced. Bioinformatic analysis was performed using the commercial softwares; NextGENe and BENCHlab NGS, as well as an in-house bioinformatic pipeline for HaloPlex data. The results obtained from the two bioinformatic anlaysis pipelines were similar. The gene panel was highly specific; 93% of sequencing reads aligned to the targeted regions. The average read depth in region of interest (ROI) was >2000 and ~98% of targeted bases in ROI had at least 30x coverage. All known variants were identified, including a 4 bp deletion and a splice-site mutation in NF1. Conclusively, the RASopathy-multi-gene panel presented here enables rapid and cost-effective high-throughput screening of RASopathies. The results furthermore show that NextGENe and BENCHlab NGS are

suitable for analyzing HaloPlex data in clinical diagnostics. Data from screening of additional patients will be presented.

Next Generation Sequencing: New approach for diagnosis of autosomal dominant Retinitis Pigmentosa patients

P. Fernandez-San Jose[1,2], *F. Blanco-Kelly*[1,2], *R. Rosa Riveiro-Alvarez*[1,2], *M. A. Lopez-Martinez*[1,2], *B. Garcia-Sandoval*[3], *I. Sánchez-Navarro*[1,2], *O. Zurita*[1,2], *M. Corton*[1,2], *C. Ayuso*[1,2];

[1]Department of Genetics, Instituto de Investigacion Sanitaria-Fundacion Jimenez Diaz (IIS-FJD), Madrid, Spain, [2]Centro de Investigacion Biomedica en Red de Enfermedades Raras (CIBERER), ISCIII, Madrid, Spain, [3]Department of Ophthalmology, IIS-Fundacion Jimenez Diaz University Hospital, Madrid, Spain.

Introduction: Retinitis Pigmentosa (RP) is an inherited disease clinically and genetically heterogeneous causing degeneration of photoreceptors. Autosomal dominant Retinitis Pigmentosa (adRP) accounts for 15-30% of cases and mutations in 24 known genes are responsible for 60% of them. The 40% of our cohort of 200 adRP Spanish patients has been characterized using classical tools: different methods of screening (Single Strand Conformation Polymorphism (SSCP), CG-clamped Denaturing Gradient Gel Electrophoresis (DGGE) and ADRP genotyping microarray (Asper Biotech)) followed by Sanger sequencing gene by gene. Patients and methods: 66 previously studied and not characterized adRP families, were analysed by Next Generation Sequencing (NGS) panel of 73 genes associate to RP and other Retinal dystrophies (RD). Sequence variants were detected using the sequence DNA capture Haloplex (Agilent) and sequencing with a Miseq platform (Ilumina). Bioinformatic analysis was performed with a specific DNA Nexus pipeline. Results: potentially pathogenic variants in known adRD genes were found in 42,4 % of families studied: SNRNP200 (7,6%), PRPF8 (6 %), BEST1 (3 %), PRPF31 (3 %), PRPH (3%), RP1 (3 %), CRX (1,5 %), FSCN2 (1,5 %), GUCA1B (1,5 %), IMPG1 (1,5 %), KCNJ13 (1,5 %), PROM1 (1,5 %), PRPF3 (1,5 %), RGR (1,5 %), RHO (1,5 %), RP2 (1,5 %), and TOPORS (1,5 %). Additionally 7,6% of cases displayed mutations in ABCA4, RPGR and USH2A allowing us a clinical or genetic reclassification. Conclusion: this new approach seems to be a fast and reliable tool to detect the disease-causing mutation for adRP patients.

P14.73-S
Visualization of *XIST* expression in a female with structural X chromosome abnormality: Single-cell analysis by three-color interphase RNA-FISH

W. Iha, *R. Kawamura, T. Yamaguchi, Y. Fukushima, K. Wakui;*
Shinshu University School of Medicine, Matsumoto, Japan.

An X-inactivation (XIA) analysis in females is commonly performed by metaphase R-banding or methylation-specific PCR (M-PCR) technique. The late-replicating X-chromosome can be recognized under a microscope at the single cell level by R-banding using BrdU incorporation, but there are limitations: 1) Not so many metaphases can be observed, and 2) Only an abnormal X which has deletion or duplication more than 10Mb can be detected. M-PCR can detect random or non-random XIA pattern in cell population, but the parental samples are needed to identify which is normal or abnormal chromosome X. A subject was a female with an X-autosome balanced translocation; 46,X,t(X;19)(p21.1;q12), and having clinical manifestations of Duchenne muscular dystrophy. The breakpoint of the derivative X was onto the *DMD* gene. We selected three kinds of BAC clones and used simultaneously for our RNA-FISH study; a clone consistent with *XIST* gene for detecting inactivation chromosome X, a clone consistent with *UTX* gene which is escaping XIA as a reference probe for both normal and abnormal Xs, and a clone consistent with *HDHD1A* gene which is escaping XIA for distinguishing between normal and abnormal Xs of this subject. We successfully visualized *XIST* gene expression at the single cell level in this subject. Normal X was inactivated in 67 cells, abnormal X was inactivated in 5 cells, and unclear XIA pattern was in 28 cells. This RNA-FISH results were in concordance with the phenotype of this subject, as an affected female of X-linked disorder.

P14.74-M
Quality control for SureSelect Strand-Specific RNA library preparation protocol using the Agilent 2200 TapeStation system

E. Schmidt[1], *A. Padmanaban*[2], *A. Inche*[3], *R. Salowsky*[1];
[1]Agilent Technologies, Waldbronn, Germany, [2]Agilent Technologies, Bangalore, India, [3]Agilent Technologies, Edinburgh, United Kingdom.

Transcriptomics reveal global changes in gene expression that may contribute to the pathogenesis of a particular disease or help drive a fundamental biological process. RNA sequencing (RNA-Seq) has emerged as a promising and rapidly growing method for studying and characterizing cellular transcripts at single base pair resolution. Among different approaches for generating libraries for transcriptomics study, strand-specific library preparation method has added advantage over other methods. The Agilent SureSelect strand-specific RNA library preparation kit generates libraries with specific adaptors ligated to each strand enabling the identity of the DNA template strand of origin to be retained in downstream sequencing and data analysis. The high throughput deep-sequencing based RNA-seq studies generate more data compared to RT-qPCR and array based methods yet they are expensive and time consuming study. Proper quality control (QC) steps within the library preparation process are therefore crucial to ensure successful sequencing. The Agilent 2200 TapeStation system offers an easy to use automated electrophoresis system with rapid analysis time as well as flexible sample throughput capabilities. Here, we compare the performance and capabilities of the RNA and D1000 ScreenTape assays for use on the Agilent 2200 TapeStation system with the respective assays run on the 2100 Bioanalyzer system. The results from the QC of the starting total RNA and final sequencing libraries generated from Agilent's SureSelect strand-specific RNA library preparation kit reveal that the RNA and D1000 ScreenTape assays are a match to the visual and quantitative results obtained with the RNA 6000 Nano and DNA 1000 Kits.

P14.75-S
Expanded carrier screening tests currently on the commercial market

B. Peterlin[1], **L. Vidmar**[1], *P. Borry*[2], *M. Cornel*[3], *C. van El*[3], *F. Fellmann*[3], *F. Forzano*[4], *L. Henneman*[3], *H. Howard*[5], *H. Kayserili*[6], *C. Patch*[7], *A. Maver*[1];
[1]Clinical institute of medical genetics; Univeristy medical centre Ljubljana, Ljubljana, Slovenia, [2]Interfaculty Centre for Biomedial Ethics and Law (K.U.Leuven), Leuven, Belgium, [3]Department of Clinical Genetics, Section Community Genetics, EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands, [4]Galliera Hospital (Genova); Department of Medical Genetics, Genova, Italy, [5]IQhealthcare, Medical Ethics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [6]İstanbul University; Medical Faculty; Department of Medical Genetics, İstanbul, Turkey, [7]Guy's and st.Thomas' NHS foundation trust, London, United Kingdom.

There has been a recent rise in the advertising of preconception genetic carrier screening tests directly to consumers via internet. We analyzed the offers with particular focus on comprehensiveness, clinical validity and utility of the genetic tests proposed.
We gathered data from the websites of Counsyl, InheriGen, Pathway genomics and Recombine in December 2013. Of about 1300 recessively inherited diseases listed in OMIM (causative gene known), current offer includes a range of 73 to 206 for a total of 286 diseases of which 30 are included in the panels of all providers and 92 in at least three providers. According to the ORPHANET catalogue, 31% of screened diseases are more frequent than 1/100,000 in the general population. On the other hand, there are relatively frequent recessively inherited diseases (e.g. Duchenne muscular dystrophy, Friedreich ataxia) not covered by any of the screening tests. 52% of screened diseases manifest neonatally, 28% during childhood and 3% in adult life(e.g. Hemochromatosis), while the onset of the others is variable. 34% can be treated if diagnosed neonatally. On average, companies test for 4% (2,2% to 7%) of all known mutations on a particular gene (HGMD).
Currently, commercial companies offer screening for around 20% of known recessively inherited diseases. The great diversity of genetic diseases screened suggests a lack of clear inclusion criteria. Although advertised as pan-ethnic, all tests include population specific diseases which are extremely rare in the general population. Because of allelic heterogeneity and relatively poor mutation coverage the tests' sensitivity pan-ethnically is unknown.

P14.76-M
Detection of rare variations in a targeted genomic region in a population by NGS analysis using pooled DNAs

T. Kaname[1], *M. Higa*[1], *A. Ganaha*[1], *K. Teruya*[2], *K. Satou*[2], *T. Hirano*[2], *K. Naritomi*[1];
[1]University of the Ryukyus, Nishihara-cho, Japan, [2]Okinawa Institute of Advanced Sciences, Okinawa, Japan.

It is important to find novel rare variations in a targeted region in some populations to get next resources for elucidation of 'missing heritability'. We developed a method to survey variations including low-frequent variations in a targeted region in a specific population by next-generation sequencing (NGS) analysis using pooled DNAs.
We present examples to trace variations and to estimate each frequency in a targeted region in Japanese and Okinawan people.
Targeted regions were amplified from each genomic DNA of 100 or 200 individuals by LA-PCR. After measuring the quantity and quality of each amplicon, equal amount of amplicon was mixed and amplicons for 100 or 200 individuals were pooled. Then, pooled targeted region was analysed using a NGS platform. After mapping of reads to the reference, SNPs and indels were called and the frequency was estimated by count rate of the reads. Then, we also performed NGS analysis for LA-PCR products from pre-pooled genomic DNAs. Next, we confirmed each variation and calculated each frequency in

the population by PCR-RFLP, allele specific PCR or direct sequencing in each individual.
Allelic frequency estimated by the NGS analysis using both pooled DNAs almost correlated the real frequency calculated by the individual analysis. For sensitivity to detection of allelic frequency, less than 0.5% of allele in the population could be detected.

P14.77-S
Increasing the detection rate of genome-wide high resolution SNP array analysis by using the right follow-up test procedures in constitutional genome diagnostics

N. de Leeuw, *J. Y. Hehir-Kwa, T. K. Rinne, N. F. A. Leijsten, G. C. Machielsen, S. L. J. Kempers-vanGessel, M. Wunderink, M. J. G. Banning, R. van Beek, M. H. A. Ruiterkamp-Versteeg, A. J. A. Kooper, S. Wezenberg, M. del Rosario, B. H. W. Faas, R. Pfundt;*
Department of Human Genetics, Nijmegen, Netherlands.

We routinely perform genome-wide high resolution SNP array analysis as the first-line diagnostic test for patients with intellectual disability and/or congenital anomalies and prenatally in case of structural ultrasound anomalies or intra uterine foetal death and a normal QF-PCR test result. So far, a total of 9,471 patient and 3,348 parental samples have been tested by SNP array in our diagnostic laboratory. A (potentially) causative copy number variant (CNV) was detected in almost 27% of the patients and analysis of SNP genotypes revealed one or more significant stretches of homozygosity in an additional 8% of patients. Follow-up testing by either gene mutation analysis or patient-parent trio information analysis subsequently led to the respective identification of pathogenic mutations in recessive disease genes or uniparental disomies (UPD), thereby increasing the diagnostic yield with at least 1%. Using the SNP genotype information also improved the detection of mosaic imbalances and enabled us to detect clinically relevant, mosaic, copy neutral changes of homozygosity in four patients. A mosaic finding (CNV, aneuploidy or allelic imbalance) was detected in a further 26 patient samples and 10 parental samples, resulting in a dramatically increased recurrence risk for these parents. The percentage of mosaicism often differed between tissues samples of mesodermal, ectodermal or endodermal origin from each of these individuals. Genome-wide high resolution SNP array analysis is a suitable and particularly effective technique in genome diagnostics to reliably detect in a single test CNVs, UPDs and mosaic imbalances as well as for homozygosity pre-screening.

P14.78-M
Classifying variations as de novo without available paternal DNA using SNP-array

J. Graakjaer, *A. Bojesen;*
Vejle Hospital, Vejle, Denmark.

Inheritance of a variation is often used as a guide for diagnostic classification in microarray analysis. If a variation is inherited from a normal parent, morbidity is less likely, compared to a variation that has appeared de novo. Unfortunately paternal DNA is frequently not available for this analysis. Therefore many variations are never properly classified and the morbidity of the variation remains unknown. To overcome this problem we have incorporated a workflow that determines whether a variation is located on the maternal or the paternal allele in the patient. The workflow requires SNP-array analysis to be done on maternal and patient DNA samples. If a variation is located on the maternal allele in the patient and the variation is not found in the maternal DNA sample, then the variation can be classified as de novo. Utilizing this workflow enhances the diagnostic value of variations found by SNP-array, when paternal DNA is not available.

P14.79-S
EGFR and KRAS mutational profiling in fresh non-small cell lung cancer (NSCLC) cells

M. Zorzetto, *R. Scabini, S. Inghilleri, S. Ferrari, P. Morbini, M. Luisetti;*
Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy.

Knowledge of tumor mutational status has become a priority for effective NSCLC-tailored treatment. NSCLC diagnosis is more often reached through biopsy; thus, there is a clear need to implement for routine tumor molecular profiling on small cytological samples. This work aims to screen and compare the EGFR and KRAS mutational prevalence in fresh tumor cells and in corresponding routinely processed samples derived from trans-thoracic fine-needle aspiration. The latter currently represents the most appropriate diagnostic procedure in case of peripheral lesions, such as adenocarcinomas, which account for almost 40 % of all NSCLCs and for the highest EGFR mutational rates.
Two hundred and forty-four patients carrying peripheral lung masses underwent CT-guided aspiration. The obtained material was split, and a part was addressed to conventional histopathological analysis while the remaining one was stored at −20 °C. In case of confirmation of adenocarcinoma, tumor genomic DNA was extracted from both fresh and fixed material, and EGFR and KRAS sequencing was performed.
We identified 136 adenocarcinomas; from 134, we could recover enough material for the study. A full match was demonstrated between EGFR/KRAS mutational prevalences through the two approaches tested. We found EGFR mutations in 13 patients (9.7 %); 7 were females and 11 never or former smokers. KRAS mutations occurred in 20 (14.9 %) patients. EGFR and KRAS mutations were mutually exclusive.
Mutational screening on fresh cancer cells is an achievable, safe and cost-effective procedure which might allow routinely tumor molecular profiling as powerful integration of conventional histopathological analysis.

P14.80-M
Identification of structural variation in whole exome sequencing and whole genome data

J. Y. Hehir-Kwa[1], *N. de Leeuw*[1], *M. del Rosario*[1], *N. F. A. Leijsten*[1], *M. H. A. Ruiterkamp-Versteeg*[1], *S. L. I. van Gessel*[1], *R. de Reuver*[1], *N. Wieskamp*[1], *D. Lugtenberg*[1], *D. T. Thung*[1], *I. M. Janssen*[1], *C. Gilissen*[1], *M. van de Vorst*[1], *B. W. M. Bon*[1], *M. H. Willemsen*[1], *M. Kwint*[1], *A. Hoischen*[1], *R. Leach*[2], *R. Klein*[2], *R. Tearle*[2], *T. Bo*[1,3], *H. G. Yntema*[1], *B. B. A. de Vries*[1], *T. Kleefstra*[1], *H. G. Brunner*[1,4], *L. E. L. M. Vissers*[1], *J. A. Veltman*[1,4], *R. Pfundt*[1];
[1]*Radboud umc, Nijmegen, Netherlands,* [2]*Complete Genomics Inc, Mountain View, CA, United States,* [3]*State Key Laboratory of Medical Genetics, Central South University, Changsha, China,* [4]*Department of Clinical Genetics, Maastricht University Medical Centre, Maastricht, Netherlands.*

Whole exome sequencing (WES) allows the detection of a wide range of variant types. With one single test it is possible to detect small variants (SNVs), and structural variation. Whilst the role of copy number variants (CNVs) in intellectual disability (ID) is well known, the role of CNVs in other diseases is less well studied, although it has been suggested that CNVs can be found in up to 10% of deafness patients. We have performed read depth WES CNV analysis on 600 patients across 5 heterogeneous disorders including ID, deafness, blindness, metabolic disorders, movement disorders. This analysis revealed several clinically relevant CNVs exerting a dominant effect, as well as CNVs unmasking a recessive mutation that lead to pathogenic compound heterozygous events. The cohort of 310 ID patients had previously screened negative for CNV microarray analysis as well as WES SNV analysis. Nonetheless clinically relevant CNVs were identified in 2% of patients. Systematic screening of the remaining patient groups identified CNVs in ~4% of individuals, including in *COL6A1*, *EYS* and deletions in *USH2A*. To further examine pathogenic structural variation, we performed whole genome sequencing on 50 patient-parent trios. In 7 patients we identified pathogenic *large* variants, including two single exon deletions, a tandem duplication, an inter-chromosomal duplication and one complex inversion/duplication/deletion event. Discordant reads provided positional information for duplicated sequences identifying an in-frame gene fusion. These results show that structural variation is not only an important cause of neurodevelopmental diseases but also a much broader range of genetic diseases.

P14.81-S
Targeted exome sequencing as a molecular diagnostic tool for skeletal dysplasias

D. L. Polla, *M. C. B. Silva, M. T. O. Cardoso, R. W. Pereira, R. Pogue;*
Catholic University of Brasilia, Brasilia, Brazil.

Skeletal dysplasias comprise a large group of more than 450 clinically distinct and genetically heterogeneous diseases associated with mutations in more than 300 genes. Clinical and radiological findings are used to diagnose these diseases. However, due to the genetic heterogeneity of these disorders, the diagnostic process is complex. With the advances in molecular genetics and the elucidation of the molecular basis of these diseases, molecular tests have become useful in the diagnosis of these dysplasias. Since many different genes have been associated with these disorders, standard diagnostic approaches using Sanger sequencing can be expensive and time consuming. To overcome these limitations, we used targeted exome sequencing and designed an 1.4Mb panel for simultaneous testing of more than 4800 exons in 309 genes involved in skeletal dysplasias, and 28 genomic regions which when deleted are associated with these diseases. DNA from 96 individuals with previous clinical diagnosis of skeletal dysplasia was sequenced in 8 multiplexed runs using an Illumina MiSeq sequencer. Reproducibility was tested by repeating the entire procedure for three patients. NGS of the captured exons resulted in an average coverage of 140X. Causative mutations were characterized in 13 patients so far including de-novo mutations in 7 cases. Analysis of the rest of the data is ongoing. Confirmation with Sanger sequencing was performed for these variants and all were confirmed. Our NGS panel provides a fast, accurate and cost-effective molecular diagnostic tool and can assist in the diagnosis of genetically heterogeneous diseases like skeletal diseases.

P14.82-M
Molecular diagnosis of hereditary spastic paraplegia: comparison of enrichment strategies for targeted next-generation sequencing

L. Raymond[1,2,3], *S. Morais*[1,2,4], *A. Rastetter*[1,2], *E. Mundwiller*[1], *G. Banneau*[3], *C. Depienne*[1,3], *M. Mairey*[1], *C. Cazeneuve*[3], *E. Leguern*[1,3], *A. Durr*[1,3], *A. Brice*[1], *Y. Marie*[1], *G. Stevanin*[1,2,3];
[1]*Institut du Cerveau et de la Moelle épinière (Sorbonne Universités, UPMC Univ Paris 6 UM75, INSERM U1127CNRS UMR7225, NEB), Paris, France,* [2]*Equipe de Neurogénétique, Ecole Pratique des Hautes Etudes, héSam Université, Paris, France,* [3]*Fédération de Génétique, CHU Pitié-Salpêtrière, Paris, France,* [4]*UnIGENe, IBMC, Porto, Portugal.*

Hereditary spastic paraplegia (SPG) is a group of neurodegenerative disorders with considerable phenotypic heterogeneity, and mutations in >70 genes involved to date. This makes conventional molecular testing arduous. We decided to develop a targeted next generation sequencing kit for diagnosis purpose.
We tested two enrichment approaches of 10 SPG genes: one using amplicons (Illumina, TruSeq Custom Amplicon - TSCA) on 48 patients, and the other using capture (Roche NimbleGen, SeqCap EZ) on 60 patients. Sequencing was performed on the MiSeq (Illumina). Coverage and variant distribution were evaluated using the Genomics Workbench software (CLC Bio).
After read mapping on whole genome (Hg19), the mean coverage per patient varied from 444X (sd 98X) for SeqCap EZ, to 587X (sd 127X) for TSCA. However, the percent of regions with minimal coverage <30X was <15% with SeqCap EZ, and decreased to <5% when the patient mean coverage reached 600X. With TSCA, this value was stable (15-20%).
We then compared the variants. Those reported in dbSNP137 were similar on both strategies. Concerning variants unknown in dbSNP137, 16-20 variants with TSCA vs 0-3 with SeqCap EZ were obtained per sample. This was explained by an enrichment of variants in some amplicons in TSCA suggesting false positives due to Taq polymerase errors.
SeqCap EZ was finally chosen to enrich our targets. We designed a new panel with 74 SPG genes, which gave <0.7% of regions with minimal coverage <30X. The challenge is now to interpret the variants discovered in our growing cohort of patient with unsolved HSP.

P14.83-S
Development of a specific and sensitive High Resolution Melting Analysis for detection of beta globin gene mutations

C. Chassanidis, *T. Tsantzali, G. Kellaris, E. Voskaridou, E. Boutou, A. Balassopoulou;*
Laiko Hospital, Athens, Greece.

Beta-thalassemia is one of most common autosomal recessive disorders worldwide. The high prevalence (8%) and heterogeneity in molecular level, observed in Greece, makes necessary the development of a reliable, cost effective and rapid scanning method for β globin gene analysis, easily adapted to a routine laboratory.
Here we describe the development of a beta-thalassaemia specific High Resolution Melting Analysis (HRMA) approach, in order to identify point mutations and small insertions or deletions of the beta globin (HBB) gene and substitute previously applied techniques (DGGE analysis, Sanger sequencing).
Specific sets of primers were designed to cover eight overlapping regions of the HBB gene containing the hitherto reported mutations of the Hellenic population. PCR conditions were identical for all amplicons, permitting thus multiplexing. Amplicons cover part of the HBB promoter region and the CDS region, except from the central part of IVS-II where practically no mutations has been reported up to now.
Initially, 150 previously genotyped samples were analysed. Different mutations produced distinct derivative plots when subtracted from the reference curve of a wild type control, resulting in 100% accurate mutation identification. In addition, HRMA analysis of 48 undefined samples totally matched subsequent diagnosis by either Sanger sequencing or DGGE analysis.
The described HRMA assay represents a rapid, simple, cost-effective and highly feasible strategy for identifying effectively underlying mutations of beta-thalassemia. The reported method is amenable to high-throughput systems and except from being highly specific and sensitive, does not require any post-PCR analysis.

P14.84-M
Optimization of an imaging cytometry protocol to determine the absolute mean corpuscular haemoglobin F in F-erythrocytes

J. Scerri, *G. Grech, A. E. Felice;*
University of Malta, Msida, Malta.

Around birth, a shift from γ- to β-globin gene expression causes a switch from foetal haemoglobin (HbF) to adult haemoglobin (HbA). Residual amounts of HbF are synthesized throughout life F-erythrocytes. Increased HbF levels ameliorate symptoms of β-haemoglobinopathies.
Krüppel-like factor 1 (KLF1) plays a central role in the developmental globin gene switch; carriers of KLF1 mutations have hereditary persistence of foetal haemoglobin (HPFH) and show variably elevated (10-40%) HbF. This variation may be due to differential expression of other modifier genes. The KLF1 interactome can be further defined by identifying potential molecular targets and observing their expression at the cellular level in comparison with HbF expression and distribution in F-cells.
The mean corpuscular HbF (MCHbF) is normally estimated by dividing the amount of HbF, determined by HPLC, by the number of F-cells, obtained by flow cytometry. Since HbF may be unequally distributed among F-cells, an imaging cytometry protocol enables quantification of HbF per F-cell by fluorescent emission measurements. Protocols presented in the literature were found lacking in efficacy, mostly due to inefficient fixation and high degree of autofluorescence. A new intracellular anti-HbF antibody-labelling technique was thus optimized for use with the Nikon Eclipse T*i* inverted fluorescence microscope. This technique resulted in images of superior quality from which the MCHbF could be determined for each F-cell observed. This protocol will be used to study the association of *KLF1* and other genes, obtained through NGS data analyses, with MCHbF in normal and HPFH individuals, to identify new therapeutic targets for β-haemoglobinopathies.

Development and verification of an Ion AmpliSeq™ *TP53* Panel

A. Langerød[1,2], *L. Silwal-Pandit*[1,2], *E. Rødland*[1,2], *A. Dahlsgaard*[1,2], *I. Bergheim*[1,2], **C. Ainali**[3], *C. Scafe*[3], *F. Hyland*[3], *G. Liu*[3], *C. Van Loy*[3], *M. Andersen*[3], *H. Viernes*[3], *R. Petraroli*[3], *A. Børresen-Dale*[1,2];
[1]*Department of Genetics, Institute for Cancer Research, Oslo University Hospital Radiumhospitalet, Oslo, Norway,* [2]*The K.G. Jebsen Center for Breast Cancer Research, Institute for Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway,* [3]*Thermo Fisher Scientific - Life Sciences Solutions, South San Francisco, CA, United States.*

A large amount of data is available on the functional impact of missense mutations in TP53 and on mutation patterns in many different cancers. TP53 direct sequencing is a time-consuming method with limitations in detection level. Here we describe the development and verification of a Next Generation Sequencing method based on Ion AmpliSeq™ technology. The panel covers TP53 coding regions comprehensively using optimized primers to minimize off-target sequencing. It is comprised of 24 primer pairs across 2 pools requiring only 20 ng of DNA. The design of short amplicons of 125 to 175 bp permits the amplification of DNA starting from formalin-fixed paraffin embedded material. We verified the panel on 30 breast cancer samples previously characterized with Sanger sequencing. Sequencing reactions were carried out with the Ion PGM™ Sequencer on Ion 318™ chip. The average % of mapped reads on target was of 96,8% and average depth of coverage 20,386X. Loading 10 samples on an Ion 318™ chip 95% of the sequenced amplicons showed coverage higher than 500X. Data analysis was performed on Ion Reporter™ Software 4.0 using optimized TP53-panel workflows. We detected all the expected somatic mutations including single base substitutions, insertions and deletion and only a complex duplication of 18bp was not detected. The overall analytical sensitivity was 95,23%. The same results were obtained using 32 samples on an Ion 318™ chip. These preliminary data demonstrate that the TP53 Ion AmpliSeq™ panel workflow and Ion Reporter™ Software analysis solution meets the requirements of clinical research laboratories.

Toward rapid identification of coding fusions and structural rearrangements in cancer genomes: Multiple Myeloma First

M. R. Rossi[1], *H. Dai*[2], *H. Cao*[2], *M. Saghibini*[2], *X. Yang*[2], *A. Pang*[2], *H. VanSteenhouse*[2], **M. Reardon**[2], *T. Dickinson*[2], *A. Nooka*[1], *J. L. Kaufman*[1], *S. M. Matulis*[1], *L. Zhang*[1], *D. F. Saxe*[1], *L. H. Boise*[1], *K. P. Mann*[1], *D. L. Jaye*[1], *S. Lonial*[1];
[1]*Emory University, Atlanta, GA, United States,* [2]*BioNano Genomics, San Diego, CA, United States.*

Karyotype and FISH have been standard diagnostic tools in monitoring response to treatment and disease progression in hematological disorders, including multiple myeloma, for over 40 years. However, with the availability of array and NGS technologies in most clinical diagnostic laboratory settings, it is time to consider evaluated the use of more modern methods in diagnosing plasma cell dyscrasias. Although we routinely run RNA-Seq, SNP-CN arrays and a deep sequencing cancer panel as a cost effective workflow for clinical trials, we find the validation of translocations and structural rearrangement by PCR and/or FISH cumbersome. More recently, we have identified the BioNano Genomics Irys System which utilizes nanochannel technology and high resolution imaging for whole genome mapping of translocations and copy number abnormalities. As proof of concept, we have used the Irys system to analyze the multiple myeloma cell line, KMS11, and will demonstrate the ultility, speed and accuracy in detecting structural re-

arrangements in this line compared to whole genome sequencing, RNA-seq and SNP-CN datasets. We will also demonstrate the use of the system with unknown CD138+ enriched bone marrow samples from consented patients currently on clinical trials compared to FISH, G-band karyotype and SNP-CN arrays. We are confident that these data demonstrate that the Irys system is a disruptive innovation with broad applicability to genome research and refinement of normal variation and disease.

P14.87-S
Mutation analysis of triple negative breast cancer patients using next generation sequencing

L. A. Pop[1], *R. M. Petric*[1,2], *O. Virtic*[1], *I. Berindan-Neagoe*[1];
[1]*Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania,* [2]*"Babes Bolyai" University, Cluj-Napoca, Romania.*

Despite the intense research in the field of breast cancer, this disease still remains the second most common cancer in women worldwide, being the first cause of death in women in Romania. Among the different subtypes of breast cancer, triple negative breast cancer (TNBC) needs a special attention due to its limitations in therapy and to its aggressiveness. Several studies have tried to identify different new mutation both in oncogenes and tumor suppressor gene in order to explain these limitations of TNBC treatment. The present study was aimed at the identification of mutations in 46 genes involved in cancer in 31 patients with TNBC operated at the Institute of Oncology "Prof. Dr. I. Chiricuta", Cluj-Napoca between 2006-2007, using Next Generation Sequencing. We used FFPE tissue samples which were sequenced using the Ion Torrent Personal Genome Machine and the Ion Reporter 1.6 software for data analysis. After data analysis we obtained 103 mutations in 34 genes of the 46 studied. The clinical assessment of the identified mutations showed that three mutations were benign, one was likely benign, 42 were likely pathogenic, 28 were pathogenic and 29 had no assessment. This study also identified KDR, TP53, PIK3CA, FGFR3 and FGFR2 genes as being the most frequently mutated genes. Our results show that TNBC has specific mutations leading to resistance to therapy and poor outcome of these patients.

P14.88-M
Four Decade Old Mummified Umbilicus Making Retrospective Molecular Diagnosis of Ornithine Carbamoyltransferase Deficiency

R. Kosaki[1], *T. Takenouchi*[2], *Y. Tsukahara*[3], *R. Horikawa*[4], *K. Kosaki*[5];
[1]*Division of Medical Genetics, National Center for Child Health and Development Hospital, Tokyo, Japan,* [2]*Department of Pediatrics, Keio University School of Medicine, Tokyo, Japan,* [3]*Department of Maternal-Fetal and Neonatal Medicine, National Center for Child Health and Development Hospital, Tokyo, Japan,* [4]*Division of Endocrinology and Metabolism, National Center for Child Health and Development Hospital, Tokyo, Japan,* [5]*Center fo Medical Genetics, Keio University School of Medicine, Tokyo, Japan.*

In inborn errors of metabolism, sampling and preservation of viable specimen is critical in reaching the correct diagnosis. Utility of preserved umbilical cords have been demonstrated in several occasions, but it remains unclear how long the mummified umbilicus can preserve genomic DNA that tolerates sequence-based genetic analysis. We report a Japanese family of successive early deaths presumably due to clinically diagnosed ornithine carbamoyltransferase deficiency. The exact molecular pathology, c. 394T>C (p. S132P), was retrospectively delineated using DNA extracted from the mummified umbilicus that had been kept in a keepsake wooden box at home for four decades after the deaths of affected individuals. This observation illustrates the striking stability of DNA preserved in mummified umbilicus, and supports an efficient way of genetic sample preservation. From cultural standpoint, preservation of mummified umbilical cord is a unique but common tradition in Japan for at least several centuries. The exact molecular diagnosis of this X-linked inborn error of metabolism of the urea cycle had an significant impact on the affected family. Hemizygous female carriers are at risk of hyperammonemic crisis, and this disorder is treatable with supplemental dietary interventions. Since naturally mummified umbilicus provides a highly effective way of genetic sample preservation, utilization such material should be considered in the retrospective genetic investigation, particularly in patients with south east Asian cultural backgrounds.

P14.89-S
Direct trans-differentiation of skin fibroblasts for functional testing of unclassified variants

J. Pals[1,2], *K. van der Kuij*[2], *D. Micha*[1], *A. Maugeri*[1], *G. Pals*[1], *M. J. Baars*[3], *V. Everts*[2], *B. Zandieh Doulabi*[2];

Introduction Unclassified variants (UVs) are a common finding in DNA diagnostic testing. The introduction of next generation sequencing, allowing the simultaneous analysis of multiple genes, has enhanced the problem of variants with unknown clinical significance. For in vitro functional testing of UVs we need cells that express the specific gene. **Aim** The aim of this study is to use direct trans-differentiation of skin fibroblasts into smooth muscle cell (SMC) phenotype in order to study the effect of UVs in genes that are involved in susceptibility to thoracic aortic aneurysms. **Methods** We used culture media with horse serum and TGFβ1 to induce trans-differentiation of patients' fibroblasts into SMCs. Gene expression was tested with RT-PCR. Splice errors were studied on cDNA. Contraction of the cells was studied on collagen matrix. **Results** Cells with SMC phenotype, derived from fibroblasts from patients with UV's in MYH11 were compared to controls. The differentiated cells expressed SMC markers, including MYH11, confirming successful differentiation. An intronic mutation in MYH11, c.3879+2dup, in a patient with TAA and type B dissection with a positive family history for aortic dissection, does not affect the canonical splice donor site, but was shown in transdifferentiated cells from the patient to result in the use of a cryptic splice site in exon 29, resulting in an in frame deletion of 78 bases. The contraction of the patient derived cells was disturbed compared to control cells. **Conclusion** Trans-differentiation of skin fibroblasts towards SMC phenotype is a powerful tool for the functional analysis of UVs.

P14.90-M
Targeted re-sequencing and USH syndrome: a robust and accurate protocol overcoming the problem of genetic heterogeneity and leading to the discovery of several new mutations

S. Lenarduzzi[1], *C. Graziano*[2], *P. Castorina*[3], *U. Ambrosetti*[4], *A. Morgan*[1], *E. Rubinato*[1], *G. Girotto*[1], *D. Vozzi*[5], *M. Morgutti*[5];

Usher Syndrome (USH) is characterized by phenotypic and allelic heterogeneity requiring a powerful and reliable molecular diagnosis. Thus, a targeted re-sequencing (TS) panel of the 10 USH genes has been developed. It covers 96% of the targeted regions being characterized by 872 amplicons using Ion Torrent™ technology (Life Technologies). This protocol has been applied to the analysis of 30 USH cases divided as follows: 16 with already known mutations were used for a validation step which demonstrated 100% accuracy, while the remaining 14 were analyzed at diagnostic level. The combination of systematic data analysis using an established bioinformatics pipeline followed by Sanger sequencing confirmation and segregation analysis led to the identification of 15 novel variants (1 in *USH2A*, 4 in *PCDH15,* 1 in *MYO7A*, 3 in *CDH23*, 4 in *GPR98*, 2 in *USH1G*). All these variants were predicted as pathogenic using several *in silico* predictor tools such as Mutation Taster, Polyphen-2, SIFT and others. Five known pathogenetic mutations were also detected. Overall, these 20 alleles explain 12 patients, one is heterozygous for a mutated allele and the second is lacking, and the last is completely negative (a new case of genetic heterogeneity or the presence of mutations in regions not yet analyzed of the USH genes?). In term of molecular epidemiology, USH2A characterizes 12 patients (40%) MYO7A 6 (20%), CDH23 4 (13%), PCDH15 3 (10%), GPR98 2 cases, USH1C and USH1G one each. In conclusion, this methodology clearly provided a reliable strategy for routine gene diagnosis of USH.

P14.91-S
p.Asp59Gly in the RAB40AL gene is a common allelic variant: no evidence for a causal relationship with Martin-Probst syndrome

M. Oldak[1,2], *A. Ścieżyńska*[1], *E. Ruszkowska*[1], *K. Szulborski*[3], *A. Pollak*[2], *M. Mueller-Malesińska*[2], *P. Stawiński*[4], *J. P. Szaflik*[3], *R. Płoski*[5];
[1]*Department of Histology and Embryology, Medical University of Warsaw, Warsaw, Poland,* [2]*Institute of Physiology and Pathology of Hearing, Warsaw, Poland, Warsaw, Poland,* [3]*Department of Ophthalmology, Medical University of Warsaw, Warsaw, Poland, Warsaw, Poland,* [4]*Department of Immunology, Medical University of Warsaw, Warsaw, Poland, Warsaw, Poland,* [5]*Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland, Warsaw, Poland.*

Two adjacent substitutions A to G (rs145606134) and C to A (rs138133927), both affecting codon 59 leading to a missense change p.Asp59Gly (GAC>GGA) in the RAB40AL gene, have been recently reported as a first association of the RAB40AL gene with a human disorder and as the molecular cause of Martin-Probst syndrome (MPS) (Bedoyan et al. 2012). This rare X-linked disorder is characterized by progressive sensorineural hearing loss, cognitive impairment, facial dysmorphism, variable renal and genitourinary abnormalities and late onset pancytopenia.
The p.Asp59Gly amino acid change resulting from the same two DNA substitutions was unexpectedly identified in our 53-year-old male proband,

who was diagnosed for a genetic cause of isolated optic atrophy using whole exome sequencing (HiSeq 1500 and TruSeq Exome Enrichment Kit, Illumina). Interestingly, the patient did not present any symptoms of MPS. Trying to further verify the pathogenicity of the RAB40AL variants, we screened a set of control DNA samples representative of the background population of Central Poland (n=788, female:male ratio 1:1) using allele-specific PCR and confirmed suspicious variants by Sanger sequencing (Applied Biosystems). The RAB40AL variants were found in 18 out of 788 subjects. It corresponds to an allele frequency of almost 2.3%. Results of our study have demonstrated that the p.Asp59Gly amino acid change in RAB40AL gene is present at a high prevalence in the general population that is typical for common polymorphisms. Our data questions the role of p.Asp59Gly as a disease causing-change for MPS.

P14.92-M
Comparative transcriptome and genome analysis down to the sequence level for individual cells

A. Meier, E. Fricke, E. Fisch, H. Wedler, U. Deutsch, **N. Neubauer**, *C. Korfhage; QIAGEN, Hilden, Germany.*

Cell heterogeneity plays a central role in biological phenomena during normal development or disease (e.g., cancer development). As gene regulation is a fundamental process, the analysis of transcript profiles and genomes of single cells to dissect phenotypic variability is of key interest to scientists.
Deep genome and transcriptome analysis of small biological samples using next-generation sequencing (NGS) is often limited by the small amount of sample available (6 pg gDNA and 0.5 pg mRNA/human cell). We developed two new methods for whole genome amplification (WGA) and whole transcriptome amplification (WTA), based on Multiple Displacement Amplification (MDA) technology, from small samples down to just a single cell.
Parallel WGA and WTA reactions begin with lysis of 25–1000 cells from the same sample. Both reactions include a ligation and multiple displacement amplification (MDA) reaction. This results in amplification products (WGA-DNA, WTA-cDNA) of the highest comparability and can be used for comparative studies of the genome and transcriptome from the same sample.
The second method (WTA) amplifies RNA from 1–1000 cells directly and includes an efficient lysis, cDNA synthesis, and amplification strategy that results in minimal bias and errors. gDNA is effectively removed to prevent false-positive results.
We amplified a variety of human cells and checked the resulting genome and transcriptome using NGS or qPCR methods. Discussed are experiments on cell-to-cell variation, GC content in comparison to genomic DNA, percentage and consistency of protein coding transcripts, genome coverage with respective error rates, and genome-wide real-time PCR analysis.

3Gb-Test: Introduction of Whole Genome Sequencing as diagnostic application

E. Bakker[1], *B. Janssen*[2], *G. Matthijs*[3], *S. Patton*[4], *S. van Vooren*[5], *H. Scheffer*[6], *K. Payne*[7], *C. Mattocks*[8], *A. Cambon-Thomsen*[9], *J. Traeger-Synodinos*[10], *H. Lochmuller*[11], *J. den Dunnen*[1], *E. Thomassen*[1];
[1]*LUMC, Leiden, Netherlands,* [2]*ServiceXS, Leiden, Netherlands,* [3]*Catolic University, Leuven, Belgium,* [4]*EMQN, Manchester, United Kingdom,* [5]*Cartagenia, Leuven, Belgium,* [6]*UMC St. Radboud, Nijmegen, Netherlands,* [7]*University of Manchester, Manchester, United Kingdom,* [8]*National Genetics Reference Laboratory, Salisbury, United Kingdom,* [9]*INSERM, Toulouse, France,* [10]*University of Athens, Athens, Greece,* [11]*Newcastle University, Newcastle, United Kingdom.*

3Gb-TEST a two year CSA-EU-FP7 project, gathers information on the gaps and needs for implementing Whole Genome Sequencing (WGS) into the diagnostic service. The aim is to prepare a detailed implementation plan or roadmap for the transition to the future of genetic testing WGS included where appropriate and applicable.
As the cost of sequencing is decreasing and the knowledge of our genome is increasing we expect that this transition to the future will take off within the next 5 years. 3Gb-TEST will define needs and gaps using questionnaires, expert meetings and literature to shed light on and obtain insights in the following topics:
- "Wet lab" innovations
- The bioinformatics
- Clinical interpretation
- Personalized medicine and pharmacogenomics.
- Quality issues and External Quality Assessment
- The clinical utility and cost effectiveness

The 3Gb-TEST project brings stakeholders together and disseminates information with respect to the desirable and undesirable developments. The Consortium will inform the healthcare community and make recommendations to the European Commission, the European Society of Human Genetics, and national organizations relevant to this field. The roadmap will address all afore mentioned topics and prepare an implementation plan for the transition to the future of genetic testing in which WGS is embedded. Substantial investments may be required and the logistic restructuring of genetic services will be addressed. Monitoring and harmonization at the European level of all developments is therefore of the utmost importance.
3Gb-TEST is actively getting in contact with the genetics community and will present the initial results and opinions at the ESHG conference.

P14.95-S
Design and evaluation of two novel methods for detection of ATP7B gene mutations

M. Poulou[1], *M. Petropoulou*[2], *M. Amvrosiadou*[2], *P. Ioannou*[2], *E. Kanavakis*[1,3], *M. Tzetis*[1];
[1]*Athens University, Department of Medical Genetics, Athens, Greece,* [2]*Athens University, Department of Chemistry, Athens, Greece,* [3]*Research Institute for the Study of Genetic and Malignant Disorders in Childhood, Athens, Greece.*

Wilson's disease is a rare autosomal recessive disorder of copper metabolism (OMIM#27790) leading to copper accumulation in the liver, brain, kidneys and cornea. It is caused by mutations in the ATP7B gene with a carrier frequency of approximately 1.2%.
We report the design and evaluation of two different screening methods for the detection of ATP7B gene mutations which could be used in conjunction in order to minimize the cost and time for genotyping.
1) A specific mutation detection assay by dry-reagent dipstick biosensors applied for the 10 commonest mutations in the Greek population (H1069Q, R969Q, Q289X, 2530delA, L936X, 2299insC, I1148T, 845delT, 1708-1G>A, X1466R) covering 80% of disease chromosomes. Fragments flanking the 10 ATP7B mutations are amplified by multiplex-PCR, followed by multiplex primer extension (PEXT) reaction using allele-specific primers. The primer extension products are simultaneously detected by visual multi-allele dipstick type DNA biosensor using anti-biotin conjugated gold nanoparticles. Optimization studies on the efficiency and specificity of the PEXT reaction were performed.
2) A gene scanning protocol using High Resolution Melting (HRM) analysis, designed to analyze all coding ATP7B regions.
The first method was evaluated by analyzing 50 samples of known genotypes (confirmed by sequencing) along with 50 blind samples. The results were fully concordant with reference methods. HRM was evaluated by testing 50 known genotypes and 100 blind samples.
The proposed methods are simple, rapid, do not require purification of the PCR products and could be particularly useful in diagnostic laboratories. The benefits and drawbacks of each will be discussed.

P14.96-M
EAA/EMQN best practice guidelines for molecular diagnosis of Y-chromosomal microdeletions: state-of-the-art 2013

C. Krausz[1], *L. Hoefsloot*[2], *M. Simoni*[3], *S. Patton*[4], *F. Tüttelmann*[5];
[1]*Department of Experimental and Clinical Biomedical Sciences, University of Florence, Firenze, Italy,* [2]*Dept Clinical Genetics, Erasmus MC, Rotterdam, Netherlands,* [3]*University of Modena and Reggio Emilia, Modena, Italy,* [4]*EMQN, Center for Genomic Medicine, St Mary's Hospital,, Manchester, United Kingdom,* [5]*Institute of Human Genetics, University of Münster, Münster, Germany.*

The molecular diagnosis of Y-chromosomal microdeletions is a common routine genetic test that is part of the diagnostic workup of azoospermic and severe oligozoospermic men. Since 1999, the European Academy of Andrology (EAA) and the European Molecular Genetics Quality Network (EMQN) have been actively involved in supporting the improvement of the quality of the diagnostic assays by publication of the laboratory guidelines for molecular diagnosis of Y-chromosomal microdeletions and by offering external quality assessment trials. We aim to present an overview on clinical novelties related to the Y chromosome and provide an update on the results of the quality control programme. The original basic diagnostic testing protocol based on two multiplex PCRs remains fully valid and appropriate for accurate diagnosis of complete AZF deletions requiring only minor modification in populations with a specific Y chromosome background. However, in light of novel data on genotype-phenotype correlations, the extension analysis for the AZFa and AZFb deletions is now routinely recommended. Novel methods and kits with excessively high number of markers do not improve the sensitivity of the test, may even complicate the interpretation of the results and are not recommended. The routine screening for gr/gr deletion, a significant risk factor for impaired sperm production, is under debate and eventually it can be performed in selected populations. Annual participation in an external quality control programme is strongly encouraged. The 12-year experience with the EMQN/EAA scheme has shown a steep decline in diagnostic (genotyping) error rate and a simultaneous improvement on reporting practice.

P14.97-S
Introduction of a targeted next generation sequencing gene panel for familial cancer in DNA diagnostics and genetic counselling

H. H. Lemmink, *A. H. van der Hout, Y. J. Vos, B. Sikkema-Raddatz, K. van Dijk-Bos, A. Knopperts, B. Leegte, J. ter Beest, H. Westers, R. J. Sinke, R. H. Sijmons;*
Department of Genetics, University Medical Centre Groningen, Groningen, Netherlands.

Aim: Our aim was to develop a targeted next generation sequencing (NGS) gene panel that enables to analyze large numbers of genes in patients with familial cancer at relatively low cost.
Methods: A panel of 70 known tumour syndrome genes based on Agilent Sure Select Target Enrichment® for simultaneous mutation detection was developed and validated in two series of twelve patients for variants of the MMR or the BRCA genes previously identified through Sanger sequencing. In an additional set of twelve patients all genes were analyzed anonymously. The samples were sequenced using 151 base pair paired-end reads on an Illumina MiSeq® sequencer and analyzed using Softgenetics' NextGENe® and Cartagenia's Benchlab NGS® software. Within the NGS panel, three virtual non-overlapping gene subpanels were designed, based on the levels of preventive options and strength of risk information for the panel genes. In genetic counselling the genes to be tested were discussed as the 3 subpanels rather than individually. For diagnostic purposes NGS with the targeted panel was performed on 75 patients, in whom a pathogenic mutation in the MMR and BRCA genes has been excluded. Only results from chosen subpanels were reported to patients.
Results and Conclusion: In the validation all pathogenic mutations, unclassified variants and neutral polymorphisms detected previously were identified by the NGS panel. In addition, 40 novel variants could all be confirmed by Sanger sequencing. The results of the first 75 patients will be presented. Genetic counselling was adopted to discuss genes as groups rather than as individual genes.

P15.01-S
Swedegene: Genome-wide association studies of adverse drug reactions

M. Wadelius[1], *N. Eriksson*[2], *Q. Y. Yue*[3], *B. Grundmark*[3,1], *P. K. Magnusson*[4], *E. Eliasson*[4], *H. Melhus*[1], *P. Hallberg*[1];
[1]*Uppsala University, Uppsala, Sweden,* [2]*Uppsala Clinical Research center, Uppsala, Sweden,* [3]*Medical Products Agency, Uppsala, Sweden,* [4]*Karolinska Institutet, Stockholm, Sweden.*

Objective: Swedegene (www.swedegene.se) is searching for genetic and clinical factors that predispose patients to adverse drug reactions (ADRs). The aim is to minimise the risks of ADRs by finding biomarkers that enable selection of the right drug for a patient. **Method:** We are assembling a biobank of patients with selected ADRs that are identified from the nationwide ADR reporting system or referred directly from collaborating physicians. Consenting patients are interviewed concerning medical and drug history, and supplementary information is collected from medical records. A blood sample for genomic testing is drawn and kept until a sufficient number of cases are available for genome-wide analyses. We are collecting generalised ADRs, e.g. liver reactions, severe skin reactions and agranulocytosis, and drug-specific ADRs, e.g. angioedema and cough related to ACE-inhibitors or angiotensin receptor blockers and statin-induced myopathy. We have 5000 unrelated controls with genome-wide data from the Swedish Twin Registry. From this cohort it is possible to select *treated* controls, i.e. twins that have been prescribed a drug without being diagnosed with the ADR in question. **Results:** Swedegene started in 2010 and currently has >1600 cases with DNA and complete phenotypes. We have promising, but inconclusive, genome-wide results for three of the ADR diagnoses. **Conclusion:** Serious ADRs are too rare to study in a single country, even using a nationwide ADR register. It is essential to collaborate internationally to obtain enough samples. We invite new collaborators interested in sampling cases with the aim to investigate genetic and clinical risk factors for ADRs.

P15.02-M
Pharmacogenomics and definition of genetic profiles as predictors of blood pressure response to antihypertensive drugs

L. Citterio[1], *C. Lanzani*[1], *S. Delli Carpini*[1], *M. Simonini*[1], *B. Elena*[1], *S. Pozzoli*[2], *S. Tentori*[2], *M. Jankarichova*[1], *P. Manunta*[3];
[1]*Ospedale San Raffaele, Milano, Italy,* [2]*Università Vita-Salute, Milano, Italy,* [3]*Ospedale San Raffaele, Università Vita-Salute, Milano, Italy.*

OBJECTIVE: In hypertensive population only 1/3 of patients reaches blood pressure (BP) targets with the main classes of antihypertensive drugs, with a heterogeneous BP response.
METHODS: We enrolled newly discovered and never treated (naïve) HT patients with BP office >140/90 and <160/110 mmHg. SNPs were genotyped by 128 SNP array on TaqMan OpenArray system, in genes for renal transport of sodium, the dopaminergic and RAAS system, vasodilation, growth factors. Eligible patients were treated with Perindopril 4 mg or Hydrochlorothiazide (HCTZ) 12.5 mg. Genetic associations with General Linear Model and chi-squared; logistic regression analysis for responder/non responder comparison after one-month therapy.
RESULTS: We derived Genetic profiles for systolic BP (SBP) response to HCTZ or Perindopril as a specific combination of variants selected by pathway-based algorithms associated to greater response to these drugs. Carriers of HCTZ genetic profile (215 HT) displayed a SBP fall of -18.21 mmHg compared to those not having the profile (-5.56 mmHg), with an effect size of -12.6 mmHg (p<0.00001, sensitivity 41%, specificity 96%, PPV 86%, Negative Predictive Value (NPV) 75%). Perindopril genetic profile (149 HT). was associated to a SBP fall of -16.3 mmHg compared to all the others (-4.7 mmHg), with an effect size of -11.6 mmHg (p<0.00001, 94% specificity, 33% sensitivity, 72% PPV, 74% NPV).
CONCLUSIONS: We developed two pathway-based algorithms for creating genetic profiles in response to HCTZ and Perindopril. We are currently employing these genetic profiles to a priori choose the first drug in naïve HT patients, as innovative methodology for treating essential HT.

The APOB insertion/deletion polymorphism (rs17240441) influences the postprandial triacylglycerol and insulin response in healthy Caucasian adults - insights from the DISRUPT cohort

K. S. Vimal[1], *R. Gill*[2], *A. Minihane*[3,4], *J. A. Lovegrove*[1], *C. M. Williams*[5], *K. Jackson*[1];
[1]*Hugh Sinclair Unit of Human Nutrition and Institute for Cardiovascular and Metabolic Research, Department of Food and Nutritional Sciences, University of Reading, Reading, United Kingdom,* [2]*Boston Heart Diagnostics, Framingham, MA, United States,* [3]*Hugh Sinclair Unit of Human Nutrition and Institute for Cardiovascular and Metabolic Research, Department of Food and Nutritional Sciences,University of Reading, Reading, United Kingdom,* [4]*Department of Nutrition, Norwich Medical School, University of East Anglia, Norwich, United Kingdom,* [5]*Institute for Cardiovascular and Metabolic Research, University of Reading, Reading, United Kingdom.*

The concept of personalized medicine is now being extended to the field of nutrigenetics with the ambition of giving personalised/stratified dietary advice with greater efficacy in health promotion and disease prevention. To this end, we investigated the impact of 18 polymorphisms (previously implicated in lipid metabolism) on postprandial lipid, glucose and insulin responses in up to 262 healthy adults. The participants consumed a standard sequential mixed test meal, which included a test breakfast (0 min; 49g fat) and lunch (330 min; 29g fat). Blood was collected at baseline (0 min) and on 11 subsequent occasions until 480 min after the test breakfast. Plasma total (TC), low density lipoprotein (LDL-C) and high density (HDL-C) cholesterol, triacylglycerol, insulin and glucose was determined. There was a significant impact of APOB insertion/deletion polymorphism (rs17240441) on fasting TC (P=0.003), LDL-C (P=0.003), HDL-C (P=0.0004), triacylglycerol (P=0.003) and insulin (P=0.003) with higher concentrations in the deletion allele carriers. A significantly higher area under the time response curve was evident for the triacylglycerol (P=1x10-6) and insulin (P=0.006) response in the deletion allele carriers (n=93) relative to the insertion/insertion homozygotes (n=52).Our findings indicate that the APOB polymorphism is likely to be an important genetic determinant of the large inter-individual variability in the postprandial response to dietary fat intake. Greater understanding of how APOB gene influences postprandial lipaemia will advance the prospects for personalised nutrition, where the deletion allele carriers may benefit from personalized dietary strategies to reduce the marked lipaemia in response to meal ingestion.

P15.04-M
rs37973 in GLCCI1 is associated with asthma treatment response

M. Žavbi[1], *A. Lopert*[2], *P. Korošec*[1], *M. Fležar*[1], *M. Rijavec*[1];
[1]*University Clinic of Respiratory and Allergic Diseases Golnik, Golnik, Slovenia,* [2]*Outpatient practice for pulmonary diseases and allergy, Murska Sobota, Slovenia.*

Asthma treatment response is highly variable and pharmacogenetic markers that predict treatment response would be one step closer to personalized treatment. Polymorphisms in *GLCCI1* could be associated with asthma treatment response. We genotyped for rs37973 in *GLCCI1* in 208 adult asthma patients treated with inhaled corticosteroids (ICS). Change in %FEV1 was analysed after 3 months and after at least 3 years of treatment. Treatment success was defined as good when FEV1 decreased less than 30 ml/year. After 3 months of treatment, change of %FEV1 was higher in patients with GG genotype than in patients with AG+AA genotype (p = 0.049), and this genotype dependent difference was only evident and even higher in non-smokers (p = 0.037). Similar results were found after at least 3 years of treatment when all patients were analysed (p = 0.041) and in non-smokers (p = 0.034). Even though, no differences in treatment success (good vs. poor response) were observed when analysing the entire group of patients, treatment success was highly influenced by genotype and smoking status.

GG genotype was overrepresented in non-smokers with good response (p = 0.030) and on contrast, AA genotype in smokers with good response (p = 0.015). There were no differences between smokers and non-smokers when they were not stratified according to genotype. Our results showed that treatment response to ICS is associated with rs37973 in *GLCCI1*, but smoking has great influence on genotype dependent treatment response and further studies are warranted to elucidate the role of *GLCCI1* in treatment response.

P15.05-S

Influence of single nucleotide polymorphisms on deferasirox C_{trough} levels and effectiveness.

J. Cusato[1], *S. Allegra*[1], *D. Massano*[2], *S. De Francia*[2], *A. Piga*[2], *A. D'Avolio*[1];
[1]University of Turin, department of medical sciences, Amedeo di Savoia hospital, Turin, Italy, [2]University of Turin, department of clinical and biological sciences, S. Luigi Gonzaga hospital, Orbassano (TO), Italy.

Deferasirox (DFX) is the only once-daily oral chelator for first-line therapy of blood transfusion-related chronic iron overload. DFX pharmacokinetic has been related with response to therapy. This drug is metabolized in liver by UDP-glucuronyltransferase (*UGT*) *1A1* and *1A3*, by cytochrome-*P450* (*CYP*) *1A1*, *1A2* and *2D6* enzymes, and it is eliminated via biliary-enteric circulation through multidrug resistance protein 2 (*MRP2*).
Our aim was to evaluate DFX plasma concentrations according to single nucleotide polymorphisms (SNPs) in genes involved in this drug metabolism and elimination, in a cohort of non paediatric β-thalassemic patients. Further aim was to define a plasma concentration cut-off value predicting an adequate response to therapy.
DFX concentrations were determined from plasma samples obtained at the end of dosing interval (C_{trough}) using an HPLC-UV method. Allelic discrimination for SNPs in *UGT1A1, UGT1A3, CYP1A1, CYP1A2, CYP2D6, MRP2* and *BCRP1* genes was performed by real-time PCR.
DFX C_{trough} levels were significantly influenced by *UGT1A1C>T* (rs887829) [p=0.045], *CYP1A1C>A* (s2606345) [p=0.017], *CYP1A2A>C* (rs762551) [p=0.014], *CYP1A2C>T* (rs2470890) [p=0.004] and *MRP2G>A* (rs2273697) [p=0.032] SNPs. According to Chirnomas and Galanello efficacy definitions, a DFX plasma cut-off value of 20,000 ng/mL was identified (ROC curve, p=0.008). A logistic regression analysis was performed to determine factors able to predict this value: both *CYP1A1 C>A* rs2606345 AA (p=0.017) and *CYP1A2 C>T* rs2470890 TT (p=0.037) genotypes may forecast drug concentrations below 20,000 ng/mL, suggesting a negative predictive role of therapy efficacy.
Our data, the first obtained in non paediatric patients, suggest the feasibility of a pharmacogenetic-based DFX dose personalization.

ADRB1 and ADBR2 gene polymorphisms and the ocular hypotensive response to topical betaxolol in healthy Mexican subjects

O. Messina-Baas[1], *G. Pacheco-Cuellar*[2], *G. Pacheco-Cuellar*[2], *J. Toral-Lopez*[3], *L. Gonzalez-Huerta*[2], *S. Lara-Huerta*[1], *H. Urueta-Cuellar*[2], *M. Rivera-Vega*[2], *I. Babayan-Mena*[1], *I. Babayan-Mena*[1], *S. Cuevas-Covarrubias*[2];
[1]Oftalmologia, Hospital General de Mexico, Mexico D.F., Mexico, [2]Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico D.F., Mexico, [3]Genetica, Department of Medical Genetics. Ecatepec Medical Center, ISSEMYM, EdoMex, Mexico D.F., Mexico.

Background The β adrenergic receptors (ADRB) are expressed in the ciliary body and trabecular meshwork, structures involved in aqueous humor production and outflow, respectively. ADRB are members of the adrenergic family of G-protein-coupled receptors. Topic β blockers have a good local and systemic tolerance; they reduce the aqueous humor production and eye strain blocking the ADRB of the ciliary body and interfering with adenylate cyclase. However, the ocular hypotensive response is not the same in all patients and could be mediated by the polymorphisms of the ADRB genes. Material and Methods Seventy two healthy subjects were studied after treatment with topical betaxolol in both eyes. We analyzed ADRB1 and ADRB2 gene polymorphisms by PCR and automated DNA sequencing. Results There was statistically significant difference between baseline IOP and final IOP of both eyes (Baseline IOP 16.2±1.2 - Follow-up IOP 13.6±2.0 (mean difference -2.5±1.3, P<0.001). Gly389 had a higher baseline IOP than Arg389 (17.0±1.2 mmHg vs. 16.0±1.2 mmHg; P=0.02) and conversely Arg389 had a greater magnitude of response than Gly389 to betaxolol therapy (-2.9±1.1 mmHg vs -0.7±0.4 mmHg; P< 0.001). Gln27 had a higher response than Glu27 (-2.7±1.3 mmHg vs -1.9±1.0 p=0.02) Conclusion Arg389 polymorphism of the ADRB1 gene and Gln27 polymorphism of the ADRB2 gene were associated with the hypotensive response to topic betaxolol in healthy Mexican volunteers.

The impact of CYP2C19, CYP3A4, CYP2B6, ABCB1, ITGB3 and PON1 gene variants on the antiplatelet effect of clopidogrel in Turkish patients with acute coronary syndrome syndrome

F. Saydam[1], *I. Değirmenci*[1], *A. Birdane*[2], *M. Özdemir*[3], *T. Ulus*[2], *C. Özbayer*[1], *C. Bal*[4], *N. Ata*[2], *H. V. Güneş*[1];
[1]Eskişehir Osmangazi University Faculty of Medicine, Department of Medical Biology, Eskişehir, Turkey, [2]Eskişehir Osmangazi University Faculty of Medicine, Department of Cardiology, Eskişehir, Turkey, [3]Eskişehir Osmangazi University Faculty of Medicine, Department of Pharmacology, Eskişehir, Turkey, [4]Eskişehir Osmangazi University Faculty of Medicine, Department of Biostatistics, Eskişehir, Turkey.

Clopidogrel is an effective inhibitor of platelet aggregation due to its selective and irreversible blockade of the P2Y12 receptor on platelet cell membranes. Antiplatelet treatment with clopidogrel and aspirin is a recommended procedure for the reduction of stent thrombosis and a vital strategy for patients undergoing percutaneous coronary interventions. It has been demonstrated that clopidogrel does not exert an antiplatelet effect in a certain proportion of patients in many studies, known as clopidogrel resistance.
In order to research the exact mechanism of clopidogrel resistance, we aimed to determine whether there is the impact of CYP2C19, CYP3A4, CYP2B6, ABCB1, ITGB3 and PON1 gene variants on the antiplatelet effect of clopidogrel in Turkish patients. We evaluated on 223 Turkish patients with acute coronary syndrome underwent percutaneous coronary intervention with stent implantation. Platelet reactivity (PRU) and % inhibition were measured with VerifyNow P2Y12 assay in blood samples collected from patients that took a standard dose of clopidogrel (75 mg/day) for at least 7 days. 12 genetic variants were genotyped using the Sequenom MassARRAY system.
The PRU and % inhibition values of the genotypes were compared statistically. The CYP2C19*2 (G636A) single nucleotide polymorphism was associated with a reduced antiplatelet response (p<0.001). Conversely, the CYP2C19*17 (C806T) single nucleotide polymorphism was associated with an enhanced antiplatelet effect (p=0.025). There was no statistically significant difference between the PRU and % inhibition values of the other genetic variant genotypes.
Our findings suggest that clopidogrel resistance might be triggered or decreased by the haplotypes of CYP2C19*2 and CYP2C19*17 variants.

P15.08-M

miR-155 and other miRNAs expression pattern in blood of breast cancer patients and healthy individuals carrying BRCA1 mutation

D. Jurkovicova[1], *M. Magyerkova*[1], *L. Copakova*[2], *M. Krivjanska*[1], *V. Krivjansky*[1], *L. Kulcsar*[1], *A. Gibadulinova*[3], *I. Oveckova*[3], *M. Chovanec*[4];
[1]KRD Molecular Technologies, Bratislava, Slovakia, [2]National Institute for Oncology, Bratislava, Slovakia, [3]Institute of Virology, Slovak Academy of Sciences, Bratislava, Slovakia, [4]Cancer Research Institute, Slovak Academy of Sciences, Bratislava, Slovakia.

miR-155 is oncogenic microRNA upregulated in many tumors including breast cancer (BC). As potential circulating biomarker, expression pattern of miR-155 can be determined from blood and may discriminate BC patients from healthy individuals, report on treatment efficacy and further prognosis. Development of BC may be a consequence of BRCA1 tumor suppressor gene mutations involved in DNA damage response and repair. BRCA1 epigenetically controls miR-155 expression and its pro-cancerous potential. In this study, we evaluated expression levels of miR-155 in circulation of individuals carrying BRCA1 mutations with no disease manifestation as well as in BRCA1 BC patients after tumor resection and therapy.
We determined miR-155 expression in lymphocytes and plasma from peripheral blood. To amplify mature form, we used qRT-PCR with 1 RT and 2 qPCR specifically designed primers. Similarly, we determined expression levels of miR-17, miR-18a, miR-21 and miR-27a, also known to be involved in BC pathogenesis.
Compared to healthy controls, individuals carrying BRCA1 mutations with no disease manifestation displayed an increased miR-155 expression in plasma, but not in lymphocytes. In BRCA1 BC patients, we observed significantly elevated miR-155 expression in both, separated lymphocytes and plasma, a phenomenon that persisted after tumor resection and therapy. Other studied miRNAs were also deregulated.
Our results point to epigenetic control of miR-155 by BRCA1 in wide time scale. Accurate identification of miRNAs from peripheral blood represents the key point of development of non-invasive blood-based detection platforms for BC diagnosis, staging, therapy monitoring and prognosis.

CYP1A2 gene non-coding region polymorphisms in Roma and Hungarian population samples

R. Szalai[1,2], *P. Matyas[1], L. Magyari[1,2], J. Bene[1], B. Duga[1,2], Z. Banfai[1], A. Szabo[1], B. Melegh[1,2];*
[1]University of Pecs, Department of Medical Genetics, Pecs, Hungary, [2]Szentagothai Research Centre, University of Pecs, Pecs, Hungary.

CYP1A2 enzyme contributes to biotransformation of wide range of therapeutically important drugs, including caffeine, clopidogrel, clozapine, warfarin, procarcinogens and endogenous substrates. The purpose of this study was to determine and describe the pharmacogenetic profile and interethnic differences of variants of CYP1A2 gene between Roma and Hungarian population. From genomic DNA, 404 Roma and 396 Hungarian healthy subjects were genotyped for two non-coding variants of CYP1A2, namely -163C>A (*1F) and
-3860G>A (*1C). Polymerase chain reaction - restriction fragment length polymorphism (PCR-RFLP) technique was applied. The minor allele frequency for CYP1A2*1C variant was significantly different between Hungarian and Roma samples (2.02% vs. 0%, p<0.001). The AA homozygous genotype was not detectable. For CYP1A2*1F polymorphism we found a remarkable differences in presence of AA genotype in Roma population compared to Hungarians (31.9% vs. 49.5%, p<0.001) and in minor allele frequency (56.9% vs. 68.6%, p=0.025). The following CYP1A2 genotypes were identified in Roma and Hungarian samples, respectively: *1A/*1A (18.1% vs. 12.4%), *1A/*1F (50% vs. 36.9%), *1F/*1F (31.9% vs. 46.7%). In Hungarian population we found the *1C/*1F genotype (4.04%), but it was not present in Roma subjects. In conclusion, analysis of distribution of CYP1A2 gene variants revealed further pharmacogenetic differences between Roma and Hungarian population samples. Hungarians have higher chance for rapid metabolism of CYP1A2 substrates, intensified procarcinogen activation and thereby elevated risk for cancers.

CYP2C9*8 frequency distribution in Puerto Ricans: Implications for warfarin dosing

K. Claudio-Campos[1], *C. Orengo-Mercado[1], L. Berrios[2], R. Pagan[2], J. Renta-Torres[1], C. Cadilla[1], J. Duconge-Soler[1];*
[1]University of Puerto Rico- Medical Sciences Campus, San Juan, PR, United States, [2]University of Puerto Rico at Rio Piedras, San Juan, PR, United States.

Warfarin is an oral anticoagulant that requires individual monitoring since serious adverse events are common. CYP2C9 encodes for the enzyme mainly responsible of S-warfarin's metabolism. Polymorphisms in CYP2C9 have been previously found to be associated with observed warfarin dose variability in different populations, but not in Caribbean Hispanics. Caribbean Hispanics originated as a result of a complex admixture among Caucasians, Africans and Amerindians ancestors-a characteristic that should be considered for warfarin management. The rare loss-of-function CYP2C9*8 allelic variant is reportedly more prevalent among individuals with African heritage. Since Puerto Ricans has a significant contribution of African ancestry in their genetic backgrounds, this cross-sectional study was aimed to determine the frequency of CYP2C9*8 in a cohort of 150 Puerto Rican patients undergoing warfarin therapy. DNA specimens were extracted and genotyped for the CYP2C9*8 using a PCR-based Taqman genotyping assay. We found 3 heterozygous for the CYP2C9*8 variant in our study cohort, corresponding to a minor allele frequency of 1% (95%CI: 0.0026-0.031). The observed frequency met Hardy-Weinberg equilibrium. Allele frequency in our cohort was found to be significantly lower than that from a previous report in African-Americans (0.01 versus 0.047, respectively, p=0.045 by two-tailed z-test), with a carrier frequency of 1 in 50 (Puerto Ricans) versus 1 in 11 (African-Americans). Due to the CYP2C9*8 prevalence found among Puerto Ricans, we concluded that this variant should be included in any pharmacogenetic-guided algorithm for warfarin dose predictions in this population.
Approved by University of Puerto Rico, Medical Sciences Campus Institutional Review Board protocol A4070109.

Extrapyramidal Disorders while Schizophrenia Therapy - analysis of Cyp2D6*4 allele Influence

I. M. Halayenka[1], *V. G. Objedkov[2], N. G. Danilenko[1];*
[1]Institute of Genetics and Cytology of the National Academy of Sciencies, Minsk, Belarus, [2]Belorusian State Medical University, Minsk, Belarus.

Introduction
A lot of clinical investigations of the schizophrenia therapy reveal the dependence of medicament concentration on the individual metabolism peculiarities. The latter depend to a greater degree on the CYP2D6*4 allelic state of the person. The discrepancy between the metabolic status of the patient and definite antipsychotic drug choice and dosage results in various side effects, among which the extrapyramidal disorders (EPD) are the most invalidating.
Methods
The CYP2D6*4 genotype (rs3892097) was revealed for 211 patients suffering from schizophrenia that were cured with various antipsychotic drugs: Fluphenazine, Trifluoperazine, Haloperidol, Flupentixol, Zuclopenthixol, Sulpiride, Risperidone. PCR with specific primers was used for allele estimation. All the patients from Republican Research and Practice Center for Mental Health where cured with definite (one) medicine for 2 weeks and then examined once for the presence of (EPD) with the help of Extrapyramidal Symptoms Rating Scale (ESRS). The analysis of the results was carried out with the WinPepi package of statistical programs for epidemiology.
Results
In the process of pharmacotherapy the patients fell into two groups: those with (99) or without (112) (EPD). The influence of CYP2D6*4 A allele as a risk factor for the EPD development was proved for Fluphenazine (P =0,001), Flupentixol (0,0001). Conclusion We proved the importance of CYP2D6*4 genotyping for the cohort of the patients we studied that were cured with special antipsychotic medication. The elaboration of informative clinical approaches to the adequate drug choice as well as their dosage must take into account the patient's CYP2D6 genotype.

P15.12-M
Towards personalized medicine in Type 2 Diabetes (T2DM): a genetic risk score for the response to the first line treatment in T2DM, metformin

N. van Leeuwen[1], *G. Nijpels[2], J. M. Dekker[2], L. M. ,t Hart[1];*
[1]LUMC, Leiden, Netherlands, [2]VU University Medical Center, Amsterdam, Netherlands.

T2DM is a common disease characterized by high blood glucose levels. The goal of T2DM treatment is lowering the blood glucose levels and the prevention of complications. For this a stepwise treatment approach is used in which metformin is the first treatment step. Unfortunately the glycaemic response to metformin is highly variable between individuals with a large proportion of patients unable to reach the treatment target, defined as glycated hemoglobin (HbA1c)<53mmol. Genetic factors appeared to be involved in the variability in metformin treatment response (h^2=0.36). At the moment only one GWAS (n=1024) for metformin treatment response has been published (Zhou et al) and this revealed a genome wide significant locus near the *ATM* gene, however, eleven other loci (MAF>0.05) reached borderline significance ($p<10^{-5}$). In this study we measured these SNPs in Dutch T2DM patients treated with metformin monotherapy (n=600) and we generated a genetic risk score of the five SNPs showing a directionally consistent association in our study (Odds Ratios (OR) for achieving treatment success ranged between 0.69 and 0.84). In a logistic regression analysis with baseline HbA1c, eGFR and metformin dose as covariates having more risk alleles lowered the OR for achieving treatment success (ORs for 2/3/4, 5/6, 7/8 or 9/10 risk alleles were 1.0, 0.54, 0.45 and 0.30 resp. p=0.027).
In conclusion, using a cohort of patients with T2DM, we showed that a genetic risk score was associated with metformin treatment response. Our results are a first step towards the introduction of pharmacogenetics in T2DM treatment.

Variant Server in a box

K. J. van der Velde[1], *M. de Haan[1], P. Neerincx[1], J. Paschall[2], A. J. Brookes[3], P. N. Robinson[4], R. H. Sijmons[1], R. J. Sinke[1], T. J. de Koning[1], M. A. Swertz[1];*
[1]UMCG, Dept. of Genetics, Groningen, Netherlands, [2]European Bioinformatics Institute, Hinxton, United Kingdom, [3]University of Leicester, Dept. of Genetics, Leicester, United Kingdom, [4]Universitätsklinikum Charité, Institute for Medical Genetics, Berlin, Germany.

Many groups have implemented annotation and analysis pipelines to asses pathogenicity of large numbers of variants observed in next-generation sequencing clinical and research assays. Despite all these efforts only 50-75% of patients receive a negative or uncertain diagnostic report because a small set of time-tested data sources and predictive tools were used and the etiology of many diseases is not known. However, there are hundreds of tools and databases emerging as well as meta-databases and –services that have information for millions of variants. Moreover, there are many more resources such as drug targets, cellular pathways, tissue specific expression, quantitative trait loci, lab tests and model organism data.
Cumulative cost of identification, download, try-out, and quality validation of all these tools and database is huge and even if new tools can be integrated, it is hard to navigate all new information without smart filtering and/or visualization tools, user interfaces for which are not cheap and difficult to create. To enable rapid evaluation of new annotation resources, their

combination in pipelines, and user interfacing in challenging clinical NGS diagnostics, we have created MOLGENIS Variant Service, an open-source web application that can be installed as virtual machine, on local servers, as shared resource, and in a cloud.
We envision an NGS data exploration app as well as a sharing platform for unified data formats and pipelines, gold standard data sets, well-curated reference knowledge-bases, and optimal user interfaces, results of which can disseminate into research institutes, clinical software companies and individual labs.

Personal genomics in Greece: An overview of available direct-to-consumer genomic services and the relevant legal framework

S. Kechagia[1], *G. Patrinos*[2], *E. Vayena*[3];
[1]*University of Geneva, Geneva, Switzerland,* [2]*University of Patras, Patra, Greece,* [3]*University of Zurich, Zurich, Switzerland.*

The aim of this study is to provide an overview of the DTC genomic services available in Greece and the legal framework within which they operate.
Based on literature review, a questionnaire that was distributed in a genetics conference in Greece and in-depth interviews with human geneticists in Greece, we assess the landscape of the DTC genomic testing market and highlight possible particularities of Greek consumers.
Furthermore, we identify the existing legal framework regarding DTC genetic testing. Our interest is not limited only to issues such as consumer protection laws, lab quality accreditation and the provision of genetic counseling. We also explore the role of medical specialties and their respective legal responsibilities in the Greek context, since for example the specialty of Clinical Geneticist does not exist. We also explore the legal authority of the National Organization of Medicines (E.O.F.) regarding the approval of genetic tests and specific issues relating to paternity tests. We identify gaps in the current regulatory scheme and conclude with recommendations for a more comprehensive legal framework.

P15.15-S
2020 vision and beyond - educating tomorrow's clinicians for the genomic era

P. Lunt, *S. Gay;*
NHS National Genetics & Genomics Education Centre, Birmingham, United Kingdom.

Genomic technology is opening-out the clinical applications of DNA from the preserve of clinical geneticists in single-gene disorders, to integration of genomic information in all clinical care by clinicians in all fields. In the UK, research underpinning this, is spearheaded by current genome sequencing initiatives including GeL and PGP (both 100K genomes), worldwide 1K (now 2.5K), vertebrate 10K, DDD 12K, and cancer 25K.
Consequently, genomic education requires basic generic training for all, plus tailored higher level focus in each specialty, rooted in present practical application, and preparing for the future. The education must be a continuum from medical student to trainee to autonomous clinician, and will require curricular and CPD learning outcomes (LOs), learning resources (LRs) and equipped educators for each level and specialty. Clinical geneticists may need wider genomic training for laboratory interface and educational roles (a recent snap survey of an 'interested expert' audience found only 21% correctly answered a question based on simple molecular report notation and interpretation); but each specialty will need genomic champions as clinical and educational leads.
Key to this is setting genomic LOs and CPD competencies, and identifying and creating appropriate accreditable LRs. At NGGEC, through working with professional groups and educators, we have developed 'genomics' LOs for medical students and trainees, and generic 'genomic' CPD competencies, and are in discussion with educational bodies regarding finalisation and implementation. An audit and evaluation of current on-line genomic LRs will be presented including our own website and e-learning modules, and our view for further resources.

Functional annotation of Estrogen Receptor binding sites in the light of the 1000 Genomes Project

B. L. Balint, *L. Ozgyin, E. Barta, A. Horváth, D. Bojcsuk, E. Erdős, K. Trang, L. Nagy;*
University of Debrecen, Debrecen, Hungary.

Understanding the person-to-person variability in diseases by using the unprecedented amount of available genomic data may be approached as never before. We propose to investigate the impact of individual genetic variations in breast cancers. We performed a meta-analysis of all the publicly available ER ChIP-Seq datasets in four ER positive cell lines: MCF7, T-47D (breast cancer derived) cell lines and ECC1, Ishikawa (endometrium cancer derived) cell lines. The number of peaks in intergenic regions is roughly 50 to 55% while depending on the cell type 30 to 40% of the peaks are localized in introns. Some of the genes may have several intronic binding sites. Intronic binding sites are most likely to regulate their own genes, therefore based on these statistics and the individual assignment of the binding sites to their genomic locations, we have identified a set of genes that have ER binding sites in their introns. The number of SNP-s available in the dbSNP database for the identified intronic binding sites of the identified genes is relatively high, that is more than one thousand. Based on our investigations a significant number of SNP-s could influence directly the estrogen dependent regulation of relevant target genes.

P15.17-S
Circulating levels of FSH in men are genetically determined: study on the combined effect of polymorphisms in the FSHR and FSHB genes

C. Vinanzi, *F. Ganz, M. Pengo, M. Menegazzo, C. Foresta, A. Ferlin;*
University of Padova, Padova, Italy.

Recent study have shown that polymorphisms in the FSHR and FSHB genes can modulate circulating levels of FSH. FSHR variants Asn680Ser and c. -29 G>A have been extensively studied in women, while FSHB variant -211 G>T seems to influence male serum FSH levels. There are no studies on the combined effect of these three polymorphism. We have studies 365 subjects: 39 azoospermic, 177 oligozoospermic and 149 normozoospermic. We evaluated seminal parameters; hormone levels; testicular volume; FSHR and FSHB polymorphisms. FSHB polymorphism -211 G>T was found significantly associated to FSH levels. FSHR polymorphism -29 G>A and Asn680-Ser alone, are not associated to different concentration of FSH. Combined analysis of the three polymorphisms again highlights that the major determinant in FSH levels is -211 G>T polymorphism, but shows also that this effect is modulated by -29 G>A polymorphism, as subjects with -211 GG/-29 GG genotype have higher FSH level. Total sperm count and testicular volume is also modulated by the genotype: Homozygotes -211 TT are invariably azoo-oligozoospermic with a reduced testicular volume and FSH <8 UI/L. Combined effect of Asn680Ser is negligible. This is the first combined study on the influence of FSHB and FSHR polymorphisms on male reproduction and shows that -211 G>T FSHB polymorphism plays an important role, only slightly modulated by FSHR polymorphisms, on FSH levels, sperm count and testicular volume. FSHB -211 G>T influences transcriptional FSH gene activity, thus causing an isolated FSH deficiency with azoospermia and thus represents the best pharmacogenetic marker to FSH treatment.

Zearalenone (ZEA) is an estrogenic secondary fungal metabolite produced by several Fusarium species. Several studies presented the cytotoxic or effect of this mycotoxin, but the specific mechanism of action of ZEA still remains unidentified. In order to decipher the molecular changes that occurred during the exposure ZEA in IPEC cells, we assessed the impact of a single dose on gene expression profile at 24 h posttreatment. 10 μM ZEA was proved to have no effect on cell viability (as displays MTT and xCELLigence data), but the microarray expression profiling data for this dose was lead to the identification of 790 genes overexpressed and 1164 downregulated, considering a fold change of □-1.5or□1.5 with a p-value of <0.05. Gene Ontology (GO) analysis of expression microarray data was done to identify the key processed altered. Some of these gene class associations as represented by GO terms are as would be predicted (cell proliferation and differentiation, apoptosis or cell cycle), while others are unexpected, like the class of the cell adhesion molecules or cellular invasion. These primarily processes altered are usefully to predict the negative impact of this toxin, by generating an interaction network analysis for the significant statistic genes. The effects of ZEA are much more complex as we observed from the bioinformatics analysis of the genes list associated with critical disease pathways for the case of a single non-cytotoxic dose of ZEA, being the first step for the acquisition of genetic alteration, particularly in the case of mycotoxin co-contamination or continuous exposure.

Taking gene-based diet in real life: a prospective study.

P. Gasparini[1,2], *P. Bianchi*[3], *N. Pirastu*[1,2];
[1]*Università degli Studi di Trieste, Trieste, Italy,* [2]*IRCCS Burlo Garofolo, Trieste, Italy,* [3]*Maniago Nuoto, Maniago (PN), Italy.*

Increased knowledge in the field of nutrigenetics led to the development of different genetic risk scores and dietary interventions. We have decided to test the efficacy of a gene-based diet (gdiet from www.genex.me) on 191 obese (BMI>25) attending the same nutritional center. Participants were randomly divided in two groups (87 test and 104 controls). For both groups a standard nutritional plan was defined subtracting 600 calories from individual need. DNA from the test group was analyzed for 19 genes known to impact on different metabolic areas and taste. Diet was modulated according to individual genetic profile (i.e. people with a non-favorable lipid metabolism profile were given less lipids in their diet) without varying the overall amount of calories. Physical activities plans were personalized in the same way in the two groups. No significant differences in age, sex and BMI distribution were present in the two groups. Follow-up took place every six months for 2y and showed, in both groups, BMI loss over time and similar compliance. Very interestingly, people in the test group (gene-based diet) lost 33% more weight than controls corresponding to 0.47 BMI points for the square root of time (-1.36 in the control group vs -1.83 in the test group, $p=1.8x10^{-8}$). Similarly, the percentage of lean mass increased more in the test group (+6.2%) than controls (+5.3%) ($p=2x10^{-4}$).
In conclusion, present findings indicate that a gene-based diet might be more effective in helping people loosing weight as compared to standard nutritional plans.

Urine-derived human renal progenitor cultures for modeling of genetic kidney disorders in subject studied by Next Generation Sequencing

B. Mazzinghi[1], *E. Lazzeri*[2], *E. Ronconi*[2,3], *F. Becherucci*[4], *A. Provenzano*[1], *G. Sansavini*[4], *A. Sisti*[2], *A. Peired*[2,3], *M. Angelotti*[2], *L. Lasagni*[2], *P. Romagnani*[2,3,4], *S. Giglio*[1,3];
[1]*Medical Genetics Unit, Meyer Children's University Hospital, Florence, Italy,* [2]*Excellence Centre for Research, Transfer and High Education for the development of DE NOVO Therapies(DENOTHE), Florence, Italy,* [3]*Department of Clinical and Experimental Biomedical Sciences, University of Florence, Florence, Italy,* [4]*Nephrology Unit, Meyer Children's University Hospital, Florence, Italy.*

The advent of high-throughput sequencing has fostered the identification of novel causative genes of kidney disorders, and has allowed the continuous discovery of genetic variants of unknown significance often raising the problem of the functional testing of their pathogenic role. However, emerging evidence implicates that influence of the genomic background of the patient, as well as epigenetic modifications are critical in determining the clinical phenotype. Renal progenitor cell (RPC) cultures obtained from the affected patient may represent an ideal alternative for personalized disease modeling. Since loss of renal cells in urine naturally occurs in patients, urine may represent a potential RPC source.
In this study, we selected and amplified RPC cultures from the urine of patients with renal disease, and we evaluated the possibility to use these cells for modeling of genetic kidney disorders. Urin-RPC were obtained from five children affected by Nephrotic Syndrome carrying mutations in genes encoding for podocyte cytoskeleton proteins, identified thought Next Generation Sequencing, as well as from children without genetic alterations (five). The first cells exhibited altered synthesis of mutated proteins, abnormal cytoskeleton structure and functional abnormalities; by contrast, the second ones showed normal phenotype, structure and function.
The development of functional assays with Urin-RPC could serve as a fundamental step for rapid testing of putative pathogenic mutations. In particular, this tool can provide an essential support for the clinical diagnosis of nephrotic syndrome in patients carrying variants of uncertain significance and provide information to optimize an affected individual's personalized medical care.

P15.21-S
The MedSeq and BabySeq Projects: Clinical trials that explore the impact of genomic sequencing in adults and newborns

R. C. Green[1], *D. M. Lautenbach*[1], *S. S. Kalia*[1], *K. Splinter*[1], *A. H. Beggs*[2];
[1]*Brigham and Women's Hospital, Boston, MA, United States,* [2]*Boston Children's Hospital, Boston, MA, United States.*

Whole exome and whole genome sequencing (genomic sequencing or GS) is becoming increasingly available and used in medical care. We are conducting the NIH-funded MedSeq and BabySeq Projects to examine the implementation and outcomes of GS in the practice of medicine.
In the MedSeq Project, we are enrolling adult patients and their physicians in both primary care and cardiology settings. In the BabySeq Project, we are preparing to enroll newborn infants and their physicians from the neonatal intensive care unit and the newborn well nursery. In both projects patients are randomized to receive standard of care with or without GS. Physicians and patients are followed through surveys, interviews and medical record review to examine the behavioral and clinical impacts of GS results.
In the GS arms of both projects, GS is conducted and interpreted in CLIA-approved molecular laboratories and the results, including all medically relevant unexpected findings, are being provided in a digestible report to the physicians. Reports summarize and present pathogenic variants in rare dominant conditions, variants indicating carrier status for rare recessive conditions, pharmacogenomics variants for commonly used medications and blood group antigens. Interviews, standardized scales and ongoing reviews of medical records are being used to track physician actions, patient (or parent) behaviors and attitudes, health outcomes and health care costs. The MedSeq and BabySeq Projects will help to illuminate the benefits, risks and limitations of GS in the medical care of both adults and infants.

P15.22-M
Single Nucleotide Polymorphisms of the Glucocorticoid-Receptor Gene Influence the Outcome of Cardiac Surgery

M. Pfob[1], *D. Hauer*[2], *R. Toth*[3], *M. Giel*[2], *C. Kowalski*[2], *E. Kilger*[2], *M. Eggert*[1], *O. Steinlein*[1], *G. Schelling*[2];
[1]*Department of Human Genetics, Munich, Germany,* [2]*Department of Anaesthesiology, Munich, Germany,* [3]*Gottsegen Gyorgy Institute of Cardiology, Munich, Hungary.*

Cardiac surgery triggers systemic inflammatory response which is associated with postoperative morbidity and mortality. Glucocorticoid effects are mediated by glucocorticoid receptors (GRs) for which a number of common single nucleotide polymorphisms (SNPs) exist that influence GR sensitivity to cortisol. We selected three common SNPs of the GR gene that are known to affect GR sensitivity and analyzed these data in relation to early outcome variables in patients undergoing cardiac surgery. We tested the effects of the following GR-SNPs: rs4123247 (BcII, increased cortisol sensitivity), rs33388 (cortisol hypersensitivity) and rs10052957 (FPB5, cortisol resistance). All study personal was blinded with regard to the patients` genotype. Study endpoints (primary outcome variables) were the required dosages of hydrocortisone during surgery and in the Intensive Care Unit. The study population consisted of 95 patients. Homozygous carriers of alleles associated with increased GR sensitivity (Bcll *G, n=10 and rs33388 *G, n=25) required significantly lower dosages of hydrocortisone in the Intensive Care Unit than non-carriers of the respective alleles. Homozygous individuals (n=6) for the TT-allele of the FPB5-SNP required significantly higher dosages of hydrocortisone during surgery and in the Intensive Care Unit than heterozygous carriers. They also needed significantly higher norepinephrinemax and epinephrinemax dosages in the Intensive Care Unit to achieve hemodynamic stability and showed a significantly longer duration of Intensive Care Unit therapy than heterozygous or non-carriers of the T-allele. In summary, hydrocortisone dosages administered according to evidence based algorithm to cardiac patients during and after cardiac surgery are influenced by SNPs in the GR.

P15.23-S
Genome-wide association study of chemotherapeutic agent-induced severe neutropenia/leucopenia for patients in Biobank Japan

S. Low[1], *A. Takahashi*[1], *T. Mushiroda*[2], *M. Kubo*[3];
[1]*Laboratory for Statistical Analysis, Center for Integrative Medical Sciences, RIKEN, Yokohama, Japan,* [2]*Laboratory for Pharmacogenomics, Center for Integrative Medical Sciences, RIKEN, Yokohama, Japan,* [3]*Laboratory for Genotyping Development, Center for Integrative Medical Sciences, RIKEN, Yokohama, Japan.*

Chemotherapeutic agents are notoriously known to have narrow therapeutic range that often results in life-threatening toxicity. Hence, it is of clinically important to identify patients who are at high risk for severe toxicity to certain chemotherapy through pharmacogenomics approaches. In this study, we carried out 17 genome-wide association studies (GWAS) with 13 122 cancer patients recruited from the Biobank Japan, who received different chemotherapy regimens, including cyclophosphamide- and platinum-based (cisplatin and carboplatin), anthracycline-based (doxorubicin and epirubicin), and antimetabolite-based (5-fluorouracil and gemcitabine) treatment, antimicrotubule agents (paclitaxel and docetaxel), and topoisomerase inhibitors (camptothecin and etoposide), as well as combination therapy with paclitaxel and carboplatin, to identify genetic variants that are associated with the risk of severe neutropenia/leucopenia in the Japanese population. In addition, weighted genetic risk score analysis was performed to evaluate the cumulative effects of common genetic variants associated with chemotherapeutic agents-induced severe neutropenia/leucopenia. Instead of illustrating all 17 GWAS, we will utilize the result from GWAS of paclitaxel-carboplatin combined therapy for further explanation. Although we failed to identify genetic variants that surpassed the genome-wide significance level

($P<5.0x10^{-8}$) through GWAS, probably due to insufficient statistical power and complex clinical features, we were able to shortlist some of the suggestive associated loci. The current study is at the relatively preliminary stage, but does highlight the complexity and problematic issues associated with retrospective pharmacogenomics studies. However, we hope that verification of these genetic variants through local and international collaborations could improve the clinical outcome for cancer patients.

P15.25-S

Preventive genetic testing for large spectrum of monogenic disorders using microarray technology in Russian population

M. M. Litvinova[1,2], *E. A. Pomerantseva*[1], *F. A. Konovalov*[1], *A. A. Isaev*[1];
[1]Human Stem Cells Institute, Moscow, Russian Federation, [2]Sechenov First Moscow State Medical University, Moscow, Russian Federation.

According to current statistics around 5% of newborns have hereditary disorder or inborn defect. Our work shows that this number is higher in reality. Often ill child is born in couple without any health problems. Nowadays the most affordable way to detect carrier status in such couples is using microarray technology. The content of such screening panels should be ethnically optimized.

To spread preventive personalized approaches in medical practice in 2013 the microarray "Ethnogene" was developed based on APEX technology. It allows detecting 60 monogenic and 4 multifactor disorders. Its content is adapted to characteristics of Russian population.

9.5% of 213 genotyped patients were diagnosed to have monogenic disease (table 1). 60% appeared to be heterozygous carriers of 1-3 mutations (table 2).

Thus using of microarray "Ethnogene" helps to reveal carrier status among couples planning pregnancy and to understand real frequencies of monogenic disorders in general population of Russia. Early detection of disorders in asymptomatic patients allows preventing severe complications by prescribing pathogenic therapy.

Table 1.

Frequency of detected monogenic disorders in cohort of 213 persons genotyped by microarray Ethnogene

Assessing the role of known MS genetic variants in the familial aggregation of MS and other autoimmune diseases

F. Esposito[1,2], *L. Ferre'*[1,2], *C. Guaschino*[1,2], *M. Sorosina*[2], *G. Liberatore*[1,2], *F. Clarelli*[2], *B. Colombo*[1], *V. Martinelli*[1], *G. Comi*[1,2], *F. Martinelli Boneschi*[1,2];
[1]Department of Neurology, San Raffaele Scientific Institute, Milan, Italy, [2]Laboratory of genetics of complex neurological disorders, Institute of Experimental Neurology, Division of Neuroscience, San Raffaele Scientific Institute, Milan, Italy.

Background: The contribution of MS loci on familial aggregation for MS or other autoimmune diseases is still unclear.

Objective: The aim is to investigate the role of MS associated genetic variants in explaining the familial aggregation for MS or other autoimmune diseases, by comparing sporadic and familial MS cases of Italian origin.

Methods: genetic and familial aggregation data were available on 572 MS patients (474 sporadic cases and 98 familial cases). A weighted genetic risk score (wGRS), based on 106 SNPs found to be associated to MS according to the Immunochip project, was calculated.

Results: we did not observe a difference in terms of wGRS between sporadic and familial cases of MS (10.67±0.038 vs 10.62±0.093). However, when assessing the impact of the known MS loci on the aggregation for MS and other autoimmune diseases, we observed that there is a statistically significant difference between sporadic and familial cases (10.71±0.046 vs 10.56±0.066, $p<0.05$). Moreover, it appears that males with other cases of MS or autoimmune diseases in the family have a higher wGRS compared to females (10.81±0.120 vs 10.45±0.078, $p=0.02$).

Conclusions: our data suggest that known MS genetic variants may have a role in explaining the aggregation for MS and other autoimmune diseases; this is in agreement with the fact that most of these loci are involved in immunological functions. When stratifying by gender, it appears that the genetic variants have a stronger impact in males, suggesting that probably in females other factors are involved, like hormones or other environmental causes.

P15.27-S

A pharmacogemonic study of long-term response to Interferon-beta treatment in patients with Multiple Sclerosis

G. Liberatore[1,2], *F. Clarelli*[2], *F. Esposito*[1,2], *M. Sorosina*[2], *S. Santoro*[2], *M. Rodegher*[1], *V. Martinelli*[1], *G. Comi*[1], *F. Martinelli Boneschi*[1,2];
[1]Department of Neurology & INSPE (Institute of Experimental Neurology), Scientific Institute and Ospedale San Raffaele, Milan, Italy, [2]Laboratory of Genetics of Neurological Complex Disorders, San Raffaele Scientific Institute, Milan, Italy.

Background: Previous pharmacogenomic studies conducted in Interferon-beta (IFN)-treated Multiple Sclerosis (MS) patients explored the influence of genetic variants on the short-term response to the drug. The aim of this study is to perform a genome-wide association study (GWAS) of long-term response to Interferon-beta observed using a follow-up period of 4 years after drug start.

Methods: The GWAS study was conducted using the Omni-express Illumi-

na® array on a cohort of 329 IFN-beta treated MS patients followed for 4 years of treatment. We used three different outcome measures of response to treatment: a disability criterion, measured as the increase of ≥1 point at Expanded Disability Status Scale (EDSS), and two composite criteria, which take into account measures of disability progression and relapse occurrence (≥2), on which separate GWAS analyses have been performed.
Results: No genome-wide significant association signal was detected. When using a cut-off p-value of 10^{-4}, 42 SNPs emerged as associated according to the disability criterion, while 28 and 41 SNPs for the two composite criteria. A modest overlap (11.8%) was observed among associations across three phenotypes.
Conclusions: Our study showed new targets potentially involved in the modulation of the response to IFN-beta treatment. An in silico replication analyses on identified targets is planned on an independent cohort of treated MS patients.

P15.28-M
Genetic polymorphisms influence the response to adalimumab in Crohn disease patients

U. Potočnik[1,2], *K. Repnik*[1], *S. Koder*[3], *R. K. Weersma*[4];
[1]*Faculty of Medicine, Maribor, Slovenia,* [2]*Laboratory for Biochemistry, Molecular Biology ang Genomics, Faculty for Chemistry and Chemical Engineering, University of Maribor,, Maribor, Slovenia,* [3]*University Clinical Center Maribor, Maribor, Slovenia,* [4]*Department of Gastroenterology and Hepatology, University of Groningen and University Medical Center Groningen, Groningen, Netherlands.*

Biological therapy using fully humanized monoclonal antibodies against TNF-α (adalimumab) is efficiently used to induce and maintain remission in around 70% of Crohn disease (CD) patients not responding to standard treatment or developing adverse drug effects to corticosteroids. We investigated if single nucleotide polymorphisms (SNPs) contributing to CD risk could help to predict the response to adalimumab (ADA) treatment in CD patients. We used IBDQ index and biological biomarkers (CRP levels) to monitor therapy response after 4, 12, 20 and 30 weeks after first treatment with adalimumab. The strongest association between CRP levels and treatment with ADA was found for ATG16L1 SNP rs10210302. After 12 weeks of treatment 85% of patients with CT or TT genotype in rs10210302 had a positive response (drop of CRP to normal levels or by more than 25%) to treatment with ADA compared to 37,5% of patients with CC genotype (p=8,11E-04). We also found significant associations between SNP rs10512734 located near PTGER4 gene and ADA treatment response measured with both, IBDQ index and biological response measured with CRP. Average increase in IBDQ index (delta IBDQ) after 12 weeks of treatment was higher in the group of patients with GG genotype for SNP rs10512734 (47,6) compared to those with AA or AG genotype (17,4, p=7,06E-03). Additional SNPs in 6 out of 33 tested CD associated genes (CASP-9, IL27,C11orf30, CCNY, IL13) showed suggestive association with ADA response. Our results suggest ADA response in CD patients in partially genetically predisposed by SNPs in CD risk genes.

P15.29-S
AlleleTyper™ Software: a flexible application for mapping SNP genotype and CNV data patterns to pharmacogenomic allele nomenclature

T. Hartshorne, *N. Mehmet, E. Shelton, H. Leong;*
Thermo Fisher Scientific, South San Francisco, CA, United States.

Pharmacogenomic (PGx) studies require genetic testing of individuals for multiple variants in drug metabolism enzyme (DME) and transporter genes. For phenotype interpretation purposes, genotyping results must be translated to star (*) allele nomenclature. Star alleles are gene level haplotype patterns that are associated with protein activity levels. Genetic variants within a haplotype can include SNPs, InDels, and copy number variations (CNVs). Knowing the combination of variants within a given haplotype, and the diploid content in an individual, is of key importance for studying drug metabolism, response and adverse reactions. To facilitate the translation of results for individuals genotyped in studies using TaqMan® SNP and DME Genotyping Assays and TaqMan® Copy Number Assays, we developed a web-based flexible software tool called AlleleTyper™. This software maps sample genotyping data to genetic pattern information translation tables to star allele or other nomenclature. User-defined monoallelic translation tables containing haplotype genetic information, for the gene variants tested in a study, are automatically converted by the software to biallelic translators containing diploid genetic patterns. AlleleTyper™ matches the sample genotypes in results files from TaqMan® Genotyper Software and/or CopyCaller® Software to the patterns in the biallelic translator and reports the star allele genotypes determined for each sample. A review of the software workflow and features will be presented, along with data analysis examples. AlleleTyper™ Software greatly facilitates PGx study data analysis. It can also be used for other genotyping applications that require translation of data from multiple TaqMan assays, including triallelic SNP data analysis and blood genotyping.

P15.30-M
ABCB1 haplotype construction in a pharmacogenetic study of cyclosporine treatment response in Greek patients with psoriasis

Y. Vasilopoulos[1], *C. Sarri*[1], *C. Stamatis*[1], *E. Zafiriou*[1], *A. Roussaki-Schulze*[1], *A. Patsatsi*[2], *D. Sotiriadis*[2], *Z. Mamuris*[1], *T. Sarafidou*[1];
[1]*University of Thessaly, Larissa, Greece,* [2]*Aristotle University of Thessaloniki, Thessaloniki, Greece.*

Psoriasis is a chronic, inflammatory skin disorder affecting 2-3% of the population worldwide. While there are a large number of effective modalities for treating psoriasis, response to therapy varies among patients which could be due to genetic factors. Cyclosporine is considered to be a cost-effective first-line systemic therapy for psoriasis, however the response rate is around 60-70%. The aim of the present study, which is based on a Greek multi-centre collaboration, was to target ABCB1, which encodes for P-glycoprotein, by selecting polymorphisms that could influence the absorption and disposition of P-glycoprotein substrate drugs like cyclosporine. In detail, T-129C (rs3213619), G1199A (rs2229109), C1236T (rs1128503), G2677T (rs2032582) and C3435T (rs1045642) polymorphisms were selected as candidate markers of response to cyclosporine treatment after 3 months of therapy and genotyped in 84 psoriasis patients under cyclosporine therapy. Fifty-two patients (62%) were defined as responders (ΔPASI ≥75%) and thirty-two (38%) as non-responders (ΔPASI ≤50%). Single-SNP and haplotype construction showed that the haplotype for marker C3435T could account for the prediction of ~20% of the non-responders to cyclosporine therapy. Notwithstanding the importance of this finding, there is a remaining 80% to be identified, which could be illuminated by systems network analysis, whereby additional pharmacogenetic targets that may be involved in cyclosporine transport, processing or metabolism are identified. Overall, systems biology coupled with experimental validation of specific markers in large independent cohorts could lead in the creation of a molecular algorithm for the prognosis of psoriasis patients' response to cyclosporine as well as for other therapies.

Clinical Trials and Statistics Unit, Institute of Cancer Research, London, United Kingdom,* [10]*University of Cambridge Department of Oncology, Oncology Centre, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom.*

Increasing evidence supports the role of genetic variants in the development of radio-induced toxicity. Therefore, we performed a three-stage genome wide association study that involved a Spanish cohort of 741 prostate cancer patients treated with radiotherapy to identify new susceptibility loci. The replication cohorts consisted of 633 prostate cancer patients from the UK, and 368 prostate cancer patients from a North-American Caucasian cohort.
Standardized total average toxicity (STAT) scores were derived from individual toxicity endpoints to assess overall acute and late toxicities. Association tests of genotype with STAT-acute or STAT-late scores were performed with linear regression. Residuals from multivariate linear regression models, including associated non-genetic covariates, were calculated for each patient to quantify the toxicity not accounted for by the available non-genetic covariates. To obtain per allele ORs by logistic regression, patients were dichotomized as ≤ or > than 1 standard deviation of the acute and late residuals.
Seven and 42 loci were associated (P-value≤10-5) with overall acute and late toxicity, respectively. Only one locus associated with overall late toxicity, 2q24.1 (STATlate P-value =6.85x10-9; OR=6.67, 95%CI: 2.25-19.80) was replicated in the UK cohort (STATlate P-value=2.08x10-4, OR=6.17, 95%CI: 2.25-16.95; meta-analysis P-value=4.16x10-10). The inclusion of the third

cohort gave a meta-analysis P-value=4.64x10-11.
Although it is biologically possible that this locus is involved in the regeneration of muscle previously damaged by radiotherapy, future efforts are needed to identify the causal variant underlying the observed association and determine the molecular mechanisms involved.

P15.32-M
Genetic determinants of methotrexate toxicity in Tunisian patients with rheumatoid arthritis: a study of polymorphisms involved in the folate pathway of methotrexate

S. Chaabane[1], R. Akrout[2], S. MARZOUK[3], H. Makni-Fourati[2], Z. Bahloul[3], **A. MAALEJ**[1];
[1]Faculty of medicine of sfax, Sfax, Tunisia, [2]Department of Rheumatology, Sfax, Tunisia, [3]Department of Internal Medicine, Sfax, Tunisia.

Methotrexate (MTX) is an anti-rheumatic drug used in the treatment of rheumatoid arthritis (RA). However, side events are present in 40% of the patients.
The aim of this study was to determine the impact of genetic polymorphisms of 5, 10-methylenetetrahydrofolate reductase (MTHFR C677T and A1298C), Dihydrofolate reductase (DHFR 19-base pair deletion allele), thymidylate synthase (TYMS 2R→3R), methionine synthase (MTR A2756G) and methionine synthase reductase (MTRR A66G) in a group of 143 Tunisian RA patients and evaluate its association with MTX toxicity.
Patients who experienced MTX adverse events were defined "with toxicity", those who did not, as "without toxicity". Genotyping was performed using PCR and PCR-RFLP method. Demographic and clinical characteristics were obtained and MTX-related adverse effects were recorded. Allele and genotype association were performed using chi2 test , genotype relative risk (GRR) and Odds ratio (OR). The regression logistic was also used to investigate the correlation between patient characteristics (MTX dose, duration of treatment, disease duration, age, sex, route of MTX administration) and toxicity.
The analysis highlighted a significant genotypic association of MTHFR C677T polymorphism with increased MTX toxicity [p=0.004], and the strongest association was shown in the T/T genotype [p=0.006]. However, The MTHFR A1298C , DHFR 19-base pair deletion allele and MTR A2756G polymorphisms were not associated with increased MTX toxicity. While TYMS 2R→3R polymorphism had a protective effect on overall MTX toxicity [p=0.038]
Moreover, our results revealed a positive correlation of both dose and route of administration of MTX with toxicity in RA patients (p=0.027; p= 0.004) respectively.

CYP1A1 variant in Roma population samples

L. Magyari[1,2], R. Szalai[1,2], **E. Kovesdi**[1,2]*, Z. Banfai[1,2], B. Duga[1,2], P. Matyas[1,2], A. Szabo[1,2], B. Melegh[1,2];*
[1]Department of Medical Genetics, University of Pecs, Pecs, Hungary, [2]Szentagothai Research Centre, University of Pecs, Pecs, Hungary.

Polycythemia vera is a rare bone marrow disorder that leads to an abnormal raising in the number of red blood cells, although the numbers of white blood cells and platelets are also on high levels. In the background of the disease a gene mutation called JAK2V617F can be found, but the cause of this and other possible disorder-causing mutations is undiscovered. Our goal was to examine the rs1048943 polymorphism located in CYP1A1 gene in 90 Roma (Gipsy) with polycythemia vera versus 95 Roma individuals without this disease. Genotypes were determined with real-time-PCR method, SPSS 20.0 statistical program was applied for evaluating the results. The preliminary data showed 6.11% G allele frequency in Romas with polycythemia vera, which it was found to be 3.70% in non-affected Roma controls. The CYP1A1 1384 A/G mutation has never been analyzed in Roma population before, but further extended studies are required to test the clinical relevance of CYP1A1 in different populations.

P15.34-M
Full resequencing of TRAF3IP2 gene in Mozambican patients with SJS/TEN induced by Nevirapine treatment: a pharmacogenetics study

C. Ciccacci[1]*, S. Rufini[1], G. Liotta[2], L. Palombi[2], G. Novelli[1], P. Borgiani[1];*
[1]Department of Biomedicine and Prevention, Genetics Section, University of Rome „Tor Vergata", Rome, Italy, [2]Department of Biomedicine and Prevention,Epidemiology Section, University of Rome „Tor Vergata", Rome, Italy.

Nevirapine (NVP) is a non-nucleoside reverse transcriptase inhibitor, widely prescribed for type 1 human immunodeficiency virus infection. A small proportion of individuals treated with NVP experience very severe cutaneous adverse events, including Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN).
In the last years TRAF3IP2 gene variants were associated with susceptibility to psoriasis, psoriatic arthritis, systemic lupus erythematosus and cutaneous manifestations in inflammatory bowel disease. We hypothesized that this gene, involved in immune response and in NF-KB activation, could be also implicated in the SJS/TEN susceptibility.
To verify our hypothesis we performed a full resequencing of TRAF3IP2 gene in a population of patients treated with NVP. Twenty-seven patients with NVP-induced SJS/TEN and 78 controls, all from Mozambique, were enrolled. All ten exons of TRAF3IP2 gene, including the intron/exon boundaries, were analyzed by direct sequencing. We performed a case/control association analysis and a multivariate logistic analysis.
We identified 8 exonic and 3 intronic variants. We did not find any novel variations. The case/control association analysis highlighted an association between the rs76228616 SNP in exon 2 and the SJS/TEN susceptibility. In particular the variant allele (C) was more present in SJS/TEN patients than in controls, resulting significantly associated with a higher risk to develop SJS/TEN (P=0.012 and OR=3.65 [95% CI 1.33-10.01]). A multivariate analysis by logistic regression confirmed the significant involvement of TRAF3IP2 (rs76228616) in the susceptibility to SJS/TEN (P=0.027). Of course, further studies on larger samples and replications in other African populations are necessary to confirm our results.

P15.35-S
Potentially Functional Single Nucleotide Polymorphisms (pfSNPs) associated with Response to Fluorouracil in Metastatic Colorectal Cancer Patients

C. G. Lee[1,2,3]*, J. Wang[2], X. Wang[2], M. Zhao[2], S. Choo[1], S. Ong[4], I. Tan[1], S. Ong[1], Y. Teo[2], S. S. Chong[2];*
[1]National Cancer Centre, Singapore, Singapore, [2]National University of Singapore, Singapore, Singapore, [3]Duke-NUS Graduate Medical School, Singapore, Singapore, [4]National Cancer Centre and National University of Singapore, Singapore, Singapore.

Colorectal cancer (CRC) is amongst the top three most commonly diagnosed cancer in the world. Majority of these patients require treatment for metastatic CRC since a third are at stage IV during diagnosis and another third of the 'curatively' resected patients (Stages I-III) will relapse. 5-fluorouracil is a common drug used for the treatment of CRC but the response rate to this drug either alone or in combination is less than 40%. Developing a reliable biomarker that can predict response can facilitate the appropriate tailoring of treatment for these patients.
Here we report a novel potentially functional Single Nucleotide Polymorphism (pfSNP) approach to identify SNPs predictive of response to 5-FU in Chinese metastatic colorectal cancer (CRC) patients. 1547 pfSNPs and one variable number tandem repeat (VNTR) in 139 genes in 5-FU drug (both PK and PD pathway) and colorectal cancer disease pathways were examined in 2 groups of CRC patients. Shrinkage of liver metastasis measured by RECIST criteria was used as the clinical end point. We identified a total of 9 novel pfSNPs including 4 non-responder-specific pfSNPs with potential functional significance that may be able to distinguish non-responders from responders to 5-FU. These may thus serve as good biomarkers for response to 5-FU.

P15.36-M
Semiconductor Next Generation Sequencing (Ion Torrent) of the ABCB1, CYP3A5, and CYP3A4 genes in kidney transplanted patients treated with Tacrolimus

B. Tavira Iglesias[1]*, C. Diaz-Corte[2], D. Coronel[2], E. Coto Garcia[2];*
[1]Hospital Universitario Central De Asturias , Oviedo, Spain, [2]Hospital Universitario Central De Asturias, Oviedo, Spain.

Tacrolimus (Tac; FK-506) is an immunosuppressive drug used to avoid the rejection of solid organs. Tac has a narrow therapeutic range and a high interindividual variability in dose-requirements. Previous studies have linked common CYP3A4-3A5 and ABCB1 (MDR-1) polymorphisms to Tac dose requirements (CYP3A5*3, CYP3A4*1B, CYP3A4*22, C3435T). Our aim was to identify new rare CYP3A5, CYP3A4 and ABCB1 variants that could influence Tac dose through massive parallel sequencing with the Ion Torrent PGM. We created three pools of 75 patients who differed in Tac dosage. The coding exons of the 3 genes were amplified in only two tubes with a custom Ampliseq, and the three pool reactions bar-coded, library amplified, and sequenced in a semiconductor PGM-318 array. These pooling + multiplex approach would facilitate the rapid screening of the three genes at a low cost and with minimum labor requirements. We identified several rare variants in CYP3A5 and CYP3A4 (P405T in CYP3A5, and S195P and I193S CYP3A4 new, non reported). These missense changes could affect protein function. No missense ABCB1 variants were found.
In conclusion, we identified new variants in CYP3A5 and CYP3A4 that could have an effect on Tac dose requirements. Our NGS-PGM procedure would help to uncover the variation in these genes at a population scale.

P15.37-S
TGF-B1 -509C>T polymorphism and response to montelukast in childhood asthma

S. Dragicevic[1], *K. Milosevic*[2], *A. Nikolic*[1];
[1]*Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia,* [2]*Department of Allergology and Pulmonology, University Children's Hospital, Belgrade, Serbia.*

Transforming growth factor-beta 1 (TGF-B1) is a key mediator in asthma airway inflammation and remodelling. Leukotriene receptor antagonists are among the most prescribed drugs for asthma management. They decrease the level of inflammation in asthmatic airways and inhibit the expression of the TGF-B1. The aim of this study was to investigate the influence of the most common polymorphism in the TGF-B1 gene, -509C>T, on the response to montelukast in childhood asthma. Response to montelukast was tested in an ex vivo experiment using induced sputum cells from six children (five girls and a boy, age 7-18 years) previously genotyped for TGF-B1 -509C>T polymorphism. The cells isolated from 1mL of induced sputum were incubated with and without montelukast (50nmol) and the levels of TGF-B1 were measured by a commercial enzyme-linked immunosorbent assay kit. In all six cases after the treatment with montelukast a decreased TGF-B1 levels in sputum were observed. Although the differences were not statistically significant, the decrease in TGF-B1 levels was different in carriers of different genotypes: CC - 738±107pg/mL, CT - 1439±616pg/mL, and TT - 397±187pg/mL. Although preliminary, the results of this study indicate that the TGF-B1 gene promoter polymorphisms may influence response to leukotriene receptor antagonists in childhood asthma. This finding should be confirmed in a larger cohort of patients and the effect of other polymorphisms should also be investigated. Ex vivo stimulation of sputum cells may be further developed into a test for assessment of individual response to asthma medications and potentially used as personalized medicine tool.

P15.38-M
Development of personalised therapeutics for lattice corneal dystrophy type I

D. G. Courtney[1], *E. Maurizi*[1,2], *S. D. Atkinson*[1,3], *M. Nesbit*[1], *J. E. Moore*[1], *C. Moore*[1,3];
[1]*School of Biomedical Sciences, University of Ulster, Coleraine, United Kingdom,* [2]*Centre for Regenerative Medicine, Stefano Ferrari, University of Modena and Reggio Emilia, Modena, Italy,* [3]*Dermatology and Genetic Medicine, Colleges of Life Sciences and Medicine, Dentistry & Nursing, University of Dundee, Dundee, United Kingdom.*

Personalised medicine offers the prospect of treating genetic conditions using novel molecular methods, and our current research seeks to establish a viable treatment for Lattice Corneal Dystrophy Type I (LCDI) using mutation-specific short-interfering RNAs (siRNAs).
Corneal dystrophies comprise a group of debilitating hereditary disorders. Most of these conditions are inherited autosomal dominantly and caused by deleterious missense mutations. To date our group has focused on two corneal disorders; Meesmann's Epithelial Corneal Dystrophy (MECD) and Lattice Corneal Dystrophy type I (LCDI), which are caused by mutations in the *KRT12* and *TGFBI* genes, respectively. The primary focus of this research was to develop a lead siRNA targeting the TGFBI-Arg124Cys mutation, the most common cause of LCDI.
A panel of 19 mutation specific siRNAs was assessed to select lead candidate siRNAs using a high-throughput dual-luciferase reporter assay and pyrosequencing to determine the lead siRNA. Potency and allele specificity of the lead siRNA was assessed in corneal epithelial cells isolated from a patient with a TGFBI-Arg124Cys mutation, using pyrosequencing, qRT-PCR and a TGFBI ELISA. Treatment with this siRNA resulted in a 44% reduction ($p<0.01$) of the endogenous Arg124Cys allele in this *ex vivo* model of LCDI, and was without effect on the wild-type allele, demonstrating allele specificity. This research confirms the potential of siRNA therapeutics as a personalised medicine approach for the management of heritable TGFBI-associated corneal dystrophies and opens the prospect for the translation of this technique to the treatment of other corneal dystrophies.

Search for potential causal variants in transcription factor binding sites using a database integrating SNPs and human genome information

V. Zazzu, *T. Nutile, R. Sorice, M. Aversano, D. Ruggiero, S. Nappo, M. Ciullo;*
Institute of Genetics and Biophysics, CNR, Naples, Italy.

Human genetic variation underlies a majority of phenotypic differences between individuals, including susceptibility to disease.
Genome wide association studies (GWAS) have identified many susceptibility loci/SNPs for complex traits and diseases. The greatest challenge in the 'post-GWAS' era is to understand the functional consequences of these loci. When SNPs occur within a gene or in a regulatory region, they may play a direct role in disease by affecting the gene function. Therefore SNPs may help to predict an individual response to certain drugs or the risk of developing particular diseases. SNPs are found everywhere and those associated to complex diseases are found preferentially in non-coding regions. The recognition and the binding of transcription factors (TF) to specific consensus sequences in the genome are crucial for a successful transcriptional regulation in cells. Therefore, we thought to predict and identify potential causal variants that can alter the binding sites of TF using a database integrating SNPs and human genome information. To this frame, we applied this approach looking for variants altering the Activator Protein 1 (AP1) binding site and we identified 7518 SNPs capturing approximately 4500 genes throughout the whole human DNA sequence. In order to screen for candidates genes to be further analysed with functional studies, predicted results were grouped and analysed with a large number of bioinformatics tools. Overall, these findings will give new insights into the value of SNPs in AP1 consensus sequence and it will provide an innovative approach that potentially yields additional new candidates genes for several disorders.

Searching for circulating epigenetic biomarkers of Alzheimer's disease

P. Tannorella[1], *A. Stoccoro*[1], *G. Tognoni*[2], *P. Bongioanni*[2], *G. Siciliano*[2], *U. Bonuccelli*[2], *L. Migliore*[1], *F. Coppedè*[1];
[1]*Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy,* [2]*Department of Neuroscience, Pisa University Hospital, Pisa, Italy.*

Increasing evidence points to a possible contribution of folate metabolism in modulating the methylation profile and the expression of disease-related genes in complex diseases, such as Alzheimer's disease (AD). Impaired folate metabolism could result in altered DNA methylation and expression of genes involved in AD pathogenesis.
Indeed, taking into account the inaccessibility of brain DNA samples until death, there is increasing interest in searching for peripheral epigenetic biomarkers of the disease.
In this regard we obtained peripheral blood DNA of 25 AD patients, 25 individuals with Mild Cognitive Impairment (MCI), and 25 matched controls and searched for changes in DNA methylation of the promoter/first exon of genes involved in DNA methylation: DNMT1, DNMT3B and MTHFR, and in amyloid beta production: BACE1 and PSEN1.
DNA methylation analyses were performed by means of Methylation Sensitive-High Resolution Melting (MS-HRM) technique. Moreover, we searched for correlation between the methylation levels of each of the studied genes and circulating levels of homocysteine, folate and vitamin B12, all involved in one-carbon metabolism the key pathway for DNA methylation reactions.
The MTHFR gene showed an inter-individual variability in methylation profiles, and we observed a significant inverse correlation between plasma homocysteine levels and the methylation status of the MTHFR gene. To further address the link between one-carbon metabolism and DNA methylation profiles, we are currently assessing global peripheral DNA methylation biomarkers by means of the analysis of long interspersed nuclear elements-1 (LINE-1).
The study was supported by the Italian Ministry of Health (GR-2009-1606229; F.C. Principal Investigator).

P16.02-M
Not all reference gene annotation is created equal

A. Frankish[1], *J. Mudge*[1], *J. M. Gonzalez*[1], *R. Petryszak*[2], *A. Brazma*[2], *J. L. Harrow*[1];
[1]*Wellcome Trust Sanger Institue, Cambridge, United Kingdom,* [2]*European Bioinformatics Institute (EMBL-EBI), Cambridge, United Kingdom.*

Having a good quality geneset is essential for the interpretation of functional genomic, functional transcriptomic, and variation data. The GENCODE geneset represents the reference human gene annotation for the ENCODE project and is produced by merging manual annotation and automated Ensembl gene predictions with extensive computational and experimental QC and validation. Using different reference genesets will inevitably give divergent results and the absence, truncation or misannotation of a gene, exon, or alternatively spliced (AS) transcript may hinder analysis. We will highlight some significant differences between the GENCODE and NCBI Reference Sequence Database (RefSeq) genesets. Specifically, we will discuss divergence in the annotation of alternative splicing (where GENCODE protein-coding loci have a mean of 7.6 AS transcripts while RefSeq only have 2.1), long non-coding RNAs (GENCODE 2.5 fold more genes and 3.7 fold more transcripts), pseudogenes (GENCODE 10% more loci), genomic coverage of annotated exons (GENCODE 1.7 fold greater coverage), degree of manual curation (GENCODE 4.5 fold more manually curated transcripts), experimental validation, and functionally descriptive biotypes. We will detail the continued extension and refinement of the GENCODE geneset, including the integration of RNAseq, CAGE, polyAseq, ribosome profiling and epigenomic data, to

identify novel loci, define 5' and 3' transcript boundaries and identify novel translation initiation sites. Finally, we will explain our use of RNAseq data to determine the expression level of all GENCODE transcripts, allowing us to present a reduced, but biologically meaningful, set of transcripts including e.g. only those that are highly expressed or expressed in a particular tissue.

P16.03-S
Jannovar: A Java library for Exome Annotation

M. Jäger[1,2], *K. Wang*[3], *S. Bauer*[1], *D. Smedley*[4], *P. Krawitz*[1,2,5], *P. Robinson*[1,2,5];
[1]*Institute for Medical and Human Genetics, Charité-Universitätsmedizin, Berlin, Germany,* [2]*Berlin Center for Regenerative Therapies (BCRT), Berlin, Germany,* [3]*Zilkha Neurogenetic Institute, University of Southern California, Los Angeles, CA, United States,* [4]*Mouse Informatics group, Wellcome Trust Sanger Institute, Hinxton, United Kingdom,* [5]*Max Planck Institute for Molecular Genetics, Berlin, Germany.*

Transcript-based annotation and pedigree analysis are two basic steps in the computational analysis of whole-exome sequencing experiments in genetic diagnostics and disease-gene discovery projects. Here, we present Jannovar, a stand-alone Java application as well as a Java library designed to be used in larger software frameworks for exome and genome analysis. Jannovar uses an interval tree to speed up the identification of all transcripts affected by a given variant, and provides HGVS-compliant annotations both for variants affecting coding sequences and splice junctions as well as UTR sequences and non-coding RNA transcripts. Jannovar can also perform family-based pedigree analysis with VCF files with data from members of a family segregating a Mendelian disorder. Using a desktop computer, Jannovar requires a few seconds to annotate a typical VCF file with exome data.

P16.04-M
Comparison of GWAS and EWAS results to identify loci and genes of interest in asthma

A. Madore[1], *F. Bonachela-Capdevila*[1,2,3], *A. Morin*[1,4], *L. Liang*[5], *P. De Causmaecker*[2,3], *M. Lathrop*[4], *W. O. C. M. Cookson*[6], *M. F. Moffatt*[6], *T. Pastinen*[4], *C. Laprise*[1];

Asthma is a complex trait with a large phenotypic diversity for which more than 300 genes have already been associated. In order to better define the heritability of the disease, "omics" technologies were used in several studies to explore genetic and epigenetic factors. The large amount of results obtained with these methods comes with complications for identifying true genes of interest. This study aims to compare genome-wide association studies (GWASs) and epigenome-wide association studies (EWASs) of asthma and related phenotypes (atopy and allergic asthma) using a well-described asthma familial collection in order to identify loci and genes of interest. GWASs and EWASs were performed on DNA samples extracted from whole blood and EWASs were also performed on DNA extracted from isolated eosinophils. GWASs were analyzed using a quasi-likelihood score test performed using the MQLS program and EWASs data were compared using a Mann-Whitney analysis implemented in the GenomeStudio software by Illumina. Analyses allow identifying 2 common loci between EWAS and GWAS analyses for asthma phenotype, 5 common loci for atopy and 3 for allergic asthma. Among them 1 principal locus (including 5 CpG sites or more) was identified in asthma (17q21.2) and 2 principal loci in atopy (5q31.1 and 6p22.1). The three loci identified have already been associated with asthma in previous studies. Analyses are in progress in order to compare common genes associated in both "omics" methods. These results highlight the potential of the combination of "omics" analyses in order to identify potential loci of interest in complex traits.

P16.05-S
DNA methylation signature of IL1R1 and IL1R2 genes in asthma

V. Gagné-Ouellet[1], *A. Boucher-Lafleur*[1], *V. Tremblay-Vaillancourt*[1], *S. Guay*[2,3], *J. Chakir*[4], *L. Bouchard*[2], *C. Laprise*[1];
[1]*Université du Québec à Chicoutimi, Chicoutimi, QC, Canada,* [2]*Université de Sherbrooke, Sherbrooke, QC, Canada,* [3]*Ecogene-21 et la Clinique Lipidique, Chicoutimi, QC, Canada,* [4]*Institut Universitaire de Cardiologie et de Pneumologie, Ste-Foy, QC, Canada.*

We have previously reported an association between interleukin 1 receptor (*IL1R*) type 1 and 2 polymorphims and asthma and related phenotypes. We have also reported *IL1R2* mRNA level differences in lung tissue of asthmatic individuals in comparison to controls. According to these results, this study aims to assess whether DNA methylation levels at both loci are also associated with asthma and allergic asthma and correlate with their mRNA levels. We measured leucocyte's DNA methylation levels at *IL1R1* and *IL1R2* gene loci for 93 individuals using bis-pyrosequencing. mRNA levels were quantified using qRT-PCR in a subsample of 37 individuals. Individuals with asthma had higher DNA methylation levels at both *IL1R1* and *IL1R2* gene loci in comparison to controls (without history of asthma and/or atopy) (15.9±4.1 vs 13.0±2.9, p=0.02 and 48.6±13.1 vs 40.8±10.8, p=0.04 respectively). Higher methylation levels were also observed in individuals with allergic asthma at two *IL1R2* CpG sites (48.4±13.4 vs 40.8±10.8, p=0.03 and 32.0±9.4 vs 25.5±8.3, p=0.02). Finally, *IL1R2* DNA methylation levels were negatively correlated with *IL1R2* mRNA levels in our subsample of 37 participants (r=-0.45, *p*=0.007). This study highlights that *IL1R1* and *IL1R2* have a specific epigenetic signature in the context of allergic asthma and that differences in *IL1R2* gene expression might be related to DNA methylation level changes.

Beckwith-Wiedemann syndrome (BWS), a congenital overgrowth disorder with variable expressivity, results from disordered expression and/or function of imprinted genes at chromosome 11p15.5. There are no generally agreed clinical diagnostic criteria, with molecular studies commonly performed to confirm diagnosis. In particular, methylation status analysis at two 11p15.5 imprinting control centres (IC1 and IC2) detects up to 80% of cases. In order to evaluate the relationship between the clinical presentation of suspected BWS and IC1/IC2 methylation abnormalities we reviewed the results of >1000 referrals for diagnostic testing.
507/1091 (46.5%) referrals had a positive diagnostic test. The rate of a positive diagnostic test increased with increasing numbers of clinical features. Previously reported genotype-phenotype correlations with paternal uniparental disomy, IC1, and IC2 epimutation groups were confirmed and potential novel associations detected. Predictive values of previously described clinical diagnostic criteria were compared, and although there were differences in sensitivity and specificity, receiver operating characteristic (ROC) analysis demonstrated that these were not optimal in predicting 11p15.5 methylation abnormalities. Using logistic regression, we identified clinical features with the best predictive value for a positive methylation abnormality. We developed a weighted scoring system (sensitivity - 75.9% and specificity - 81.8%) to prioritise patients presenting with the most common features of BWS, and ROC analysis demonstrated superior performance (area under the curve - 0.85; 95% CI: 0.83-0.87) compared to previous criteria.
We suggest that this novel tool will facilitate selection of patients with suspected BWS for routine diagnostic testing and so improve the diagnosis of the disorder.

P16.07-S
Genome-wide methylation analysis on epimutated BWS patients for detection of known and novel imprinted loci multilocus defects

L. Calzari[1], *S. Russo*[1], *S. Guzzetti*[1], *D. Gentilini*[1], *M. Bonati*[1], *A. Mussa*[2], *G. Ferrero*[3], *S. Di Candia*[4], *C. Gervasini*[5], *L. Larizza*[1,6];
[1]*Istituto Auxologico Italiano, Milano, Italy,* [2]*Div of Pediatric Endocrinology, Dpt of Pediatrics, University of Turin, Torino, Italy,* [3]*Div Pediatric Endocrinology, Dpt of Pediatrics, University of Turin, Torino, Italy,* [4]*Pediatric Unit (S.D.C., G.C.), Ospedale San Raffaele, Milano, Italy,* [5]*Health Sciences Department, University of Milan, Milano, Italy,* [6]*Health Sciences Department, University of Milan, Milan, Italy.*

Loss of imprinting (LOI) through methylation loss (LOM) or gain (GOM) may result in imprinting disorders (IDs). Beckwith Wiedemann syndrome is a paradigmatic ID, which arises from dysregulated expression of imprinted growth regulatory genes at 11p15.5. We pursued a genome-wide methylation study to investigate our cohort of IC2 hypomethylated BWS patients for the occurrence of Multilocus Methylation Defects (MMD) at imprinted loci. To this purpose we selected from a cohort of 171 patients with clinical presentation in the spectrum of Beckwith-Wiedemann syndrome carrying an 11p15.5 epimutation, 18 cases hypomethylated at IC2: 14 with a complete phenotype, 2 with isolated hemihyperplasia (IH) and two couples of monozygous twins with discordant phenotype, but concordant for the IC2 defect in blood tissue. The Processing of genomic DNAs from peripheral blood on an Infinium Human Methylation 450K BeadChip Kit Array (Illumina)showed that 7/16 (44%) of IC2 epimutated BWS and 2/2 IH patients

had multilocus defects. These comprised hypermethylation at GNAS DMRs and hypomethylation at GNAS, PLAGL1, DIRAS3, FAM50B and ZNF331 loci, confirming the view of a network of imprinting deregulated genes. MMD were detected in blood and saliva from both affected twin members, but complementary pyrosequencing and MS-MLPA analyses showed that methylation defects were absent/attenuated in the DNA from saliva in the unaffected co-twins. This findings will enhance clinical practice and epigenotype phenotype correlations. In conclusion 450K genome approach appears a reliable technique to profiling the methylation status of all known imprinted loci and unravel their recurrent simultaneous deregulation Supported by 2009MBHZPR_003(to LL).

Comprehensive methylation profiling in Beckwith-Wiedemann syndrome and Silver-Russell syndrome

B. Lan-Leung[1], *R. Dias*[1], *J. Bauer*[2], *E. R. Maher*[1,2];
[1]*University of Birmingham, Birmingham, United Kingdom,* [2]*University of Cambridge, Cambridge, United Kingdom.*

The investigation of human imprinting disorders has provided important insights into the role of genomic imprinting in normal health and development. Beckwith-Wiedemann syndrome (BWS) is a congenital overgrowth disorder associated with abnormal function of 11p15.5 imprinted genes. The most common cause of BWS is loss of methylation (epimutation) at the imprinting centre 2 (IC2/KvDMR1). We and others have found that a subgroup of BWS patients also harbour epimutations at other imprinting centres (ICs) outside of 11p15.5. This multiple epimutation (ME+) phenotype has been associated with assisted reproductive technologies births though the clinical significance of these additional epimutations has not been clearly defined. Another human imprinting disorder, Silver-Russell syndrome (SRS) is also linked to the 11p15.5 imprinted gene cluster but, in contrast to BWS, is characterized by pre- and postnatal growth retardation and, most commonly, epimutations (loss of paternal allele methylation) at IC1. In order to comprehensively define potential ME+ epigenotypes in BWS and SRS patients we undertook methylation profiling in 67 and 22 patients respectively with the Illumina 450k methylation BeadChip. Analysis of methylation status at 37 imprinted differentially methylated regions (DMRs) (31 well characterized known DMRs (kDMRs) and 6 recently reported novel DMRs (nDMRs) (PMID:24402520)). The most frequently affected non-11p15.5 kDMRs in ME+ BWS patients were on chromosome 1, 6 and 15. In addition, epimutations at nDMRs located on chromosome 8 and 22 were frequent. Further analysis of the ME+ epigenotype patterns and clinical correlates in BWS and SRS patients will be presented in detail.

P16.09-S
Highlander: variant filtering made easier

R. Helaers, *M. Vikkula;*
Laboratory of Human Molecular Genetics, De Duve Institute (Université catholique de Louvain), Brussels, Belgium.

The field of human genetics is being revolutionized by exome and genome sequencing. A massive amount of data is being produced at ever-increasing rates. Targeted exome sequencing can be completed in a few days using NGS, allowing for new variant discovery in a matter of weeks. The technology generates considerable numbers of false positives, and the differentiation of sequencing errors from true mutations is not a straightforward task. Moreover, the identification of changes-of-interest from amongst tens of thousands of variants requires annotation drawn from various sources, as well as advanced filtering capabilities. We have developed Highlander, a Java software coupled to a MySQL database, in order to centralize all variant data and annotations from the lab, and to provide powerful filtering tools that are easily accessible to the biologist. Data can be generated by any NGS machine (such as Life Technologies' Solid or Ion Torrent, or Illumina's HiSeq) and most variant callers (such as Life Technologies' LifeScope or Broad Institute's GATK). Variant calls are annotated using DBNSFP and SnpEff, then imported into the database. The Highlander GUI easily allows for complex queries to this database, using shortcuts for certain standard criteria such as "sample-specific variants", "variants common to specific samples" or "combined-heterozygous genes". Users can then browse through query results using sorting, masking and highlighting of information.

P16.10-M
Somaticaller: a somatic and post-zygotic mutation detection software from DNA-seq data

Y. Duffourd[1], *J. St-Onge*[1,2], *J. Courcet*[1,3], *L. Faivre*[1,3], *P. Vabres*[1,4], *J. Rivière*[1,2];
[1]*Université de Bourgogne - Equipe GAD, Dijon, France,* [2]*CHU Dijon - Molecular Genetics Laboratory, Dijon, France,* [3]*CHU Dijon - FHU-TRANSLAD, Dijon, France,* [4]*CHU Dijon - Dermatology, Dijon, France.*

The ability to detect low-level genetic variants in heterogeneous populations of cells is necessary for identifying postzygotic or somatic mutations underlying human diseases such as mosaic birth defects involving the skin. Existing bioinformatics methods for detecting such variations have been mainly developed for cancer genomics and are usually based on the analysis of paired samples. Furthermore, they have limited sensitivity in detecting certain types of variants such as insertions/deletions. SomatiCaller was developed to systematically detect low-level variants in next-generation DNA sequencing data. It consists in browsing aligned sequence data (BAM files) of pairs or trios (i.e. index case and parents) to systematically identify positions with candidate variants. Statistical tests are first performed between different samples to measure the sample's independence of a candidate position for a given variation. In a second time, allelic ratios from all candidate sites are compared to a series of negative controls by Student's t-test to discriminate true positive variants from probable sequencing or alignment errors. Applied to targeted deep sequencing of a gene associated with mosaic overgrowth syndromes (PIK3CA), SomatiCaller led to identification of variants with allelic fractions as low as 0.01. Experiments from trio-based exome sequencing data demonstrated its ability to readily detect variants with allelic fractions as low as 0.05. Compared to standard variant callers, SomatiCaller showed increased sensitivity for genetic variants present in less than 10% of reads. Potential applications of this tool are numerous in the growing field of the genetics of mosaic diseases, both for research and molecular diagnosis purposes.

P16.11-S
An extensive, interactive variant-centered annotation browser

M. Arnold[1], *J. Raffler*[1], *G. Kastenmüller*[1], *K. Suhre*[2];
[1]*Helmholtz Zentrum München GmbH, Neuherberg, Germany,* [2]*Weill Cornell Medical College, Doha, Qatar.*

Genome-wide association studies and, more recently, next-generation sequencing studies have created a huge amount of genetic associations with hundreds of common human traits. A still unsolved problem in this context is the correct annotation of the gene(s) linked to the mostly small effects observed for genetic variants. The current catalog of genomic annotations is multi-layered and highly complex, the annotation of variants on the other hand is often conducted using very basic heuristics. We try to even out this imbalance by integrating many different genome-wide annotation datasets into a user-friendly web-accessible resource. Our collection of tools combines linkage disequilibrium data, genetic associations, gene annotations, expression data and several layers of regulatory annotations. Besides evidence-based prediction of variant-to-gene projections, our resource provides data browsing and retrieval, as well as publication-ready plotting and an interactive variant-centered genome browser.

P16.12-M
Molecular diagnosis of bladder cancer by detecting gene p16INK4a from body fluids by methylation-specific polymerase chain reaction (MSP)

R. Dumache, *M. Puiu, R. Bardan, M. Licker, V. Dumitrascu, D. David;*
University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania.

Background: Carcinoma of the urinary bladder is the 5th leading causes of death worldwide. Hypermethylation of the CpG islands of gene promoter is one of the earliest and most frequent epigenetic alterations leading to cancer as well as in its development. The purpose of our study was to investigate if hypermethylation of gene $p16^{INK4a}$ can be used as a serum biomarker for early detection of bladder cancer. **Materials and methods:** Using the methylation-specific polymerase chain reaction (MS-PCR) method, we analyzed the methylation status of gene $p16^{INK4a}$ from serum and its matched tumor in 42 bladder cancer patients, and 35 samples from cancer-free individuals, as controls. Genomic DNA was extracted from serum and tissue samples. **Results:** Hypermethylation of gene $p16^{INK4a}$ was found in 38 (90.5%) of the 42 bladder cancer patients, and in only 2 (5.8%) of the 35 cancer-free individuals. Hypermethylation status of gene p^{INK4a} was found in both serum and its matched bladder biopsy sample. **Conclusion:** We conclude that hypermethylation of gene p^{INK4a} is involved in early bladder carcinogenesis and therefore might be used as a noninvasive serum biomarker for early detection of bladder cancer.

Extracellular matrix plays a significant role in tumor development. Our study focuses on the epigenetic regulation of 12 laminin-encoding genes (*LAMA1, LAMA2, LAMA3A, LAMA3B, LAMA4, LAMA5, LAMB1, LAMB2, LAMB3, LAMC1, LAMC2, LAMC3*), 8 genes of integrins (*ITGA1, ITGA2, ITGA3, ITGA4, ITGA6, ITGA7, ITGA9, ITGB1*), 2 nidogen genes (*NID1,NID2*), 2 genes of the cadherin family(*CDH2,CDH3*) and the dystroglycan gene *DAG1*.We have surveyed 109 samples of breast cancer, 109 paired adjacent nonmalignant samples, 6 samples of normal mammary gland from autopsy and 6 samples of breast cancer cell lines for aberrant promoter methylation of all 25 genes.
Promoters of 11 genes (*LAMA1, LAMA2, LAMB1, ITGA1, ITGA4, ITGA7, ITGA9, NID1, NID2, CDH2, CDH3)* have demonstrated abnormal methylation in 1,9% to 42% samples of breast cancer and/or adjacent tissues. Our results may be important for understanding of the dramatic changes in the extracellular matrix during tumor growth and development.
Extracellular matrix proteins genes abnormally methylated in breast cancer

Comprehensive transcriptome profiling of breast cancers

V. del Monaco[1], *V. D'Argenio*[1,2], *M. D'Aiuto*[3], *F. D. E. De Palma*[1,2], *D. Montanaro*[1], *G. Liguori*[3], *G. D'Aiuto*[3], *G. Botti*[3], *A. Baldi*[1], *R. A. Calogero*[4], *F. Salvatore*[1,2,5];
[1]*CEINGE-Biotecnologie Avanzate, Naples, Italy,* [2]*Department of Molecular Medicine and Medical Biotechnologies, University of Naples Federico II, Naples, Italy,* [3]*Istituto Nazionale tumori - IRCCS Fondazione Pascale, Naples, Italy,* [4]*Department of Computer Sciences, University of Torino, Turin, Italy,* [5]*IRCCS-Fondazione SDN, Naples, Italy.*

Breast cancer is one of the most frequent malignancies among women and is a major cause of cancer-related mortality, despite advances in early detection and treatment. Breast cancer is a heterogeneous disease with a poorly defined genetic landscape, which poses a major challenge in diagnosis and treatment. Recent reports have described an intricate interplay among diverse RNA species, including protein-coding mRNAs and ncRNAs (long ncRNAs, pseudogenes, miRNAs and circular RNAs) which are also implicated in numerous diseases such as cancer.
By massively RNA-sequencing, we obtained 7.8 billion reads from 55 healthy and tumour breast tissues belonging to Basal, HER2-positive and Luminal breast cancers, with or without hereditary predisposition. At the beginning, we aim to define their comprehensive digital transcriptome. In order to analyse the transcriptomes in specific tumour cells, we used Laser Capture Microdissection system. Furthermore, we performed a RiboZero-based rRNA depletion in order to focus the sequencing effort on the non-ribosomal portion of the total RNA. Comparative transcriptomic analyses highlighted differentially expressed transcripts, between the different breast cancer groups, identifying transcripts which may be possible modulator RNAs.
This global transcriptomic profiling can illustrate the intricate internal mechanism of the transcriptome at a very high resolution, allowing us to explore the distinct nature of these breast cancer subtypes, and could provide a new inventory of diagnostic and therapeutic targets.

P16.15-S
Genetics of Cardiomyopathies: In-silico Analysis of Variants in Cardiomyopathies-Associated Genes

O. O. Akinrinade[1], *S. Myllykangas*[1], *J. Koskenvuo*[2], *T. Alastalo*[1];
[1]*University of Helsinki, Helsinki, Finland,* [2]*University of Turku, Turku, Finland.*

Cardiomyopathies are genetically heterogeneous group of diseases of the myocardium. Mutations in multiple genes have been associated with cardiomyopathy and many cases of cardiomyopathy have a genetic component. Genetic factors may be responsible for 30-50% of cases of dilated cardiomyopathy (DCM), and about 90% of cases of Hypertrophic cardiomyopathy (HCM) are familial. As clinical genetic testing is rapidly emerging with a principal rationale of identifying at-risk asymptomatic relatives, knowledge of predisposing loci can guide clinical surveillance for disease onset, thereby enhancing preventive and treatment interventions.
We collected over 6000 genetic variants from over 80 genes with known associations with cardiomyopathies, and queried the 1000 Genomes Project database for exonic variants in the genes. We analyzed and compared the rate of missense variation in the two datasets using a window bin of 50bp. Though most variants are rare (78.7%), and 58.4% (2751/4708) being private, 25.7% (655/2544) of missense variants from 1000 Genomes Project database are predicted to be pathogenic. Of the overlapping variants, 20.4% (42/206) and 42.2% (87/206) are known and predicted pathogenic variations respectively. We identified 104 regions distributed among 15 genes, including *LMNA, MYH7, TNNT2*, and *MYBPC3,* with high density of pathogenic variants and no or extremely low variant in the population data. Majority of the identified loci overlap protein domains that play critical roles.
The identified regions with high density of pathogenic missense variants are likely hotspots that could predispose to cardiomyopathies, hence no or extremely rare variations have been reported in them in the population data.

P16.16-M
Complex Chromosomal Rearrangements In B-cell Lymphoma: Evidence Of Chromothripsis?

G. V. N. Velagaleti[1], *V. Ortega*[1], *C. Mendiola*[1], *E. William*[1], *V. S. Tonk*[2];
[1]*University of Texas Health Science Center, San Antonio, TX, United States,* [2]*Texas Tech University, Lubbock, TX, United States.*

Genomic instability is a well-known hallmark of cancer. Recent genome sequencing studies have identified a novel phenomenon called chromothripsis in which complex genomic rearrangements are thought to be derived from a single catastrophic event rather than by several incremental steps. While chromothripsis is well documented in solid tumors and leukemias, chromothripsis in lymphoma is rarely reported. We report a case of possible chromothripsis in a patient presenting with a thyroid mass suspicious for diffuse large B-cell lymphoma. Chromosome analysis showed a complex karyotype with multiple rearrangements, including a translocation of chromosomes 3 and 7 involving the BCL6 gene region, chromosomes 14, 7 and 22 with involvement of the IGH gene region and an unbalanced structural rearrangement involving chromosomes 8 and 18 involving the BCL2 gene region.. The karyotype was interpreted as 51~56,XX,+X,+2,t(3;7)(q29;p11.2),der(7)t(3;7)t(14;7;22)(q32;p11.2;q12),+der(7)t(14;7;22),der(8)t(8;18)(p12;q21),+der(9)t(5;9)(q13;q22),+13,der(14)t(14;7;22),+21,+1~4r[cp20]. FISH analysis confirmed the BCL6 gene rearrangement, IGH gene rearrangement/extra copies of IGH and 3 copies of BCL2. Array comparative genomic hybridization studies with Cytochip 60K custom oligo array showed multiple complex copy number variations including a previously unidentified chromosome 12 abnormality. However, array analysis did not reveal any imbalance involving the BCL6, BCL2 or IGH gene regions whose rearrangements were observed by FISH, thus suggesting that these rearrangements are balanced in nature. Our patient's genomic abnormalities show characteristics suggestive of chromothripsis and provides initial evidence that chromothripsis is not confined to solid tumors, but can also be seen in B-cell lymphomas with well characterized one or two-step lymphomagenesis.

P16.17-S
Describing chromothripsis using HGVS sequence variation nomenclature, suggested extensions

P. E. M. Taschner[1], *L. Nazaryan*[2], *Z. Tümer*[2], *J. T. den Dunnen*[1];
[1]*Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands,* [2]*Applied Human Molecular Genetics, Kennedy Center, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark.*

Large chromosomal rearrangements are traditionally described using ISCN nomenclature based on chromosomal banding patterns (1). Due to the limited number of translocation breakpoint sequences identified the sequence variation nomenclature guidelines of Human Genome Variation Society (HGVS, http://www.hgvs.org/mutnomen), which are mainly focused on simple variants, did not require specific rules for detailed description of genetic rearrangements. This changed with the introduction of new technologies allowing rapid discovery of breakpoint sequences from complex structural rearrangements including translocations and chromothripsis. The description of such complex variants challenges the existing guidelines. Previously, we have proposed new HGVS rules for detailed translocation descriptions (2). Here, we suggest extending the HGVS nomenclature guidelines to facilitate unambiguous descriptions of chromothripsis. The main feature of these descriptions is that the precise combination and order of chromosomal fragments can be derived easily. The suggested format should provide sufficient flexibility and consistency limiting alternative interpretations and ambiguous descriptions. The new rules can be combined with those proposed previously for complex changes, which included: i) nesting to support description of changes within inversions and duplications, ii) composite changes to support concatenation of inserted sequences (3). We have applied the rules in practice by describing an instance of stably inherited chromothripsis. The specifications should allow easy implementation in

sequence variant nomenclature checkers (e.g. Mutalyzer, https://Mutalyzer.nl).

Concordance of methods for CNV detection from whole-exome sequencing as compared with microarray: 100 sample autism cohort

L. J. Culot[1], *K. Schmitz Abe*[2], *R. Keshavan*[1], *S. Shams*[1];
[1]*BioDiscovery, Inc, Hawthorne, MA, United States,* [2]*Department of Pediatrics Harvard Medical School, Boston, MA, United States.*

Copy number variants have been implicated as drivers of many developmental disorders, including autism spectrum disorder. The platform of choice to detect genome-wide CNVs has traditionally been microarray (including SNP arrays that can also detect copy neutral LOH regions); however, since samples have often undergone sequencing to discover pathogenic sequence variants, it is desirable to exploit these data to also detect CNVs. Various methods have been proposed to detect CNVs from NGS data, but little information is available which compare the success of these approaches to orthogonal methods. Using a large data set of constitutional samples from an autism cohort that have been subjected to both whole-exome sequencing (WES) and to a genome-wide SNP microarray, we compare the ability to detect CNVs between these platforms. Several algorithms for CNV detection from the WES data are examined, and the results are compared with an established HMM-based method for detection of CNVs from the microarray platform.

P16.19-S

De Novo Assembly and Structural Variation Discovery in Complex Genomes Using Extremely Long Single-Molecule Imaging

J. Baeten[1], *A. Hastie*[1], *E. Lam*[1], *H. Dai*[1], *A. Pang*[1], *S. Chan*[1], *W. Andrews*[1], *M. Saghbini*[1], *X. Yang*[1], *P. Kwok*[2], *H. Cao*[1];
[1]*Bionanogenomics, San Diego, CA, United States,* [2]*UCSF, San Francisco, CA, United States.*

De novo genome assemblies using only short read data are generally incomplete and highly fragmented due to the intractable complexity found in most genomes. This complexity, consisting mainly of large duplications and repetitive regions, hinders sequence assembly and subsequent comparative analyses. As a result of the remaining limitations of DNA sequencing and analysis technologies, it is not feasible to create similarly high quality assemblies of individuals to detect and interpret the many types of structural variation that are refractory to high throughput or short-read technologies.
We present a single molecule genome analysis system (Irys) based on NanoChannel Array technology that linearizes extremely long DNA molecules for direct observation. This high-throughput platform automates the imaging of single molecules of genomic DNA hundreds of kilobases in size to measure sufficient sequence uniqueness for unambiguous assembly of complex genomes. High-resolution genome maps assembled de novo preserve long-range structural information necessary for structural variation detection and assembly applications. We have used Irys genome mapping for the assembly and characterization of several genomes, including human, plant, fungi, and bacteria.
In addition to describing the technology and analysis approaches useful for dissecting complex genomes, we demonstrate results from several genomes, where genome maps span remaining reference gaps, identify known and novel structural variants (including balanced rearrangements) and phase variation within haplotype blocks. We also resolve and measure long tandem repeat regions that are likely impossible to assemble by other methods.

We recently applied Methylation Sensitive-High Resolution Melting (MS-HRM) technique to evaluate the methylation levels of APC, MGMT, hMLH1, RASSF1A and CDKN2A genes in over 100 colorectal cancer (CRC) samples and 80 adjacent healthy mucosa specimens (Coppedè F et al. Epigenetics 2014, DOI: 10.4161/epi.27956).
Our analysis revealed a correlation between hMLH1 methylation, a marker of the CIMP high phenotype, with low folate levels, tumor location, increasing age, female gender, high number of methylated genes, and the TYMS 1494 6bp ins/del polymorphism. Increasing age correlated also with MGMT methylation levels in CRC, and both tumor stage and the MTR 2756A>G polymorphism with RASSF1A methylation.
The APC gene resulted frequently methylated in both CRC tissues and healthy adjacent mucosa specimens. APC methylation levels correlated with the TYMS 1494 6bp ins/del polymorphism in CRC samples and with both increasing age and the MTR 2756A>G polymorphism in healthy mucosa.
In order to shed some light on complex gene-environment interactions leading to impaired DNA methylation in CRC we are currently elaborating those data by means of artificial neural networks (ANNs) searching for correlation with lifestyle factors evaluated by means of a detailed questionnaire on lifestyles and dietary habits filled in by each CRC patient. ANNs are able to understand non-linear relationships among studied variables and to highlight through a graph the complexity of connections among the studied variables.
The study was supported by Istituto Toscano Tumori (ITT).

P16.21-S

Copy Number Calling for Gene Panels with Next-Generation Sequencing (NGS)

A. Vadapalli, *J. Ghosh;*
Agilent Technologies, Santa Clara, CA, United States.

Detection of copy number variation (CNV) from NGS data is an important mechanism for understanding and identifying genetic factors in constitutional diseases and cancer. Our evaluation of existing public algorithms revealed that they did not reliably detect short length CNVs from NGS gene panel data. A new CNV detection algorithm is introduced in SureCallv2.0 software for target enriched NGS data generated from SureSelect and Haloplex. This algorithm is able to predict breakpoints using the low genomic coverage of small panels. This feature makes it different from other algorithms based on read depth that require adequate genomic coverage to normalize the data and model copy number of different regions. A diploid reference is used to compute log ratio values from the normalized read depths with respect to the sample that minimizes the need to make additional corrections with respect to GC content and mappability. Reference and sample can either be run together or taken from different sequencing experiments. An internal read depth normalization step handles the difference in the number of sequencing reads between sample and reference. The resolution of detection is that of a single interval where the interval boundaries are defined from the baits or amplicons that cover the regions of interest in the genes. Aberrant intervals are labeled as significant after applying an iterative method that optimizes the tradeoff between least-squares fit of the data and the penalty caused by break points. An adaptive interval sizing feature allows for the detection of sub-exon copy number changes.

P16.22-M

Quantification of FCGR3B gene CNVs using Digital PCR highlights tandem repeat copies in Rheumatoid Arthritis patients

M. S. Ben Kilani[1], *F. Cornélis*[2], *V. Chaudru*[1], *E. Petit-Teixeira*[1];
[1]*GenHotel-EA3886, Université d'Evry-Val-d'Essonne, Evry-Genopole, Evry, France,* [2]*GenHotel-Auvergne, EA4679, Service de Génétique Clinique, CHU Clermont Ferrand, Clermont Ferrand, France.*

Introduction: Copy number variation (CNV) was more and more investigated in complex diseases. We analysed CNVs of Fc fragment of IgG, low affinity IIIb, receptor (FCGR3B), a candidate gene in Rheumatoid Arthritis (RA). Droplet® Digital PCR was used to quantify CNVs and to identify tandem repeat. Patients and Methods: Thirty-eight RA trio families (one patient with two parents) and seven control samples (with known copy number) were genotyped using Droplet® Digital PCR (ddPCR, BioRad), which performs an absolute quantification using up to 20,000 reactions for one sample. Digestion reactions were done in the reaction mix for each sample with several concentrations of endonuclease FokI enzyme, in order to separate replicated copies in tandem on the same chromosome. Results: CNVs quantification showed 1 (9.65%), 2 (83.33%) or 3 (7.02%) copies. Comparison of results from undigested and digested DNAs (2U of enzyme with 33ng of DNA) showed a difference in copy number (CN) estimation for samples with tandem copies. The CN value obtained without digestion was under estimated in comparison with digestion. However, when one copy of the gene was located on each chromosome, the CN estimation was not different between the two protocols. Conclusion: Use of ddPCR with digested and undigested DNAs allowed CNVs quantification for FCGR3B. We also highlighted recombination mechanisms (tandem copies) leading to a better genotype characterization. Further investigation of FCGR3B CNVs and their transmission in 200 trio families will be performed, to better understand the impact of these candidate gene variations in RA.

P16.23-S
Variable R.Msp1 fragmentation in genomic DNA due to DNA hypomethylation in CRF patients with MTHFR C677Tgene polymorphism: from genetics to epigenetics

M. Urfali[1], *O. Ozdemir[1], F. Silan[1], A. Uludag[1], E. ARI[1], M. Kayatas[2];*
[1]Canakkale Onsekiz Mart Universty, Faculty of Medicine Department of Medical Genetics, Canakkale, Turkey, [2]Cumhuriyet University, Faculty of Medicine, Department of Nephrology, Sivas, Turkey.

Background and Objective: The role of inflammation, hyperhomocysteinemia, familial genetic markers and epimutations remains incompletely understood in chronic renal failure(CRF). DNA methylation is a post-replicative modification mechanism that is strongly involved in the physiological control of epimutations and gene expression. In the current study it was aimed to find out the possible role of epigenetic alterations in renal failure due to functional MTHFR deficiency in CRF patients that requiring long-term haemodialysis. Method: Current cohort includes 228 CRF patients and 212 healthy individuals from the same population. The MTHFR C677T SNP was genotyped by real-time PCR analysis and genomic DNA fragmentation sizes were correlated for wild, heterozygous and homozygous mutated CRF patients after methyl marker cognate enzyme of R.Msp1 digestion. Fragments were compared by Scion Image histogram plot analysis. Results: Increased T allele frequency was detected in CRF patients when compared to the health individuals from the same population. MTHFR 677TT (homozygous) genotype was found 6.1% and the T allele frequency 2.5-fold increased in CRF when compared with control group. Distinct global DNA methyl patterns that showed variable R.Msp1 fragmentations were also detected in current MTHFR gene mutated CRF patients when compare to the wild CRF patient. Conclusions: The current results indicate that individuals with germ-line MTHFR C677T mutations have a risk for CRF pathogenesis due to the reduced enzyme activity and global DNA hypomethylation. Results needs to be confirmed with a larger scale of sample size.

P16.24-M
DNA methylation changes at the 24-dehydrocholesterol reductase gene are associated with High Density Lipoprotein serum levels

DNA methylation modifications may occur in response to a wide variety of exposures, including diet and metabolic status. In the context of the EPICOR study aimed at identifying relationships between DNA methylation status and myocardial infarction risk (292 cases, 292 controls from the EPIC-Italy cohort), we evaluated the association of lipidic profiles to genome-wide DNA methylation in a sample of 277 subjects (153 cases, 124 controls) not treated for diabetes nor under cholesterol/blood pressure-lowering treatments. DNA methylation was assessed with the Illumina HumanMethylation450 BeadChip, and data analysed according to standard procedures (MethyLumi, Bioconductor), correcting for gender, BMI, season and centre of recruitment, estimated white blood cells percentage, chip position and batch. At a linear regression analysis, we found an interesting association between a CpG site in the promoter region of the 24-dehydrocholesterol reductase gene (*DHCR24*) and serum HDL levels (effect size $1.2*10^{-3}$, $p=3.93*10^{-5}$). The result was strengthened and overcome the Bonferroni threshold ($1.03*10^{-7}$) when including in the analysis further 186 EPIC-Italy subjects belonging to other on-going studies (N_{TOT}=463, effect size $6.7*10^{-3}$, $p=2.52*10^{-9}$). Among the CpG beadchip probes in the *DHCR24* gene region, only one is clearly and significantly associated with HDL levels, making it a putative biomarker of HDL serum levels. Interestingly enough, recent papers report an anti-inflammatory effect of HDLs in vascular endothelial cells through the upregulation of *DHCR24* expression. Our preliminary findings are thus worthy of further investigation and may contribute to better describe the regulation of *DHCR24* in the HDL mediated inhibition of vascular inflammation.

DNA methyltransferases and acute inflammatory pain

E. Abzianidze[1], *E. Kvaratskhelia[1], T. Tkemaladze[1], K. Kankava[1], G. Gurtskaia[2], L. Nozadze[1], M. G. Tsagareli[2];*
[1]Tbilisi State Medical University, Dept. of Molecular and Medical Genetics, Tbilisi, Georgia, [2]Ivane Beritashvili Centre of Experimental Biomedicine, Dept of Pain and Analgesia, Tbilisi, Georgia, Tbilisi, Georgia.

Pain is the most unpleasant symptom of illness, which is mediated by a variety agents released from local inflammatory cells. Recent studies points to the involvement of epigenetic mechanisms both in the development and maintenance of pain states. One of the most fundamental epigenetic marks is the methylation of cytosine residues in DNA, catalyzed by DNA-methyltransferase enzymes. The aim of the present study was to analyze the changes of DNMT1, DNMT3a and DNMT3b in the trigeminal ganglia (TG) neurons during the maintenance phase of pain states and their modulation by NSAID.
The Mustard oil (10%) was applied to four- month-age rats to induce acute inflammatory pain and responses to mechanical and heat stimuli were assessed. All animal studies conformed to the Guidelines of International Association for the study of Pain regarding investigations. The levels of DNMT1, DNMT3a and DNMT3b were measured in nuclear extracts of Trigeminal ganglia (TGs) neurons in study and control groups. DNMTs assay kits were used to measure the amount of DNA- methyltransferases.
We found that the Mustard oil-evoked pain increased the levels of DNMT3a and DNMT3b, while it has no significant effect on levels of DNMT1 in the same regions compare to control sample. Previous administration of the NSAID revials reduced levels of DNMT3a and DNMT3b.
This study provides the evidence that DNA methylation plays a role in development of pain in animal models. This has important implications for understanding the mechanisms involved transition from acute to persistent pain and for pain therapy.

SNPs identification in duchenne muscular dystrophy female carriers as biomarkers to discriminate symptomatic/asymptomatic phenotypes

F. R. Di Raimo[1], *C. Scapoli[2], M. Neri[1], C. Scotton[1], C. Passarelli[1], A. Carrieri[2], T. Castrignanò[3], G. Pesole[4], E. Kotelnikova[5], E. Schwartz[5], F. Gualandi[1], A. Ferlini[1];*
[1]Department of Medical Sciences, Section of Medical Genetics, University of Ferrara, Ferrara, Italy, [2]Department of Life Sciences and Biotechnology, University of Ferrara, Ferrara, Italy, [3]CINECA Interuniversity Consortium, Roma, Italy, [4]Institute of Biomembranes and Bioenergetics, CNR, Bari, Italy, [5]ARIADNE Genomics Inc, Rockville, Maryland, US, Rockville, MD, United States.

Duchenne muscular dystrophy female carriers are clinically asymptomatic. Nevertheless a small group, defined as manifesting carriers, can develop symptoms, varying from a mild muscle weakness to a DMD-like phenotype. Manifesting carriers may also present cardiac involvement (dilated cardiomyopathy), either alone or in addition to the muscle weakness. Lack of relationship between X-inactivation, transcription balancing and asymptomatic/symptomatic phenotype was recently observed. To date, the molecular mechanism underlying the clinical heterogeneity in female carriers is unknown.
In this study, the combined approach of high-troughput technologies and novel statistical analysis methods has allowed us to identify a group of SNPs which could discriminate the symptomatic/asymptomatic phenotypes.
We performed Whole Exome Sequencing and RNA-seq analysis (Illumina GAIIe, Agilent Sure Select enrichment) on a symptomatic DMD carrier. The interrogation of the NGS output for a list of 883 genes correlated with the dystrophin pathway (MedScan Pathway Study, Ariadne Genomics), resulted in 29 candidated SNPs: 17 in coding regions, 4 in the 3'UTR and 8 in non coding regions.
These selected SNPs have been investigated in two cohorts of carriers: 18 symptomatic (muscle weakness) and 16 asymptomatic (family history of dystrophinopathy or mild myopathic signs, but absence of muscle weakness).
Novel statistical approaches on selected SNPs based on multidimensional scaling and membership probability, allowed us to identify three SNPs in 3'UTR region which could discriminate the symptomatic/asymptomatic phenotypes.
Finally, the combined approaches of NGS and novel statistical analysis could be a very useful approach for the investigation of small cohorts of patients affected by rare diseases.

Effects of Duplex-specific nuclease on human cells expression profiling using RNA-seq

V. Mijatovic[1], *G. Buson[2], M. Valenti[3], L. Dalle Carbonare[3], A. Ferrarini[2], A. Dal Molin[1], A. Mori[1], L. Xumerle[1], E. Caviola[4], P. Pertile[4], M. Delledonne[2], P. F. Pignatti[1], G. Malerba[1];*
[1]Department of Life and Reproductions Sciences, University of Verona, Verona, Italy, [2]Department of Biotechnology, University of Verona, Verona, Italy, [3]Department of Medicine, Clinic of Internal Medicine, Section D, Verona, Italy, [4]Cutech Srl, Padova, Italy.

RNA-seq is a next-generation sequencing method able to characterize thoroughly gene expression profiles and to perform very accurate differential gene expression analysis. High expression of some genes could both influ-

ence the estimate of relative expression of less expressed genes, as well as reduce the estimate accuracy of gene expression levels of low expressed genes. Therefore, it would be convenient to apply a method able to reduce excessively abundant mRNA transcripts. A cDNA depletion method for the most represented transcripts called duplex-specific nuclease (DSN) has been effectively used in several studies. Three different cell types were studied: blood, monocytes and keratinocytes. From each cell type two RNA-seq libraries were produced (untreated libraries), for a total of 6 libraries. A part of each library was then treated with DSN, producing a total of 6 DSN treated libraries. Overall, 12 RNA-seq libraries (6 untreated and 6 treated) were prepared.
In blood tissue the most abundant transcripts in both DSN-treated and DSN-untreated samples corresponded to globins (HBA2, HBA1 and HBB), accounting for ~70% of total transcripts. In this sample maximum effects of DSN treatment was observed. Transcripts found to be the most expressed in monocyte sample were ~10 times smaller than globins expression in blood sample. Gene expression of keratinocyte libraries was not influenced by DSN treatment.
DSN treatment has been able to strongly reduce globins expression. DSN treatment also reduced, even if with a smaller effect, the most expressed genes in monocyte sample.

P16.28-M
Effects of the culture condition and chromatin remodeling agents on the epigenetics of organotypic cultures

S. M. Sirchia[1,2], *A. Faversani[2], M. V. Russo[2], S. Tabano[3,2], D. Ricca[2], E. Bonaparte[2], A. Del Gobbo[2], R. Falcone[2], F. Savi[4], A. Palleschi[5], S. Bosari[2,3], M. Miozzo[2,3];*
[1]Department of Health Sciences, Università degli Studi di Milano, Milano, Italy, [2]Division of Pathology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [3]Department of Pathophysiology and Transplantation; Università degli Studi di Milano, Milano, Italy, [4]Division of Pathology, Ospedale San Paolo, Milano, Italy, [5]Division of Thoracic Surgery and Lung Transplantation, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy.

Alterations of the epigenetic pathways are established as hallmarks of tumorigenesis, together with genetic/genomic variations. Tumor epigenetic alterations are of increasing relevance to clinical practice, because they are important "druggable" targets for cancer therapy using chromatin remodeling agents (CRAs). New evidences highlight the relevance of microenvironment on the epigenetics and the need to use culture models that preserve the tissue morphology, to better understand the mode of action of CRAs. We studied the epigenetic response induced by culture condition and CRAs treatment, in a preclinical model based on organotypic culture from normal and neoplastic lung specimens, that preserves ex vivo the original tissue microenvironment and morphology. We assessed the expression pattern of histone deacetylases (HDACs) and methylation profile of "long interspersed nuclear elements" LINE1s and a panel of tumor suppressor genes. We observed a different behavior of the organotypic culture respect to that reported for other ex vivo models. Interestingly, culture induced an overall increase of LINE1s methylation, whereas CRAs caused LINE1s demethylation. Differently, culture and CRAs induced opposite effects on the genes: the samples responded specifically, showing demethylation for some promoters and increased methylation for others. Moreover, we noted that the culture caused alterations in the HDACs expression pattern.
These overall data reveal the importance of the maintaining the cells in their original organ architecture to study the mode of action of the CRAs, and suggest that CRAs do not work only in a non-specific way, as previously thought, in particular on the gene promoters.

P16.29-S
Bioinformatic approaches for next generation sequencing variant calling in matched sensitive-resistant ovarian tumor pairs

L. Beltrame[1], *M. Di Marino[1], L. Clivio[1], B. A. Chapman[2], R. Baldo[3], S. Magni[3], M. D'Incalci[1], S. Marchini[1];*
[1]Department of Oncology, IRCCS Istituto di Ricerche Farmacologiche, Milano, Italy, [2]School of Public Health, Harvard University, Boston, MA, United States, [3]S.Gerardo Hospital, Monza, Italy.

Introduction Epithelial ovarian cancer (EOC), is generally sensitive to first line platinum based therapy, however more than 80% of patients experience relapse within 18 months and become resistant to subsequent lines, until the disease becomes incurable. Despite recent advances, the mechanisms underlying drug resistance in EOC have yet to be clearly identified. Transcrptional profiling, performed in a cohort of patients from which matched biopsies were taken at primary surgery (PS-O) when tumor was naïve to chemotherapy and at time of relapse (SCR) when the tumor was resistant, identified the EMT pathway as a key player in relapse (Marchini et al., 2013). Here we describe the development of computational approaches to identify somatic variants using targeted DNA resequencing with an Illumina MiSeq on our cohort of SCR and PS-O samples.
Methods We improved an existing community developed bioinformatics pipeline: bcbio-nextgen. After an examination of existing programs, we added support for tumor samples in the pipeline using three best-practice somatic variant callers (MuTect, VarScan2, and FreeBayes). The pipeline was tested on a a high performance cluster computing platform (Cloud4CARE project).
Results The method was initially tested on a reduced data set from the Cancer Genome Atlas, then run on the complete data set of matched PS-O - SCR samples. Variants identified by the pipeline were correctly discriminated as germline or somatic, and confirmed by external validation.
Conclusions Our results suggest that our bioinformatic approach is sensitive, robust, reproducible and viable for analysis of matched EOC samples.

P16.30-M
Benign copy number variations in the human exome: focusing on intellectual disability genes

M. A. Zelenova[1,2], *S. G. Vorsanova[1,2,3], Y. B. Yurov[1,2,3], S. A. Korostelev[4], K. S. Vasin[1], I. Y. Iourov[1,2,5];*
[1]National Research Center of Mental Health, RAMS, Moscow, Russian Federation, [2]Institute of Paediatrics and Paediatric Surgery, Ministry of Health, Moscow, Russian Federation, [3]Moscow City University of Psychology and Education, Moscow, Russian Federation, [4]The State Educational Institution of Professional Training under the Federal Agency of Health Care and Social Development, Moscow, Russian Federation, [5]Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.

The human exome seems to represent a dynamic system in terms of interindividual variability. However, due to the lack of widely accepted criteria for determining copy number variation (CNV) pathogenic value, the creation of a map depicting the wide spectrum of benign CNV in the human exome is hindered. To make a step forward on the road to the map of human exome variations, we have evaluated 151 unrelated individuals using high-resolution CNV analysis by Affymetrix 2.7M SNP-array and an original bioinformatics technology. CNV affecting exons of intellectual disability genes were associated with X-linked mental retardation, X-linked dominant conditions and autosomal dominant intellectual disability. Exome CNV affecting X-linked mental retardation genes in males were as follows: duplication of one OPHN1 exon (3 individuals) and four DLG3 exons (3 individuals), duplication of twenty six L1CAM exons (7 individuals). Benign intragenic CNV affecting X-linked dominant genes in females were associated with duplication of twelve SMC1A exons (Cornelia de Lange syndrome 2) in 8 individuals and duplication of six PORCN exons (Focal dermal hypoplasia) in 3 individuals. Benign exome variations affecting genes associated with autosomal dominant intellectual disability were associated with deletion of one SMARCA2 exon (3 individuals) and duplication of one TSC1 exon (12 individuals), KANSL1 duplication (18 individuals) and deletion of two NHEJ1 exons (5 individuals). Our data demonstrate that benign exome CNV affecting intellectual disability genes are relatively common in humans representing a pitfall for molecular diagnosis of genomic and single-gene disorders. Supported by the Russian Federation President Grant (MD-4401.2013.7).

P16.31-S
The Utility of Clinical Diagnostic Exome Sequencing in Adults with Suspected Genetic Disorders

M. J. Dasouki[1,2], *J. Roberts[1], K. Gonzalez[3], S. Tang[3], W. Zeng[3], M. Butler[1], L. Graves[1], A. Belousov[1], I. Saadi[1];*
[1]University of Kansas Medical Center, Kansas City, KS, United States, [2]King Faisal Specialist Hospital, Riyadh, Saudi Arabia, [3]Ambry Genetics, Aliso Viejo, CA, United States.

Clinical diagnostic exome (CDE) sequencing is being increasingly used in the clinical management mostly of young children with diagnoses or phenotypes which do not allow a clear presumptive clinical diagnosis. CDE is offered either as a trio or proband only study depending on the laboratory and availability of other family members. To date, the positive yield of these studies, mostly in children, ranged from 25-32% with 5-7% of cases showing a de novo variant identifiable only on a trio based study. gDNA from seven adult patients seen in our adult genetics clinic who presented respectively with spontaneous carotid artery dissection, skin laxity, adult onset progressive neurodegenerative disease of unknown etiology, severe familial osteoporosis, recurrent aseptic meningitis, lower limb weakness and peripheral neuropathy, and non-alcoholic steato-hepatitis (NASH) with autoimmune phenomena was subjected to clinical diagnostic exome sequencing (5 trios and 2 probands only). Deleterious or likely deleterious variants were identified in COL3A1, GJB5 and GJB2, VPS35 genes which led to the diagnosis of Ehlers-Danlos Syndrome type IV (vascular type), Cutis laxa, and Parkinson disease 17 in the first three patients. Additionally, medically significant variants, not related to the presenting symptoms were identified in the first two patients. Variants of unknown significance were identified in two patients

with osteoporosis and aseptic meningitis while the remaining two exomes were negative. We conclude that CDE is a clinically helpful tool both for the diagnosis and management of adults with complex phenotypes and that it should be considered early in the evaluation of such individuals.

P16.32-M
A bioinformatics pipeline to identify candidate disease-causing variants from exome sequencing data

N. Paramasivam[1,2], *F. Schäfer*[2], *G. Rappold*[3], *U. Moorg*[3], *D. Choukair*[2], *T. Opladen*[2], *B. Assmann*[2], *C. Staufner*[2], *B. Niesler*[3], *P. Romero*[2], *M. Bettendorf*[2], *G. F. Hoffmann*[2], *C. R. Bartram*[3], *R. Eils*[1,3], *M. Schlesner*[1];
[1]*DKFZ, Heidelberg, Germany,* [2]*Universitätsklinik Heidelberg, Heidelberg, Germany,* [3]*University of Heidelberg, Heidelberg, Germany.*

In a three year pilot study we sequence around 900 exomes of patients suffering from various genetic disorders. In these patients the disease causing variants are unknown: either known disease-related genes have initially been found to be unaffected, or the cause of the disease is generally unclear. Depending on the expected mode of inheritance either patient/parent trios or only the patients are sequenced.
From the total set of single nucleotide variants (SNVs) and small indels, we remove common polymorphisms and calling artifacts by comparison to the 1000 Genomes database and an in-house control database. From the remaining variants we identify a candidate set based on the assumed mode of inheritance, which are then prioritized based on the predicted functional effect of the variant and the tolerance of the gene to coding mutations. In addition, network analysis of the candidate genes together with a list of genes known to be associated with the particular disease is performed to identify the most promising candidate(s) which then undergo functional evaluation.
We found a rare homozygous mutation in the COQ6 gene in a nephrotic syndrome patient. A homozygous mutation in the same gene was reported earlier to be associated with nephrotic syndrome and sensorineural deafness. Since the patient also suffers from severe hearing impairment, it is highly likely that the candidate variant is the cause of the symptoms. This case emphasizes the efficiency of our filtering and prioritization strategy.

P16.33-S
Implementation of an IT-platform for the multicenter analysis and clinical annotation of exomes of 250 children with intellectual disability

T. Wieland[1], *A. Zink*[2], *H. Lüdecke*[3], *E. Graf*[4], *K. Cremer*[2], *C. Czeschik*[3], *E. Wohlleber*[2], *T. Schwarzmayr*[1], *J. Gundlach*[1], *M. M. Nöthen*[2], *B. Horsthemke*[3], *T. Meitinger*[1,4,5], *H. Engels*[2], *D. Wieczorek*[3], *T. M. Strom*[1,4,5];
[1]*Institute of Human Genetics; Helmholtz Zentrum München, Neuherberg, Germany,* [2]*Institute of Human Genetics; Rheinische Friedrich-Wilhelms-Universität Bonn, Bonn, Germany,* [3]*Institut für Humangenetik; Universitätsklinikum Essen; Universität Duisburg-Essen, Essen, Germany,* [4]*Insitute of Human Genetics; Technische Universität München, Munich, Germany,* [5]*DZHK (German Centre for Cardiovascular Research) partner site; Munich Heart Alliance, Munich, Germany.*

The introduction of exome and whole genome sequencing into clinical diagnostics requires new structures for sequencing and data analysis. In principle, data analysis in this context is as simple as comparing a list of variants identified in a patient with a comprehensive list of disease causing variants. In practice, this is currently limited by the substantial number of DNA variants with false annotation or uncertain significance.
We set up an IT environment that supports central sequencing and automated primary data analysis and subsequently provides the results via a web interface to researchers and geneticists for manual curation, annotation and experimental validation.
As a pilot project, three cooperating diagnostic teams are investigating 250 trios consisting of patients with severe to mild ID and their healthy parents for which high coverage exome sequences have been generated.
Variant data including Pindel and CNV calls are generated by an analysis pipeline and stored in a database. Preliminary analysis revealed 1.7 de novo non-synonymous coding and canonical splice site mutations per patient. 20% of the investigated cases carried a mutation in genes already known to cause ID. In addition, evidence for novel ID candidate genes is being generated from the detection of SNVs and indels in specific genes from known microdeletion regions.
In summary, we show that exome sequencing in a multicenter setting with an appropriate IT environment can efficiently be used to generate clinical diagnoses by integrating the advantage of standardized central sequencing and distributed evaluation of the resulting data in the clinical context.

P16.34-M
Unbiased functional clustering of gene variants with a phenotypic-linkage network

F. Honti, *C. Webber;*
MRC Functional Genomics Unit, University of Oxford, Oxford, United Kingdom.

Groupwise functional analysis of gene variants is becoming standard in next-generation sequencing studies. As the function of many genes is unknown and their classification to pathways is scant, functional associations between genes are often inferred from large-scale omics data. Such data types - including protein-protein interactions and gene co-expression networks - are used to examine the interrelations of the implicated genes. Statistical significance is assessed by comparing the interconnectedness of the mutated genes with that of random gene sets. However, interconnectedness can be affected by confounding bias, potentially resulting in false positive findings. We show that genes implicated through *de novo* sequence variants are biased in their coding sequence length and longer genes tend to cluster together, which leads to exaggerated p-values in functional studies; we present here a method that addresses these bias. To discern molecular pathways relevant to complex disease, we have inferred functional associations between human genes from diverse data types and assessed them with a novel phenotype-based method. Examining the functional association between *de novo* gene variants, we control for the heretofore unexplored confounding bias in coding-sequence length. We test different data types and networks and find that the disease-associated genes cluster more significantly in an integrated phenotypic-linkage network than in other gene networks. We present a tool of superior power to identify functional associations among genes mutated in the same disease even after accounting for significant sequencing study bias and demonstrate the suitability of this method to functionally subcluster gene variants underlying a complex disorder.

P16.35-S
VarElect: phenotype-based variation prioritizer in GeneCards

G. Stelzer, *A. Alkelai, T. Olender, S. Zimmerman, M. Safran, D. Lancet;*
Weizmann Institute of Science, Rehovot, Israel.

Next generation sequencing has provided the scientific community with a key technology for deciphering the genetic cause of human diseases. Typical whole exome sequences depict ~25,000 non-reference coding variants; only a few signify disease. As a rule, one relies on criteria such as rarity in the general population, predicted damage, and evolutionary conservation in the encoded protein and segregation in more than one affected individual, to shorten the potential gene list. We have constructed the VarElect tool for phenotype-dependent variant prioritization, leveraging the rich information and scoring mechanisms of GeneCards and MalaCards, the human gene and disease compendiums, to enable the zooming in on a handful or even just one candidate gene. Its algorithm affords inferring direct as well as indirect links between genes and phenotypes, matching the provided keywords best describing the disease and its symptoms. An example of an indirect GeneCards-based inference of GeneA to Phenotype PhenX is when the disease is found to be linked to GeneB, which in turn shares a pathway with GeneA. Such gene-to-gene relations are also formed (among others) by interaction networks, paralogy relations, domain-sharing, and mutual publications. MalaCards, in turn, allows one to produce a comprehensive phenotype search expression by utilizing this database's built-in information about diseases, their relationships, and their underlying symptoms. Thus VarElect provides a robust algorithm for ranking genes within a short list, and pointing out their likelihood to be related to a disease, which will prove indispensable in future clinical applications.

Background WGS/WES translation from research to a clinical setting requires a governance framework that addresses: • informed consent for clinical and research genetic testing • management of findings • storage of clinical and genetic data Development of a protocol for governance review has catalysed local policy formulation in this rapidly developing field which accommodates clinical and research regulatory regimes, the interests of researchers, clinicians, patients and families, and diverse approaches to the risk and handling of incidental findings. **Methods** Extensive discussions were held between researchers, clinicians, genetic counsellors, clinical scientists and ethicists to gauge expectations and areas of potential divergence of interests. Reviews were undertaken of current bioethics literature. European and US guidelines and existing WES/WGS patient consent documents

were used as the basis for discussion and development. Final patient documents were reviewed by patient groups. **Results** Multidisciplinary discussions have resulted in a protocol which anticipates uncertainties in results and interpretation. A phased approach to consent will be taken, in which patients can elect to undergo a process which begins with current clinical testing, progresses to a targeted analysis of WES/WGS data and ends with analysis of the full sequence. All findings will be subject to clinical verification and a multidisciplinary committee will determine whether and how incidental findings relating to serious and clinically actionable diseases should be reported according to consent. **Future Work** Will involve monitoring and evaluation of the consent process, MDT decision process, participant engagement and qualitative research into participant understanding, attitudes and preferences concerning WGS/WGS.

P16.37-S
Genome-wide DNA methylation analysis identifies novel differentially methylated regions in patients with imprinting disorders

D. J. G. Mackay[1,2], *F. I. Rezwan*[1], *L. E. Docherty*[1,2], *D. I. Wilson*[1], *J. W. Holloway*[1], *I. Temple*[1,3];
[1]*Faculty of Medicine, Southampton, United Kingdom,* [2]*Wessex Genetics Service, Salisbury Foundation Healthcare Trust, Salisbury, United Kingdom,* [3]*Wessex Genetics Service, University Hospitals Southampton NHS Foundation Trust, Southampton, United Kingdom.*

Genomic imprinting is the regulation of gene expression by parent of origin. Imprinting is maintained by epigenetic mechanisms including parent of origin-specific DNA methylation, and its disruption leads to imprinting disorders affecting growth, metabolism and predisposition to cancer. Eight 'classical' imprinting disorders are known, linked to (epi)mutations of specific loci. However, some individuals have methylation anomalies affecting multiple imprinted loci (HIL) throughout the genome. Here we used epigenomewide analysis to investigate aberrant DNA methylation in HIL patients.
We used the Illumina Infinium Human Methylation450 BeadChip array to assay genomic DNA methylation at ~475,000 sites in ten HIL patients with two clinical presentations (Beckwith-Wiedemann syndrome and neonatal diabetes). We developed a novel informatic pipeline capable of small sample number analysis, and statistical criteria to quantify DNA methylation.
The pipeline robustly detected hypomethylation at known imprinted loci, and 25 further candidate imprinted regions (nine shared between patient groups) including one in the Down syndrome critical region (WRB) and another previously associated with bipolar disorder (PPIEL). Targeted analysis of three candidate regions (NHP2L1, WRB and PPIEL) confirmed allelic expression, methylation patterns consistent with allelic maternal methylation, and frequent hypomethylation among HIL patients.
This study has identified new candidate imprinted genes, and shown a remarkable epigenetic similarities between patients with different imprinting syndromes. Our informatic methods make possible epigenomic profiling of small groups or even individual patients, and have potential to expand our understanding of epigenetic regulation in health and disease.

P16.38-M
Genomic imprinting defects: role of cis-acting elements and trans-acting factors

A. Riccio[1,2], *F. Cerrato*[1], *A. Sparago*[1], *A. De Crescenzo*[1], *A. Freschi*[1], *Z. Anvar*[1], *V. Riso*[1], *M. Cammisa*[1], *H. Kukreja*[1], *A. Oneglia*[1];
[1]*Second University of Naples, Caserta, Italy,* [2]*CNR, Institute of Genetics and Biophysics A. Buzzati-Traverso, Naples, Italy.*

Gamete-of-origin dependent gene expression, namely genomic imprinting, is controlled by allele-specific epigenetic modifications of Imprinting Control Regions (ICRs). Either hypo- or hyper- DNA methylation abnormalities abolishing the epigenetic asymmetry at the ICRs result in altered gene expression and disease. DNA methylation changes are accompanied by changes in histone modifications and long-range protein interactions. ICR epigenetic alterations result from either mutations acting in cis or lesions affecting factors acting in trans, but in many cases their cause is unknown. A large cluster of imprinted genes lies on a conserved region of chromosome 11p15.5 and is associated with the growth disorders Beckwith-Wiedemann syndrome (BWS) and Silver-Russell syndrome (SRS). By studying several mutations affecting the IGF2/H19 ICR, we recently observed that the penetrance of the BWS phenotype correlated with the intensity of ICR hypermethylation and that this is dependent on the affinity of the mutant allele for CTCF. We also implicated CDKN1C imprinting defects in prenatal growth restriction by demonstrating a deletion of the CDKN1C ICR in a case of severe familial intra-uterine growth restriction (IUGR). Finally, we found that in mouse embryonic stem cells (ESCs) the ZFP57/KAP1 complex is required to maintain CpG methylation and histone H3K9 trimethylation by specifically interacting with a methylated target motif that is enriched at the ICRs. The role of novel cis-acting elements and trans-acting factors in the origin of the imprinting defects is being investigated further by high-throughput analysis of ZFP57 binding in human and mouse cells cells and 11p15.5- and exome-targeted resequencing of patient DNAs.

P16.39-S
PECAS: Prokaryotic and Eukaryotic Classical Analysis of Secretome

J. L. Lavin[1], *A. R. Córtazar*[1], *J. A. Oguiza*[2], *A. M. Aransay*[1];
[1]*CIC bioGUNE, Derio, Spain,* [2]*Public University of Navarre, Pamplona, Spain.*

Secretome analysis is a topic of study in different fields such as biomarkers identification for cancer development, neurobiology, stem cells, exosomes and hormonal regulation in relation to tyroid disorders[1]. Next-Generation Sequencing (NGS) is currently the main source of raw data at genomics research but tools for secretome analyses out of such data are lacking. Here, we present the web server PECAS (Prokaryotic and Eukaryotic Classical Analysis of Secretomes) that provides a well established prediction tool on secreted proteins starting from multiple data sources, allowing users to retain most sensible raw data files. These goals are achieved through a well established pipeline on secreted proteins prediction by screening different features for each of the evaluated proteins: (i) location of the predicted N-terminal signal peptide (SP), (ii) detection of the presence and location of SP cleavage sites in amino acid sequences, (iii) presence of a maximum of one transmembrane domain and (iv), glycosylphosphatidylinositol membrane anchoring. Other analysis like Gene-Ontology enrichment has also been implemented as an optional complement to the prediction steps. It is to be highlighted that it is the first tool designed to perform secretome analysis on data derived from NGS technologies. Moreover, the whole process is carried out through a user-friendly interface in a single submission step, which displays a series of downloadable graphical results and a table with the features predicted. All in all, we expect this tool will aid to decipher straightforwardly clue biological questions as emphasized recently[1].

Human genome resources in Ensembl

A. Zadissa;
EMBL-European Bioinformatics Institute, Hinxton, United Kingdom.

Ensembl provides up-to-date annotation for the human genome including comprehensive updates for all of our resources whenever a new assembly is released. Here we present all the available and upcoming human genome resources in Ensembl.
In December 2013, the Genome Reference Consortium released the latest version of the human assembly GRCh38. A fully annotated version of this assembly will be part of Ensembl v76 scheduled for summer 2014. Before the full release, preliminary Ensembl annotation based on GRCh38 will be available at http://pre.ensembl.org. This preview site, available in spring 2014, includes alignments of human-specific cDNA, protein and EST sequence data as well as the current GENCODE gene set, based on GRCh37.p13, projected onto the new assembly alongside variation data.
For the full release, the GENCODE gene set will be reassessed and rebuilt from the component Ensembl and Havana annotation sets. The complete set of variation data, regulatory features and all comparative data such as sequence alignments will be recomputed for the new assembly. HumanBodyMap 2.0 RNASeq data will also be reanalysed and remapped. In addition to the primary assembly, the new human genome also contains 35 „assembly units", with a total of 261 alternative loci that encompass all fix and novel patches to the GRCh37 assembly. Ensembl fully annotates all of these alternative sequence regions.
Moving a research project to a new version of the human genome assembly is a major undertaking and so we are committed to supporting the previous GRCh37.p13 annotation resources for use by the scientific community.

P16.41-S
Full deconvolution of clonal populations in recurrent hematological cancer using gaussian mixture model

D. Cittaro, *D. Lazarevic, C. Toffalori, E. Stupka, L. Vago;*
Ospedale San Raffaele, Milano, Italy.

We performed Whole Exome Sequencing on five samples collected in eight years during the disease history of in a single patient with hematological cancer (Acute Lymphoblastic Leukemia, Remission and therapy-related Myelodysplastic Syndrome at three different time-points). We identified a joint set of 1201 variants that were present at least in one stage of the disease, for which we calculated allele frequencies corrected by the estimate of tumor purity. These were used to train a set of Gaussian Mixture Models (GMM) allowing for increasing number of classes. We selected the best mo-

del using Akaike Information Content criterion and assigned each mutation to a specific GMM clone. We calculated mutational signatures of each GMM clone according to the procedure proposed by Alexandrov (Nature, 2013) and estimated distance between them. We identified a single clone common to all relapses but not LLA, we built parent/child relationships with other clones using distance among signatures. Our analysis reveals a branching evolution of clones that putatively diverge in response to the clinical treatment. We show GMM is an effective and unbiased technique that can be applied to deconvolve clonal populations in cancer data only using allele frequencies. Clones can be then characterized by their mutational landscape, this information is sufficient to build clonal relationships when studying the evolution of the disease.

P16.42-M
H3M2: Detection of Runs of Homozygosity from whole-exome sequencing data

A. Magi[1], *L. Tattini*[1], *F. Palombo*[2], *M. Benelli*[3], *G. Romeo*[2], *T. Pippucci*[2];
[1]*University of Florence, Florence, Italy,* [2]*University of Bologna, Bologna, Italy,* [3]*Careggi Hospital, Florence, Italy.*

Runs of homozygosity (ROH) can be defined as sizable chromosomal stretches of homozygous genotypes, ranging in length from tens of kilobases to megabases. ROHs can be relevant for population and medical genetics, playing a role in predisposition to both rare and common disorders. ROHs are commonly detected by SNP microarrays, but attempts have been made to use Whole Exome Sequencing (WES) data. Currently available methods developed for the analysis of uniformly spaced SNP-array maps do not fit easily the sparse and non uniform distribution of the WES target design. To meet the need of an approach specifically tailored to WES data we developed H3M2, an original algorithm based on Heterogeneous Hidden Markov Model that incorporates inter-marker distances to detect ROH from Whole Exome Sequencing (WES) data. We evaluated the performance of H3M2 to correctly identify ROHs on synthetic chromosomes and examined its accuracy in detecting ROHs of different length (short, medium and long) from real 1000 genomes project data. H3M2 turned out to be more accurate than GERMLINE and PLINK, two state-of-the-art algorithms, especially in the detection of short and medium ROHs. H3M2 is freely available at https://sourceforge.net/projects/h3m2/.

Hepatitis C Virus genome variability analysis from high-throughput pyrosequencing data

E. Radu[1,2], *S. Spandole*[1,3], *S. Dinu*[4], *G. Cardos*[1], *P. I. Calistru*[5], *E. Ceausu*[5], *G. Tardei*[5], *Collaborative Team of the HepGen Project, M. D. Teleman*[4], *G. Oprisan*[4];
[1]*Personal Genetics Medical Genetics Center, Bucharest, Romania,* [2]*Molecular Biology and Pathology Research Lab "Molimagex", University Hospital Bucharest, Bucharest, Romania,* [3]*Department of Genetics, University of Bucharest, Bucharest, Romania,* [4]*"Cantacuzino" National Institute of Research - Developement for Microbiology and Immunology, Bucharest, Romania,* [5]*"Dr Victor Babes" Hospital of Infectious and Tropical diseases, Bucharest, Romania.*

High-throughput pyrosequencing enables discovery of rare Hepatitis C Virus (HCV) variants and estimation of viral diversity within a host, which may play an important role in understanding patient's response to personalized therapy. The aim of our study was to estimate intra-host genomic variation of HCV 1b in naïve and Pegylated Interferon-Ribavirin treated patients. Serum viral RNA from 11 patients was reverstranscribed and amplified to produce 7.5 kb-long amplicons that were random-fragmented. A sequencing library was generated by specific adaptor-ligation and analyzed using Roche 454 Titanium chemistry and GS FLX platform. Data were analyzed using software published by The Broad Institute. Reads from each patient were assembled into contigs (Vicuna), oriented and frameshift-corrected (V-Fat). Raw-reads were corrected for pyrosequencing errors (RC454) and sequence variants were called using V-Phaser 2.0 and analysed with V-Profiler. The HCV 1b Con1 isolate was used as control sample. The sequencing run resulted in over 1 million passed filter reads with an average length of 397 bases and 30.81 quality score. Sustained viral response was associated to lower number of non-synonymous mutations within the initial viral population compared to non-responders. Also, NS2 mutation frequency seems higher in non-responding patients. High-throughput pyrosequencing is an effective tool for assessing intra-host variability of HCV genome, able to reveal differences in genomic variation of viral communities from patients with diverse response to therapy. Acknowledgement: This work was supported by a grant of the Romanian National Authority for Scientific Research, CNDI-UEFISCDI, project number 88/2012, PN-II-PT-PCCA-2011-3.2 (GO).

Systems biology approaches to the search for disease genes in Hirschsprung's disease

B. Luzón-Toro[1,2], *M. Bleda*[2,3], *R. Fernández*[1,2], *L. García-Alonso*[3], *Y. Sribudiani*[4], *C. Besmond*[5], *F. Lantieri*[6], *A. Torroglosa*[1,2], *M. Enguix-Riego*[1,2], *M. García-Barceló*[7], *P. Tam*[7], *I. Ceccherini*[6], *S. Lyonnet*[5], *R. Hofstra*[4], *G. Antiñolo*[1,2], *J. Dopazo*[2,3], *S. Borrego*[1,2];
[1]*Institute of Biomedicine of Seville (IBIS), University Hospital Virgen del Rocío/ CSIC/ University of Seville, Sevilla, Spain,* [2]*Centre for Biomedical Network Research on Rare Diseases (CIBERER), Sevilla and Valencia, Spain,* [3]*Centro de Investigación Príncipe Felipe (CIPF), Valencia, Spain,* [4]*Erasmus MC, Rotterdam, Netherlands,* [5]*INSERM U-781, AP-HP Hôpital Necker-Enfants Malades, Paris, France,* [6]*Laboratorio di Genetica Molecolare, Istituto Gaslini, Genova, Italy,* [7]*Li Ka Shing Faculty of Medicine and Queen Mary Hospital, The University of Hong Kong, Hong Kong, China.*

The availability of new methodologies of high performance has revolutionized our ability to discovery. However, the high resolution of such technologies can become a double-edged sword. Reduced sample sizes available in rare diseases are often an obstacle for the detection of candidate genes or the study of their molecular basis. The limitations of the approaches based on isolated genes can be overcome using systems biology approaches.
This study shows as a combination of pathway-based analysis (PBA) and network analysis allowed to discover four new loci (RASGEF1A and IQGAP2, DLC1 CHRNA7) related to signalling and migration processes associated with the disease, which were then validated in a cohort of 106 independent trios.
The further study of an international cohort of 162 HSCR trios allowed us to confirm the molecular bases of disease using PBA. We found a significant association of processes related to signalling and its regulation as well as formation of the enteric nervous system. Although the genes associated with HSCR varied in different populations, the functions and interaction of affected networks of proteins were always the same, which reflects the complexity of the disease. This methodology of prioritization of candidate genes can be extrapolated to any technology of high performance (WES, RNA-seq, etc.).

The impact of antisense transcription on epigenetic signals

C. Wadelius[1], *S. Bornelöv*[1], *J. Komorowski*[1,2];
[1]*Uppsala University, Uppsala, Sweden,* [2]*Polish Academy of Sciences, Warszawa, Poland.*

Several histone post-translational modifications are preferentially located in the promoter region of genes and are associated to the promoter activity. It is debated whether the histone modifications regulate the gene expression i.e., the histone code hypothesis or if they are put there as a consequence of transcription.
In an earlier study we observed that the histone 3 acetylation signal upstream of the transcriptional start site (TSS) was lower in unidirectional compared to bidirectional genes. Following this observation, we hypothesized that the transcribed region is modified during transcription and that the observed upstream signal is caused by transcription in the opposite direction from the TSS. Promoters directing transcription in both directions are frequent in the genome, which would explain the common occurrence of upstream signals.
Here we identified bidirectional or unidirectional genes based on TSS identified from cap analysis of gene expression and database searches. We compared histone modification signals between these two classes of genes across several cell types. We have found significant differences for well-known histone modifications, e.g. H3K4me3, H3K9ac and H3K27ac for which the upstream signal is higher in the bidirectional genes. Furthermore, we have compared transcription factor bindings between bidirectional and unidirectional genes and found examples of differences in their prevalence and position relative to the TSS.
In conclusion, our results support the model of histone modifications occurring in transcribed regions and thus being a consequence of transcription. In addition, we have identified transcription factors which may be involved in the direction of transcription initiation.

Gene expression profile of human amniotic stem cells xenotransplantated in a sheep achilles tendon defect model

S. Sperduti[1,2], *V. Russo*[3], *S. Franchi*[2], *M. D'Aurora*[1,2], *L. D'Onofrio*[1,2], *I. Antonucci*[4], *P. Berardinelli*[3], *M. Mattioli*[3], *B. Barboni*[3], *G. Palka*[5], *L. Stuppia*[2,4], *V. Gatta*[2,4];
[1]*Department of Neuroscience and Imaging, "G. d'Annunzio" University, Chieti, Italy,* [2]*Functional Genomics Unit, Center of Excellence on Aging (Ce.S.I.), Chieti, Italy,* [3]*Department of Comparative Biomedical Science, University of Teramo, Teramo, Italy,* [4]*Department of Psychological, Humanities and Territorial Sciences, School of Medicine and Health Sciences, "G. d'Annunzio" University, Chieti, Italy,* [5]*Department of Oral Health and Biotechnological Sciences, School of Medicine and Health Sciences, „G. d'Annunzio" University, Chieti, Italy.*

Amniotic derived cells are ideal seed cells for regenerative medicine proto-

cols since they conjugate a remarkable plasticity to safety properties. This study investigated the role exerted by human amniotic cells during the process of tendon healing, evaluating by microarray technique, the presence of transcriptome variations in human amniotic epithelial (hAECs) and mesenchymal (hAMCs) stem cells when xenotransplanted into the preclinical ovine model of tendon defect, compared to freshly isolated ones. This analysis allowed to understand in which way, after transplantation, hAECs and hAMCs transcripts have been affected.
Functional analysis of the affected transcripts revealed that the main biological functions involved are: Cell Death and Survival, Cellular Growth and Proliferation, Inflammatory Response, Cellular Function and Maintenance, Skeletal and Muscular System Development and Function and Connective Tissue Development and Function.
These results show that hAECs and hAMCs after xenotranplantation produce a modulation of the genes involved in their survival, and in the inflammatory response. Intriguingly, it has been observed also the up-expression of the transcripts related to the connective tissue development and function as COL11A1 which is involved in the synthesis of collagen type I, the most expressed protein in the tendon. In conclusion, the present study demonstrates that human amniotic derived cells have a direct involvement in new tendon matrix remodeling and tissue regeneration. Altogether these results strongly support the idea that human amniotic cells could be effectively proposed as a prompt stem cell-based therapy that does not require any preliminary in vitro differentiation or any genomic transfection.

Differential methylation between the two alleles of a gene has been observed at imprinted regions, where the methylation of one allele occurs on a parent-of-origin basis, the inactive X-chromosome in females, and at those loci whose methylation is driven by genetic variants. We have extensively characterized imprinted methylation in a substantial range of normal human tissues, reciprocal genome-wide uniparental disomies and hydatidiform moles, using a combination of whole genome bisulphite sequencing and high-density methylation microarrays. This approach allowed us to define methylation profiles at known imprinted domains at base-pair resolution, as well as identifying 24 novel loci harbouring parent-of-origin methylation, 18 of which are restricted to the placenta. We observe that the extent of imprinted differentially methylated regions (DMRs) is extremely similar between tissues, with the exception of the placenta. Further we profiled all imprinted DMRs in sperm and embryonic stem cells derived from parthenogenetically-activated oocytes, individual blastomeres and blastocysts to identifying primary DMRs and reveal the extent of reprograming during pre-implantation development. These results have important implications for individuals with imprinting disorders with underlying multi-locus methylation defects, including Transient Neonatal Diabetes Mellitus patients with ZFP57 mutations.

Computational pipeline to analyze genomic variants with respect to clinical phenotypes by mining literature. Study of genomic regions related to intellectual disability

E. Pranckevičienė, *A. Pranculis, E. Preikšaitienė, V. Kučinskas;*
Department of Human and Medical Genetics, Vilnius University, Lithuania.

Whole exome sequencing (WES) in clinical diagnostics is used as a tool to identify genomic variants in a patient's genome that may possibly give rise to a particular disorder. Variant interpretation partially relies on consulting databases like OMIM and DECIPHER containing known genomic variants causative of the specific disorders and databases of common genomic variants such as dbSNP.
Novel variants identified by WES have to be characterized with respect to a particular clinical context in order to improve the diagnostics. The functional effect of the variant can be assessed by programs such as PolyPhen, SIFT and Evolutionary Rate Profiling. Cross-referencing of novel variants with genomic databases and literature can be challenging mostly because these variants and their impact on the associated genes causing the manifestation of the phenotype of interest are poorly characterized.
We present a computational exome analysis pipeline based on the ABI SOLiD Lifescope platform. The novel added feature in our pipeline is augmenting the ANNOVAR variant annotations by links to genes strongly connected to the disease phenotypes through the MeSH terms. These connections are deduced computationally by utilizing MEDLINE database and gene ontology annotations of the genes.
The utility of our approach is demonstrated by analyzing genomic regions linked to the intellectual disability phenotype identified in Lithuanian patients.
The research leading to these results has received funding from Lithuanian-Swiss cooperation programme to reduce economic and social disparities within the enlarged European Union under project agreement No CH-3-ŠMM-01/04.

IntSplice: A tool to predict the effect on pre-mRNA splicing of intronic nucleotide substitutions

A. Shibata, *T. Okuno, A. Masuda, K. Ohno;*
Division of Neurogenetics, Nagoya University Graduate School of Medicine, Nagoya, Japan.

Precise spatiotemporal regulation of splicing is mediated by splicing *cis*-elements on pre-mRNA. The next generation sequencers disclose a large amount of single nucleotide variations (SNVs) in the human genome. Tools to analyze the effects of SNVs on the protein functions have been recently published PolyPhen-2 and SIFT. SNVs affecting intronic *cis*-elements potentially compromise splicing, but no dedicated tool has been available. We thus sought for a prediction model. According to the effect size analysis of each nucleotide at intronic positions -50 to -3 on alternative splicing, we extracted 34 parameters that possibly dictated the strength of splicing signals. We also partitioned all the alternative 3' splice sites in the human ENSEMBL annotation into 500 categories and generated a neural network model. The model predicted the efficiency of alternative splicing events with a correlation coefficient greater than 0.8 for a validation dataset. The model discriminated splicing consequences of intronic single nucleotide variations in dbSNP134 and the Human Gene Mutation Database. We next compared the ENSEMBL-based model with models deduced from RNA-seq of normal human brain, cerebral cortex, heart, liver, skeletal muscle, and colon, and found that a colon-based model yielded the best discrimination. We created a web service program, IntSplice. IntSplice is the first tool for predicting splicing consequences of nucleotide variations at intronic positions -50 to -3.

Genome-wide methylation analysis in Klinefelter syndrome

A. Skakkebæk[1,2], *M. Switnicki*[3], *A. Bojesen*[1], *J. Hertz*[4], *J. Østergaard*[5], *A. Pedersen*[6], *M. Wallentin*[7,8], *K. Sørensen*[3], *C. Gravholt*[2,3];
[1]*Department of Clinical Genetics, Vejle Hospital, Vejle, Denmark,* [2]*Department of Endocrinology and Internal Medicine (MEA), Aarhus University Hospital, Aarhus, Denmark,* [3]*Department of Molecular Medicine, Aarhus University Hospital, Aarhus, Denmark,* [4]*Department of Clinical Genetics, Odense University Hospital, Odense, Denmark,* [5]*Centre for Rare Diseases, Department of Pediatrics, Aarhus University Hospital, Aarhus, Denmark,* [6]*Department of Psychology and Behavioral Sciences, Aarhus University Hospital, Aarhus, Denmark,* [7]*Centre for Functionally Integrative Neuroscience, Aarhus University Hospital, Aarhus, Denmark,* [8]*Center for Semiotics, Aarhus University, Aarhus, Denmark.*

Background: Epigenetic changes such as DNA methylation have been proposed to play a role in human disorders such as psychiatric, autoimmune and metabolic diseases. Klinefelter syndrome (KS) is associated with an increase risk of these disorders, however no study to date have investigated global methylation changes in patients with KS. The aim of this study is to investigate the global methylation pattern in KS. We hypothesize that the methylation pattern is changed in KS and that the methylome changes will explain phenotypic characteristics present in KS. **Methods:** We performed genome-wide DNA methylation analysis on blood leucocytes from 73 patients with KS and 73 age- and gender-matched controls using the Illumina Infinium Human Methylation 450K BeadChip. **Results:** 70.525 CpG-sites covering over 15.000 genes were found to be differentially methylated in patients with KS compared to the age-matched controls. Among these 61.567 were on autosomal chromosomes, 8903 were on the X-chromosome and 55 were on Y-chromosome. One of the genes with promotor associated differentially methylated CpG sites is the NSD1 gene which is involved in the androgen receptor (AR) transactivation. Other genes possibly involved in the phenotype of KS and differentially methylated were ABI3BP, APOB, C1orf59, CACYBP, DPPA5,GABRG1, HOXA4, LRRC61, NLRP2, PEX10, RPLP1, RFPL2, SDHAF1, SPEG. **Conclusions:**For the first time we show that KS is associated with pervasive genome-wide methylation changes, changes which could play a role in the clinical phenotype seen with KS.

P16.51-S
Locus Reference Genomic (LRG) records: reference resource for the reporting of clinically relevant sequence variants

J. Morales[1], *J. A. L. MacArthur*[1], *R. E. Tully*[2], *L. Gil*[1], *A. Astashyn*[2], *E. Bruford*[1], *R. Dalgleish*[3], *E. Birney*[1], *P. Flicek*[1], *D. R. Maglott*[2], *F. Cunningham*[1];
[1]*European Molecular Biology Laboratory, European Bioinformatics Institute, Cambridge, United Kingdom,* [2]*National Center for Biotechnology Information, Bethesda, MD, United States,* [3]*Department of Genetics, University of Leicester, Leicester, United Kingdom.*

A Locus Reference Genomic record (LRG) is a manually curated resource designed specifically for the reporting of clinically relevant variants. An LRG provides a stable and non-versioned genomic DNA sequence for a region of the human genome, along with transcripts used as reference standards and their protein products. These sequences are selected in consultation with the diagnostic and research communities, locus specific database curators, and mutation consortia. Once an LRG is made public, this core sequence content will not change. However, associated metadata, such as genome mapping information, annotation of additional transcripts, overlapping genes and legacy exon numbering systems, is regularly updated to reflect current knowledge on the LRG locus.
The LRG's stable nature enables unambiguous reporting of variants using stable identifiers (e.g. "t1", "t2" for transcripts, and "p1", "p2" for proteins) and HGVS nomenclature. Variant reporting is possible in LRG genomic DNA (e.g. LRG_1:g.8463G>C), mRNA (e.g. LRG_1t1:c.572G>C), non-coding RNA (e.g. LRG_163t1:n.71a>g) or protein (e.g. LRG_1p1:p.Gly191Ala) coordinates. Variants can also be submitted to public databases through the LRG submission process outlined on the website (http://www.lrg-sequence.org/). LRGs can be viewed in Ensembl (http://www.ensembl.org/) and NCBI (http://www.ncbi.nlm.nih.gov/) genome browsers.
Over 800 LRGs have been requested, of which over 400 are public. The intent is to create an LRG for every locus with clinical implications. Widespread use of this resource will ensure consistent variant reporting over time. LRGs are created jointly by the NCBI and EBI (http://www.ebi.ac.uk/). All LRG records are available on the LRG website, which also provides the complete LRG specification.

P16.52-M
Whole blood DNA methylation changes are associated to malignant pleural mesothelioma

E. Casalone[1,2], *S. Guarrera*[1,2], *G. Fiorito*[1,2], *M. Betti*[3], *D. Ferrante*[3], *C. Di Gaetano*[1,2], *F. Rosa*[1,2], *A. Russo*[1,2], *S. Tunesi*[3], *M. Padoan*[3], *A. Aspesi*[3], *C. Casadio*[3], *F. Ardissone*[4], *E. Ruffini*[4], *P. Betta*[5], *R. Libener*[5], *R. Guaschino*[5], *E. Piccolini*[6], *D. Mirabelli*[7], *C. Magnani*[3,2], *I. Dianzani*[3,2], *G. Matullo*[1,2];
[1]*Human Genetics Foundation, Turin, Italy,* [2]*University of Turin, Turin, Italy,* [3]*University of Piemonte Orientale, Novara, Italy,* [4]*University of Turin, Torino, Italy,* [5]*Azienda Ospedaliera Nazionale SS, Antonio and Biagio and Cesare Arrigo, Alessandria, Italy,* [6]*Santo Spirito Hospital, Casale Monferrato, Italy,* [7]*CPO-Piemonte and University of Turin, Turin, Italy.*

Malignant pleural mesothelioma (MPM) is a rare and aggressive tumor strongly associated with asbestos exposure. Its onset is usually 30-40 years after the first exposure, and it is characterized by a poor prognosis with a median survival of 12 months. Alterations in DNA methylation have been reported in several cancers, and are becoming an established hallmark of tumor. MPM is frequently associated with genetic mutations but also epigenetic changes leading to gene expression modifications. The identification of MPM-specific epigenetic markers in peripheral blood might be a useful methodology for defining biomarkers for potential early detection and may define methylation changes due to asbestos exposure. We conducted an epigenome-wide analysis (>450K CpG sites) on DNA from whole blood cells of 129 MPM cases and 127 controls to evaluate differences in methylation profiles. The sample population was randomly split into two sets: training and test set. In the training set 60 differentially methylated regions (DMRs) between cases and controls, adjusting for gender, age, asbestos exposure, and white blood cells percentage were found (FDR adjusted p< 0.01). Using a cluster algorithm we validated the DMRs prediction performance in the test set (AUC=0.7625). We found significant enrichment for genes involved in leukocyte trans-endothelial migration, natural killer cell mediated cytotoxicity and cell adhesion molecules pathways. Moreover we identified several genes belonging to the inflammation pathways and related to the cancer progression. Our results suggested that methylation status in whole blood DNA might provide a useful biomarker for potential MPM early detection.

Melan-OMICS: whole-exome and transcriptome sequencing to dissect molecular complexity of cutaneous malignant melanoma

I. Cifola[1], *A. Pietrelli*[1], *M. Severgnini*[1], *A. Magi*[2], *L. Tattini*[2], *E. Mangano*[1], *S. Anand*[1,3], *V. Russo*[4], *C. Battaglia*[5,1], *G. De Bellis*[1];
[1]*Institute for Biomedical Technologies, ITB-CNR, Segrate (Milan), Italy,* [2]*Department of Clinical and Experimental Medicine, University of Florence, Florence, Italy,* [3]*Department of Science and Technology, University of Sannio, Benevento, Italy,* [4]*Cancer Gene Therapy Unit, San Raffaele Scientific Institute, Milan, Italy,* [5]*Dipartimento di Biotecnologie Mediche e Medicina Traslazionale, Università degli Studi di Milano, Milan, Italy.*

Cutaneous melanoma is the most fatal skin cancer and, although some effective molecular therapies exist, novel targets and drugs are still needed. To provide new insights for novel targets discovery, we performed an extensive characterization by next-generation sequencing (NGS) of a collection of melanoma cell lines derived from metastatic cases. Samples were profiled by whole-exome sequencing (WES) and RNA-sequencing using Illumina technology. Starting from WES data, we developed a bioinformatics pipeline to catalogue 2,172 novel mutations affecting genes in melanoma key pathways targeted by current therapies (MAPK and glutamate pathways) as well as genes never described for melanoma [Cifola, 2013]. Moreover, WES data were used to perform copy number alteration (CNA) analysis using a novel software developed by us, called Excavator, which is very sensitive and precise in DNA copies estimation even in situations of great sample heterogeneity [Magi, 2013]. CNA results were concordant with 250K SNP Array data and used to explore CN state of mutated genes. To collect and share these results, we created a Melanoma Exome Database (https://155.253.6.64/MExDB/). On the same samples, we also carried out RNA-sequencing and performed both a traditional gene expression analysis and more sophisticated structural evaluations. Focusing on fusion transcripts, we identified 72 putative events generated by either inter-chromosomal translocations or intra-chromosomal rearrangements, recently defined "conjoined genes" and representing an additional gene regulation mechanism. Globally, NGS proved to be extremely powerful to dissect cancer complexity at both genomic and transcriptomic levels, and to identify novel potential targets for personalized treatment of cutaneous melanoma.

Integrated sequence analysis pipeline provides one-stop solution for identifying disease-causing mutations

H. Hu[1], *T. F. Wienker*[1], *L. Musante*[1], *V. M. Kalscheuer*[1], *P. N. Robinson*[2], *H. Ropers*[1];
[1]*Max-Planck Institute for Molecular Genetics, Berlin, Germany,* [2]*Universitätsklinikum Charité, Berlin, Germany.*

Next-generation sequencing has greatly accelerated the search for disease-causing defects, but even for experts the implementation of data analysis can be a major challenge. To facilitate the data processing in a clinical setting, we have developed a novel Medical Re-sequencing Analysis Pipeline (MERAP). MERAP assesses the quality of sequencing, and has optimized capacity for calling variants, including Single Nucleotide Variant, insertion and deletion, Copy Number Variation, and other structural variants. MERAP identifies polymorphic and known causal variants by filtering against public-domain databases, and flags non-synonymous and splice-site changes. MERAP uses a logistic model to estimate the causal likelihood of a given missense variant. MERAP considers the relevant information such as phenotype and interaction with known disease-causing genes. MERAP compares favorably with GATK, one of the widely used tools, because of its higher sensitivity for detecting indels, its easy installation, and its economical use of computational resources. Upon testing more than 1,500 individuals with mutations in known and novel disease genes, MERAP proved highly reliable, as illustrated here for 5 families with disease-causing variants, including a novel ANKS1A mutation identified in a patient with autosomal recessive non-syndromic intellectual disability. We believe that the clinical implementation of MERAP will expedite the diagnostic process of many disease-causing defects.

P16.55-S
Epigenome-wide analysis identified highly significant age-related DNA methylation changes

A. Russo[1,2], *S. Guarrera*[1,2], *G. Fiorito*[1,2], *C. Di Gaetano*[1,2], *F. Rosa*[1,2], *A. Allione*[1], *F. Modica*[1], *L. Iacoviello*[3], *M. Giurdanella*[4], *R. Tumino*[4], *S. Grioni*[5], *V. Krogh*[5], *A. Mattiello*[6], *S. Panico*[6], *P. Vineis*[1,7], *C. Sacerdote*[1,8], *G. Matullo*[1,2];
[1]*Human Genetics Foundation, Torino, Italy,* [2]*University of Turin, Turin, Italy,* [3]*Catholic University, Campobasso, Italy,* [4]*"Civile-M.P. Arezzo" Hospital, Ragusa, Italy,* [5]*Fondazione IRCSS Istituto Nazionale dei Tumori, Milano, Italy,* [6]*Federico II University, Napoli, Italy,* [7]*Imperial College London, London, United Kingdom,* [8]*CPO-Piemonte, Turin, Italy.*

Aging is associated with an increased risk for many complex diseases. DNA methylation represents one of the most promising biomarkers of aging. To evaluate the effect of age on DNA methylation, we examined the methylation levels of more than 450K CpG sites in 206 cases and 206 matched controls belonging to the Italian section of the EPIC cohort. EPIC healthy volunteers were recruited between 1994-98 and followed up for myocardial infarction and other diseases. For the CpG methylation level assessment on blood DNA we used the Illumina HumanMethylation450 BeadChip. Data were analyzed according to standard procedures (MethyLumi, Bioconductor). All analyses were corrected for sex, BMI, season, center of recruitment, cellular subtypes

and batch effect. Linear regression analysis showed that 10,000 CpG sites were significantly associated with age after Bonferroni correction (p<10-7). Positive correlation with age was found for 5,687 CpG sites (57%), whereas 4,313 CpG sites (43%) were negatively correlated with age. The top four significant loci (p<10-28) were located in the CpG islands of ELOVL2 and FHL2 genes. Methylation levels of the 4 CpG sites were positively correlated with increasing age, according to previously published results. These results confirm that DNA methylation alterations occur during aging and that ELOVL2 and FHL2 genes could be used as biomarker of aging. Moreover, the methylation differences associated with age could help in understanding molecular mechanisms that underlie the development of age-related diseases.

Whole genome methylation analysis in idiopathic generalized epilepsies

O. Ozdemir[1], *S. A. U. Iseri[1], O. U. Sezerman[2], E. Egemen[2], N. Bebek[2], B. Baykan[3], U. Ozbek[1];*
[1]Institute for Experimental Medicine, Istanbul, Turkey, [2]Biological Sciences and Bioengineering, Sabanci University, Istanbul, Turkey, [3]Istanbul Medical Faculty, Department of Neurology, Istanbul, Turkey.

Genetic factors play a predominant role in the etiology of common idiopathic generalized epilepsy(IGE) syndromes. An increased rate of maternal inheritance and excess number of affected females implicate involvement of epigenetic effects in the etiology of IGE syndromes.
In this study, we have performed a whole genome methylation analysis for 15 parent-offspring trios with vertical inheritance of the IGE trait. DNA samples were subjected to bisulphite conversion prior to IlluminaHuman Methylation 450K Beadarray application. Beadchips were scanned through Illumina iScan platform. We used a comprehensive R-Bioconductor package, namely „RnBeadsV0.99.11“, which implements an analysis workflow that can be used for paired and unpaired differential methylation analysis.
After data normalization, quality control, filtering and methylation profiling steps, differential methylation analysis revealed 239 genes with p-values smaller than 0.05. As an alternative approach, we have run a pathway-based analysis to see if genes with differential methylation values map to common pathways. This analysis with PANOGA software revealed various pathways particularly with synaptic and immunological functions.
Analysis of high throughput methylation data has proven to be challenging where various pipelines with alternative normalization and filtering methods should be applied. Two approaches presented herein have resulted in identification of new epilepsy related genes and pathways that could as well be applied to analysis of other trio based methylation studies.

P16.57-S
Molecular characterization of a de novo mutation in a pediatric patient with isolated ectopia lentis as a diagnostic criterion for Marfan syndrome

V. Procopio[1], *M. E. Sana[2], A. Spitaleri[3], C. Liuzzo[1], P. D. Romeo[1], S. Briuglia[1], L. C. Rigoli[1], C. D. Salpietro[1];*
[1]O. U. of Pediatric Genetics and Immunology, „G. Martino“ Hospital, Messina, Italy, [2]USSD Medical Genetics Laboratory , „Papa Giovanni XXIII“ Hospital, Bergamo, Italy, [3]D3 - Drug Discovery & Development, Italian Institute of Technology, Genova, Italy.

Marfan syndrome is an inherited multisystem disorder that affects the connective tissue. The typical onset is in adulthood and often occurs in children with isolated clinical signs. The revised Ghent criteria allow to confirm the diagnosis if ectopia lentis is in concomitance with a mutation in the FBN1 gene definitely associated with Marfan syndrome. Our patient (5 years old) presents a mutation (p. C154Y) never reported in the literature, hence the difficulty in establishing a diagnosis. We perform molecular dynamic simulation to investigate how this mutation affects the protein stability. Analysis was carried out on the mutated form of the N-terminal domain of the human fibrillin-1 (pdb code 2M74) . Structural analyses indicates that mutation perturb the secondary structure of the protein, which reduce the folding stability of the system. The C154Y mutation disrupts the C154-C166 disulfide bridge and consequently the two antiparallel beta sheets are impaired. In conclusion, the mutation leads to a destabilization of the native folding of the protein, and therefore a probably reduction of the physiological activity. The patient is monitored in follow-up because it has all probability of developing the Marfan syndrome. This study emphasizes the utility to characterize a mutation through molecular modeling in all late-onset diseases in order to correct follow up of patients.

P16.58-M
Prediction of LHX1-target genes relevant to Müllerian aplasia

F. Fernández[1], *V. Avila-Magaña[1], E. Martínez[1], S. Kofman[1,2];*
[1]Hospital General de Mexico, Mexico, Mexico, [2]Facultad de Medicina, Universidad Nacional Autónoma de México, México, Mexico.

LHX1 is a putative transcription factor widely distributed among vertebrates. In mice, *Lhx1* acts as a high-hierarchy regulator during urogenital development, as female *Lhx1*-null mutants lack Müllerian derivatives. Deletions and point mutations affecting *LHX1* have been found in female patients with Müllerian aplasia (MA). However, the low recurrence of these alterations indicates that this disorder is multifactorial, and few reports using high-resolution genome mapping techniques have been published. Hence, the identification of candidate genes for MA demands deeper analysis. In order to identify candidate genes for MA, we used a bioinformatic approach to predict LHX1-target genes, and the results were contrasted against the set of genes with copy-number alterations compiled from the microarray reports on MA patients. Starting from 4 documented *Lhx1* regulation targets in *Xenopus* and their homologs in 5 other species, a highly conserved 50-nt signature was identified (e-value $1.34e^{-36}$). Several known transcription factor-binding sites were contained in such signature, including those of HOXA5 and HNFB1, which have been previously associated to MA. The refined motif was further searched against the human genome promoter regions, and 45 putative target-genes of LHX1 were identified. Of these, 38 genes are expressed in uterine tissues, 19 during embryogenesis, and 15 in both conditions. Two genes, *NPHP1* and *PIAS3,* were found deleted in MA patients. In conclusion, our approach will be useful to prioritize genes relevant to Müllerian development and may help to establish future validation protocols.

P16.59-S
Age at onset and disease severity in primary progressive multiple sclerosis: a genome-wide association study, pathway and network analysis

G. Giacalone[1], *F. Clarelli[1], A. Osiceanu[1], C. Guaschino[1], P. Brambilla[1], M. Sorosina[1], G. Liberatore[1], N. Barizzone[2], D. Vecchio[3], PROGEMUS, PROGRESSO, V. Martinelli[1], M. Leone[3], G. Comi[1], S. D'Alfonso[2], F. Martinelli Boneschi[1];*
[1]Institute of Experimental Neurology, San Raffaele Scientific Institute, Milan, Italy, [2]Department of Health Sciences and Interdisciplinary Research Center of Autoimmune Diseases (IRCAD), University of Eastern Piedmont, Novara, Italy, [3]MS Centre, SCDU Neurology, AOU Maggiore della Carità, Novara, Italy.

Background: the mechanisms underlying the accumulation of neurological disability during the progressive phase of Multiple Sclerosis (MS) are currently unresolved. It is hypothesized that a complex polygenic background could regulate the clinical expression of progressive MS, in particular of the rare primary progressive course (PPMS). Aim: to look for common genetic variants associated to age at onset (AAO) and severity of PPMS, the latter measured as Multiple Sclerosis Severity Score (MSSS). Methods: 451 PPMS patients of Italian origin were genotyped for 296,589 SNPs using Illumina® OmniExpress and Human660-Quad chips, and allelic association with AAO and MSSS was studied; a protein-interaction based pathway and network analysis was performed using the following tools/databases: VEGAS, GTEx eQTL-browser, STRINGV9.05, WebGestalt, GeneCodis, GO, KEGG, MetaCoreTM. Results: no single association signal exceeded genome-wide significance in both AAO and MSSS analyses. We observed a replication at nominal level for the SNP rs758944A (p=1.15*10-3; beta=0.76), previously identified as suggestively associated to MSSS in MS patients (IMSGC,2011). Nominally associated loci to AAO (n=950) were enriched for chemokine signaling (adjusted-p=9*10-4) and oxidative phosphorylation (adjusted-p=9*10-4), while for MSSS, 845 loci were mainly associated to leukocyte trans-endothelial migration (adjusted-p=2.4*10-3) and B-cell receptor activity (adjusted-p=2.2*10-3). The genes p53 and CREB1 were identified as central hubs in network analysis. Conclusions: despite no major-effect signals were detected in our GWAS, our data suggest that common low-risk genetic variants acting mainly in the context of immune processes could play a significant role in modifying the clinical severity of PPMS. These observations could have interesting therapeutic implications.

P16.60-M
Genetic and epigenetic biomarkers of thymomas in Myasthenia Gravis

M. Denaro[1], *R. Ricciardi[2,3], A. Lopomo[1,4], M. Maestri[2], A. De Rosa[2], M. Lucchi[3], A. Mussi[3], F. Coppedè[1], L. Migliore[1];*
[1]Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy, [2]Department of Neuroscience, Division of Neurology, University of Pisa, Pisa, Italy, [3]Cardiac and Thoracic Department, Division of Thoracic Surgery, University of Pisa, Pisa, Italy, [4]Doctoral School in Genetics, Oncology, and Clinical Medicine, University of Siena, Siena, Italy.

Thymomas, epithelial neoplasms of the thymus, are present in about 10-20% of the patients affected by Myasthenia Gravis (MG), an autoimmune disease characterized in almost 80% of the cases by auto-antibodies against the nicotinic acetylcholine receptor (AChRAb). Changes in DNA methylation might contribute to the risk of thymomas but the role of epigenetics in MG and MG-associated thymomas is still not clarified.
Polymorphisms in one-carbon metabolism genes, the key pathway for nu-

cleotide synthesis and DNA methylation, have been often linked to aberrant DNA methylation and risk of various types of cancer. We investigated four polymorphisms in genes of this pathway, namely methylenetetrahydrofolate reductase (MTHFR) 677C>T, thymidylate synthase (TYMS) 28 bp repeats, DNA methyltransferase (DNMT3B) -149C>T and DNMT3B -579 G>T, in 110 AChRAb+ MG patients with thymoma (64 females and 46 males, mean age 56.1±13.1 years) and 429 matched healthy controls (276 females and 153 males, mean age 61.4±16.8 years). No difference in allele and genotype frequencies was observed between patients and controls in MTHFR and TYMS gene polymorphisms but an increased frequency of both the DNMT3B -579TT genotype (P = 0.03) and of the combined DNMT3B -579TT/-149CT genotype (P = 0.01) was observed in the total cohort of thymoma patients with respect to controls. After gender stratification both associations resulted significant in males. We are currently evaluating the methylation levels of the promoters of tumour-related genes, such as CDKN2A, hMLH1, and MGMT, in thymoma cells of MG patients, searching for correlation between DNA methylation levels and DNMT3B polymorphisms.

P16.61-S
Behind the scenes: the hidden challenges of exome sequencing in consanguineous populations

J. P. Casey[1,2], *P. McGettigan*[2,3], *E. Crushell*[1], *D. Slattery*[1], *A. Green*[4,2,1], *S. Ennis*[2,4], *S. Lynch*[4,1,2];
[1]*Temple Street Children's University Hospital, Dublin 1, Ireland,* [2]*Academic Centre on Rare Diseases, University College Dublin, Dublin 4, Ireland,* [3]*UCD School of Agriculture, Food Sciences and Veterinary Medicine, Dublin 4, Ireland,* [4]*National Centre for Medical Genetics, Dublin 12, Ireland.*

Our research aims to identify recessive mutations in the endogamous Irish Traveller population using exome sequencing. Through our studies, we have identified issues that may complicate identification of disease mutations in consanguineous populations: (a) increased number of candidate variants due to higher than expected levels of genome homozygosity, (b) the effect of cryptic relatedness on the use of population-matched controls and (c) increased phenotypic variability due to increased likelihood of multiple disorders in the same individual.
Homozygosity levels in patients from traditionally endogamous populations are often much higher than the predicted levels from first-cousin marriages in non-endogamous populations. This results in a large number of novel/rare homozygous variants per patient exome. Population-matched controls are very useful in this situation to distinguish benign from pathogenic variants. However, due to Traveller culture, key pedigree information is often not forthcoming. Therefore, there is an increased risk of cryptic relatedness between the patients and the controls, which can lead to the erroneous filtering out of pathogenic variants.
Inter- and intra-familial variability in patients with the same disease mutation may be due to variable expressivity. However, in families from endogamous populations there is the increased possibility of patients having more than one recessive disorder, thus distorting the phenotype. When faced with phenotypic variability, we found it useful to analyse each patient's phenotype and exome individually and have identified patients with up to three different recessive disorders using this approach.
Our findings support the need for customised approaches to exome sequencing in families from endogamous populations.

P16.62-M
Similarity metrics can be used to avoid multiple entries of a single individual in databases of genomic sequence variants

V. Heinrich;
Charité Universitätsmedizin Berlin, Berlin, Germany.

Removing frequently detected variants is one of the most effective approaches to reduce the number of candidate mutations in the data analysis of next-generation sequencing studies. The incidence of a
rare disorder in a population serves as an upper bound for the allele frequency or genotype frequency that can be used as a filter for dominant or recessive disorders. However, the frequentist inference
requires that genotypes of a single individual are represented in the database only once. With many and decentralized data submitters the risks increases that samples of the same individual are sequenced multiple times and are contributed independently under different pseudonyms. We developed a metric that computes the distances to reference samples of the 1000 genomes project. The distance profile of a sample is a unique signature that may be used to assess whether a
list of sequence variants has already been submitted. We show that this distance signature is highly specific for a sample but still error tolerant. This allows the identification of replicates from different enrichment procedures, sequencing platforms and bioinformatics pipelines. Furthermore the distance signature of a sample provides also a possibility to identify a pseudonymized sample without using the sequencing variants itself and might help to protect medically sensitive patient information.

A new PCR primer design tool for Sanger sequencing confirmation

M. Wenz, *S. Berosik, A. Karger, P. Brzoska, F. Hu, X. You;*
Life Technologies, S San Francisco, CA, United States.

High data quality and accuracy are recognized characteristics of Sanger resequencing projects and are primary reasons that next generation sequencing projects compliment their results by capillary electrophoresis data validation. We have developed an on-line tool called Primer Designer™ to streamline the NGS-to-Sanger sequencing workflow by taking the laborious task of PCR primer design out of the hands of the researcher by providing pre-designed assays for the human exome. The primer design tool has been created to enable scientists using next generation sequencing to quickly confirm variants discovered in their work by providing the means to quikkly search, order and receive suitable pre-designed PCR primers for Sanger sequencing.
Using the Primer Designer™ tool to design M13-tailed and non-tailed PCR primers for Sanger sequencing we will demonstrate validation of 28-variants across 24-amplicons and 19-genes using the BDD, BDTv1.1 and BDTv3.1 sequencing chemistries on the 3500xl Genetic Analyzer capillary electrophoresis platform.

P16.64-M
Towards integrative family analysis on OMICs data for individual patient diagnostics

B. Wolf[1,2], *T. Dandekar*[2], *P. Kuonen*[1];
[1]*University of applied sciences and arts western switzerland, Fribourg, Switzerland,* [2]*University of Würzburg, Würzburg, Germany.*

During recent years generating OMICs data became cheaper and faster. Notably DNA sequencing benefited from this change, becoming more popular and frequently used, specially in the domain of diagnostics. As became apparent, the data from DNA sequencing does often not allow for conclusive diagnostics, as it only shows one aspect of what contributes to the patients phenotype. The combination of OMICs data like genomics, transcriptomics and proteomics presents itself as a solution to this problem, especially in the context of family analysis which helps to identify interesting features. While many methods have been developed combining different OMICs sources to create more complete and comprehensive analyses of a patients genotype, doing family analysis in the context of OMICs data with an user friendly visualization of the data is still explored very little. We present our vision of a comprehensive, user friendly application which concentrates on several key features of OMICs data for comparative analysis. Our vision concentrates on family analysis of three key features. Individual SNP comparison on genomic data, gene expression comparison with transcriptomic data and protein variation from proteomics data. While those features are well understood individually, our vision is to create an easy to use tool to combine those three data sources based of GensearchNGS, an application that already provides the required genomics tools and allows for visualization of the analysis and underlying data. Examples will pertain to genetic disorders in myopathies, where we recently could show some progress regarding functional understanding and therapy (Walter et al., 2013)

P16.65-S
Transcription as a key determinant of the DNA methylation landscape in oocytes

L. Veselovska, *S. Smallwood, P. Ewels, S. Andrews, G. Kelsey;*
The Babraham Institute, Cambridge, United Kingdom.

DNA methylation in gametes, particularly in oocytes, marks a subset of genes for appropriate expression in the next generation, as in the case of imprinted genes. Imprinting errors have been associated with assisted reproduction technologies (ART): because ART may involve manipulation of oocytes when methylation may be most vulnerable, it is important to understand the mechanisms of methylation establishment. In oocytes, methylated CpG islands (CGIs) often localise within transcription units, as in the case of the differentially methylated regions of imprinted genes; moreover, methylation has been described as being predominantly over gene bodies. These observations suggest that methylation is governed by the activity of promoters induced during oocyte development.
To investigate the fraction of the methylome linked to transcription, we integrated genome-wide methylation maps with deep RNA-seq from different stages of oocyte development. This revealed that most hypermethylated domains precisely match active transcription units; this is true especially where transcription units do not match standard genome annotation because of the existence of unannotated upstream transcription start sites (TSS)

in oocytes. Conversely, most hypomethylated domains are transcriptionally silent. We also conclude that methylated CGIs are predominantly intragenic, while unmethylated CGIs are intergenic or at active TSSs. To test the association functionally, we investigated the imprinted gene *Zac1*; deletion of its oocyte-specific promoter led to absence of DNA methylation across its entire gene body.
These results suggest that perturbations in transcriptional regulation during oogenesis could have profound effects on the oocyte methylome and may provide a link between aberrant methylation and ART.

P16.66-M
The influence of genetics on personality development

K. B. Wolffhechel[1], *H. Jarmer*[1], *S. M. van den Berg*[2], *M. H. M. de Moor*[3], *D. I. Boomsma*[3];
[1]Center for Biological Sequence Analysis, Technical University of Denmark, Kongens Lyngby, Denmark, [2]Department of Research Methodology, Measurement and Data Analysis, University of Twente, Enschede, Netherlands, [3]Department of Biological Psychology, VU University Amsterdam, Amsterdam, Netherlands.

Personality is known as hereditary to a certain extent. In this work we attempt to classify personality traits as binary traits based on genetic information only. For this we used the 60-item NEO-FFI and over 8 million SNPs from 6655 Dutch participants. For feature selection we performed a genome-wide association for each personality trait in a five-fold cross validation setup. All SNPs with a p-value <0.01 were chosen as predictors for a given fold and a given personality trait, amounting to approximately 2,500 associated SNPs for each trait. An artificial neural network was trained with the SNPs as input and the personality scores as output. We found it possible to classify a person's personality to the two sides of the scale significantly better than random. The results of this study prove in a novel way that genetics have an influence on personality. The next step is to identify, which genes these SNPs belong to, which hopefully will lead to a greater understanding of the processes involved in personality development and the onset of personality disorders.

Analysis of GSTP1 promoter hypermethylation in urine samples of Bulgarian prostate cancer patients and controls

D. L. Kachakova[1], *E. P. Popov*[2], *A. V. Mitkova*[1], *A. I. Vlahova*[3], *T. I. Dikov*[3], *S. L. Christova*[3], *C. K. Slavov*[2], *V. I. Mitev*[1], *R. P. Kaneva*[1];
[1]Molecular medicine centre, Medical University- Sofia, Department of Medical Chemistry and Biochemistry, Sofia, Bulgaria, [2]Department of Urology, Medical University –Sofia, Clinic of Urology, Alexandrovska University Hospital, Sofia, Bulgaria, [3]Department of General and Clinical Pathology, Medical University–Sofia, General and Clinical Pathology, Sofia, Bulgaria.

Introduction: Prostate caner (PC) is one of the most commonly diagnosed cancer in men of the developed countries. The epigenetic modifications in PC are frequent and extensively studied. One potential noninvasive biomarker in urine is GSTP1 DNA methylation.
Materials and Methods: Using HRM technology we have analyzed GSTP1 promoter hypermethylation in urine samples of 64 PC patients, 26 controls with benign prostatic hyperplasia (BPH) and 20 young asymptomatic men (YAM). Our goal was to determine the diagnostic accuracy and correlations of this biomarker with clinicopathological characteristics in Bulgarian PC patients.
Results: Methylation was found in 70.31% of the patients, in 65.38% of the BPH controls and 15% of the YAM. Our results demonstrated that there was not significant difference of GSTP1 methylation among patients and BPH controls but among patients and YAM (p=0.000016). The ability of the biomarker to distinguish patients from BPH controls was evaluated. Serum PSA levels outperformed GSTP1 with estimated AUCs in ROC curve analysis 0.745 and 0.525 respectively. Methylation of GSTP1 correlates with age (Pearson's correlation coefficient 0.225, p =0.018) but not with Gleason score, tumor stage and PSA.
Conclusions: In our study the GSTP1 promoter hypermethylation in urine did not prove to be sensitive and specific diagnostic biomarker for PC and probably it is associated with age. Further investigations are needed to confirm these observations.
Acknowledgements: This work was supported by Infrastructural Grant: DUNK01/2/2009 funded by National Science Fund, Ministry of Education and Science, Bulgaria

Solving the cold case - A diagnostic and clinical trial framework for WGS based rare disease discovery.

R. Kreuzhuber, *R. Pandey, I. Visne, A. Weinhaeusel, K. Vierlinger, A. Kriegner;*
AIT - Austrian Institute of Technology, Wien, Austria.

The number of rare monogenic diseases is estimated to be >5000. For half of these the underlying genes are unknown (McKusik V.A., 2011). An increasing proportion of common diseases, such as schizophrenia or autism, previously thought to be due to complex multifactorial inheritance, are now thought to represent a heterogeneous collection of rare monogenic disorders (Mitchell KJ, Porteous DJ, 2011), the large majority of which is still unknown. For the efficient investigation of genetic mutations next generation sequencing (NGS) technology has revolutionized molecular diagnostics. Its big advantage is the ability to sequence enormous amounts of nucleic acids in a short time at an affordable cost. However, the benefits come with a number of challenges like NGS data management, quality control, mapping, variant calling and their annotation. We have developed a mutation screening and decision support for analysis of data generated by most common sequencing platforms: Illumina, 454, Ion Torrent, and Sanger Sequencing. The system furthermore allows the clinician to identify causal mutations through NGS data analysis and suggests which regions need to be validated with ABI Sanger sequencing. This makes it much easier to the scientist and the clinician to find causative Mutations. Samples of multiple patients can be processed and their mutations can be compared with ease. Keeping all gathered information of patients together grants for traceability and enables re-use and re-analysis of existing data. For questions where a single causative mutation is to be found in millions of other mutations, comprehensive data management and data analysis is essential.

From NGS back to Sanger Sequencing: Connecting and Synchronizing NGS and CE Variant Files with the VR Toolkit

E. Schreiber, *S. Berosik, S. Samsani, S. Chang, S. Sharp;*
Thermo Fisher Scientific, South San Francisco, CA, United States.

Whole exome or panel sequencing projects performed by next generation sequencing technologies typically reveal a large number of variants which may require verification by an orthogonal method. To that end, Sanger sequencing is the method of choice since it is accurate, affordable and easy to perform. To facilitate the re-sequencing of any exon in the human genome we have recently made available to the scientific community a free to use tool called Primer Designer™ . The tool provides the designs for over 350.000 PCR primer pairs that cover 99% of all exons in the human genome. Amplicons generated with these primers can be readily sequenced using the BigDye® Direct sequencing kit on the Genetic Analyzer capillary electrophoresis platforms. For variant identification the sequencing files are analyzed with Applied Biosystems Variant Reporter® software which requires the import of a text file with a reference sequence for alignment and comparison. Here we show the utility and workflow of a new on-line tool called VR toolkit that generates a reference file from Primer Designer -derived PCR amplicons that contains the chromosomal coordinates. Use of this annotated reference file in Variant Reporter allows the generation of an output file that can be compared and matched to a variant call file (vcf) from an NGS instrument. The VR toolkit enables the connection and synchronization between NGS data and traditional Sanger sequencing data analyzed with Variant Reporter software and should be of benefit for all researchers seeking to validate NGS data by Sanger sequencing.

P16.71-S
Analysis of Genomic Loci in Single Cells on the Fluidigm® C1™ Single-Cell Auto Prep System Without Whole Genome Amplification

J. Qin, *J. Wang, R. Ramakrishnan;*
Fluidigm Corp., South San Francisco, CA, United States.

Genomic DNA in single cells can be analyzed using whole genome amplification (WGA) on the Fluidigm C_1 Single-Cell Auto Prep System, followed by next-generation sequencing [1]. This approach is invaluable when screening for variants, for studying *de novo* mutations, as well as for looking for defined variants. We present an alternative to WGA for looking at predefined variants, with a simpler workflow, completed in less than eight hours with about three hours of hands-on time.
We isolated single GM12752 B-lymphocyte cells, extracted genomic DNA and preamplified [2, 3] 96 specific loci on the C_1 System, using a pool of 96 genotyping assays (all heterozygous) that amplify SNP loci on 22 human chromosomes. The products were directly analyzed on a 96.96 Dynamic Array™ IFC (integrated fluidic circuit), and the overall allelic dropout rate was found to be very low (≈4% for single alleles).
The approach described here can quickly provide insight into specific genes or loci from single cells. We believe this technique will find its applications in single-cell genotyping, variant detection, targeted sequencing, and, potentially, copy number variation.

P16.72-M
The influence of structural variants on alternative splicing

E. Ait Yahya Graison[1], *A. Necsulea*[2], *A. Reymond*[1];
[1]*CIG, Lausanne, Switzerland,* [2]*EPFL, Lausanne, Switzerland.*

Structural variants (SVs) impact tissue transcriptome by modifying the level and timing of expression of genes that localize within and on their flanks. We used mouse inbred strains to extensively gauge the influence of structural variants on the transcriptome complexity and regulation. We generated extensive RNA-seq data from mice liver and brain and intersected them with the Mouse Genomes project catalog of SVs encompassing insertions, inversions, deletions and copy number gains to assess simultaneously the impact of genome structural changes on both gene expression and alternative splicing.
While large SVs directly impact transcript expression levels, smaller SVs significantly influence splicing diversity in several manners. When lying in an exon, SVs significantly favor the emergence of alternative splicing through usage of multiple donor sites regardless of the maintenance or disruption of the open reading-frame. Conversely, a deletion or insertion within an intron significantly increases the number of alternative splice acceptor sites of the surrounding exons. Finally, exons that lie just upstream or downstream of a SV-containing intron are significantly more often skipped out by splicing. These impacts are independent from the SV size suggesting that it is a property of the rearrangement per se rather than the consequence of a change of size of the intron or exon. Interestingly, when several SVs are embedded within an exon or intron they appear to have a cumulative effect on splicing events.
We show that SVs do impact tissue transcriptome on a global scale by altering its complexity and diversity through alternative splicing.

Rapid Detection of Large Structural Variations in a Human Genome Using Nanochannel Genome Mapping Technology

H. Cao[1,2], **A. Hastie**[3], *D. Cao*[1], *E. Lam*[3], *Y. Sun*[1,4], *H. Huang*[1,4], *W. Andrews*[3], *M. Requa*[3], *T. Anantharaman*[3], *M. Austin*[3], *M. Saghibini*[3], *H. VanSteenhouse*[3], *A. Krogh*[2], *H. Cao*[3], *X. Xu*[1];
[1]*BGI-Shenzhen, Shenzhen, China,* [2]*University of Copenhagen, Copenhagen, Denmark,* [3]*BioNano Genomics, San Diego, CA, United States,* [4]*South China University of Technology, Guangzhou, China.*

Large structural variations (SVs) are less common than SNPs and indels in the population but collectively account for a significant fraction of genetic polymorphism and diseases. Base pair differences arising from SVs are on a much higher order (>100 fold) than point mutations, however, none of the existing prevailing methods can comprehensively and effectively detect them. To address these challenges, we first applied a high-throughput, cost-effective genome mapping technology using long single molecule (>150kb) to discover genome wide SVs and structure differences in the YH genome. We detected 278 large SVs (>10 kb), of which 251 of 278 (90%) are retrospectively supported by multiple orthogonal methods such as whole genome or fosmid end sequencing (200/278) and historical evidence contained in the DGV database (51/78). To further investigate the SVs that couldn't be validated by sequencing based tests, we found that 71 out 78 (91%) intersected with repeat elements, often the blind spot of re-sequencing and de novo assembly methods.. More than 70% of detected SVs are insertion events, known to be difficult to detect by sequencing. In this study, genome mapping also provides valuable information for complex regions (MHC, KIR, TRB/TRA, IGH/IGL et.al) with haplotypes.
In addition, for the first time, with long single molecule labeling patterns, inserted exogenous viral sequence and locations can be mapped on a whole genome scale important for understanding virus induced oncogenesis.
Nanochannel based genome mapping make it now feasible and cost effective to conduct large population-based comprehensive SV studies efficiently on a single platform.

P16.74-M
Analysis and correction of crosstalk effects in pathway analysis

M. Donato;
Wayne State University, Detroit, MI, United States.

Identifying the pathways that are significantly impacted in a given condition is a crucial step in understanding the underlying biological phenomena. All approaches currently available for this purpose calculate a p-value that aims to quantify the significance of the involvement of each pathway in the given phenotype. These p-values were previously thought to be independent. Here we show that this is not the case, and that many pathways can considerably affect each other's p-values through a ``crosstalk'' phenomenon. Although it is intuitive that various pathways could influence each other, the presence and extent of this phenomenon have not been rigorously studied and, most importantly, there is no currently available technique able to quantify the amount of such crosstalk. Here, we show that all three major categories of pathway analysis methods (enrichment analysis, functional class scoring, and topology-based methods) are severely influenced by crosstalk phenomena. Using real pathways and data, we show that in some cases pathways with significant p-values are not biologically meaningful, and that some biologically meaningful pathways with non-significant p-values become statistically significant when the crosstalk effects of other pathways are removed.
We describe a technique able to detect, quantify, and correct crosstalk effects, as well as identify independent functional modules. We assessed this novel approach on data from four real experiments coming from three phenotypes involving two species. This method is expected to allow a better understanding of individual experiment results, as well as a more refined definition of the existing signaling pathways for specific phenotypes.

EVA: A Completely New Variation Resource at EMBL-EBI

I. Medina;
EMBL-EBI, Cambridge, United Kingdom.

European Variation Archive (EVA) is a new resource from EMBL-EBI aimed at accepting submissions of and providing access to all types of genetic variation data for all species. To this end, EVA works with partner databases, such as dbSNP, to guarantee free global access to all this genetic variation data. Where available, data submitted to EVA, mainly in VCF format, are closely linked with supporting BAM files in the ENA database. The web portal of EVA aims to provide a dynamic and visually interactive set of queries and filters based on HTML5. Users can browse and explore our study or variation catalogue, visualize variations and alignments via our genome browser tool or search for a gene or disease topic. Access to EVA variation data is also provided in a programmatic way by using RESTful web services for a variety of applications, such as annotation pipelines. Performance and functionality are also important goals. EVA backend datastore is being developed with most advanced computing technologies to scale up to PetaBytes of data whilst still being responsive. Some other functionalities developed include data mining and visualisation in order to allow direct access to variation data from a number of entry points including gene, disease, genomic location, variation type and consequence. Technology implementations are only as valuable as the use cases they serve. EVA also aims to be an important resource for clinical, evolutionary and systems biology researchers by linking and combining regulatory information, pathways and protein-protein interaction data from different resources of EMBL-EBI.

Migraine is a common neurological disorder characterized by recurrent disabling attacks of headache and that affects roughly 14% of the population. Family and twin studies suggest significant genetic basis of migraine. Previous studies have identified several genetic variants by different approaches such as linkage, candidate gene and genome-wide association studies, however, the results remains inconsistency. In order to identify genetic variants for migraine in Taiwan, we performed whole exome sequencing on thirteen individuals from two tetra and one penta migraine families. Except for the father, all subjects in the family are affected. All the three pedigree were compatible with autosomal dominant inheritance. Among these subjects, a total of 3,271,336 variants were identified and an average of 269,865 variants was detected in each individual. Of which 14 variants were identified to be shared by all affected individuals but not by three unaffected fathers after filtering procedures. The variants we identified were mapped to four gene s (FRAS1, ABLIM3, FOXD4L5, and BAGE2) and three intergenic regions (1p22.2, 4q13.3, and Xq11.1). Eight variants clustered in ABLIM3 were compatible with autosomal recessive inheritance. One novel single nucleotide polymorphism in FOXD4L5 gene was detected and was compatible with autosomal dominant inheritance. Our results reveal several novel gene variants for migraine and further studies are required to confirm this finding.

P16.77-S

Epigenetic mechanisms potentially influencing gene expression in a rare form of familial Wilms Tumour

A. K. Brown[1], *M. A. LeBlanc*[1], *D. Gaston*[1], *J. Majewski*[2], *W. Foulkes*[3], *C. Fernandez*[4], *C. R. McMaster*[5], *K. Bedard*[1];
[1]*Department of Pathology, Dalhousie University, Halifax, NS, Canada,* [2]*Department of Human Genetics, McGill University, Montreal, QC, Canada,* [3]*Department of Medical Genetics, McGill University, Montreal, QC, Canada,* [4]*Department of Pediatrics, IWK Health Centre, Dalhousie University, Halifax, NS, Canada,* [5]*Department of Pharmacology, Dalhousie University, Halifax, NS, Canada.*

Wilms Tumour is the most prevalent type of pediatric kidney cancer. Most occurrences are sporadic, however approximately 5% of cases are hereditary; one such familial case has been identified in Atlantic Canada. None of the mutations that are currently known to cause Wilms Tumour are present in this family. Although our research to date has yielded no obvious causative mutation, whole-genome sequencing and RNAseq expression data have led to a long list of genes that could potentially be involved. The need to prioritize this list, coupled with the clinical observation that age of onset differed depending on whether the disease was inherited maternally or paternally, have led us to consider epigenetic modifications. We have started by considering DNA methylation. Methylation occurs on cytosine residues of CpG islands, and can cause gene inactivation by hindering access of transcriptional machinery to the promoter regions of genes. Therefore, gene transcription can be inhibited through hyper-methylation or gene expression may be promoted by hypo-methylation. We have assessed the methylation status of three genes (HDAC5, IGF2BP1, and POU6F2) in two patient and three control kidney samples using a methylation digest assay followed by qPCR. POU6F2 methylation was significantly decreased in both patient samples, which correlates with the increased expression we observed through RNA-seq. However, the percent methylation varied between digest replicates, so we are currently attempting to confirm the results using bisulphite conversion. Next, we will assess the methylation status of other candidate genes and will also investigate another epigenetic mechanism, histone acetylation.

Genetic relationship of European Roma people and eight ethnic groups from the Caucasus area which suggest Romas probably admixed with during their migration

A. Szabó[1,2], *Z. Bánfai*[1,2], *B. Duga*[1,2], *R. Szalai*[1,2], *L. Magyari*[1,2], *P. Mátyás*[1,2], *E. Kövesdi*[1,2], *K. Sümegi*[1,2], *B. Melegh*[1,2];
[1]*University of Pécs, Department of Medical Genetics, Pécs, Hungary,* [2]*Szentagothai Research Centre, Pécs, Hungary.*

Historical and genetic studies have suggested that Roma people migrated from India about 1500 years ago and settled in Europe. We investigated the genetic connection of Central European Romas to populations they could be connected or admixed with during their migration through the Caucasus. Population samples were from Abhkasians, Armenians, Chechens, Kumyks, Kurds, Nogais, North-Ossetians and Tadjiks living in the Caucasus area. We used publicly available Caucasus datasets and our Roma samples genotyped on Affymetrix Genome-wide Human SNP Array 6.0 chip. We also used Stanford-HGDP, HapMap Phase 3 and Indian datasets in order to get a better perspective about population relationships. Applying linkage disequilibrium based pruning method, our datasets contained 88781 SNPs, respectively. Using advanced algorithms which are capable of processing large autosomal SNP datasets, we investigated genetic connection of these populations. In order to infer the structure and relationship of populations, principal component analysis (PCA) and ADMIXTURE analysis were applied. PCA results show that Romas, compared to Central European and Indian populations, have more common genetic elements with the 8 investigated populations of the Caucasus area. Roma samples were most closely to Tadjiks and Nogais, while the others clustered farther from Romas, approximately in the same distance. ADMIXTURE analysis supports PCA results and shows that the eight populations from Caucasus contain also more Indian ancestry than Central Europeans. The data may also suggest that despite the short interval of contact they still admixed or populations of the Caucasus also have the same strong Ancestral North Eurasian origin as Romas.
This research was supported by TÁMOP-4.2.3-12/1/KONV-2012-0028.

Study of the influence of HLA alleles on the premature biological aging

M. Cenit, *A. Blanter, K. Nederveen, A. Serrano, C. Wijmenga, A. Zhernakova;*
Department of Genetics, University Medical Centre Groningen, University of Groningen,, Groningen, Netherlands.

Objective:. There is growing evidence of a premature biological aging in many autoimmune diseases. So far, the different genetics factors involved on premature aging have not been established. The decline of thymus function is a measurement of biological aging and can be determined by measuring sjTRECs concentration (signal joint excision circles produced during T-cell development). Our aim was to investigate the potential contribution of the major HLA II alleles associated with autoimmunity on the premature biological aging. **Methods:**. A total of 670 healthy individuals were included in the current study. The sjTRECs concentration was determined by qPCR in duplo per individual using sjTRECs primers and probe as well as albumin as a reference gene (dCTvalue albumin-dCT value sjTRECs). The different HLA alleles were determined by imputation based on Immunochip data using a Type 1 Diabetes Genetics Consortium (T1DGC, 5,225 individuals) as a reference panel. **Results:**. We found a statistically significant lower sjTRECs concentration in male compared with females (p=2.04*10-9). In addition, we found a lower sjTRECs concentration in males carrying *HLA-DQA1*01:02/DQB1*06* haplotype, compared with *HLA-DQA1*01:02/DQB1*06* negative male individuals (p=0.01) regardless of the carried *HLA-DRB1* allele (either *HLA-DRB1*15:01* or *HLA-DRB1*13:02*), although the difference does not remain significant after corrections for multiple testing. **Conclusion:** Our results indicate that gender affect thymic output and HLA alleles do not seem to play a key role on the speed of thymic involution and senescence of T-cells.

Asthma is a chronic inflammatory disease of the airways, associated with genetic and environmental factors. Despite the heritability of asthma-related traits, suggesting an important genetic contribution in disease susceptibility, a number of genome-wide association studies (GWAS) have only revealed a handful of firm susceptibility genes to explain the architecture of this disease. In order to reveal new *loci*, here we leverage the distinctive genetic features of the Spanish population, which harbors 4-20% North African admixture on average, and the information provided by the 1000 Genomes Project (1KGP), by performing a two-stage GWAS with unrelated subjects. We have analyzed over 6.5 million common variants of the genome (MAF>5%, Rsq>0.3) in 380 physician-diagnosed asthmatics, from the Genetics of Asthma (GOA) study, and 552 population-based controls, using the Axiom Genome-Wide CEU1 array and imputation in 1KGP. Our findings provide evidence for enrichment of genes from the cytokine-receptor interaction (FDR=0.006) and the WNT-signaling (FDR=0.04) canonical pathways. We have prioritized 21 *loci* associated at $p \leq 5.0E\text{-}05$ significance, some of them nearby firm susceptibility genes (e.g. *IL1RL1-IL18R1*, *HLA*, and *IL33-PTPRD*), while the remaining 76% have not been previously associated with asthma traits in previous GWAS. These results are being validated in independent Spanish samples from 795 cases and 1436 controls.

P17.04-M

Childhood growth patterns linked to grandmothers' smoking in pregnancy

M. Pembrey, *K. Northstone, J. Golding;*
University of Bristol, Bristol, United Kingdom.

Emerging evidence indicates that population variation in growth and development is influenced by the early life experience of parents and ancestors. For example, paternal smoking in mid childhood is associated with excess fat mass (5-10kg) in his sons by age 17ys (Northstone et al 2014). Here we use smoking in pregnancy by either grandmother as the exposure to test for transgenerational effects on growth. The Avon Longitudinal Study

of Parents and Children (ALSPAC) has information on prenatal exposure of father (n=9677) and mother (n=12,707) with detailed follow up (including DXA scans) on their children to age 17ys .
With *non-smoking* mothers, those with prenatal exposure themselves had larger sons at birth, who went on the have increased lean mass and grip strength by 17ys; no effects in daughters. By contrast, with non-smoking mothers, *paternal* prenatal exposure showed no effects at birth but increased growth (weight, BMI, lean and bone mass) in both sons and daughters by 17ys; the daughters additionally had increased height and fat mass.
With *smoking* mothers prenatally exposed themselves, there was no effect on sons at birth or later, whilst daughters had later decreases in height, weight, and fat, lean and bone mass. The only transgenerational effect with smoking mothers and *paternal* prenatal exposure was decreased head circumference at birth in sons which was associated with reduced IQ at 8ys. Taken together, these data evoke the transgenerational plasticity theory of evolved human life history strategy. Interaction analysis with imprinted genes PHLDA2 and INS VNTR/IGF2 are underway.

Ancient mtDNA diversity in Bulgaria

D. V. Nesheva[1], *S. Karachanak-Yankova[1], M. Lari[2], Y. Yordanov[3], A. Galabov[4], D. Caramelli[2], D. Toncheva[1];*
[1]Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria, [2]Department of Biology Laboratory of Anthropology Molecular Anthropology / Paleogenetics Unit University of Florence, Italy, Florence, Italy, [3]Institute of Experimental Pathology, Morphology and Anthropology, Bulgarian Academy of Science, Sofia, Sofia, Bulgaria, [4]The Stephan Angeloff Institute of Microbiology, Bulgarian Academy of Science, Sofia, Sofia, Bulgaria.

Background: The study of the genetic origin of the Bulgarian population helps for determination of population evolution and furthers our understanding of changes in the gene pool in space and time. We try to present the formation of our population based on available ancient mitochondrial DNA data.
Materials and methods: Using the main criteria for working with ancient mtDNA we analyzed 122 ancient samples dating from III Millennium B.C. to VIII - X Century A.D. from different regions of Bulgaria. We've performed several steps of amplification of overlapping fragments which cover the first hypervariable segment (HVS I) of mtDNA. The amplified fragments were cloned by using specific competent cells (E.coli), followed by sequencing of 360bp of HVS I.
Results: Preliminary results from phylogenetic analysis of 20 ancient samples have shown 18 independent haplotypes. Four of the samples are dating from III Millennium B.C. and 16 of them are dating from VIII - X Century A.D, which coincides with the First Bulgarian state. From the16 samples dating VIII - X Century A.D eleven have European origin, two - Western Eurasian origin and three- unknown origin. From the 4 samples dating III Millennium B.C. one is with European origin, one with Western Eurasian, one with controversial origin- Western Eurasian or East Asia and one is with unknown origin.
Conclusion: This research presents first original data on ancient and medieval mtDNA samples from individuals who inhabited in time the current Bulgarian territories.

P17.07-S
The ancient genomic DNA (anDNA) and analysis of genetic risk factors related to autoimmune rheumatic diseases HLA linked

A. Poma, *S. Colafarina, G. Fontecchio;*
University of L'Aquila, L'Aquila, Italy.

The mountain areas of L'Aquila city, such as Barete and Rocca di Cambio are characterized by environmental conditions (low temperature and humidity) that facilitate the preservation of the humans remains and anDNA: this factor explains the often tempering of a number of paleoanthropological findings. The migratory events surely resulted in the disappearance of several genes as well as the introduction of foreign alleles, among which some responsible for the development of autoimmune diseases HLA-restricted. In this work we show some preliminary genetic data generated by applying different bone anDNA extraction protocols, innovative and/or suitably modified from commercially available kits for forensic analysis. The immunogenetic assays have showed the positivity for HLA gene HLA-Cw3 (an increased frequency of HLA-Cw3 and HLA-Dw4 is tipically observed in Rheumatoid Arthritis). This work has laid the foundation for the design of protocols for extraction and PCR reaction improved and optimized, to be applied to paleogenetics and paleopathology samples on which to assess genetic risk factors related to autoimmune rheumatic diseases „HLA-Linked".

P17.08-M
Association between Azoospermia Factor c (AZFc) rearrangements and Y chromosome lineages

P. Noveski[1], *E. Sukarova Stefanovska[1], M. Mirchevska[1], T. Plaseski[2], D. Plaseska-Karanfilska[1];*
[1]Macedonian Academy of Sciences and Arts, Research Center for Genetic Engineering and Biotechnology "Georgi D. Efremov", Skopje, Macedonia, The Former Yugoslav Republic of, [2]Clinic of Endocrinology and Metabolic Disorders, Faculty of Medicine, Skopje, Macedonia, The Former Yugoslav Republic of.

Complete deletions of Azoospermia Factor c (AZFc) region are common genetic cause of male infertility, while the contribution of partial deletions and duplications to spermatogenic impairment is still controversial. Some studies suggested that Y chromosome background affects the formation of AZFc rearrangements and contributes to spermatogenic failure. The aim of our study was to investigate the association of AZFc rearrangements and Y chromosomal lineages among 474 men from R. Macedonia (328 Macedonians, 110 Albanians and 36 of other ethnicity). AZFc rearrangements were determined by STS markers and gene dosage analysis. Y lineages were assigned using multiplex SNaPshot of 26 Y-SNPs and fluorescent PCR of 17 Y-STRs. Five different AZFc rearrangements (b2/b4, gr/gr and b2/b3 deletions and b2/b3 and b2/b4 or gr/gr duplications) and 18 different haplogroups were detected, of which five [E1b1b, I2a1(xI2a1a), R1a, R1b and J2b] were present in 85% of the studied men. The presence of any AZFc rearrangement was positively associated with R1a (p=3.53x10-19) and negatively with R1b (p=5.88x10-5) and J2b (p=8x10-3) haplogroups. Most of the b2/b4 duplications were found on R1a, with a higher frequency among Albanians than Macedonians. The b2/b4 and gr/gr deletions were detected on different haplogroups with gr/gr present almost exclusively among Macedonians. B2/b3 deletion was present in four men with E1b1b and in the only two men with N haplogroup. In conclusion, determination of both AZFc rearrangements and Y chromosome lineages in ethnically matched populations may improve our understanding of their role on male infertility.

P17.09-S
Association BDNF Val66Met genotype and personality traits in healthy female subjects

M. Franzago[1], *M. Sergi[1], F. Cieri[1], M. Balsamo[2], L. D'Onofrio[1,3], A. Grilli[2], L. Picconi[2], M. Tommasi[2], A. Saggino[2], V. Gatta[2,3], L. Stuppia[2,3];*
[1]Department of Neuroscience and Imaging, "G. d'Annunzio" University, Chieti, Italy, [2]Department of Psychological, Humanities and Territorial Sciences, School of Medicine and Health Sciences, "G. d'Annunzio" University, Chieti, Italy, [3]Center of Excellence on Aging (Ce.S.I.), Chieti, Italy.

Brain-Derived Neurotrophic Factor (BDNF), a member of the nerve-growth-factor family, plays an important role in the regulation of plasticity synaptic and seems to be involved in the expression of personality traits.
The aim of this study was to understand the effects of the BDNF Val66Met functional genetic variant on several personality dimensions assessed using self-reported instruments. We administered the Big-Five-Questionnaire (BFQ-2) and the Temperament and Character Inventory-Revised (TCI-R) for the measure of personality; the Emotional Intelligence Scale (EIS) and the Emotional Quotient Inventory (EQ-I) for the measure of Emotional Intelligence construct; a new instrument for the measure of Fluid Intelligence construct (CAT-FIT). We tested the possible interactions between these variables on a cohort of 154 healthy female students recruited at the G. d'Annunzio University, Chieti. A significant and positive correlation has been observed between the BFQ-2 Agreeableness score and the BDNF 66Met carriers compared with the BDNF Val66Val genotype ($r = .17$; $p < .05$). In addition, an association has been evidenced between BDNF 66Met carriers and the TCI-R Reward Dependence subscale ($r = -.20$; $p < .05$); furthermore, the BDNF 66Met carriers was significantly associated with the TCI-R Self-Trascendence subscale ($r = .17$; $p < .05$). No significant association was demonstrated for the BDNF polymorphism and for any of the constructs analyzed. Our findings support the association between Agreeableness, Dependence and Self-Transcendence personality traits and the BDNF 66Met variant in female healthy subjects.

P17.10-M

Radboud Biobank: a central facility for prospective clinical biobanking in the Radboud university medical center, Nijmegen

P. Manders[1,2], *A. Siezen*[1], *S. Gazzoli*[1], *A. Heister*[2], *G. van Duijnhoven*[2], *D. Swinkels*[1], *G. Zielhuis*[1];
[1]*Radboud Biobank, Radboud university medical center, Nijmegen, Netherlands,* [2]*Department of Human Genetics, Radboud university medical center, Nijmegen, Netherlands.*

Biobanking is crucial for science-based health care solutions in the 21st century. In order to improve the diagnosis, prevention and treatment of complex, multifactorial disorders and diseases a better understanding is needed of the underlying genetic and environmental pathways. Therefore, there is a growing need for large-scale biobanks for biomedical research.
The Radboud university medical center is building a central biobank facility for disease-based biobanks to optimize the use of biomaterial. The Radboud Biobank encompasses biomaterial and their descriptions (patient, disease-specific and phenotypic data) and subsequent data (genotypic data, microarray gene expressions).
For all patient groups included in the Radboud Biobank different samples types are being stored, however, DNA is stored for all groups. The isolation and storage of DNA-samples takes place at the department of Human Genetics of the Radboudumc. An automated sample flow for sample handling, storage and retrieval of all DNA-samples is present . DNA is stored in an automated -20 storage system. This system will assure sample security over the long term, sample integrity and efficient and quality based sample management .
At the moment DNA-samples are available of, among others, the following patient groups: individuals with a confirmed form/an increased risk of colorectal cancer, patients with a cerebrovascular infarct/cerebral hemorrhage/venous thrombosis, or with rheumatoid arthritis/arthrosis, neurodegenerative disorders, type 2 Diabetes Mellitus, Crohn's disease/ulcerative colitis, leukemia/multiple myeloma/lymphoma and related disorders, chronic (progressive) renal failure and patients who have had a cerebrovascular vascular accident (18-50 years). There are also DNA-samples available of healthy individuals.

P17.11-S

Establishing of national birth defects registry in Thailand

S. Pangkanon[1,2], *S. Sawasdivorn*[1,2], *C. Kuptanon*[1,2], *U. Chotigeat*[1,2], *W. Vandepitte*[1,2], *P. Phadungkiatwattana*[3,2], *Y. Yanase*[3,2];
[1]*Queen Sirikit National Institute of Child Health, Bangkok, Thailand,* [2]*College of Medicine, Rangsit University, Bangkok, Thailand,* [3]*Rajavithi Hospital, Bangkok, Thailand.*

Background: Deaths attributed to birth defects are a major cause of infant and under-five mortality as well as a lifetime disability among those who survive. In Thailand, birth defects contribute to 21% of neonatal deaths. In 2012, Queen Sirikit National Institute of Child Health has initiated a Birth Defects Registry to capture birth defects among newborn infants. **Methods:** The birth defects data come from 4 mainly sources: National Birth Registry Database; National Health Security Office's reimbursement database; Online Birth Defect Registry Database designed to capture new cases detected later; and birth defects data from 20 participated hospitals. All data are linked by unique 13-digit national identification number and International Classification of Diseases (ICD)-10 codes. This registry includes 19 common structural birth defects conditions and pilots in 20 hospitals. The registry is hospital-based, hybrid reporting system, including only live births whose information will be collected up to 1 year of age. **Results:** During the first year of implementation, 20 hospitals from 16 provinces participated. A total of 3,696 infants were diagnosed as having congenital anomalies among 67,813 live births. The prevalence rates (per 1,000 live births) of major anomalies were 26.12. The 5 most common birth defects were congenital heart defects, limb anomalies, cleft lip/cleft palate, Down syndrome and congenital hydrocephalus respectively. **Conclusion:** Information obtained from the birth defect surveillance is the essential in the planning for effective intervention. We suggest that this program should be integrated in the existing public health system to ensure sustainability.

P17.12-M

Results of exome sequencing in familial patients with non-HHT Brain Arteriovenous Malformations

N. Bendjilali[1], *L. Tang*[2], *D. Guo*[3], *R. Hernandez*[4], *M. Segal*[5], *C. McCulloch*[5], *S. Inoue*[6], *A. Koizumi*[7], *W. Young*[3], *L. Pawlikowska*[3,2], *H. Kim*[3,2,5];
[1]*Rowan University, Glassboro, NJ, United States,* [2]*Institute for Human Genetics,University of California, San Francisco, San Francisco, CA, United States,* [3]*Center for Cerebrovascular Research, Department of Anesthesia and Perioperative Care, University of California, San Francisco, San Francisco, CA, United States,* [4]*Department of Bioengineering and Therapeutic Sciences, University of California, San Francisco, San Francisco, CA, United States,* [5]*Department of Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, United States,* [6]*School of Pharmacy, Suzuka University of Medical Science, Suzuka, Japan,* [7]*Department of Health and Environmental Sciences, Kyoto University Graduate School of Medicine, Yoshida, Japan.*

Background: Brain arteriovenous malformations (BAVMs) are a tangle of poorly formed blood vessels. Patients with Hereditary Hemorrhagic Telangiectasia (HHT), a disease caused by mutations in *ALK1*, *ENG* or *SMAD4*, often have BAVMs. We sought to identify novel functional variants that may contribute to non-HHT BAVMs.
Methods: Exome sequencing was performed on 5 unrelated families (8 non-HHT BAVM samples, 2 BAVM-free controls). Illumina Truseq exome capture kit was used for exome capture and sequencing was performed on the Illumina HiSeq2000. Reads were mapped to the reference human genome with (BWA). Variants were called using (GATK) and annotated using (Annovar). Cases were screened for variants reported in the HHT Mutation Database http://arup.utah.edu/database/HHT. Potentially pathogenic variants were kept and variants present in the 2 controls,1000 Genomes Project, ESP6500, dbSNP137 and segmental duplications were filtered out. Variants with unknown prediction of functional impact or predicted deleterious were included. Variants shared between affected siblings were kept.
Results: On average, we obtained 4.3GB of mappable sequence data; target coverage of 69x and 43,339 variants per individual. No subjects had variants reported in the HHT Mutation Database. 23 genes had unique novel variants in at least 2 families. *TMEM87B* and *SHISA7* had novel variants in three families. *NACAD*, *KRT75* and *IGFN1* had novel variants in 4 families.
Conclusions: We identified several genes bearing novel potentially pathogenic variants in multiple families in pathways relevant to BAVM. Experiments are needed to confirm these findings and determine the potential role of these genes in BAVM pathogenesis.

P17.13-S

Variation in mutation spectrum partly explains regional differences in the breast cancer risk of female *BRCA* mutation carriers in the Netherlands

J. C. Oosterwijk[1], *J. R. Vos*[1], *N. Teixeira*[1], *D. M. van der Kolk*[1], *A. H. van der Hout*[1], *L. Jansen*[1], *F. E. van Leeuwen*[2], *M. Collee*[3], *C. van Asperen*[4], *M. A. Rookus*[5], *A. Mensenkamp*[6], *M. Ausems*[7], *T. A. van Os*[8], *E. B. Gomez Garcia*[1], *H. Meijers-Heijboer*[9], *R. Brohet*[9], *M. J. Mourits*[1], *G. H. de Bock*[1], *HEBON;*
[1]*UMCG, Groningen, Netherlands,* [2]*NKI/AVL, Amsterdam, Netherlands,* [3]*EUR, Rotterdam, Netherlands,* [4]*LUMC, Leiden, Netherlands,* [5]*NKI/AvL, Amsterdam, Netherlands,* [6]*UMCN, Nijmegen, Netherlands,* [7]*UMCU, Utrecht, Netherlands,* [8]*AMC, Amsterdam, Netherlands,* [9]*VUMC, Amsterdam, Netherlands.*

Background: Previously, relatively high cancer risks were observed in BRCA2 mutation carriers (BRCA2 carriers) over 60 in the Northern Netherlands. We aimed to quantify these regional differences in the breast cancer risk, and analyzed whether they could be explained by mutation spectrum or population background risk. **Methods:** This consecutive cohort study included all known BRCA1/2 carriers in the Northern Netherlands (N = 1,050). Carrier and general reference populations were: BRCA1/2 carriers in the rest of the Netherlands (N = 2,013) and the general population in both regions. Regional differences were assessed with hazard ratios (HR) and odds ratios (OR). HRs were adjusted for birth year and mutation spectrum. **Results:** All BRCA1 carriers and BRCA2 carriers under age 60 had a significantly lower breast cancer risk in the Northern Netherlands, HR were 0.66 and 0.64, respectively. Above age 60, the breast cancer risk in BRCA2 carriers in the Northern Netherlands was higher than in the rest of the Netherlands (HR = 3.99, 95%CI 1.11-14.35). Adjustment for mutational spectrum changed the HRs for BRCA1, BRCA2 <60 and BRCA2 ^{3}60 years by -3%, +32% and +11%, respectively. There was no difference in background breast cancer incidence between the two regions (OR = 1.03, 95%CI 0.97-1.09). **Conclusions:** Differences in mutation spectrum only partly explain the regional differences in breast cancer risk in BRCA2 carriers, and for an even smaller part in BRCA1 carriers. **Impact:** The increased risk in BRCA2 carriers over 60 may warrant extension of intensive breast screening beyond age 60.

Immunochip SNP effect on candidate gene expression in Celiac Disease

L. Plaza-Izurieta, *N. Fernandez-Jimenez, A. Jauregi-Miguel, I. Irastorza, C. Tutau, J. R. Bilbao;*
BioCruces Reserch Institution/UPV-EHU, Leioa, Spain.

Celiac disease (CD) is an immune mediated disorder caused by intolerance to ingested gluten that develops in genetically susceptible individuals. The major genetic risk factor is HLA but it is not sufficient to explain all genetic susceptibility. GWAS and IMMUNOCHIP identified 39 non-HLA regions associated with CD, and a long list of candidate genes mapping these regions has been proposed. We aimed to analyze the influence of the associated SNPs in proposed candidate gene expression in the intestinal mucosa of active/treated CD patients and controls. 14 control individuals and 9 sample pairs from the disease group with genotype and expression data were included in

this study. Merlin 1.1.2 was used for the association test, performed independently in each of the studied groups in order to avoid false associations due to duplicated genotypes in CD sample pairs. Genotype effect of SNPs in the expression of many genes was found, but in none of them was the candidate gene located under the association peak of its putative SNP affected. We analyzed the genomic area around the associated SNPs searching in online data bases (Haploreg, Ensembl and UCSC) to find possible common regulatory elements that could be altering the expression of genes far away. Findings include open chromatin regions, novel protein coding sequences, novel anti-sense processed transcripts, processed pseudogenes, microRNAs, novel LincRNAs and some altered motifs in the SNPs showing regulatory power. Further functional studies must be done to determine if those elements could be real players in the development of CD.

P17.15-S
Gaining access to large European population cohorts through the transnational biobanking infrastructure BBMRI-LPC

O. M. Törnwall[1], *M. Johansson*[2], *K. Zatloukal*[3], *P. Brennan*[2], *G. J. B. van Ommen*[4], *M. Perola*[1];
[1]*Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland,* [2]*International Agency for Research on Cancer, Lyon, France,* [3]*Medical University of Graz, Graz, Austria,* [4]*Leiden University Medical Center, Leiden, Netherlands.*

Large Prospective Cohorts are essential in studies of disease etiology. After collecting biospecimens and extensive lifestyle information, the prospective cohorts follow the initially healthy study participants for years until disease occur. This gives investigators the opportunity to study biomarkers and other exposure prior to disease onset, an essential feature for evaluating pre-diagnostic biomarkers and etiological factors. However, accessing the biospecimens and data across borders is costly and sometimes hindered by ethical and legal regulations. To overcome these issues and to make the large European prospective cohorts on human health and disease more accessible for research, an EU-funded biobanking network infrastructure BBMRI-LPC (Biobanking and Biomolecular Resources Research Infrastructure - Large Prospective Cohorts) project was established in 2013.
BBMRI-LPC involves 30 partners from 17 different countries including universities, research centres and private companies offering their expertise in science, technology, ethical and legal aspects. The partnering biobanks include 20 large cohorts from which high quality biospecimens and data are available. BBMRI-LPC offers funding and administrative support for access to these cohorts to research investigators throughout Europe and EU associated states, in an open call followed by competitive, peer-reviewed selection. The 1st scientific call entertains study proposals in the field of common chronic diseases including cardiovascular disease, Type II diabetes and cancer, and is open from 15 May till 15 July 2014. The poster will present the specifics of the call, which offers a unique opportunity for scientists to carry out innovative research projects by EU-funded access to the unprecedented collection of European cohorts.

P17.16-M
Risk assessment of chronic kidney disease based on linear mixed models in Korean populations

J. W. Park, *E. P. Hong, S. G. Heo;*
Hallym University College of Medicine, Chuncheon, Korea, Republic of.

Recent genome-wide association studies (GWASs) have found multiple single-nucleotide polymorphisms (SNPs) associated with chronic kidney disease (CKD); however, these variants explained only a small fraction of genetic variation. The linear mixed models (LMM) have been proposed to control for population stratification and other confounding factors in GWAS. In this study, we developed models combining the effects of genetic and non-genetic risk factors to predict the risk of CKD in Korean populations. We conducted a GWAS using LMM and estimated the heritability of CKD using a set of 491,680 tag SNPs (r^2<0.8) selected from 4,721,497 SNPs being directly genotyped or imputed based on the 1000 Genomes data after adjustment for age and gender in 943 patients with CKD and 950 healthy controls. The narrow sense heritability of CKD was 0.23 (P<0.05). We created genetic and non-genetics risk scores and validated their predictability in two independent studies. The best fit model contains five non-genetic factors: age, gender, body mass index, triglycerides, and total cholesterol/ high-density lipoprotein cholesterol ratio (Hosmer-Lemeshow X^2 test, P_{model}=0.021). Although the most significant variant, rs35645016 located in the RB1CC1 gene, did not reach genome-wide significance (OR=1.1, P=1.7×10^{-6}), the predictability of non-genetic model was improved from 61% to 78% by considering the effects of 49 CKD-associated tagSNPs (P<1×10^{-4}). These models further validated in two independent studies (e.g. AUC, 72 to 77; $P_{difference}$<0.0001). Incorporating genetic information in a model of conventional risk factors may lead to improved predictability of developing CKD.

P17.17-S
Genetic adaptation of the human circadian clock to day-length latitudinal variations

D. Forni[1], *U. Pozzoli*[1], *R. Cagliani*[1], *N. Bresolin*[1], *M. Clerici*[2], **M. Sironi**[1];
[1]*Scientific Institute IRCCS E. Medea, Bosisio Parini, Italy,* [2]*University of Milan, IRCCE Don C. Gnocchi, ONLUS, Mian, Italy.*

The temporal coordination of biological processes into daily cycles is a common feature of most living organisms. Day/night cycles represent a major circadian synchronizing signal and vary widely with latitude. In humans disruption of circadian rhythms is a common feature in psychiatric diseases including schizophrenia, bipolar disorder, depression and autism. We applied an approach that analyses spatial correlations between genetic variation and environmental factors. We exploited genotype data from 52 human populations distributed worldwide and determined the annual maximal variation in day-length (Δphotoperiod), this latter used as a measure of selective pressure. With this approach we analyzed 5 independent sets of genes involved in circadian regulation or in sleep homeostasis. For all sets a significant enrichment of variants showing signals of photoperiod-driven selection was detected. Analysis of population genetic differentiation (FST) confirmed strong spatial signatures of natural selection at photoperiod-selected variants. Also, tests based on haplotype homozygosity indicated that a significantly high proportion of photoperiod-selected SNPs underwent selective sweeps in non-African populations. Finally, using variants identified in genome-wide association studies we determine that a significantly high proportion of risk SNPs for schizophrenia and/or bipolar disorder correlates with Δphotoperiod. Notably, many risk variants showing signals of photoperiod-driven selection map to genes with strong evidence of involvement in circadian rhythm regulation. Thus, human populations adapted to life at different latitudes by tuning their circadian clock systems. This process also involved risk variants for neuropsychiatric conditions. Data herein suggest possible genetic modulators for chronotherapies and candidates for interaction analysis with photoperiod-related environmental variables.

P17.18-M
Using mean inbreeding coefficient to estimate total pathogenic allele frequency in autosomal recessive disorders results in a biased estimate of this frequency

L. P. ten Kate[1], *M. A. Jonker*[2], *M. E. Teeuw*[1], *M. C. Cornel*[1];
[1]*Dept of Clinical Genetics and EMGO-Institute, VU University Medical Center, Amsterdam, Netherlands,* [2]*Dept of Epidemioology and Biostatisitcs, VU University Medical Center, Amsterdam, Netherlands.*

Some years ago we suggested to estimate total pathogenic allele frequency (q) of autosomal recessive disorders from the proportion of compound heterozygotes among affected patients with consanguineous parents. The method works well when all parental couples in the sample have the same value of F (provided F>0). The effect of combining data with different F's, was never examined, although taking a weighted average was already reported in literature. While testing the use of simulation as a method to examine the accuracy of estimating q, it was discovered by one of us that taking a mean value for F would always overestimate q. Here we illustrate the impact of using an average F in a hypothetical data set consisting of two equally sized populations, one with an F=0 and the other with a variable F (1/16, 1/64/ 1/256 and 1/1024). It is assumed that 4 different pathogenic alleles are involved, with relative frequencies 0.4, 0.3, 0.2 and 0.1. The table shows the resulting biased estimates for two different values of the true q.

		F			
		1/16	1/64	1/256	1/1024
True q	0.01	0.0419	0.0178	0.0119	0.0105
	0.02	0.0516	0.0278	0.0219	0.0205

Using mean inbreeding coefficient to estimate total pathogenic allele frequency clearly overestimates true q. The same applies when combining samples with different F's, all of which are >0. One possible solution is to estimate q for each subset with a particular F separately, and then take the weighted average of the estimated q's.

Pre-Processing Mining in Congenital Malformation Database

R. A. Cedeno;
Genetic Medical Institute, Zulia University, Maracaibo, Venezuela, Bolivarian Republic of.

The increase in healthcare data volume causes great difficulties in extracting useful information for decision support. Traditional manual data analysis has become inadequate, and methods for efficient computer-based analysis indispensable. To satisfy this need, medical informatics may use the technologies developed in the new interdisciplinary field of knowledge discovery in databases (KDD), encompassing statistical, pattern recognition, machine learning, and visualization tools to support the analysis of data and the dis-

covery of regularities that are encoded within the data. DM is the search for new, valuable, and nontrivial information in large volumes of data.The Registry of Congenital Malformations in Maracaibo, Venezuela is a study for the clinical and epidemiological This paper presents a future proposal for a study of Congenital malformation monitoring program in Maracaibo, Venezuela with techniques for Data Mining (DM) and discuss how we carry out knowledge discovery on the Congenital Malformation database (CMDB) of the ECLAMC (F01) The aim of this paper is to demonstrate that the techniques of pre-processing dates are the focus of DM processes and we will present step–by step the CRISP-DM standard approach to help the physician explore their CMDB

In summary, DM algorithms can be applied using the prepared data. The adequacy of data preparation often determines whether this data mining is successful or not speciality in Congenital Malformation database.

Siberian populations represent a unique case for the study of human adaptation to the extreme cold environment. Our previous selection scans based on genome-wide genotype data highlighted a 3Mbp region on chromosome 11 with 79 genes as the strongest candidate region under positive selection in Northeast Siberians. However, it was not possible to distinguish which gene specifically was causing the signal. Here, using whole genome high coverage sequence data and additional neutrality tests, we identify the most likely causative mutation of this selection signal in the CPT1A gene which is a key regulator of long-chain fatty acid oxidation. We find a non-synonymous mutation (P479L) at >80% frequency in the coastal Northeast Siberian populations while it is absent in other Siberian populations and public genomic datasets. The only other known ethnic groups with this mutation are Canadian and Greenland Natives among whom the P479L mutation has been reported in association with hypoketotic hypoglycaemia and high infant mortality. The mutation is also present in the genome of the Paleo-Eskimo from Greenland suggesting that the mutation is at least 4KYA. The localised high frequency and associated haplotype homozygosity of the P479L mutation in the Arctic region supports the hypothesis that its selective advantage is either due to specific dietary or thermoregulation associated adaptation.

Genome-wide association study and functional characterization of a locus associated with CRIPTO serum levels in Cilento isolates

S. Nappo[1], *D. Ruggiero*[1], *T. Nutile*[1], *R. Sorice*[1], *E. Giorgio*[1], *C. Bellenguez*[2,3,4], *A. Leutenegger*[5,6], *G. Liguori*[1], *M. Ciullo*[1];

[1]*Institute of Genetics and Biophysics A. Buzzati-Traverso, CNR, Napoli, Italy,* [2]*Institut Pasteur de Lille, Lille, France,* [3]*Inserm, U744, Lille, France,* [4]*Université Lille 2 de France, Lille, France,* [5]*Inserm, U946, Paris, France,* [6]*Univ Paris Diderot, Sorbonne Paris Cité, IUH, UMR-S 946, Paris, France.*

CRIPTO, the founding member of the EGF-CFC genes, plays an essential role in embryo development and cancer progression. Very little is known about the variability of serum levels of CRIPTO in humans and the genetic contribution underlying this variability remains still unknown. We performed a GWAS of CRIPTO serum levels in two isolated villages from Cilento area in South Italy. The most associated SNPs (p-value<10-8) were all located on the chromosome 3p22.1-3p14.3, around the CRIPTO gene. Performing a conditional analysis for the best signal (rs3806702, p-value=1.03*10-159) no loci remain associated at genome-wide significance, while many SNPs were associated at 5*10-8<p-value<1*10-4, twenty of those were replicated in an independent sample. Genes closest to the replicated SNPs were included in a unique network involved in cellular development, death and survival. The replicated loci explain the 89.8% of the CRIPTO variance, with the 84.9% explained by the most associated SNP. Among the top associated SNPs, the rs112481213 variant (p-value=1.53*10-158), located within the 5′UTR of the CRIPTO gene, was predicted to create a binding site for AP-1 transcription factor. To assess a functional role of this SNP, allele effect was tested on the transcriptional activity of luciferase in a cell system: the A allele was more efficient in driving transcription than the T allele, demonstrating that rs112481213 is a functional regulatory element of CRIPTO transcription. Further, EMSA experiments demonstrated that the A allele acts creating a AP-1 consensus binding site. Further investigation is warranted to detect association between the functional SNP and diseases susceptibility.

Twelve-year experience in CFTR gene mutation screening at Sant'Anna General Hospital, Como Italy

C. Giudici[1], *S. Macchi*[1], *D. Armenante*[1], *G. Bianchi*[1], *L. Miele*[2], *M. C. Bianchi*[3], *I. Cino*[3], *M. Corinti*[4], *P. Modena*[1];

[1]*Unit of Genetics, Sant'Anna General Hospital, San Fermo della Battaglia Como, Italy,* [2]*Genetica e Citogenetica, Unilabs, Lugano, Switzerland,* [3]*Center for medically assisted procreation, Sant'Anna General Hospital, Cantù, Italy,* [4]*Unit of Urology, Sant'Anna General Hospital, San Fermo della Battaglia Como, Italy.*

Cystic Fibrosis (CF) is the most frequent severe inherited disease among Caucasians, having prevalence of 1:3000 and a carrier frequency of 1:27 in Italy. Three mutations in CFTR gene (F508del, N1303K, G542X) represent approximately 60% of mutated alleles, while a multitude of additional mutations exhibit a low prevalence. In addition, the distribution of individual mutations varies throughout the country and several mutations are peculiar to specific regional areas, i.e, T338I is typical in Sardinia (15.1% of mutated alleles), 2183AA->G and R1162X are frequent in Northeastern Italy (8% each). We now present data on CF genetic testing in Como, a 0.6 million population regional area of Lombardia (Italy), for which mutation prevalence information is limited.

From 2002 to 2013, our Unit of Genetics analyzed 3369 individuals for CFTR mutations, using reverse dot blot-based commercial diagnostic kits with a detection rate ranging from 75% to 85%. The laboratory successfully accomplished National Health system (ISS)-sponsored external quality control program since 2003. Most of the individuals were tested for CF in the context of clinical examinations for infertility or as partners of known carriers. Additional cases represented symptomatic patients with suspected cystic fibrosis or prenatal diagnosis testing.We detected 147 mutated alleles (4.3% CF carrier frequency). Frequency of individual mutations were F508del (40.1%), G542X (11.6%), N1303K (8.8%), 2789+5G->A (6.8%), 2183AA->G (6.1%). Additional 16 mutations comprised 26.6% of mutated alleles. A survey of mutations in relation with medical indications (including male infertility) and compared to literature data on different Italian areas will be presented.

P17.23-S

Polymorphism A2756G at methionine synthase (MTR) and the maternal risk of Down syndrome: evidence from a meta-analysis of case-control studies

D. B. Victorino[1], *M. F. Godoy*[2], *E. M. Goloni-Bertollo*[1], *E. C. Pavarino*[1];

[1]*Unidade de Pesquisa em Genética e Biologia Molecular – UPGEM, Faculdade de Medicina de São José do Rio Preto – FAMERP, São José do Rio Preto, Brazil,* [2]*Laboratório de Pesquisa e Teoria do Caos Aplicada à Medicina, Faculdade de Medicina de São José do Rio Preto – FAMERP, São José do Rio Preto, Brazil.*

A2756G is a common polymorphism related to the methionine synthase (MTR). Since it has been suggested a role for the folate pathway in chromosome 21 nondisjunction, many studies have demonstrated a relationship between *MTR* A2756G and Down syndrome (DS). However, the data from these studies have shown conflicting results. Therefore, we performed this meta-analysis to derive a precise estimation of this association. Studies were searched from PubMed up to January, 2014 and were eligible if they included case mothers (DSM) that gave birth to at least one child with DS, and controls mothers (CM) that have given birth to children without abnormalities. Pooled odds ratios (ORs) with 95% confidence intervals were estimated by fixed or random effects models. Heterogeneity among studies was evaluated using Q test and I^2 statistic. Publication bias was examined by a Begg's (funnel plot) and Egger's tests. Sensitivity analysis were performed by using allelic, dominant, recessive and codominant genetic models, Hardy-Weinberg equilibrium (HWE) and ethnicity. Eight case-control studies (987 DSM and 1,334 CM) were included. No association evidence has been found, neither in the overall analysis, nor in the stratified analysis by ethnicity (ORs with $P > 0.05$). The shape of funnel plots was symmetrical in almost all genetic models. There is no evidence of heterogeneity, the genotype distributions of the controls of all studies were consistent with HWE and sensitivity analysis indicated robustness of our results. Taken together, our meta-analysis suggested that *MTR* A2756G polymorphism did not contribute as an independent risk factor of DS.

FFBSKAT: fast family-based sequence kernel association test

N. M. Belonogova, *G. R. Svishcheva, T. I. Axenovich;*
Institute of Cytology & Genetics SD RAS, Novosibirsk, Russian Federation.

Background: The kernel machine-based regression is an efficient approach to region-based association analysis aimed at identification of rare genetic variants. However, it is computationally complex. The running time of kernel-based association analysis becomes especially long for samples with genetic (sub)structures, thus increasing the need to develop new and effective methods, algorithms, and software packages.
Results: We have developed a new R-package called Fast Family-Based Sequence Kernel Association Test (FFBSKAT) for analysis of quantitative traits in samples of related individuals. This software implements a score-based variance component test to assess the association of a given set of single nucleotide polymorphisms with a continuous phenotype. In the development of FFBSKAT, we applied several analytical and algorithmic improvements to speed up the analysis without any loss of accuracy.
We compared the performance of our software with that of two existing software for family-based sequence kernel association testing, namely, ASKAT and famSKAT, using the Genetic Analysis Workshop 17 family sample. Results demonstrate that FFBSKAT is several times faster than other available programs, while being similarly accurate. With respect to the available analysis modes, we combined the advantages of both ASKAT and famSKAT and added new options to empower FFBSKAT users.
Conclusion: The FFBSKAT package provides fast, accurate, and easy-to-use method to perform kernel machine-based regression association analysis of quantitative traits in samples of related individuals. The FFBSKAT package, along with its manual, is available for free download at http://mga.bionet.nsc.ru/soft/FFBSKAT/

Exome sequencing revealing Nunavik Inuit specific variants in genes regulate lipid metabolism

S. Zhou[1], *L. Xiong*[2], *P. Xie*[1], *A. Ambalavanan*[1], *C. Bourassa*[1], *A. Dionne-Laporte*[1], *D. Spiegelman*[1], *N. Dupré*[3], *M. Dubé*[4], *P. Dion*[1], *G. A. Rouleau*[1];
[1]*Montreal Neurological Institute, Montreal, QC, Canada,* [2]*Centre de recherche, Institut universitaire en santé mentale de Montréal, Montreal, QC, Canada,* [3]*Department of Neurology, Université Laval, Quebec, QC, Canada,* [4]*Pharmacogenomics Centre, Montreal Heart Institute, Montreal, QC, Canada.*

Nunavik comprises the northern part of Quebec, with 90% of its habitants being Inuit. The modern Inuit of Nunavik came from the Thule people from coastal Alaska and traveled eastward along the Arctic tree line and reached Nunavik around 1500 AD as they became the ancestors of current Inuit residents. In this study, we performed exome sequencing on 113 Nunavik Inuit, using Agilent SureSelect V4 capture kit and Illumina HiSeq platform. Standardized data processing is used to extract all exonic variants. We performed preliminary analysis in order to identify Inuit specific novel or rare nonsynonymous variants. The analysis yielded 62 protein changing variants which have allele frequency over 0.5 in Inuit while less than 0.01 in other populations. Among these, a variant p.P479L in the Carnitine Palmitoyltransferase 1A (CPT1A) gene is the most prominent one with allele frequency 0.94. This variant is absent in non-Inuit populations, which frequency also appears to be the highest in Nunavik when compared to other Inuit populations. Further analysis revealed Nunavik Inuit also have significantly higher mutation burden in other carnitine acyltransferase family genes compared to non-Inuit populations such as Asian and Caucasian. The specific genetic profile of Nunavik Inuit with higher number and frequency of damaging variants in genes regulate lipid metabolism such as carnitine acyltransferase genes may be associated with the adaptation to their special diet and living environment in the extreme cold climate. Understanding the role of Inuit unique variant(s) is very important to the study of Inuit special health care.

P17.26-M

GWAS and candidate gene analysis highlight many novel loci associated to food preferences

N. Pirastu[1,2], *M. Kooyman*[3], *M. Traglia*[4], *A. Robino*[1,2], *S. M. Willems*[3], *G. Pistis*[4], *N. Amin*[3], *C. Sala*[4], *L. C. Karssen*[3], *C. Van Duijn*[3,5], *D. Toniolo*[4], *P. Gasparini*[1,2];
[1]*Università degli Studi di Trieste, Trieste, Italy,* [2]*IRCCS Burlo Garofolo, Trieste, Italy,* [3]*Genetic Epidemiology Unit, Department of Epidemiology, Erasmus Medical Center, Rotterdam, Netherlands,* [4]*Division of Genetics and Cell Biology, San Raffaele Scientific Institute, Milan, Italy,* [5]*Centre for Medical Systems Biology, Leiden University Medical Center, Leiden, Netherlands.*

Food preferences are the first factor driving food choice, nutrition and ultimately diet-related diseases. To understand the genetic component of food preferences we used two phase approaches: PHASE1: association of bitter taste receptors and coffee liking and PHASE 2: two-step GWAS of 42 different food likings.
PHASE1 revealed a significant association between coffee liking and H212R variant of TAS2R43 gene. Moreover, this variant is also associated with different thresholds in caffeine perception.
For PHASE 2 2311 Italian subjects were used for the discovery step while 1755 from Europe and Central Asia for replication. Association analysis revealed 17 independent GWAS significant replicated loci/genes (combined $p<5x10^{-8}$). Briefly Artichokes (CHSY3, LOC100128714 and CCRN4L); Bacon (CNTN5 5.93E-09); Broccoli (KIF2B, RYBP 4.50E-09); Coffee (FIBIN); Chicory (CSMD1 2.56E-09); Dark Chocolate (DFNA5); Blue Cheese (TCF7L18.81E-09); Ice Cream (IRX4); Liver (RNU6−66); Oil or Butter on Bread (BPNT1 3.62E-10); Orange Juice (FARS2); Plain Yogurt (IGLV4-60); White Wine (HLA-DOA) and Mushrooms (C9orf123).
Regarding possible effects on metabolic traits we found that rs12994253 (TCF7L1) is associated to lower Blue Cheese liking and lower BMI (p=0.0048) while rs2530184 (KIF2B) is associated to lower Broccoli liking and higher total cholesterol (p=0.0042)
None of the identified genes belong to taste or olfactory receptors thus highlighting new genes and pathways. 13 out of 17 loci show a non-additive inheritance highlighting the need of considering alternative genetic models in GWAS.
Our results represent a first step towards unraveling the genetic bases of food liking, and in understanding the genetics of human nutrition in general.

FTO gene rs1421085 polymorphism is associated with obesity and metabolic syndrome in the Turkish adults

F. Guclu-Geyik[1], *A. Yuzbasiogullari*[2], *A. Onat*[3], *N. Coban*[2], *G. Can*[4], *T. Lehtimäki*[5], *N. Erginel-Unaltuna*[2];
[1]*Istanbul University, Institute for Experimental Medicine, Department of Genetics,, Istanbul, Turkey,* [2]*Istanbul University, Institute for Experimental Medicine, Department of Genetics,, ISTANBUL, Turkey,* [3]*Emeritus, Istanbul University, Cerrahpasa Medical Faculty, Department of Cardiology, ISTANBUL, Turkey,* [4]*Istanbul University, Cerrahpasa Medical Faculty, Department of Public Health, ISTANBUL, Turkey,* [5]*Tampere University, Tampere University Hospital, Department of Clinical Chemisty, Tampere, Finland.*

Background and aim: Common polymorphisms in the fat mass and obesity-associated gene (FTO) have shown strong association with obesity, metabolic syndrome (MetS) and type 2 diabetes mellitus (T2DM) in several populations. In the present study, we explored the association of FTO rs1421085 gene polymorphism with obesity, MetS, T2DM and other biochemical parameters in a larger cross-sectional population-based random sample of Turkish Adults (TARF Study). Methods: Genotyping was performed using the Taqman Sistem (ABI PRISM 7900 HT) in 1977 adult individuals (mean age 50.1±12.0; 48.3% male). Results: The frequency of the FTO risk-allele (C) was 0.42, and the genotype distribution was in Hardy-Weinberg equilibrium. Not women but men, carriers of C allele of the rs1421085 polymorphism were at increased risk for the presence of MetS (OR = 1.52; 95% CI: 1.13 to 2.04), elevated insulin level (8.31 ± 1.04, p=0.013), adjusted for age, smoking status, alcohol consumption, and physical activity. Logistic regression analysis demonstrated a significantly increased likelihood for obesity in women rs1421085 C allele carriers (OR = 1.56; 95% CI: 1.16 to 2.10), after adjustment for age, cigarette smoking, alcohol usage and physical activity, diabetes mellitus and menopausal status. The rs1421085 polymorphism was not associated with T2DM in both gender. Conclusion: Our findings indicate that the rs1421085 polymorhism in the FTO gene contribute to obesity and MetS in the Turkish adults depending on gender.

Generation Scotland's Scottish Family Health Study (GS:SFHS) includes over 24,000 participants from across Scotland with records for health-related traits and environmental covariates, 10,000 genotyped for ~700K SNPs. The cohort represents an important resource for the study of complex traits and diseases. We have analysed the genomic structure of GS:SFHS as a preliminary step towards choosing appropriate subsets of individuals and statistical techniques for future studies. Initially we merged the GS:SFHS data with 1092 individuals of diverse ancestries from the 1000 Genomes project and estimated genomic relationships using the ~700K SNPs. A Principal Component Analysis on the resulting relationships facilitated identification of a group of 70 individuals of likely Italian ancestry and a number of individuals with African or Asian ancestry. We characterised the amount

of genetic introgression and were able to differentiate between individuals with a few small exogenous regions in their genome, and those with long exogenous haplotypes covering a large part of the genome. We found that the pattern of homozygosity was very similar to that of other European populations and identified an individual carrying a chromosome 1 uniparental disomy. Overall, there is very limited evidence for geographic differentiation or stratification of the GS:SFHS sample within Scotland. These findings provide a genomic perspective on the history of the Scottish population, and have implications for further analyses, such as studying the contributions of common and rare variants to trait heritabilities and evaluation of genomic and phenotypic prediction of disease.

P17.30-M
Identification of mutations in the GLI2 gene in Combined Pituitary Hormone Deficiency (CPHD) in Italian patients

R. Muniswamy[1], *D. Babu*[1], *I. Fusco*[1], *S. Mellone*[1], *F. Prodam*[2], *S. Bellone*[2], *A. Petri*[2], *G. Bona*[2], *M. Giordano*[1];
[1]*Laboratory of Human Genetics, Department of Health Sciences, University of Eastern Piedmont, Novara, Novara, Italy,* [2]*Paediatric Unit, Department of Health Sciences, University of Eastern Piedmont, Novara, Novara, Italy.*

The GLI2 transcription factor is a major effector protein of the sonic hedgehog pathway and it is suggested to play a key role in pituitary development. *GLI2* mutations cause holoprosencephaly or holoprosencephaly-like features. In some cases heterozygous *GLI2* mutations have been associated with hypopituitarism without other anomalies. However *GLI2* is not routinely screened in pituitary hormone disorders. The aim of this study was to determine the frequency of *GLI2* mutations in patients with combined pituitary hormone deficiency (CPHD) in Italian patients that resulted negative for mutations in other causative genes (*PIT1, PROP1, HEXS1, LHX3,LHX4*).
In this analysis, we screened the entire gene in 75 CPHD patients. Primers were specifically designed for the 13 coding exons that were analysed by direct sequencing in 18 separate fragments. We identified two novel missense mutations: c.731A>T in exon5 leading to the amino acid substitution p.Asp244Val and c.1157C>T in exon7 resulting in the change p.Pro386Leu. These two variants were absent in about 13.000 individual present in the Exome Variant Server. Both these mutations were predicted as probably damaging using the online tool Polyphen v2, with a high score (1.00 for Asp244Val and 0.923 for p.Pro386Leu). They fall within the NH2 terminal repressor domain and an *in vitro* functional analysis will help to clarify their significance.
These preliminary results are encouraging and we are planning to increase the number CPHD patients and extend the analysis also to Isolated Growth Hormone Deficiency (IGHD).

P17.31-S
A Genome-wide Association Analysis of Lipid traits in a sample of indigenous population from Mexico

S. Romero-Hidalgo[1], *M. Villalobos-Comparán*[1], *C. Márquez-Luna*[1], *M. Menjivar*[1,2], *V. Acuña-Alonso*[3], *S. Canizales-Quinteros*[1,2];
[1]*INMEGEN, Mexico City, Mexico,* [2]*UNAM, Mexico City, Mexico,* [3]*ENAH, Mexico City, Mexico.*

Given the high prevalence of diferent forms of dyslipidemia in Mexican population, in contrast to European populations, it has been suggested that genetic susceptibility in this population is probably related to its indigenous component as a result of adaptive processes related to energy savings. It is therefore of great importance to identify the genetic variation of the native Mexican population. In this study, 319 individuals from four indigenous populations (174, 70, 25 and 50 from Nahua, Maya, Totonac and Zapotec, respectively) were included. Genotyping was performed using Affymetrix SNP 6.0 microarray. The analysis included a local ancestry estimation to remove segments infered to be of European origin and mixed linear models using EMMAX, adjusted for age, gender and two principal components. Two steps of quality control were performed, before and after the European segments were removed. Log-transformed values of tryglecides (TG), total cholesterol (TC) and HDL cholesterol (HDL) were analyzed. By removing segments of European origin in the analysis we identify three suggestive signals, one for each trait. For HDL, TC and TG, an association was found in intergenic regions on chromosome 11 (p≤9.5x10-6), chromosome 21 (p≤8.8x10-5) and chromosome 2 (p≤6.1x10-5), respectively. In the three cases, the risk allele frequency is 20%, 16% and 10% higher in Indigenuos population than in European population. This regions have not been identified in previous GWAS studies thus it is important to replicate these results to confirm the involvement of these new regions.

P17.32-M
Selecting significant SNPs in Genome-wide Association Studies using a global False Discovery Rate

A. Mukherjee, **S. Bhattacharjee***;*
National Institute of BioMedical Genomics, Kalyani, India.

Standard methods for assessing significance in Genome-wide Association Studies (GWAS) are generally too stringent as they are based on controlling the Family-Wise Error Rate. The FDR (False Discovery Rate) approach provides a more realistic and less stringent alternative. However, controlling the FDR for correlated entities is difficult without making specific assumptions on the correlation structure that may not be realistic. In this study, we define an FDR-like criterion (global-FDR) for assessing statistical significance of SNPs in GWAS accounting for correlation (Linkage Disequilibrium) between neighboring SNPs. The criterion extends the local-FDR criterion of Efron and ensures control of the False Discovery Proportion (FDP) under arbitrary correlation structure. We develop a fast and easily scalable Gibbs-type iterative algorithm to approximate the posterior class membership probabilities that are otherwise hard to compute in general. Unlike the non-parametric estimation approach used in local-FDR, we use a parametric three-group normal mixture model for SNP Z-scores with a known correlation matrix. Using simulations under different correlation scenarios, we found that the global-FDR approach performs significantly better than local-FDR, both in terms of power and accurate control of the type-I error (FDP). We also considered a sequential procedure to select the most strongly associated SNPs from independent (non-redundant) regions of the genome discarding correlated surrogates in the same LD region. We assessed the sensitivity and specificity of our single-step and sequential SNP-selection strategies. The methods were also validated against known associated regions using published GWAS data from the Collaborative Association Study of Psoriasis.

P17.33-S
A genome-wide association study identifies two susceptibility loci for non-syndromic cleft lip with or without cleft palate in the Polish population

A. Mostowska[1], *P. Wójcicki*[2,3], *K. K. Hozyasz*[4], *K. Żukowski*[5], *A. Gurgul*[6], *A. Lasota*[7], *K. Wójcicka*[3], *D. Galas-Filipowicz*[1], *S. Matuszewska-Trojan*[1], *I. Dunin-Wilczyńska*[7], *P. P. Jagodziński*[1];
[1]*Department of Biochemistry and Molecular Biology, Poznan University of Medical Sciences, Poznan, Poland,* [2]*Plastic Surgery Clinic, Wroclaw Medical University, Wroclaw, Poland,* [3]*Department of Plastic Surgery, Specialist Medical Center, Polanica Zdrój, Poland,* [4]*Department of Pediatrics, Institute of Mother and Child, Warsaw, Poland,* [5]*Department of Animal Breeding and Genetics, National Research Institute of Animal Production, Balice n. Krakow, Poland,* [6]*Laboratory of Genomics, National Research Institute of Animal Production, Balice n. Krakow, Poland,* [7]*Department of Jaw Orthopedics, Medical University of Lublin, Lublin, Poland.*

Non-syndromic cleft lip with or without cleft palate (NSCL/P) is one of the most common congenital anomalies, with a complex and not yet fully elucidated etiology. Therefore, we conducted a genome wide association study (GWAS) for NSCL/P in a Polish population-based cohort consisting of 288 oral cleft cases and 576 controls. GWAS was carried out with the Illumina Human OmniExpressExome BeadChip technology. We confirmed the association between the previously identified 8q24.21 locus and the risk of NSCL/P. The most significant nucleotide variant in this 330-kb region (rs17242358) had a p-value of 3.21E-09. Under assumption of a dominant and recessive models, the calculated Odds Ratios for rs17242358 were 2.28 (95%CI: 1.70 - 3.06, p = 2.53E-08) and 2.99 (95%CI: 1.60 - 5.59, p = 3.32E-04), respectively. In addition, we found a novel cleft-associated region at chromosome 22q12.3, with a p value of 1.22E-08 for the most significant polymorphism (rs210804). The dominant model OR for the rs210804 variant was 8.20 (95%CI: 3.51 - 19.13, p = 1.19E-08). Four other chromosomal regions 6p12.3 (*DEFB112*), 22q12.3 (*MYH9*), 6p24.3 and 11q13.4 (*POLD3*) were associated with the NSCL/P risk at close to genome wide significance level (p values of 5.12E-08, 3.26E-07, 3.40E-07 and 8.15E-07, respectively). To confirm our GWAS findings further, larger sample size studies in different populations are needed.
Supported by grant no. 2012/07/B/NZ2/00115 from the Polish Ministry of Science and Higher Education.

P17.34-M
Family-Control analysis based on Hamming distance for prioritizing candidate sequence variants

A. Imai[1], *J. Ott*[2], *Y. Asano*[1], *Y. Sakata*[1], *S. Takashima*[1];
[1]*Osaka University, Suita, Japan,* [2]*Rockefeller University, New York, NY, United States.*

Linkage analysis has been used to narrow down disease loci for autosomal dominant (AD) traits. However, small pedigrees are underpowered for significant linkage results. We developed a novel method to detect disease loci in pedigrees.

For a set of basepairs flanking a candidate locus, we calculate Hamming Distance Ratio (HDR, proportion of basepairs differing between two individuals) for all pairs of individuals (an affected family member and 41 control individuals) and distinguish pairs containing the affected (group 1) from those that do not (group 2). We assess the difference in distribution of HDR values between the two groups by the Kolmogorov-Smirnov statistic at sets of variants 10KB to 100KB around each of ~600 candidate variants. In two hypertrophic cardiomyopathy families, known pathogenic mutations were previously detected: c.173G>A (p.R58Q) in MYL2 gene (rs104894369, family A) and c.746G>A (p.R249Q) in MYH7 gene (rs3218713, family B). We combine results over the 10 regions with suitable test statistics evaluated in permutation analyses and are able to narrow down known disease variants as small as 5% (rank as small as 29 out of 606 candidates, p=0.0001).
In a negative control, a restrictive cardiomyopathy pedigree with de novo mutation in the TNNI3 gene in one affected sibling, TNNI3 mutation was ranked 221th out of 631 variants.
Our new statistical method for prioritizing disease region by Hamming distance between affected family member and unrelated controls will be useful for small AD pedigrees and for differentiating AD and de novo mutations.

P17.35-S
Mitochondrial DNA variation analysis in historical provinces of Romania

R. Cocos[1,2], *S. Schipor*[3], *P. Cianga*[4], *L. C. Bohiltea*[1], *F. Raicu*[1,5];
[1]*Carol Davila University of Medicine and Pharmacy, Chair of Medical Genetics, Bucharest, Romania,* [2]*Genome Life Research Center, Bucharest, Romania,* [3]*National Institute of Endocrinology "C. I. Parhon", Romania, Bucharest, Romania,* [4]*Grigore T. Popa University of Medicine and Pharmacy, Department of Immunology, Iasi, Romania,* [5]*"Francisc I. Rainer"Anthropological Research Institute, Romanian Academy, Bucharest, Romania.*

Since the Middle Ages, Romanian population lived in three distinct provinces Wallachia, Moldavia and Transylvania until the 19th century. Over the centuries, their territories were repeatedly invaded by different peoples and subjected to external political influences resulting in demographic changes that could affected the genetic structure of populations. We performed mitochondrial DNA analysis in order to visualize the relationships between Romanian and other populations Europe based on HVSI and HVS II mtDNA sequence data using Sanger sequencing. We presented here a large scale mtDNA analysis of 612 Romanians from these historical provinces of Romania. Multidimensional scaling (MDS) plot was constructed from the pairwise Fst values. The results showed that present day Romanians in all provinces share their maternal ancestry with both eastern/central European and Balkan populations. The three populations of Romania analyzed here exhibit slightly different mtDNA lineage compositions, mainly consisting of the haplogroups H, U, J, T, K, N and W, with significant frequency differences corresponding for H, U and W haplogroups. H haplogroup accounts for 47% in Moldavia, 35 % in Wallachia and 33 % in Transylvania. Overall, this study provides a first comprehensive analysis of mtDNA genome variation in Romania revealing the existence of different degrees of provincial differences of haplogroup frequencies.

P17.36-M
Heritability of age related cognition

A. M. Töglhofer, *E. Hofer, K. E. Petrovic, P. Freudenberger, A. Fixa, R. Schmidt, H. Schmidt;*
Medical University of Graz, Graz, Austria.

The role of genetic and environmental factors in specific cognitive abilities in the elderly is poorly understood. Here we estimated their contributions to variation in the cognitive domains memory, executive function and fine motor skills and tested the genetic correlations between these domains.
The study was conducted in the Austrian Stroke Prevention Study (ASPS), a population-based cohort study (n=479, mean age=64.6 years, 54.9% women) and in the ASPS-Family including relatives of the ASPS participants (n=376, 177 families, mean age=63.6 years, 60.1% women). The neuropsychological test battery included Bäumler's Lern-und Gedächtnistest, Trail Making B, Digit Span Backward, the Wisconsin Card Sorting and the Perdue Pegboard Test. Heritability was estimated by variance component analyses using SOLAR and by SNP genotypes using GCTA. Bivariate heritability was computed using SOLAR. We adjusted for age, gender, education and APOE.
Heritability of memory, executive function and fine motor skills using family structure were 60, 41 and 59%, and 11, 23 and 29% using SNP genotypes. Genetic and environmental correlations between memory and executive function were 53% and 20%, between memory and fine motor skills 41% and 14%, respectively. We found no genetic correlation between executive function and fine motor skills, the environmental correlation was 37%.
There is a substantial heritability of memory and fine motor skills and a moderate of executive functions. Half of the heritability of executive function and fine motor skills can be explained by common SNP. Our results support shared genetic factors for executive function and memory as well as fine motor skills.

P17.37-S
Involvement of HMGA2 (High-Mobility Group A2) in Idiopathic Short Stature (ISS).

I. Fusco[1], *D. Babu*[1], *S. Mellone*[1], *A. Fanelli*[1], *R. Muniswamy*[1], *F. Prodam*[2], *S. Bellone*[2], *A. Petri*[2], *G. Bona*[2], *M. Giordano*[1];
[1]*Laboratory of Human Genetics, Department of Health Sciences, University of Eastern Piedmont, Novara, Novara, Italy,* [2]*Paediatric Unit, Department of Health Sciences, University of Eastern Piedmont, Novara, Novara, Italy.*

Several lines of evidences point to *HMGA2* as a candidate gene in ISS: i) independent GWAS identified some SNPs on chromosome 12q14 in the vicinity of *HMGA2* (rs1042725, rs7968682 and rs7968902) as one of the major determinants of height, ii) microdeletions on 12q14 have been identified in syndromic patients with short stature as common feature. Among these, one patient with only severe growth retardation carried the smallest deletion encompassing *HMGA2.* The aim of this study was to investigate the involvement of *HMGA2* in ISS through the search for mutations/deletions and perform an association study between the *HMGA2* SNPs and ISS. One hundred-four patients (48 males and 56 females) with height ranging from -3,8 and -2 SDS were analyzed by direct sequencing and MLPA. None of the patients carried mutation/deletion in the coding sequences and intron/exon boundaries. The same 104 patients and 330 normal stature matched controls were analyzed in an association study with rs7968682. The allele frequency was significantly different between patients and controls ($p=4x10^{-2}$). When the genotypes were considered the TT genotype showed an even stronger association ($p=6x10^{-3}$). In conclusion, our cohort of ISS patients did not show any pathological mutation in *HMGA2*, suggesting that high penetrance mutations are not a frequent cause of ISS. However our preliminary results suggest that *HMGA2* might be involved in the susceptibility to ISS. We are thus planning to replicate the data in an independent cohort and analyze the tag SNPs surrounding *HMGA2* to identify the variations directly responsible for the association.

P17.38-M
Thioredoxin reductase 1 (TXNRD1) gene variability influences quality of aging and longevity

G. Rose, *S. Dato, P. Crocco, G. Passarino;*
Department of Biology, Ecology and Hearth Sciences, Ponte Pietro Bucci cubo 4C, University of Calabria, 87036 Rende (Cs), Italy.

Oxidative stress is a major determinant of human aging and a common hallmark of age-related diseases. A protective role against free radicals accumulation has been shown for Thioredoxin (Trx) system and in particular thioredoxin-reductase TrxR, a key selenoprotein antioxidant enzyme, able to reduce Trx and other substrates, detoxifying cells from oxidative injuries. An effect of this antioxidant system in human aging can be hypothesized from the association reported between TrxR gene (TXNRD1) with late-life survival in a Northern-European nonagenarian cohort (Soerensen et al, 2013). Using a tagging approach, we investigated the association of 14 SNPs with longevity and quality of aging, by analyzing their variability in relation to markers of functional (Activities of Daily Living, ADL; Hand Grip, HG; Walking speed, WS) and cognitive (Mini Mental State Examination, MMSE) status, in a Southern-Italian elderly cohort (626 subjects, age range 65-104 years). The work confirms the association of TXNRD1 gene with human survival, with two intronic SNPs, rs7310505 and rs4964728, showing association with longevity ($p<0.04$). Furthermore, three other SNPs, two intronic (rs7962423, rs10861203) and one located in the promoter region (rs1128446), were significantly associated with ADL, HG and WS ($p<0.05$). Haplotypic analyses confirmed the single-SNP results. Moreover, bioinformatic analyses indicated the associated SNPs as putative regulatory sites, whose function should be further experimentally investigated.
On the whole, this study confirms a role of Trx antioxidant system on human age-related functional decline and longevity, possibly mediated by modulation of oxidative stress.

P17.39-S
Genetic analysis of thyroid peroxidase (TPO) gene in patients whose hypothyroidism was found in adulthood in West Bengal, India

B. Bankura[1], *S. Chowdhury*[2], *M. Das*[1];
[1]*University of Calcutta, Kolkata, India,* [2]*Institute of Post Graduate Medical Education & Research, Kolkata, India.*

Recent research has revealed that genetic defects due to mutation in the Thyroid Peroxidase (TPO) gene can lead to thyroid dysfunction in the population. We aimed to study the association between genetic defects in TPO

gene and patients with hypothyroidism found in adult age. Two hundred consecutive treatment naive hypothyroid patients (age ≥ 18 years) (cases) who were negative for anti TPO antibody and their corresponding sex and age matched two hundred normal individuals (controls) were enrolled. The 17 exonic regions of the TPO gene were amplified and sequenced directly. We identified 6 different previously known single nucleotide polymorphisms (SNPs) and 2 novel deletions in TPO gene. Two of the six SNPs revealed a significant association with hypothyroidism; Thr725Pro (rs732609) and Asp666Asp (rs1126797). The c.2173C allele of the Thr725Pro in TPO showed a significant association among hypothyroid patients compared to controls (p = 0.01; Odds ratio=1.45; 95% CI: 1.09–1.92) suggesting it to be a potential risk allele toward disease predisposition. Analysis of genotype frequencies of the polymorphism between the two groups demonstrated CC as a potential risk genotype (p = 0.006; Odds ratio=1.95; 95% CI: 1.2–3.15) for the disease while another SNP Asp666Asp (c.1998T allele) showed protectiveness towards the disease (p = 0.006; Odds ratio = 0.67; 95%CI: 0.50-0.89). To our knowledge, this is first study reporting the role of TPO gene with hypothyroidism in a population of Asian Indian origin. The study threw up the possibility of TPO gene polymorphisms as a possible pathogenetic mechanism of hypothyroidism.

P17.40-M
Genes involved in interleukin-1 receptor type II (IL1R2) activities are associated with asthma related phenotypes

V. Vaillancourt[1], *E. Bouzigon*[2,3], *C. Sarnowski*[2,3], *F. Monier*[2,3], *M. H. Dizier*[2,3], *F. Demenais*[2,3], *C. Laprise*[1];
[1]*UQAC, chicoutimi, QC, Canada,* [2]*INSERM, Paris, France,* [3]*Université Paris Diderot, Paris, France.*

We previously demonstrated that *IL1R2* (Interleukin-1-receptor-type-II) is overexpressed in bronchial biopsies of allergic asthmatic individuals and we also associated it with atopy (n>5500). This study aims to test for the effect of SNPs and interactions between 182 SNPs belonging to nine genes involved in *IL1R2* activities on asthma related phenotypes in the Saguenay-Lac-St-Jean familial asthma collection (SLSJ) and in French families of the Epidemiological study on the Genetics and Environment of Asthma (EGEA)). Single SNP analysis was performed using Family-Based Association Tests software (FBAT). In order to correct for multiple tests, we used a critical P-value threshold equal to $2x10^{-4}$ that took into account the number of independent SNPs and independent phenotypes. Interactions between SNPs were tested using Unphased software. SLSJ and EGEA results were combined through meta-analysis using the Stouffer's Z-score method. No SNP reached the critical threshold for significance but suggestive association were observed. The rs3732131 SNP in *IL1R1* was associated with asthma (p=0.0004), atopy (p=0.0005) and allergic asthma (p=0.002). We also found associations between three SNPs in *ERAP1* and allergic asthma ($0.0006 \leq p \geq 0.001$). Regarding SNPxSNP interactions, four interactions were found in SLSJ at $p<1.0X10^{-4}$ and one of those was replicated in EGEA for atopy (p=0.002, combined $p=3.62X10^{-7}$) between rs2241343 of *IL1RAP* and rs10208708 of *IL1R1*). The observed SNP-associations in the combined SLSJ and EGEA samples and the SNPxSNP interaction suggest that genes involved in the IL1R2 activities play a role in asthma and, especially in its allergic component.

P17.41-S
The frequency of SHOX mutations in patients with mild short stature is comparable to the frequency detected in severe Idiopathic Short Stature

D. Babu[1], *S. Mellone*[1], *I. Fusco*[1], *R. Muniswamy*[1], *F. Prodam*[2], *S. Bellone*[2], *A. Petri*[2], *G. Bona*[2], *M. Giordano*[1];
[1]*Laboratory of Human Genetics, Department of Health Sciences, University of Eastern Piedmont, Novara, Novara, Italy,* [2]*Paediatric Unit, Department of Health Sciences, University of Eastern Piedmont, Novara., Novara, Italy.*

Mutations within the pseudo-autosomal Short stature Homeobox gene (*SHOX*, Xp22.33 and Yp11.3) and the downstream enhancer are among the few known causes of Idiopathic Short Stature (ISS). Routine diagnostic testing for the genetic alterations in this gene is carried out in ISS patients, selected with strict criteria regarding the phenotype, who generally show a good response to GH treatment. We analysed 217 ISS patients by sequencing and MLPA to screen for deletion/duplication in the coding sequence and the downstream enhancer region. Among these patients, 90 were severe short stature with a height SDS ranging from -3.9 to -2.0 and 127 patients had a milder phenotype with a height SDS ranging from -1.9 to -0.9. The age at diagnosis was 8.6±3.9 and did not differ significantly between the two groups. Mutations were identified in 7 patients (7.7%) with the most severe phenotype and in 7 patients (5.5%) with mild short stature. There was no significant difference in the mutation number, types and the extension of the detected deletions between the two groups. All the available relatives of the probands were analysed for segregation analysis. Consequently to the high recombination frequency within PAR1 region we observed several *SHOX* mutations moving from the Y to X chromosome and vice versa. This must be taken into consideration in genetic counselling. Notably, this study revealed the presence of SHOX mutations in individuals with mild short stature with a frequency comparable to that observed in ISS selected with the stringent classical criteria.

P17.42-M
Insights into the genetic variability of Italian population inferred from 2.5M single-nucleotide polymorphisms

C. Di Gaetano[1], *G. Fiorito*[2,1], *F. Rosa*[2], *S. Guarrera*[2], *B. Pardini*[2], *A. Piazza*[1,2], *G. Matullo*[1,2];
[1]*Department of Medical Sciences, University of Turin, Turin, Italy,* [2]*HuGeF Human Genetic Foundation, Turin, Italy.*

Aim: This study aims to characterize the genetic variability within Italian population and the level of inter-population variation between the Mediterranean basin and the Italian peninsula.
Methods: A total of 314 samples, collected from the Italian peninsula and Sardinia island were genotyped, with more than 2,370,000 single-nucleotide polymorphisms investigated. Newly acquired data were analyzed together with the already available genome-wide data sets of individuals of the Mediterranean basin. Several analyses have been performed to investigate intra e inter-population variability.
Results: The analysis highlighted that Italy is one of the genetically most diverse region within Southern Europe. These results may be due to the country's complex demographic history, to the large longitudinal extension of the territory and because of its position as a sort of natural bridge in the center of the Mediterranean basin.
Conclusion: We confirmed the high genetic diversity of some areas within Italy, such as Sardinia, and of other populations located along boundaries of the Italian territory.
We showed that the current genetic landscape of the Italian Peninsula may be explained by isolation-by-distance rather than a barrier to gene flow and may also reflect a genetic exchange for the Southern Italian populations between the 2 coasts of the Mediterranean basin.

P17.43-S
Familial Hypercholesterolemia screening in Patients with Coronary Artery Disease

I. Braenne[1,2], *M. Kleinecke*[1,2], *B. Reiz*[1,2], *E. Graf*[3], *T. Strom*[3,4], *T. Wieland*[3,4], *T. Meitinger*[5,4], *H. Schunkert*[6,4], *J. Erdmann*[1,2];
[1]*Institute for Integrative and Experimental Genomics, University of Luebeck, Luebeck, Germany,* [2]*DZHK (German Research Centre for Cardiovascular Research), partner site Hamburg/Luebeck/Kiel, Luebeck, Germany,* [3]*3 Institute of Human Genetics, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany,* [4]*DZHK (German Centre for Cardiovascular Research), partner site Munich Heart Alliance, Munich, Germany,* [5]*Institute of Human Genetics, Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Germany,* [6]*Deutsches Herzzentrum München, Technische Universitätt München, Munich, Germany.*

Background: Familial hypercholesterolemia (FH) is an autosomal-dominant disease that leads to markedly elevated low-density-lipoprotein cholesterol (LDLC) levels and high risk for premature coronary-artery disease (CAD). Despite well-established criteria for clinical diagnosis, it is estimated that in most European countries only around 5% of FH are identified. One hypothesis is that FH is simply overlooked in the large number of unselected CAD patients. Moreover, variable LDLC-levels and small family sizes may hamper the clinical diagnosis. Around 90% of known FH disease-causing mutations are found in the LDLR gene. Hence, systematic molecular-genetic screening of the LDLR gene in patients with premature CAD may improve diagnosis and allow preventive treatment of mutation carriers.
Aim: To evaluate the frequency of FH, we screened LDLR gene for deleterious mutations in 256 unselected CAD patients with disease manifestation before the age of 50 years.
Methods and Results: We filtered for rare (<1% 1000G) and non-synonymous variants. Around 6% of the screened CAD patients carried deleterious variants in the LDLR gene. The 10 variants were confirmed using Sanger-sequencing and validated by co-segregation. Nine are reported to cause FH. One of the reported variants (rs45508991) was found in six unrelated CAD patients. This variant shows incomplete co-segregation and is also found in internal control samples. Some of the identified LDLR-variants were also found in family members without a known manifestation of CAD but elevated LDLC levels.
Conclusion: These results underline the need for molecular-genetic screening to diagnose FH and to allow timely preventive treatment.

Study homozygosity disequilibrium in human genome using the whole-genome sequencing data

H. C. Yang[1,2], *Y. T. Lin*[1];
[1]*Institutue of Statistical Science, Academia Sinica, Taipei, Taiwan,* [2]*School of Public Health, National Defense Medical Center, Taipei, Taiwan.*

Homozygosity disequilibrium (HD), a non-random sizable run of homozygosity in the human genome, has been found related to the evolution of populations and able to confer susceptibility to diseases. In this study, we characterized HD in global populations based on the whole-genome sequencing data of 1,092 individuals from 14 populations of the 1000 Genomes Project. The whole-genome homozygosity intensity was estimated by using LOHAS (Yang et al, Genetic Epidemiology, 2011). Using the homozygosity intensity we identified common genomic regions undergoing HD. We found a high proportion of regions of HD to be population-specific but also identified functionally important regions of HD shared by multiple populations. Genetic differentiation of global populations can be characterized using the patterns of HD. In summary, this large-scale whole-genome sequencing study derives the distribution of HD in the human genome and proves that HD carries genetic information of human population important for studying genetic background. The information also provides important clues for the differential disease prevalence and drug responses in populations.

P17.45-S

A signal near FRMD4A is associated with lower extremity arterial disease in patients with type 2 diabetes in GoDARTS

N. R. van Zuydam[1], *C. N. A. Palmer*[2], *H. M. Colhoun*[2], *SUMMIT;*
[1]*University of Oxford, Oxford, United Kingdom,* [2]*University of Dundee, Dundee, United Kingdom.*

Lower extremity arterial disease (LEAD) is a common macrovascular complication of type 2 diabetes (T2D). Twin studies of ankle brachial index (ABI), the main diagnostic criterion of LEAD, estimate the heritability of ABI at ~30%. Two genome wide signals have been identified for LEAD near CHRNA3 and 9p21.3 irrespective of diabetes status. The aim of this study was to identify genetic determinants of LEAD in patients with T2D. LEAD cases were patients with T2D and an ABI < 0.9 or ABI>1.3 and or mid-thigh to mid-foot amputations and or corrective procedures related to LEAD and or prescriptions for medication used to treat claudication. Controls were patients with T2D free of LEAD, coronary artery disease and ischaemic stroke. Allelic effects of 5,882,833 SNPs estimated from 1223 LEAD cases and 5638 LEAD free controls were combined in fixed-effects 1000G meta-analysis. A signal represented by rs72780858 near FRMD4A reached genome wide significance (p=3.7E-8). SNPs in FRMD4A have been associated with nicotine dependence which may influence smoking status. Smoking is known to increases the risk of LEAD 10 fold. Other suggestive signals are located near genes that contain genome wide significant hits for risk factors related to LEAD: rs271946 (p=8.1E-6) near PCSK1 (T2D); rs34562 (p=8.2E-6) near EFNA5 (Coronary artery disease) and rs75417257 (p=1.2E-6) near CCSER1 (Glomerular filtration rate and albumin excretion rate). This is the first study of the genetic determinants of LEAD in patients with T2D and several signals including one at genome wide significance were identified.

P17.47-S

Molecular screening of major thalassemia mutations observed in 2012-2013 in eastern Sicily

S. Cara, *C. Di Bella, V. Procopio, M. Amorini, M. A. La Rosa, C. D. Salpietro, L. C. Rigoli; Department of Pediatrics, Medical School, Messina, Italy, Messina, Italy.*

In this study we evaluated the incidence of alpha, beta and delta thalassemia in the province of Messina, in the past two years.
236 people were analyzed (Molecular Genetics Laboratory of Genetics and Immunology Pediatric UOC), after healthy carrier screening of I and II level of Thalassemia by the diagnostic procedure that provides for the CBC, the determination of the hemoglobin fractions and the assessment of iron status. The phenotypic framework (classical and non classical), who had hematological parameters indicative of mutations at the level of alpha clusters and/or non-alpha-globin, were studied by molecular analysis of related genes. This investigation has shown that in the alpha globin gene, the $-\alpha^{3.7}/\alpha\alpha$ (genotype frequency 13,1%; allele frequency 7,83%) is the most common genotype, followed by the α_2IVS1:-5nt α/WT (genotype frequency 4,66 %; allele frequency 2,33%), and the $-\alpha^{20.5}$/WT (genotype frequency 2,11%; allele frequency 1,05%) genotypes; instead, in the beta globin gene, the βcd39/WT(genotype frequency 5,08%; allele frequency 2,54) is the most typical genotype, followed by the βIVS1:6/WT (genotype frequency 3,81%; allele frequency 2,75%) and the βIVS1:110/WT (genotype frequency 3,81%; allele frequency 1,90%) genotypes; and finally, in the delta globin gene, the δcd 27/WT (genotype frequency 6,35%; allele frequency 3,17%) is the most common genotype found, with the δcd142 C>A(Hb Fitzory)/WT (genotype frequency 0,42% %; allele frequency 0,21%) and the δIVS2:1/WT (genotype frequency 0,42%; allele frequency 0,21%) genotypes. These data show the importance of a careful assessment about haematological indices to carry out a correct diagnosis of genetic defects.

Variations in ncRNA gene LOC284889 and MIF-794CATT repeats are associated with malaria susceptibility in Indian populations

S. Pandarisamy, *A. N. Jha, V. K. Singh, T. Kumarasamy;*
Centre for Cellular and Molecular Biology, Hyderabad, India.

LOC284889 is an uncharacterized ncRNA gene on reverse strand to *MIF* mapped to 22q11.23. MIF, a lymphokine, regulates innate immune response by up-regulating the expression of *TLR4*, suppressing the p53 activity and has been shown to be involved in malaria pathogenesis. In this study, the possible effect of *MIF* variations on malaria susceptibility was investigated by re-sequencing the complete *MIF* gene along with 1 kb each of 5′ and 3′ region in 425 individuals from malaria endemic regions of the Orissa and Chhattisgarh states of India. The subjects comprised of 160 cases of severe malaria, 101 of mild malaria and 164 ethnically matched asymptomatic controls. Data were statistically compared between cases and controls for their possible association with *Plasmodium falciparum* malarial outcome. It is the first study, which shows that the allele *A* (rs34383331*T* > *A*) in ncRNA is significantly associated with increased risk to *P. falciparum* malaria [severe: OR = 2.08, p = 0.002 and mild: OR = 2.09, P = 0.005]. In addition, it has been observed that the higher *MIF-794CATT* repeats (>5) increases malaria risk (OR = 1.61, p = 0.01). Further, diplotype (*MIF-794CATT* and rs34383331*T* > *A*) *5 T* confers protection to severe malaria (OR = 0.55, p = 0.002) while *6A* (OR = 3.07, p = 0.001) increases malaria risk. These findings support the involvement of ncRNA in malarial pathogenesis and further emphasize the complex genetic regulation of malaria outcome. In addition, the study shows that the higher *MIF-794CATT* repeats (>5) is a risk factor for severe malaria. The study would help in identifying people who are at higher risk to malaria and adapt strategies for prevention and treatment.

P17.49-S

Epidemiology of Meckel-Gruber syndrome in Europe: a registry-based study

I. Barisic[1], *L. Boban*[1], *M. Loane*[2], *E. Garne*[3], *D. Wellesley*[4], *E. Calzolari*[5], *H. Dolk*[2], *EUROCAT Working Group, EUROCAT Working Group;*
[1]*Children's Hospital Zagreb, Medical School University of Zagreb, Zagreb, Croatia,* [2]*EUROCAT Central Registry, University of Ulster, Newtonabbey, United Kingdom,* [3]*Pediatric Department, Hospital Lillebaelt, Odense, Denmark,* [4]*Wessex Clinical Genetics Service, Princess Anne Hospital, Southampton, United Kingdom,* [5]*Registro IMER, Unita di Terapia Intensiva Neonatale e Neonatologia,Azienda Ospedaliero-Universitaria di Ferrara, Ferrara, Italy.*

Meckel-Gruber syndrome is a rare autosomal recessive lethal ciliopathy characterized by the triad of cystic renal dysplasia, occipital encephalocele and postaxial polydactyly. We present the largest population-based epidemiological study to date using data provided by the European Surveillance of Congenital Anomalies (EUROCAT) network of congenital anomaly registries. The study population consisted of 191 cases of Meckel-Gruber syndrome identified between January 1990 and December 2011 in 34 European registries. The mean prevalence of Meckel-Gruber syndrome was 2.6 per 100 000 births. The prevalence was stable, but regional differences were observed. There were 145 (75.9%) terminations of pregnancy after prenatal diagnosis, 13 (6.8%) fetal deaths, 33 (17.3%) live births and of these 11 (33%) neonatal deaths. In addition to cystic kidneys (97.7%), encephalocele (83.9%) and polydactyly (87.3%), frequent features include other central nervous system anomalies (68.8%), fibrotic/cystic changes of the liver (65.5% of cases with post mortem examination) and orofacial clefts (31.8%). Various other anomalies were present in 64 (37%) patients. As nowadays most patients are detected very early in pregnancy when liver or kidney changes may not yet be developed or may be difficult to assess, none of the anomalies should be considered obligatory for the diagnosis. Most cases (90.2%) are diagnosed prenatally at 14.3±2.6 (range 11-36) gestational weeks and pregnancies are mainly terminated, reducing the number of live births to one fifth of the total prevalence rate. Early diagnosis is important for timely counseling of affected couples regarding the option of pregnancy termination and prenatal genetic testing in future pregnancies.

P17.50-M

Genetic markers predicting menopausal age associate with diabetes and lipid traits in 11864 Finns

A. Joensuu[1,2], *J. Kettunen*[1,2], *S. Ripatti*[1,2,3], *J. Sinisalo*[4], *M. S. Nieminen*[4], *M. Lokki*[5], *A. Jula*[6], *V. Salomaa*[2], *M. Perola*[2,1,7], *K. Auro*[2,1];
[1]*Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland,* [2]*National Institute*

for Health and Welfare (THL), Helsinki, Finland, [3]Hjelt Institute, University of Helsinki, Helsinki, Finland, [4]Heart and Lung Center HUCH, Helsinki University Central Hospital, Helsinki, Finland, [5]Haartman Institute, University of Helsinki, Helsinki, Finland, [6]National Institute for Health and Welfare (THL), Turku, Finland, [7]University of Tartu, Tartu, Estonia.

Later age at menopause has been associated with decreased risk of cardiovascular diseases and increased life expectancy, but associations with diabetes are controversial and no genetic links have been reported. Additionally, smoking lowers and obesity raises menopausal age, which might disturb the seen associations. Stolk et al. reported of 17 genetic polymorphisms which associate with menopausal age (Nat Genet. 2012). We constructed a genetic score of menopausal age by summing the reported effect sizes (years/allele) of these polymorphisms in four Finnish cohorts (FINRISK1997, PredictCVD, Health2000 and Corogene) and studied its associations to common diseases and their risk factors. Linear, logistic and survival analysis corrected by age and geographical variables were performed in individual cohorts and combined in meta-analysis.
One-year increase in the genetic score (range -2.3 - 3.1 years) associated significantly with future diabetes in women (N=2831, hazard ratio=1.46, P=0.0083) but not in men (P=0.3). Interestingly, the genetic score associated nominally (P<0.05) with prevalent diabetes in men (N=5547, odds ratio=0.87, P=0.042) but no association was seen in women. In women nominal association of higher menopausal age score was seen also with higher triglyceride levels and lower HDL cholesterol. Controlling for BMI and smoking did not affect these associations.
Our results suggest that the genetic variants associated with the timing of menopause in women have different effects on metabolism in different genders. In women polymorphisms raising menopausal age raise also the risk of future diabetes 1.5-fold whereas in men the same variants have a slight protective effect on prevalent diabetes.

P17.51-S

Exome-wide association analysis of 4,522 individuals from the Oxford Biobank study reveals novel low frequency variants influencing human serum metabolite levels

K. Banasik[1,2], *M. A. Rivas[1], A. Mahajan[1], M. Neville[3,4], M. Ala-Korpela[5,6,7], M. I. McCarthy[1,3], F. Karpe[3,4];*
[1]Wellcome Trust Centre for Human Genetics, Oxford, United Kingdom, [2]The Novo Nordisk Foundation Center for Basic Metabolic Research, Section on Metabolic Genetics, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, [3]Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, United Kingdom, [4]NIHR Oxford Biomedical Research Centre, OUH Trust, Oxford, United Kingdom, [5]Computational Medicine, Institute of Health Sciences, University of Oulu, Oulu, Finland, [6]NMR Metabolomics Laboratory, School of Pharmacy, University of Eastern Finland, Kuopio, Finland, [7]Computational Medicine, School of Social and Community Medicine and the Medical Research Council Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom.

Small molecule metabolites are intermediates in disease pathways, and identification of genetic variants influencing metabolite concentrations could provide insight into disease pathogenesis. Common variant effects have been thoroughly scrutinised, but the impact of low frequency (LF) variants (minor allele frequency (MAF) <5%) remains largely unexplored.
Here we report an exome-wide association study of metabolite concentrations in 4,522 healthy individuals (age 29-53 years, 55% women) from the population-based Oxford Biobank study. Approximately 230,000 markers were genotyped using the Illumina HumanExome Beadchip and tested for association with 123 metabolites (80 lipoproteins, 15 lipids, 22 low molecular weight metabolites, and 6 ratios related to fatty acid saturation) quantified by nuclear magnetic resonance of serum samples. After log normalisation, inverse normalised residuals were generated adjusting for age, gender, and principal components. A linear mixed model was used assuming an additive genetic effect. In the single marker analyses, we identified 15 loci with genome-wide significant associations (p<5x10-8) for one or more metabolites. For two of the loci, the strongest signal involved a LF marker. We also performed gene-level tests: using SKAT for protein-altering variants (MAF<1%) we identified two novel genes (p<2x10-6) associated with alanine (PI16, p=4x10-7) and glycoprotein acetyls (C8A, p=2x10-6), both of them driven by single variants with large effects. An analysis focused on protein-truncating variants (using SEMGEM) revealed a significant association between COQ10A and glutamine (log10 (Bayes factor)=4.25). The identification of genetic variants influencing metabolite concentrations will allow us to explore the causal relationships between these metabolites, other metabolic risk factors and disease.

P17.53-S

A common functional polymorphism in miR-196a2 is associated with waist to hip ratio

M. Ghanbari, *S. Sedaghat, M. J. Peters, J. B. van Meurs, A. G. Utterlinden, A. Hofman, O. Franco, A. Dehghan;*
Erasmus medical Center, Rotterdam, Netherlands.

MicroRNAs (miRNAs) are small non-coding RNAs that function as crucial regulators in a broad range of biological processes. They have recently gained extensive attention as mediators of complex disorders and highlighted as promising diagnostic biomarkers for cardiometabolic diseases. Given the central role of miRNAs in gene expression, genetic polymorphisms in miRNA genes are expected to alter miRNA processing and function that may contribute to disease susceptibility. Here we retrieved 788 single nucleotide polymorphisms (SNPs) in all pre- and mature miRNA sequences and systematically investigated their association with 17 cardiometabolic traits. We used data of the largest meta-analyses of genome wide association studies (GWAS) on glycemic hemostasis indices, lipid traits, blood pressure, coronary artery disease, type 2 diabetes, and anthropometric measures including information up to 133,000 individuals. We found that a common variant in miR-196a2 (rs11614913:T>C) is significantly associated with waist to hip ratio (WHR) (p-value =3.4×10^{-5}). To explore whether this miRNA affect WHR, we examined the association of all miR-196a2 target genes with this phenotype and revealed *SFMBT1* to be significantly (p-value =2.8×10^{-6}) and *SMAD6* suggestively (p-value = 6.9×10^{-5}) associated with WHR. Additionally, a trans-expression quantitative trait loci (eQTLs) analysis in 762 subjects of the Rotterdam Study suggested an increased trend in the expression levels of *SFMBT1* and *SMAD6* in individuals carrying the risk allele. These findings may help improve our understanding of the regulatory role of miRNAs in fat distribution.

P17.54-M

A robust strategy for the calculation of Allele Frequencies from NGS data of pooled DNA samples

S. Anand[1,2], *E. Mangano[1], R. Bordoni[1], N. Barizzone[3], L. Corrado[3], M. Sorosina[4], S. Santoro[4], F. Martinelli-Boneschi*[4,5], S. D'Alfonso*[3], G. De Bellis*[1];*
[1]Institute for Biomedical Technologies (ITB) - National Research Council (CNR), Milan, Italy, [2]Department of Science and Technology, University of Sannio, Benevento 82100, Italy, [3]Department of Health Sciences and Interdisciplinary Research Center of Autoimmune Diseases (IRCAD), University of Eastern Piedmont, Novara, Italy, [4]Laboratory of Genetics of Neurological Complex Disorders, Institute of Experimental Neurology (INSPE), Division of Neuroscience, San Raffaele Scientific Institute, Milan, Italy, [5]Department of Neurology, Institute of Experimental Neurology (INSPE), Division of Neuroscience, San Raffaele Scientific Institute, Milan, Italy.

Sequencing large number of individual genomes at high coverage, which is needed for population genetics studies, is still economically challenging despite substantial reduction in cost of NGS in recent years. An alternative approach is to sequence DNA from pools of individuals which has other potential benefits like: needing less DNA from each single individual and less time in sample preparation.
We have developed a robust strategy for the analysis of DNA sequencing data from pooled individuals and the calculation of allele frequency (AF) of identified sequence variations. We used CRISP [1] to call the variants, ANNOVAR to annotate them, and custom R-scripts to calculate AF. We applied this strategy in targeted re-sequencing (1.9Mb) of 600 (12 individuals * 50pools) Italian Multiple Sclerosis (MS) patients. For 129 variants, AFs have been independently validated by genotyping the single individuals with SNP-array. For each pool, the comparison of AFs in NGS pool data and those at the single individual level with SNP-array shows an excellent concordance between the two methods: mean correlation R^2=0.976 ± 0.004, and mean delta frequencies = (2.5 ± 0.2)*10^{-2}. Moreover, the comparison of AF with that of 1000 genomes (European individuals) for further 5980 SNPs showed an excellent concordance: mean difference of AF = (3.07±.05)*10^{-2}. Overall, we show that pooling the samples for population genetics and disease association studies is a robust and cost- and time-saving alternative to single sample NGS analysis.

Whole-genome sequencing of an Italian multiple sclerosis multiplex family identifies a novel functional variant in the GRAMD1B gene.

F. Martinelli Boneschi[1], *F. Esposito[1], A. Osiceanu[1], M. Sorosina[1], S. Santoro[1], A. Zauli[1], D. Cittaro[2], A. Calabria[3], D. Lazarevic[2], V. Masella[2], P. Brambilla[1], P. Provero[2], E. Stupka[2], G. Comi[1];*
[1]Department of Neurology & Laboratory of Genetics of Neurological Complex Disorders, Division of Neuroscience, INSPE, Scientific Institute San Raffaele, Milan, Italy, [2]Center of Translational Genomics & Bioinformatics Scientific Institute San Raffaele, Milan, Italy, [3]San Raffaele Telethon Institute for Gene Therapy (HSR-TIGET), Scientific Institute San Raffaele, Milan, Italy.

BACKGROUND: While the role of common genetic variants is clearly established from recent studies on sporadic cases of multiple sclerosis (MS), the contribution of rare variants is unclear. AIMS: To identify rare genetic

variants contributing to MS susceptibility in an Italian multiplex family. DESIGN: SNP microarray genotyping and whole-genome sequencing (WGS) in 4 MS patients and 4 unaffected individuals belonging to an Italian multiplex family descending from a first cousin marriage were performed. RESULTS: We identified 437 variants with high functional impact, two of which under one of the two LOD peaks on chromosome 8p21.2 and 11q23.3. The first one is in the OR8G5 gene, an olfactory receptor gene under positive selection, while the second one falls within the GRAMD1B gene, causing an aminoacid substitution (S601P). This second variant is not present in dbSNP and in the 1,000 Genome project, and segregates within the family, being homozygote in 3 affected and heterozygote in the left MS patient. Sanger sequencing confirmed the segregation with the disease. GRAMD1B is a very conserved gene from yeast to human. It encodes a membrane protein, which is part of the GRAM containing domain family protein. In the mouse it is highly expressed in the CNS and in specific immune cell subtypes, like dendritic cells and neutrophils. CONCLUSIONS: The use uf WGS in an Italian MS multiplex family has been successful in identifying novel rare genetic variants. Further investigations are ongoing to explore the role of the variant on protein function and its involvement in MS.

Statistical methods for the analysis of gene expression in single-family studies for genetic and complex disease

S. Merella[1], *F. Esposito*[2], *P. Brambilla*[2], *M. Sorosina*[2], *F. Martinelli Boneschi*[2], *E. Stupka*[1], *P. Provero*[1,3];
[1]*Center for Translational Genomics and Bioinformatics, San Raffaele Scientific Institute, Milan, Italy,* [2]*The Laboratory of Genetic of Neurological Complex Disorders, INSPE & Division of neuroscience, San Raffaele Scientific Institute, Milan, Italy,* [3]*Dept of Molecular Biotechnology and Health Sciences, University of Turin., Turin, Italy.*

Multiplex families are a powerful tool to investigate heritability of genetic components in complex disease. Heritability can be investigated using gene expression analysis with specific challenges. Previously developed approaches were focused on identifying significant genes across families but each family can present different genetic makeup producing heterogeneous gene expression. Moreover it is important to disentangle the strong genetic component of gene expression from the disease effect or other factors affecting gene expression, such as environmental exposures.
We developed a statistical method for the analysis of gene expression data from single-family studies to minimize the problem in interpreting these data. We applied the Ornstein-Uhlenbeck model previously used to describe evolutionary processes. The model has been transferred to a context in which the quantitative trait has different values in diseased and healthy individuals and it is defined by trees derived from family pedigrees to explicitly model the inheritance of gene expression, thus to identify those genes that are affected by the disease status. In order to validate the method, simulated datasets were generated starting from a family pedigree taking into accounts the genetic component and the disease status of every gene for every individual. We also used a real dataset from a family pedigree with 4 multiple sclerosis affected individuals. The results obtained on simulated datasets reports that the OU model provides increased sensitivity with respect to traditional gene expression analysis approaches. The analysis of the MS affected family also identified genes and pathways relevant to the disease.

P17.57-S
Simultaneous estimation of the locations and effects of multiple disease loci in case-control studies

L. Chien, **Y. Chiu**;
National Health Research Institues, Zhunan, Taiwan.

The genetic basis of complex diseases often involves multiple linked causative loci. Under such a disease etiology, assuming one disease locus in linkage disequilibrium mapping is likely to induce bias and lead to efficiency loss in disease locus estimation. An approach is needed for simultaneously localizing the positions of multiple functional loci. However, due to the increasing number of parameters accompanying disease loci, these estimates can be computationally infeasible. To circumvent this problem, we propose to estimate the main and gene-gene interaction effects and a nuisance parameter at the disease loci separately through a linear approximation. Estimates of the genetic effects are entered into a generalized estimating equation to estimate disease loci, and the procedure is conducted iteratively until convergence. The proposed method provides estimates and confidence intervals (CIs) for the disease loci, the genetic main effects, and the interaction effects between loci, with the CIs for the disease loci providing useful regions for further fine-mapping. We apply the proposed approach to a data example of case-control studies. Results of the simulations and data example suggest that the developed method performs well in terms of bias, variance, and coverage probability, regardless of the underlying number of disease loci.

Evolutionary analysis identifies an MX2 haplotype associated with natural resistance to HIV-1 infection

R. Cagliani[1], *M. Sironi*[1], *M. Biasin*[2], *F. Gnudi*[2], *I. Saulle*[2], *C. Pontremoli*[1], *A. Caruz*[3], *M. Clerici*[4,5];
[1]*Scientific Institute IRCCS E. Medea, Bosisio Parini, Italy,* [2]*University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy,* [3]*University of Jaen, Immunogenetics Unit, Department of Experimental Biology, Jaen, Spain,* [4]*University of Milan, Chair of Immunology, Department of Physiopathology and Transplantation, Milan, Italy,* [5]*Don C. Gnocchi Foundation ONLUS, IRCCS, Milan, Italy.*

The protein product of the MX2 (myxovirus resistance 2) gene restricts HIV-1 and simian retroviruses. We demonstrate that MX2 evolved adaptively in mammals with distinct sites representing selection targets in rodents and primates; selection mainly involved residues in loop 4, previously shown to carry antiviral determinants. Modeling data indicated that positively selected sites form a continuous surface on loop 4, which folds into two antiparallel α-helices protruding from the stalk domain. Population genetic analyses demonstrated that natural selection operated on MX2 during the recent history of human populations: distinct selective events drove the frequency increase of two haplotypes in populations of Asian and European ancestry. The Asian haplotype carries a susceptibility allele for melanoma; the European haplotype is tagged by an intronic variant. Analyses performed on three independent European cohorts of HIV-1 exposed seronegative individuals with different geographic origin and distinct exposure route showed that the ancestral allele of the intronic variant protects from HIV-1 infection with a recessive effect (combined p value = 1.55x10-4). The same allele is associated with lower in vitro HIV-1 replication and increases MX2 expression levels in response to IFN-α. Data herein exploit evolutionary information to identify a novel host determinant of HIV-1 infection susceptibility.

P17.59-S
Improving power in family-based association of rare variants via wavelet-based test

H. Wang, *Y. Lin, C. Fann;*
Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan.

With the advances in next generation sequencing (NGS) technology, a huge amount of data on high dimensional genomic variant was generated and the association of rare variants with complex disease was analyzed for finding the etiology of disease. A variety of statistical approaches for the analysis of rare variants were developed in population-based designs. However, many common diseases such as cancer, diabetes, cardiovascular disease, immune disorders and psychiatric disorders are known to cluster in pedigrees. Recently, many researches have modified existing population-based methods for detecting the family-based association of rare variants such as family-based collapsing methods, family-based functional principal component analysis (FPCA) and extended FBAT method. Rare variants may provide contributions to detect disease gene, however, the existence of noisy signals reduced the power of association. In this study, we modified the wavelet-based test in family-based design to increase power by suppressing noise and therefore reducing false positives. Using simulations with several types of data structure, our proposed method generated a reasonable type I error rate and a comparable or better power (0.4~0.7). We demonstrated that our proposed method can increase power relative to other existing association tests (family-based smoothing FPCA, family-based collapsing methods and extended FBAT) in the presence of genetic heterogeneity. Finally, we illustrated our approach to analyze the association of rare variants using cardiovascular disease from the Framingham Heart Study.

Whole exome sequencing: Follow-up of a rare non-synonymous variant in GRHL3 in a German family with nonsyndromic orofacial clefting

A. C. Böhmer[1,2], *P. Gültepe*[1,2,3], *L. Gölz*[4], *H. Reutter*[1,5], *T. H. Beaty*[6], *I. Ruczinski*[7], *M. M. Nöthen*[1,2], *M. Knapp*[8], *E. Mangold*[1], *K. U. Ludwig*[1,2];
[1]*Institute of Human Genetics, University Bonn, Bonn, Germany,* [2]*Department of Genomics, Life and Brain Center, University of Bonn, Bonn, Germany,* [3]*Department of Medical Biology and Genetics, Marmara University, Instanbul, Turkey,* [4]*Department of Orthodontics, University of Bonn, Bonn, Germany,* [5]*Department of Neonatology, University of Bonn, Bonn, Germany,* [6]*Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [7]*Department of Bioistatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [8]*Institute of Medical Biometry, Informatics and Epidemiology, University of Bonn, Bonn, Germany.*

Nonsyndromic cleft lip with or without cleft palate (nsCL/P) is one of the most common congenital malformations and has a complex multifactorial etiology. In the context of a large collaborative study, whole exome sequen-

cing (WES) was performed in two distantly related cousins of an extended nsCL/P family of German origin. After stringent filtering of variants shared between both individuals, one variant in the grainy-head like 3 (GRHL3) gene was identified as potentially causal. This variant, rs138381915, is located in exon 13 and the potential risk allele mediates an amino acid change (p.Arg490His) of the GRHL3 protein. Prediction programs (Polyphen, Mutation Taster) predict this alteration to be disease-causing. Sequencing datasets (ESP6500, dbSNP, 1000genomes) report the frequency of the minor allele at rs138381915 to be below 0.5 %. Literature search revealed GRHL3 as an interesting candidate gene for nsCL/P. Based on the hypothesis that rs138381915 might be the causal variant in the family, we first confirmed the variant in the two index probands by Sanger Sequencing. We then tested all other (29) family members for whom DNA was available for the presence of the putative risk allele. Of these (10 affected, 19 unaffected), the risk allele was observed in a heterozygous state in seven individuals, only two of them were affected. Five individuals carried the putative risk allele but were not affected. Eight affected individuals did not carry the putative risk allele. These data suggest that rs138381915 is unlikely to be a causal variant regarding the nsCL/P phenotype in this particular family.

Novel mutations described in Saudi Arabia

J. Y. Alaama[1], **A. Y. Edrees[2]**;
[1]King abdulaziz University, Jeddah, Saudi Arabia, [2]Princess Al Jawhara Center of Excellence in Research of Hereditary Disorders, Jeddah, Saudi Arabia.

Jeddah is the second largest city in the Kingdom of Saudi Arabia with a population of over 5 million. The Genetic Medicine Department at King Abdul-Aziz University is the major referral center for genetic disorders in Jeddah and was established in 2005. Over this period 1842 patients and families with genetic disease were seen. Patients were assessed clinically and where indicated by genetic testing.They were categorized into the following types based on etiology: chromosomal, single gene disorders, multifactorial, mitochondrial and others. They were then further subdivided into categories. Most mutations identified were novel and different from the western literature. We will present the types of genetic diseases present and the novel mutations identified both locally and nationally and put forward recommendations for future studies including the current set up of a data bank will discussed.

Contribution of SNPs (rs9939609 and rs8057044) and haplotypes of FTO gene to the genetic risk for obesity in children from Yucatan, Mexico

L. J. Gonzalez-Herrera, *M. Lopez-Gonzalez, Z. Cardeña-Carballo, G. Perez-Mendoza, A. Andrade-Olalde, D. Pinto-Escalante;*
Universidad Autonoma de Yucatan, Merida, Mexico.

The fat mass and obesity-associated (FTO) gene has been identified as a strong candidate for obesity-related phenotypes in several populations. Significant associations of the SNPs rs9939609 and rs8057044 with body mass index (BMI) and with the risk for obesity have been suggested in homozygotes AA. The central role of FTO might be through an effect on cerebrocortical insulin sensitivity. Each FTO risk allele increases BMI by 0.26 to 0.66 units (kg/m2), and the odds of being obese by ~1.3. In this study, we evaluated the association of the SNPs (rs9939609 and rs8057044) and haplotypes of FTO gene with the risk for obesity in children from Yucatan, Mexico; where child obesity is the first cause of morbidity. We included 155 obese children, and 189 non-obese healthy children under a case-control association study. Genotype and allele frequencies between cases and controls were compared using SNPstats software. Genotype and allele frequencies were distributed according to Hardy-Weinberg expectations ($p>0.05$) in cases and controls, except for rs9939609-FTO in controls ($p<0.05$). Significant differences were found for the heterozygous AT genotype of the SNP rs9939609-FTO ($p= 0.03$) between cases and controls, suggesting that the heterozygous AT genotype of rs9939609-FTO might be a genetic risk factor associated with child obesity in the population of Yucatan. No significant associations were found for the SNP rs8057044 nor for the haplotypes of FTO gene ($p>0.05$). However homozygotes for the A allele showed a higher mean BMI and higher waist circumference than TT or GG allele carriers.

P17.63-S
Molecular Analysis of *TYR, OCA2, TYRP1* , *SLC45A2* and *GPR143* Genes in 158 Patients with Oculocutaneous and Ocular Albinism

L. Mauri[1], E. Manfredini[1], S. Penco[1], A. Del Longo[2], G. Marsico[2], M. Mazza[2], M. C. Patrosso[1], G. P. Gesu[1], E. Piozzi[2], **P. Primignani[1]**;
[1]S.S. Genetica Medica, Dip. di Medicina di Laboratorio, A.O. Niguarda Ca' Granda, Milan, Italy, [2]S.C. di Oculistica Pediatrica, A.O. Niguarda Ca' Granda, Milan, Italy.

Albinism is an heterogeneous group of inherited genetic diseases present at birth. This disorder can affect all ethnic backgrounds with an overall prevalence of approximately 1/17.000 people but prevalence of the different forms of Albinism varies considerably worldwide. It can be classified as Ocular Albinism (OA1) caused by mutations in the *GPR143* gene located on the X-chromosome, or as Oculocutaneous Albinism (OCA) an autosomal recessive inherited condition. OCA1-4 forms are recognized based on the expression of mutations in four different genes: *TYR*, *OCA2*, *TYRP1* and *SLC45A2*. A cohort of 158 OCA or OA1 subjects were recruited from the Medical Genetic Unit and Department of Pediatric Ophthalmology of Niguarda Ca' Granda Hospital of Milan (Italy) and characterized for *TYR*, *OCA2*, *TYRP1*, *SLC45A2* and *GPR143* gene defects, associated to the different phenotypes, in order to describe their frequencies variation in Italian population. We identified *TYR* mutations in 83 subjects (66,6% missense, 11,1% nonsense, 8,5% frameshift, 2,6% deletions in frame, 9,2% splicing mutations and 2% exons deletion), *OCA2* mutations in 34 subjects (70,2% missense, 5,2% frameshift, 15,8% splicing mutations and 8,8% exon deletions), *TYRP1* mutations in 4 patients (42,9% missense and 57,1% nonsense mutations), *SLC45A2* mutations in 12 patients (63,66% missense, 4,55% nonsense, 22,74% frameshift and 9.1% splicing mutations) and *GPR143* mutations in 7 subjects (14,3% missense, 14,3% nonsense, 42,8% frameshift, 14,3% splicing mutations and 14,3% exon deletions). Here we also report about the OCA1-4 and OA1 gene frequencies in our cohort of albino patients (mainly of Italian origin).

P17.64-M
Genetic landscape of populations along the Silk Road reveals a haplotype associated with hyposmia in Tajikistan's population

M. Mezzavilla[1,2], *S. Ulivi[2], P. Gasparini[1,2], V. Colonna[3];*
[1]University of Trieste, Trieste, Italy, [2]Institute for Maternal and Child Health - IRCCS "Burlo Garofolo", Trieste, Italy, [3]Institute of Genetics and Biophysics „A. Buzzati-Traverso", National Research Council (CNR), Napoli, Italy.

Smell is a versatile mechanism for recognizing different odours and is mediated by olfactory receptors. While collecting phenotypes related to smell in six countries along the Silk Road, we found an increased rate of failure to discriminate odorants in individuals from Tajikistan respect to the other countries. Using haplotype-based association we linked this to a 15 kb region within olfactory receptor gene cluster on chromosome 6 (p-value 3.86e-05). This region is embedded in the largest intron of OR5V1 and is downstream OR11A1 and upstream OR12D3. We also analysed genetic variability in 1,114 unrelated samples either from the Silk Road and ten other worldwide populations at over 300,000 polymorphic sites and characterized population genetic structure of the Silk Road within a worldwide context with a resolution never obtained before. We identified genetic components peculiar to Central Asia and observed that Tajikistan behaves as an outlier population. Indeed Tajiks share a consistent number of unusually large stretches of homozygosity and have the lowest effective population size (Ne) among the studied populations, most likely as the result of past isolation and/or consanguinity. Altogether these novel findings clarify the complex genetic patterns of the Silk Road populations and suggest that the smell misperception phenotype observed in Tajikistan might be the result of a combination of genetic drift and relaxed selection at the olfactory receptors genes.

P17.65-S
Targeting a gene network of ADAMTS genes contributing to pediatric stroke

A. Witten[1], *A. Arning[1], A. Barysenka[1], M. Hiersche[1], F. Rühle[1], C. Strauss[1], U. Nowak-Göttl[2], M. Stoll[1];*
[1]Genetic Epidemiology, lifa at the University of Muenster, Muenster, Germany, [2]Institute of Clinical Chemistry, University Hospital Schleswig-Holstein, Kiel, Germany.

Pediatric stroke (PS) is an important childhood disease and several genetic polymorphisms contributing to PS risk have been established in numerous candidate gene based association studies. Recently, we have reported results of the first family-based genome wide association study identifying a gene network of ADAMTS genes in the predisposition to PS. To investigate possible causative gene variants in the resulting linkage disequilibrium based candidate regions; we performed a next generation resequencing approach in 48 affected children and 48 unaffected siblings. The selected target regions of about 6.8Mb comprise 42 gene regions including ADAMTS2, ADAMTS12, ADAMTS13 and ADAMTS17. Custom target enrichment was performed using the NimbleGen SeqCap EZ Choice technology. The resulting DNA libraries were paired-end sequenced (100 cycles) on an Illumina HiScanSQ instrument yielding in 300 Gb sequence data in total and 87.1% bases with a QScore > 30. Sequence reads were mapped by using the BWA algorithm and analyzed by GATK yielding in 80% median target specificity and median target region coverage of 176x. Variant annotation was done by using SNPEff and Annovar software tools. A sibship disequilibrium test was applied on the 16,586 identified variants, 4060 of which were novel, to compare the

two sample groups. 32 significant (p<0.05) coding non-synonymous or UTR SNPs in 14 genes were identified and selected for validation using capillary sequencing and subsequent genotyping within the full cohort of 270 nuclear families. The resulting data may help to understand the genetic architecture of ADAMTS genes and their impact on PS.

P17.66-M
A genome-wide association study of Agreeableness suggests a novel association in the NAV2 gene in Korean women

H. Kim[1], *S. Roh*[1], *B. Kim*[1], *H. Kim*[1], *H. Cho*[1], *N. Cho*[2], *C. Shin*[3], *J. Sung*[4], *H. Kim*[1];
[1]Ewha Womans University, Seoul, Korea, Republic of, [2]Ajou University, Seoul, Korea, Republic of, [3]Korea University, Seoul, Korea, Republic of, [4]Seoul National University, Seoul, Korea, Republic of.

Data from genome-wide association (GWA) studies have been used to find the common variants of personality. In a previous study, we reported that neurotransmitters and the olfactory receptor 1A2 gene are associated with neuroticism in a cohort of young Korean women. However, many genetic variants that are highly associated with certain personality traits are still unknown. Here, we report on a meta-analysis of GWA data for personality in three cohorts samples (2045 individuals). All participants were of Korean ancestry. Personality traits were measured with the Revised Neuroticism-Extraversion-Openness Personality Inventory to assess five factors: Neuroticism, Extraversion, Agreeableness, Openness, and Conscientiousness. In either discovery stage, classical association analyses were performed under an additive model followed by meta-analysis using the weighted inverse variance method. We observed consistent direction of effect and significant association of the NAV2 gene and Agreeableness in either the discovery and combined stage (p=7.85×10-7, for meta-analysis). NAV2 gene involves in optic nerve development and sensory perception of smell and sound. We previously reported that the sensory system may play an important role in personality, and the present study leads to the same conclusion. The sensory system affects personality as a filter of the acceptance system, which may have an advantage to reconstruction.
This study was supported by a grant of the National Project for Personalized Genomic Medicine, Ministry for Health & Welfare, Republic of Korea (A111218).

P17.67-S
New genetic matching methods for handling population stratification in genome-wide association studies

A. Lacour[1], *T. Becker*[1,2];
[1]German Center for Neurodegenerative Diseases (DZNE), Bonn, Germany, Bonn, Germany, [2]Institute of Medical Biometry, Informatics and Epidemiology (IMBIE), Bonn, Germany.

A usually confronted problem in association studies is the occurrence of population stratification. In this talk, we propose a decisive extension to the Cochran-Armitage Trend test in order explicitly take into account structures obtained from matchings and clusterings. We employ pairwise and groupwise optimal case-control matchings and present an agglomerative hierarchical clustering, both based on a genetic similarity score matrix. By simulations of genotype data under the null hypothesis we assess our framework, in order to affirm that it correctly controls for the type-1 error rate. By a power study we ascertain, that structured association testing using our framework displays reasonable power. We compare the results from our methods with those obtained from a logistic regression model with principal component covariates. We also highlight and discuss a possible false-positive association to Alzheimer's disease using the principal components approaches, which is neither reproduced by our new methods nor by the results of a most recent large meta analysis.

P17.68-M
The causal role of insulin-like growth factors and binding proteins in prostate cancer: a Mendelian randomization study

C. Bonilla[1], *M. Rowlands*[1], *S. J. Lewis*[1], *T. Palmer*[2], *T. R. Gaunt*[1,3], *G. Davey Smith*[1,3], *D. Gunnell*[1], *J. L. Donovan*[1,3], *F. C. Hamdy*[4], *D. E. Neal*[5], *the PRACTICAL consortium, M. Lathrop*[6,7], *R. M. Martin*[1,3,8], *J. M. P. Holly*[1];
[1]University of Bristol, Bristol, United Kingdom, [2]University of Warwick, Warwick, United Kingdom, [3]MRC Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom, [4]University of Oxford, Oxford, United Kingdom, [5]University of Cambridge, Cambridge, United Kingdom, [6]McGill University, Montreal, QC, Canada, [7]Commissariat a l'Energie Atomique, Centre National de Génotypage, Evry, France, [8]NIHR Bristol Biomedical Research Unit in Nutrition, University of Bristol, Bristol, United Kingdom.

Epidemiological studies reported positive associations of circulating IGF-I and IGF-II, and inverse associations of IGF binding protein 3 (IGFBP-3) with prostate cancer risk, whilst IGFBP-2 has been associated with low grade disease. However, systematic review findings have been inconsistent which may reflect confounding or reverse causality. We examined the causal role of IGF-I, IGF-II, IGFBP-2 and IGFBP-3 in prostate cancer using multiple genetic variants to construct allelic scores as instruments for measured circulating IGFs and IGFBPs, in a Mendelian randomization approach.
We investigated 1131 SNPs, previously reported to be associated with IGFs and IGFBPs, in ~700 population controls from the ProtecT study. We generated allelic scores that consisted of the most strongly -and exclusively- associated SNPs with each biomarker. Finally, we used the allelic scores and instrumental variable analysis to estimate the causal effect of IGFs and IGFBPs on prostate cancer in ~40,000 cases and controls from 21 studies included in the international PRACTICAL consortium.
IGF-I and IGF-II were positively associated with prostate cancer risk. The estimated causal odds ratios for the effect of a standard deviation (SD) increase in circulating IGF-I and IGF-II was 1.15 (95% CI 1.06, 1.26) and 1.14 (95% CI 1.02, 1.26), respectively. Notably, IGF-II increased risk for advanced and high grade disease. Conversely, IGFBP-2 and IGFBP-3 were not associated with prostate cancer susceptibility. In conclusion, this Mendelian randomization study provides additional support for a causal relationship between IGF-I and IGF-II and prostate cancer risk.

P17.69-S
Combining different sources of information to optimise genomic prediction of complex traits

A. Spiliopoulou[1], *R. Nagy*[1], *J. Huffman*[1], *M. Bermingham*[1], *C. Hayward*[1], *I. Rudan*[2], *H. Campbell*[2], *A. Wright*[1], *J. Wilson*[2], *R. Pong-Wong*[3], *C. Haley*[1,3], *F. Agakov*[4], *P. Navarro*[1];
[1]MRC Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom, [2]Centre for Population Health Sciences, University of Edinburgh, Edinburgh, United Kingdom, [3]The Roslin Institute and Royal (Dick) School of Veterinary Studies, University of Edinburgh, Edinburgh, United Kingdom, [4]Pharmatics Limited, Edinburgh, United Kingdom.

In the last decade there has been substantial progress in identifying genetic loci associated with complex phenotypes but limited progress in using genomic information to predict phenotypic performance. In this study, we assess the advantage of using previously published results to inform genomic predictors of complex traits. Our goal is to compare model performance with respect to trait architecture and latent population structure. We consider linear, additive models with different sparsity levels, either learned from the data using lasso or elastic nets, or determined a priori by considering markers and their corresponding effects from large meta-analysis association studies. We characterise the predictive signal captured by each model and explore whether prediction accuracy can be increased by combining these simpler predictors into a meta-model.
We evaluate predictive performance using height, body mass index and high density lipoproteins in two population cohorts, originating in Croatia and Scotland. We examine how to maximise prediction accuracy when the target individuals come from the same or a different population to the training samples. Our results demonstrate that between population prediction is possible using samples from the target population to perform model selection, subject to sample size and trait architecture. Furthermore, we show that a model combining the predictions from penalised regression with meta-analysis-based polygenic scores performs better than either model on its own. Our findings suggest that incorporating previous results into statistical models as well as exploiting the predictive signal from latent data structure can lead to improved predictions of complex traits.

P17.70-M
Technical issues of using Next Generation sequencing for rare-variant association

C. G. F. de Kovel, *R. van ,t Slot, B. P. C. Koeleman;*
UMC Utrecht, Utrecht, Netherlands.

To assess the role of rare variants in multifactorial diseases, next-generation sequencing in combination with targeted enrichment is used to provide genotypes. Subsequently, statistical methods such as SKAT are used to compare case and control data in various ways. For GWAS, the use of datasets from different sources for cases and controls has been adequately addressed. For NGS, the role of data quality is less clear. To test our ability to perform rare-variant association, we set up a pilot experiment, including 64 samples with juvenile myoclonic epilepsy, a multifactorial disorder, 64 with epileptic encephalopathy, a presumed monogenic disorder, and 64 healthy controls, in the same way as a larger experiment for a set of 348 genes. We analysed whether batch effects and other lab variables could affect the outcome of the association.
Between two series of library preparation about five months apart differences in coverage and complexity were visible, as well as differences in the number of detected variants, especially rare variants. Within a series of library preparation, different runs on the sequencing machine had different quality characteristics, but the differences in number of variants between runs were small. We tried various methods of correction, but no correction

removed batch effects beyond all doubts.
Based on our experiences, the use of control sequences from earlier experiments or even other labs cannot be recommended. It is likely to lead to spurious associations or lack of associations.

P17.71-S
A Script for Linkage Analysis of Rare variants

I. Zorkoltseva, *T. Axenovich;*
Institute of Cytology and Genetics, Novosibirsk, Russian Federation.

For the past years genome-wide association analysis provided progress in detection of common genetics variants contributing to variation in many common disorders and quantitative traits. However, for many traits, genome-wide significant associations did not result in the establishment of the causal underlying variants. Now, whole-exome resequencing of large population samples and formation of databases of annotated functional variants may help to solve this problem. Causal functional variants with a large effect on the variation of traits are rare in populations, but can be aggregated in families. Analysis of samples from isolated populations makes possible to detect genetically informative families where rare variants co-segregate with diseases or traits. To facilitate a search for families with aggregation of the rare variants of interest from extended pedigrees or samples from isolated population and then to test its co-segregation with trait by the methods of linkage analysis we developed a software LARA (Linkage Analysis of Rare Allele). LARA combine commonly used package for linkage analysis MERLIN (Abecasis et al 2002) and PedCut software (Liu et al 2008) for the pedigree splitting into a set of sub-pedigrees. LARA searches for rare allele carriers, automatically generates and transfers the data, necessary for the analysis. LARA can help to test all functional variants located in the genomic regions already detected by linkage or associations methods. The software LARA is freely available at http://mga.bionet.nsc.ru/soft/index.html.

P17.72-M
Correcting for population substructure in rare variant - rare disease association studies

N. Zhu[1], *V. Heinrich*[1], *P. Krawitz*[1], *P. N. Robinson*[1], *T. Dickhaus*[2];
[1]*Institute for Medical Genetics and Human Genetics, Berlin, Germany,* [2]*Weierstrass Institute for Applied Analysis and Stochastics, Berlin, Germany.*

Sophisticated techniques have been developed for genome wide association studies (GWAS) to correct for population substructure that may cause substantial inflation of test statistics and spurious associations. For rare variants in spatially structured populations the existing methods do not effectively control for stratification. We developed an approach to build up a control group that is most similar to the individuals in the case group considering all exomic variants especially also the rare ones. We show with simulations of real exome data that the power of association studies for rare variants can be optimized if case-control groups are similarity-matched. We also found that the power could be further improved when we increased the control:case group ratio by adding additional exome data.

P17.73-S
Functional linear model for regional association analysis of rare genetic variants in family-based samples

G. R. Svishcheva, *N. M. Belonogova, T. I. Axenovich;*
Institute of Cytology and Genetics, Novosibirsk, Russian Federation.

Methods based on the linear regression models are widely used for genome-wide association analysis of family-based samples. To use these models for region-based analysis, a collapsing approach is commonly used. However its power decreases if effects of causal variants have opposite directions.
We developed a new method for the region-based association analysis of family-based samples, using techniques of functional data analysis. The individual discrete genotypes and effects of multiple variants in the analyzed region are considered as the continuous data, which can be described by stochastic functions constructed on the physical positions of the variants, using a finite set of basis functions. Thus, under the functional linear model, the genetic effects of the multiple variants are described by coefficients of the basis functions. The null hypothesis of zero values for the coefficients is tested by standard statistical tests. We introduced a covariance matrix defined through a relationship matrix in the trait inheritance model to take into account a genetic relationship between individuals. High power of our method is provided by the simultaneous consideration of genetic information on not only genotypes of multiple variants, but also their physical positions, and by taking into account related structure of the samples. Our method is implemented in the software package FFB-FLM available for free download (http://mga.bionet.nsc.ru/soft/FFB-FLM/).

Genome wide inbreeding estimation within Lebanese communities using SNP arrays

N. Jalkh[1,2], *M. Sahbatou*[3], *E. Chouery*[1], *A. Megarbane*[1], *A. Leutennegger*[4,5], *J. Serre*[2];
[1]*Unité de Génétique Médicale et Laboratoire associé INSERM à l'Unité UMR_S910, Faculté de Médecine, Université Saint-Joseph, Beirut, Lebanon,* [2]*EA 2493 « pathologie cellulaire & génétique, de la conception à la naissance », Université de Versailles-Saint Quentin en Yvelines, Paris, France,* [3]*Fondation Jean Dausset-CEPH, Paris, France,* [4]*Université Paris Diderot, Institut Universitaire d'Hématologie, UMR-S946, Paris, France,* [5]*Inserm, U946, F-75010, Paris, France.*

Consanguineous marriages have been widely practiced, with variable rates, in several global communities depending on religion, culture, and geography. The populations of the Middle East are among those with the highest inbreeding level and frequency of inbred individuals. A genome wide analyses of 165 unrelated Lebanese has been performed either through the estimation of LOH (Loss of Heterozygosity) or through the FEstim algorithm depending on SNP frequencies. Relying on these genome-wide data that identify regions of homozygosity by descent (HBD), this study was able to estimate total inbreeding levels, remote consanguinity, and population admixture and structure. The inbreeding coefficient value was estimated to be 1.6% in offspring of unrelated parents (over 3 generations) and 8% in offspring of first cousins. In either case, the remote consanguinity (RC) value was approximately equal to 0.6% resulting from genetic drift or recurrent consanguineous unions. This RC value suggests that for any unrelated marriages in Lebanon, the mates could be related as third cousins or as second cousins once removed. Under the hypothesis that 25% of marriages occur between first cousins, the mean inbreeding (F) value of 2.2% found may explain the increased incidence of recessive disease within offspring. The LOH and FEstim genome wide approaches were applied to investigate the genomic similarity of Lebanese communities. Both approaches revealed a unique ancestral population of the four studied communities (Greek Orthodox, Maronite, Shiite and Sunni).

Population genomics analysis in whole genome sequencing of 152 rhesus macaques

F. Yu[1], *C. Xue*[1], *M. Raveendran*[1], *G. Fawcett*[1], *S. White*[1], *D. R. Deiros*[1], *A. Harris*[1], *M. Dahdouli*[1], *W. Salerno*[1], *Z. Johnson*[2], *E. Vallender*[3], *R. Wiseman*[4], *H. M. Kubisch*[5], *L. Cox*[6], *S. Kanthaswamy*[7], *B. Ferguson*[8], *D. Muzny*[1], *R. Gibbs*[1], *J. Rogers*[1];
[1]*Baylor College of Medicine, Houston, TX, United States,* [2]*Yerkes National Primate Research Center, Atlanta, GA, United States,* [3]*New England NPRC, Southborough, MA, United States,* [4]*Wisconsin NPRC, Madison, Madison, WI, United States,* [5]*Tulane NPRC,, Covington, LA, United States,* [6]*Southwest NPRC,, San Antonio,, TX, United States,* [7]*California NPRC,, Davis, CA, United States,* [8]*Oregon NPRC,, Beaverton,, OR, United States.*

Rhesus macaques (Macaca mulatta) are the most widely studied nonhuman primate model species in biomedicine, critical to various aspects of disease research. We applied next generation whole genome sequencing for 152 unrelated individuals (144 Indian-origin, 8 Chinese-origin) using either deep (30X) or low coverage (6X) strategies. Analysis using SNPTools identified 51.6 million SNPs. On average, Indian-origin individuals have >9.5 million variants, while Chinese animals have >12 million, representing much higher diversity than humans. Current effective population size (Ne) is estimated at 65,000 for Indian-origin animals, 79,000 for Chinese-origin. Both estimates are substantially higher than values for humans. Analyses also reveal dramatic demographic changes over time in details to more than 10 million years ago. Functional annotation in coding sequences found >250,000 missense variants and >4600 stop-codon-gained mutations. In addition, about 110,000 SNPs mapped to conserved ENCODE transcription factor binding motifs. We used position weight matrices from the JASPAR database to assess these SNPs and found >25,000 candidate variants that may significantly affect TF binding, and thus gene expression. We mapped rhesus SNPs to the 4% of the genome identified as conserved across 29 mammals, and found reduced SNP density and MAF, consistent with negative selection in those regions. We also applied a number of site frequency spectrum tests and found significant new evidence for both positive and negative selection in both coding and noncoding regions in the macaques. Analyses of LD and local recombination rates are in progress.

P17.76-M
Association of five confirmed risk gene polymorphisms with Rheumatoid Arthritis in the Algerian population

M. Fodil[1,2], *A. Benzaoui*[3], *F. Zemani-Fodil*[1], *M. Aberkane*[1], *W. Boughrara*[1], *E. Petit-Teixeira*[2], *A. Boudjema*[1];

Objectives: The aim of this study was to investigate the role of five con-

firmed gene polymorphisms (PTPN22rs2476601, STAT4rs7574865, IRF5rs2004640, TRAF1/C5rs10818488 and TNFAIP3rs6927172) in Rheumatoid Arthritis risk among the Algerian population.
Methods: The study sample comprised 110 patients with RA and 197 ethnically matched healthy control subjects. Each polymorphism was genotyped using a predesigned TaqMan® assay. Allele and genotype frequencies in patients and control subjects were compared by chi-square test and odds ratios with 95% confidence intervals CI.
Results: Statistically significant association of all studied polymorphisms with RA was detected. The strongest signal was obtained for PTPN22 (rs2476601) with an allelic P value = 10-11 (OR = 9.83, 95% CI [4.28 - 22.56]).
Conclusion: This case/controls study lead, for the first time in the Algerian population, to highlight the association of five risk genetic factors with RA. This contributes to the characterization of RA genetic component in a population still under genetic investigation.

How does this Arab Genome differ from other genome?

I. B. N. M. Alabdulkareem, *M. A. Aljumah, M. A. Albalwi;*
King Abdullah International Research Center, Riyadh, Saudi Arabia.

Whole genome from Caucasian, African, Chinese and Korean individuals have been studied and published to date. Here, we successfully generated, assembled and analyzed the first full genome of a 32 Saudi healthy volunteers from using NGS technology (5500xl Genetic Analyzer). Alignment of the Saudi genome with H19 references revealed nearly more than 1.7 million unique SNPs. However, SNPs comparison analysis with HapMap phase III populations showed the highest share was with ASW population (1,545,053) while the lowest share was noticed to be with JPT population (1,280,257). The SNPs counts and frequencies per chromosome were partitioned into heterozygous and homozygous categories ranging from 258,174 SNPs (chromosome 2) to 1,182 SNPs on Y chromosome. The SNP frequency was calculated by dividing the number of called SNPs by the length of the covered consensus sequence, omitting unknown regions from the reference genome. The heterozygous and homozygous SNPs frequency was calculated based on their share of the total number of SNPs. A de novo assembly of 9,011 contigs sequences was not represented in NCBI reference genome. This project is pointing to perform a whole genome/exome of 1000 Saudi individuals towards Establishment Saudi Genome Database for comprehensive view of genetics variant such as large structural rearrangement and SNPs. Conversely, the whole genome/exome of some of the common chronic diseases in the Saudi population is already started such as multiple sclerosis.

P17.79-S
Soluble CD40 ligand is regulated by membrane CD40 expression in platelet concentrates

C. Aloui[1,2], *C. Sut*[1], *S. Tariket*[1], *A. Prigent*[1,2], *J. Fagan*[2], *F. Cognasse*[1,2], *O. Garraud*[1], *S. Laradi*[1,2];
[1]*GIMAP-EA3064, Faculté de médecine, Université de Lyon, 42023 Saint-Etienne, France, Saint-Etienne, France,* [2]*Etablissement Français du Sang Auvergne-Loire, 42023 Saint-Etienne, France, Saint-Etienne, France.*

Introduction:
Soluble CD40 ligand (sCD40L) is a platelet-derived proinflammatory mediator that accumulates during platelet storage. Unfortunately, in some cases, high levels of sCD40L cause acute transfusion reactions (ATRs). We investigated 2 polymorphisms previously associated with high levels of plasma sCD40L in some diseases, in the aim to identify 'dangerous' platelet concentrates (PCs).
Material and methods:
Levels of sCD40L were measured by Luminex® in 142 PCs (EFS Auvergne-Loire). We performed a Tetra-primer ARMS-PCR to genotype CD40-rs1883832 [C>T] and CD40L-rs3092952 [A>G]. Differences of plasma sCD40L concentrations among groups of genotypes were compared by ANOVA followed by Bonferroni correction (significance when P<0.017).
Results:
Genotype frequencies didn't deviate from Hardy-Weinberg expectations.
The distribution of genotypes for CD40L-rs3092952 was 68, 43 and 30 for AA+A, AG and GG+G respectively. No difference was observed between the 3 genotypes in sCD40L levels.
The distribution of genotypes for CD40-rs1883832 was 68, 52 and 8 for CC, CT and TT respectively. sCD40L was higher in PCs derived from donors with TT genotype (TT vs CC: P<0.001; TT vs CT: P<0.001; CT vs CC: P=0.7).
Discussion:
The CD40-rs1883832 polymorphism has been reported to regulate CD40 expression. sCD40L may activate cells expressing CD40 receptor as in platelets. We hypothesize that those with TT genotype may express a high amount of CD40 on their surface and thus may capture sCD40L, becoming more activated, thus secreting more sCD40L.
Further studies are required in larger samples to confirm this result allowing the discard of PCs with high sCD40L amounts and consequently preventing ATRs.

P17.80-M
Inferring rare disease risk variants based on exact probabilities of sharing by multiple affected relatives

I. Ruczinski[1], *A. Bureau*[2];
[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*Universite Laval, Quebec, QC, Canada.*

Family based study designs are regaining popularity because large-scale sequencing can help to interrogate the relationship between disease and variants too rare in the population to be detected through any test of association in a conventional case-control study, but may nonetheless co-segregate with disease within families. When only a few affected subjects per family are sequenced, evidence that a rare variant may be causal can be quantified from the probability of sharing alleles by all affected relatives given it was seen in any one family member under the null hypothesis of complete absence of linkage and association. We present a general framework for calculating such sharing probabilities when two or more affected subjects per family are sequenced, and show how information from multiple families can be combined by calculating a p-value as the sum of the probabilities of sharing events as (or more) extreme. We also examine the impact of unknown relationships and propose methods to approximate sharing probabilities based on empirical estimates of kinship between family members obtained from genome-wide marker data. We apply this method to a study of 55 multiplex families with apparent non-syndromic forms of oral clefts from four distinct populations. Whole exome sequencing was performed by the Center for Inherited Disease Research (CIDR) on two or three affected members from each family. The rare single nucleotide variant rs149253049 in the gene ADAMTS9 was shared by affected relatives in three Indian families (p=2e-6), illustrating the power of this sharing approach.

P17.81-S
A Founder Effect for PPIB-associated recessive osteogenesis imperfecta in Acadian and Cajun Populations

L. M. Currie[1], *U. Schwarze*[2], *D. Leistritz*[2], *E. N. Aberg*[1], *L. Gaudet*[3,4], *L. Murphy-Kaulbeck*[3,4], *P. H. Byers*[2,5], *L. S. Penney*[1,4];
[1]*IWK Health Centre, Halifax, NS, Canada,* [2]*Department of Pathology, University of Washington, Seattle, WA, United States,* [3]*Horizon Health Network, The Moncton Hospital, Moncton, NB, Canada,* [4]*Dalhousie University, Halifax, NS, Canada,* [5]*Department of Medicine, University of Washington, Seattle, WA, United States.*

Mutations in PPIB, a gene that encodes cyclophilin B, a prolyl cis-trans isomerase, cause recessively inherited osteogenesis imperfecta (OI) that ranges in severity from moderately deforming to perinatal lethal. Among Acadians in New Brunswick and Cajuns in Louisiana, who represent geographically distinct populations derived from the same ancestral group in France, we identified 2 families from the Acadian group and 2 from Louisiana, both presumed to be from the Cajun group, with severe/lethal OI caused by a homozygosity for a previously unreported PPIB mutation (c.344-1G>T, IVS3-1G>T). All transcripts from this allele use a cryptic acceptor site 5nt into exon 4 that results in a frameshift and mRNA instability. Both Canadian families presented prenatally; the first family had features of a lethal skeletal dysplasia on ultrasound and on autopsy was thought to have perinatal lethal OI. The second family was thought to have a severe moderately deforming OI on ultrasound. The two families from Louisiana presented with clinical diagnoses of perinatal lethal OI. None had mutations in COL1A1 or COL1A2. There is no known consanguinity within these families or relationships between them.
Because of the probable founder effect for PPIB-associated recessive OI among Acadians and Cajuns, likely tracing back to early 17th century France, in pregnancies/children of Acadian/Cajun ancestry (and their antecedents) presenting with severe skeletal dysplasia, PPIB-associated OI should be considered. Targeted analysis based on ethnic background may help facilitate more timely diagnosis and subsequent genetic counselling.

P17.82-M
Genetic survival modeling with large-scale population cohorts

C. Benner[1], *M. Pirinen*[1], *E. Tikkanen*[1,2], *S. Ripatti*[1,2,3];
[1]*Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland,* [2]*Hjelt Institute, University of Helsinki, Helsinki, Finland,* [3]*Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom.*

Recent methodological development on linear mixed models has provided a common framework for heritability estimation, multi-locus association testing and genomic prediction of quantitative traits in population cohorts

with arbitrary relatedness structures. The possibility to use population cohorts rather than family structures opens up a multitude of new avenues also for genetic epidemiological research on time-to-event outcomes. However, connecting time-to-event outcomes to whole-genome sequencing data has so far not been computationally feasible with hitherto existing software. We introduce an R package ("GSM") for heritability estimation, multilocus association testing and genomic prediction of time-to-event outcomes that is scalable to sequencing data. The package implements a very flexible piece-wise constant hazard model that contains an individual-specific Gaussian random effect with an arbitrary covariance structure. Computationally, we transform the problem to a Poisson model, which we analyze by fitting interconnected Generalized Linear Models. The underlying computational algorithm is written in C++ to enable analyses with millions of genetic markers and events in thousands of individuals. We demonstrate the runtime efficiency of our implementation and give an example of heritability estimation and multi-locus association testing for cardiovascular disease related events. Our work extends the computational tractability of linear mixed models from quantitative traits to time-to-event outcomes and will prove useful, e.g., for combining information across individuals' genomes and their hospital records.

P17.83-S
Genome- wide association analysis of swallowing symptoms related to dysphagia in a healthy older adult cohort

A. Raginis-Zborowska, *N. Pendleton, S. Hamdy, W. Ollier;*
The University of Manchester, Manchester, United Kingdom.

Background: Patients with swallowing difficulties (oro-pharyngeal dysphagia) caused by neurological damage (stroke, Parkinson's disease, ageing) show different recovery patterns which may be caused by genetic determinants.
Aim: To find an association between human genetic variations and swallowing impairments within the ageing cohort.
Materials and methods: We performed case-control genome wide association study (GWAS) of self-reported swallowing symptoms related to dysphagia. The analysis included 555 community dwelling, unrelated, older adults (mean years of age = 81.4; SD = 5.349) with known phenotype and genetic information consisting of 512 806 single nucleotide polymorphisms (SNP). Gene-based association analyses of these traits was also conducted. The genetic data underwent quality control procedures prior to the study. This included analysis of population architecture using Multidimensional Scaling of the genome wide genotype data.
Results: Analysed cohort showed European ancestry with no major population stratification. The results shown one genome wide significant SNP rs17601696 (P=4.83x10-8) from non-coding region of chromosome 10. Analyses of individual genes did not result in any genome-wide significant association**.**
Conclusion and future work: SNP rs17601696 may have an impact in swallowing impairment among elderly individuals. The results require replication in an independent cohort with appropriate phenotype/genotype data. Presented GWAS results will be replicated in the human model study using Transcranial Magnetic Stimulation (TMS). Identified genetic loci may play a role of potential markers to predict individual's outcome from swallowing impairments.

P17.85-S
Investigation of hellenic families with microscopic hematuria reveals the frequency of collagen IV mutations and evidence for activation of the unfolded protein response

L. Papazachariou;
University of Cyprus, Nicosia, Cyprus.

Familial hematuria(s) comprise a genetically heterogeneous group of conditions which include heritable glomerulopathies (Alport Syndrome (AS) and thin basement membrane nephropathy (TBMN)). AS is rare, caused by X-linked *COL4A5* or autosomal recessive *COL4A3/A4* mutations (ARAS), while TBMN is frequent. We sought to evaluate the prevalence of *COL4A3/A4* mutations among patients presenting with microscopic hematuria (MH), belonging to 91 Hellenic families. Also we studied 28 sporadic patients with MH and four patients with ARAS. We performed functional studies in cultured podocytes, focusing on the induction of the unfolded protein response (UPR) after overexpression of wild type or mutant *COL4* chains.
Among 91 families, heterozygous mutations were found in 11 (12,1%). Restricting the calculation to 68 families with ≥3 patients with MH, the positive finding is 11/68 (16,2%). Three heterozygous mutations were found in three of the 28 sporadic patients (10,7%). Altogether, among 52 heterozygous patients 17,3% reached end-stage kidney disease (ESKD). Of those aged >50 years, 26% reached ESKD, in keeping with previous findings that TBMN is not always benign. Functional studies showed that mutant *COL4A3/A4* chains expressed in podocytes are preferentially retained in the cells, compared to wild type chains. Mutant chains differentially triggered activation of the UPR pathway, as evidenced by activation of BiP, a sensitive ER stress marker.
TBMN may emerge as a more frequent cause of ESKD than AS. The ability of mutant chains to elicit the UPR pathway when overexpressed in podocytes may prove of functional significance and prognostic value.

P17.86-M
Variation in BTBD9 gene is associated with Tourette syndrome in the Polish population

M. Berdynski[1], *P. Janik*[2], *M. Kobrys*[1], *K. Safranow*[3], *C. Zekanowski*[1];
[1]*Mossakowski Medical Research Centre Polish Academy of Sciences, Warsaw, Poland,* [2]*Medical University of Warsaw, Warsaw, Poland,* [3]*Pomeranian Medical University, Szczecin, Poland.*

Tourette syndrome (TS) is a childhood-onset neuropsychiatric disorder manifested by tics. The anatomical location, number, frequency, complexity, and severity of tics change over time. The etiology of the disorder is unknown, though the predominant role of genetic factors has been established. Variants of the BTBD9 gene (rs4714156, rs9296249 and rs9357271) were reported to be associated with GTS in French Canadian and Chinese Han populations.
The study group comprised 162 TS patients, and the control group consisted of 180 healthy persons. The rs4714156, rs9296249 and rs9357271 variants of the BTBD9 gene were genotyped.
Analyzed SNPs indicated a strong linkage disequilibrium (D= 1, r2=0.938-1).). MAFs, genotype frequency, allelic, genotypic and haplotype association analysis within examined variants of the BTBD9 gene revealed no significant differences between controls and TS patients. However, there were significant associations between the BTBD9 gene variants and a clinical phenotype of TS. Minor alleles of all three SNPs were found significantly less frequently in patients with ADHD and were more frequent in patients with no comorbidities. There was a borderline statistical significance for minor alleles to be less frequent in patients with severe tics. All three SNPs were not found to be associated with the family history and the age of tic onset.
Our results indicate that the examined variants of the BTBD9 gene are not associated with the risk of developing GTS, but may be associated with comorbidity and tic severity in the Polish population.

P17.87-S
The investigations of susceptibility genes/variants related to type 2 diabetes in Turkish

H. -. Arikoglu[1], *D. Erkoc Kaya*[1], *A. Arslan*[2];
[1]*Selcuk university, Department of Medical Biology, Konya, Turkey,* [2]*Gaziantep University, Department of Medical Biology, Gaziantep, Turkey.*

Rapidly increasing prevalence of diabetes in Turkey as worldwide has made diabetes as a public health problem which mostly uses the sources of health services on personal and social levels. As well as ethnic and geographical differences, contribution of multiple genes on the emergence of the disease makes type 2 diabetes (T2D) even more complicated to understand. It was noted that prominent genes in all of the studies are the genes coding proteins usually functional in pathways related to insulin release or activity. IRS1 and 2, KCNJ11, ABCC8, TCF7L2 and Adiponectin genes which are of prominent genes in literature have been scanned among type 2 diabetic individuals living in Konya region and risk allels were determined in our study. For this purpose, patients applied to Selcuk University, Faculty of Medicine, Endocrinology Department and diagnosed with T2D were included. Forty seven SNPs in six gene regions were genotyped among about 200 diabetic and 150 healthy individuals. Association analyses with disease and biochemical data and genotypes, Hardy-Weinberg analyses, genotype-phenotype relationship were evaluated statistically. The silent substitution R1273R and exon 16-3t/c of ABCC8 gene, SNP −11391Ġ→A in proximal promoter and SNP +276G→T in intron 2 of Adiponectin gene and intronic SNPs rs7903146 and rs12255372 in TCF7L2 gene were significantly associated with T2D (P<0,001). We also found an effect of the E23K variant in KCNJ11 gene on insulin secretion in our population (P<0.05). Consequently, our results suggest that ABCC8, Adiponectin, TCF7L2 and KCNJ11 genes are significant determinants of T2D development also in Turkish population.

P17.88-M
The T allele of rs7903146 in TCF7L2 is associated with type 2 diabetes in Iranian: a large population-based cohort study

A. Ebrahimi[1], **M. Safarpour**[2], *M. Daneshpour*[2], *M. Fallah*[2], *K. Guity*[2], *D. Khalili*[3], *F. Azizi*[4];
[1]*1. Cellular and Molecular Endocrine Research Center, Obesity research center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Cellular and Molecular Endocrine Research Center, Obesity*

research center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran, [3]Prevention of Metabolic Disorders Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran, [4]Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.

Introduction: The precise mechanisms underlying the development and progression of type 2 diabetes have not been elucidated yet; however, a combination of multiple genetic and/or environmental factors contributes to the pathogenesis of the disease. The two main pathophysiological mechanisms leading to type 2 diabetes are impaired insulin secretion and insulin resistance which have a significant genetic component. TCF7L2 is one of the genes involved in insulin secretion, and the TCF7L2 rs7903146 constitutes the best-established risk allele to be associated with diabetes. Therefore, this study was carried out to replicate the previous findings in Iranian population using samples from the Tehran lipid and glucose study (TLGS), a large population-based cohort study. Methods: This case-control study included 2173 affected patients and 2400 controls selecting among TLGS participants. The genetic variants on transcription factor 7-like 2 (TCF7L2) namely rs7903146 was genotyped genotyped using the Centaurus (Nanogen) platform in DeCODE genetics. Association of T-allele with type 2 diabetes was examined using plink software after age and sex adjustment. Results: In this study, the minor allele (T) of rs7903146 increased risk of type 2 diabetes 1.33 fold higher in case group compared to control group (OR:1.33; p= 1.8E-10). Conclusion: The findings revealed the association between the presence of T allele in rs7903146 and type 2 diabetes among Iranian population which confirmed previous result in other ethnicity. Keywords: Type 2 diabetes, TCF7L2, rs7903146, SNP, TLGS

The first genetic study of Type 2 Diabetes in the Cypriot population

C. Votsi[1], *C. Toufexis[1,2], N. Scordis[3], A. Antoniades[4], M. Karaolis[4], C. Pattichis[4], K. Christodoulou[1];*
[1]The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus, [2]Hippocrateon Private Hospital, Nicosia, Cyprus, [3]Paedi center for specialized Pediatrics of St George's University Medical School, University of Nicosia, Nicosia, Cyprus, [4]University of Cyprus, Nicosia, Cyprus.

Type 2 diabetes (T2D) mellitus is a chronic complex multifactorial disease of glucose metabolism. It is a serious worldwide public health problem which has reached epidemic proportions with an increasing prevalence and obvious substantial familial clustering. Therefore, T2D has been the subject of numerous medical-genetic studies aiming at the elucidation of the genetic mechanisms involved in the disease. Candidate gene studies, genome-wide association (GWA) scans and meta-analysis of these scans identified several genetic T2D susceptibility loci.
We initiated T2D genetic studies in the Cypriot population. We collected a representative number of diabetic and non-diabetic samples, extracted DNA and created the first Cypriot T2D DNA Bank. Twenty one already established in other population susceptibility loci were investigated in our population. Four of the 21 tested loci [*TCF7L2* rs7901695, *FTO* rs8050136, *HHEX/IDE* rs5015480 and *SLC30A8* rs13266634] that are among the strongest associated SNPs worldwide have been also associated with T2D susceptibility in our population. Furthermore, 4 statistically significant associations were detected between the following specific variables of the phenotype and the tested loci: 1) age at T2D onset with *THADA* rs7578597 and *TCF7L2* rs7901695, 2) body mass index with *FTO* rs8050136 and *KCNJ11* rs5219, 3) glycosylated haemoglobin levels of patients with *ADAMTS9* rs4607103 and 4) cardiovascular disease with *TCF7L2* rs7901695.
Our findings expanded the genetic assessment of T2D in a distinct population and reconfirmed 4 of the worldwide established loci. Our study population will be further studied for the identification of additional and maybe novel T2D susceptibility loci.

The southern migration route: a supporting clue from aboriginal Vedda people of Sri Lanka

L. Ranaweera[1,2], *S. Kaewsutthi[2], A. WinTun[2], H. Boonyarit[2], S. Poolsuwan[3], P. Lertrit[2];*
[1]Department of Anatomy, Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka, [2]Department of Biochemistry, Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand, [3]Faculty of Sociology and Anthropology, Thammasat University, Bangkok, Thailand.

Being located along the proposed southern migration route and the presence of earliest skeletal evidences of anatomically modern human (37,000 B.P.) with aboriginal Vedda population, the island of Sri Lanka could provide the knowledge of genetic variation of modern humans in South Asia. In order to reveal the genetic relationship of the Vedda people with the tribal groups along the southern coastal migration route, the present study compared the mitochondrial DNA (mtDNA) hypervariable segment 1 variations from 75 Vedda people from Sri Lanka with 33 world tribal groups from published data bases. The Vedda people signal out as an exceptional tribal group of South Asia having less than 30% of individuals sharing haplogroup M with 64% of haplogroups R30, U1 and U7. The latter two haplogroups were recognized as West Eurasian ancestry. In principal component analysis (PCA) some Vedda groups occupied separate positions while some were closely related to South Indian tribal groups. Most interestingly, by viewing PCA from the point of view of the Southeast Asian foragers, it is evident that their closely related groups are the Vedda people. This fascinating genetic footprint is suggestive of yet another piece of evidence of the dispersal of anatomically modern human out of Africa via the southern migration route. And also this mtDNA study highlights Sri Lanka's strategic location along the southern migration route, thereby providing a genetic gold mine, which will offer insight into the initial settlements and peopling of South Asia.

RNA-Sequencing reveals differential gene expression between visceral and subcutaneous adipose tissue in Greek women undergoing abdominal surgery

E. Katsareli[1], *C. Amerikanou[1], K. Rouskas[2], M. Reczko[2], A. C. Dimopoulos[2], S. Glentis[2], D. Bielser[3], I. Padioleau[3], I. Griniatsos[4], T. Diamantis[4], E. T. Dermitzakis[3], I. Ragoussis[5,2], A. S. Dimas[2], G. V. Dedoussis[1];*
[1]Harokopio University of Athens, Department of Nutrition and Dietetics, Kallithea, Athens, 17671, Greece, [2]Biomedical Sciences Research Center Al. Fleming, Vari, 16672, Greece, [3]Department of Genetic Medicine and Development, University of Geneva Medical School, Geneva 1211, Switzerland, [4]First Department of Propaedeutic Medicine, Laiko General Hospital, Athens University Medical School, Athens, 11527, Greece, [5]Genome Quebec Innovation Centre and Department of Human Genetics, McGill University, Montréal, QC, Canada.

Adipose tissue is a major endocrine organ that contributes to whole body metabolic homeostasis. The role of body fat distribution in the development of obesity-related metabolic consequences, such as type 2 diabetes, hyperlipidemia and cardiovascular disease is of great importance. Fat depots from different areas of the body display distinct structural and functional properties and have specific roles in pathology.
We applied RNA sequencing (RNA-Seq) to quantify transcript levels in visceral and subcutaneous adipose tissue. RNA was extracted from 81 tissue samples (42 subcutaneous, 39 visceral) of women from the Greek population spanning the BMI range (sample collection is ongoing), who underwent bariatric surgery or surgical treatment for non-inflammatory disease. RNA-Seq was performed on the Illumina HiSeq 2000 platform with paired-end 49 bp sequencing. Reads were mapped using the GEM mapper with an average of 27.4 million reads per sample. We report here results on differential gene expression determined using DESeq. We have also performed genotyping of the above samples on the Illumina Omni 2.5 exome v1 chip and aim to report candidate regulatory variants through association of SNP genotype with mRNA levels for each tissue. Gene expression of the two types of tissues will be further tested with the levels of cardiometabolic biomarkers. We are also performing formaldehyde-assisted isolation of regulatory elements (FAIRE)-Seq on a restricted number of samples from both tissues to identify regions of open chromatin. Combining all the above information will contribute to our understanding of adipose tissue biology and as a result to obesity-related pathogenesis.

P17.92-M

Meta-analysis of Y chromosome haplogroups C, N and Q in Eurasian populations for the perspectives of proto-Bulgarian ancestry

S. Karachanak[1], *D. Nesheva[1], V. Grugni[2], N. Al-Zahery[2], V. Battaglia,[2], A. S. Galabov[3], D. Toncheva[1];*
[1]Department of Medical Genetics, Medical Faculty, Medical University of Sofia, Sofia, Bulgaria, [2]Department of Biology and Biotechnologies "Lazzaro Spallanzani". University of Pavia, Pavia, Italy, [3]The Stephan Angeloff Institute of Microbiology, Bulgarian Academy of Sciences, Sofia, Bulgaria.

Bulgaria is situated on the presumed trajectory of the pioneer colonization of Europe. Since then it has been subjected to a series of demographic events with disputable impact on the contemporary Bulgarian gene pool. One of the most controversial issues of the Bulgarian past is the origin of the proto-Bulgarians, which were previously considered as a sparse Turkic population.
In order to delve into Bulgarian patrilineal origins we have performed a survey of Y-chromosome haplogroups followed by meta-analysis of haplogroups C, N and Q distinctive for Altaic populations.
The analysis was performed on a sample comprising 808 Bulgarian males using RFLP and DHPLC analysis. We have found that only 1.49 % of the contemporary gene pool belongs to haplogroups C, N and Q. Our results were used to upgrade and extend the distribution maps of these haplogroups and

to compare their frequency in 240 Eurasian (sub-) populations with more than 20 000 samples.
The comparison reveals a statistically significant difference in the distribution of the studied haplogroups between Bulgarians and Altaic populations as well as between Bulgarians and Eastern Slavic populations. Based on the novel historical studies which point to a substantial contribution of the proto-Bulgarians to the modern Bulgarian gene pool the obtained results suggest that there is no common genetic ancestry between proto-Bulgarians and present day Altaic populations as they reject the hypothesis of the Turkic origin of proto-Bulgarians.

P17.93-S
Forensic parameters and allele frequency distribution of 15 autosomic STR loci in a Mestizo population from the State of Yucatan, Mexico

J. Sosa-Escalante[1], *A. Acosta-Tun*[1], *P. Chable-Castillo*[1], *C. Herrera-Najera*[1], *M. Rivera-Guzman*[2], *L. J. Gonzalez-Herrera*[3];
[1]*DIMYGEN Laboratorio, Merida, Mexico,* [2]*Genomelab, Tijuana, Mexico,* [3]*Universidad Autonoma de Yucatan, Merida, Mexico.*

The State of Yucatan is a region with a high density of population with Mayan ascendancy at Southeastern, Mexico. Short tandem repeat (STR) polymorphisms are mainly used in forensic fields for paternity tests and personal identification. Since, there are no STR databases from Yucatan, Mexico, a sample of 200 mestizos was PCR-typed for fifteen STR loci with the Power Plex 16 Promega kit (D3S1358, THO1, D21S11, D18S51, Penta E, D13S317, D7S820, D16S539, CSF1PO, Penta D, VWA, D8S1179, TPOX and FGA). Genotype distribution by locus was in agreement with Hardy-Weinberg expectations for all fifteen STRs. The most highly polymorphic loci were Penta E and D18S51, showing 19 and 17 alleles, respectively. Heterozygosity index ranged from 61.5 for D3S1358 to 94.5 for Penta E. For each locus, allele frequencies were obtained, ranging from 0.003 to: 0.455 for D3S1358; 0.380 for THO1, 0.283 for D21S11, 0.203 for D18S51, 0.188 for penta E, 0.480 for D5S818, 0.243 for D13S317, 0.323 for D7S820, 0.328 for D16S539, 0.363 for CSF1PO, 0.278 for penta D, 0.390 for VWA, 0.345 for D8S1179, 0.468 for TPOX, 0.210 for FGA. The most discriminating loci were Penta E (PD = 0.981) and D18S51 (PD = 0.965). The combined power of exclusion was 0.9999999 in the studied population. Our results suggest that this system provide powerful discrimination and remarck the importance of the generation of local databases for STRs when these markers are being currently used in forensic casework.

Retrospective analysis of live birth prevalence of children with Down syndrome in Denizli, Turkey

I. Acikbas[1], *A. G. Tomatir*[1], *B. Akdag*[2], *A. Koksal*[3];
[1]*Pamukkale University, Medical Faculty, Department of Medical Biology, Denizli, Turkey,* [2]*Department of Biostatistics, Pamukkale University, Denizli, Turkey,* [3]*Denizli Vocational School of Health Services, Pamukkale University, Denizli, Turkey.*

Down syndrome (OMIM: #190685) is the most frequent chromosome abnormality among live births. Its prevalence increases with maternal age, and can be diagnosed by antenatal screening. The average incidence in the USA is 1/700-800 live births and 1-3/1000 births in the EU. We examined prevalence variations of DS in Denizli, Turkey, through a retrospective study. Sixteen years of survey data were retrieved from the two main state hospital registry records between 1994 and 2010, subject had diagnosis as ICD-90. We also obtained some demographical, marital and child bearing trends in Turkish population from Turkey Demographic and Health Survey and TurkStat. Additionally we search some data from EUROCAT for EU and CASP for USA. We identified 113 DS live births in Denizli for 16 years. The prevalence of DS was 9.07 per 10,000 live births before the year 2000 and 9.90 after 2000. The prevalence did not change significantly. The population in Turkey is still young; the fertility rate is high in women under 35 years old, in contrast to EU, and prenatal screening programs are extensively applied; for these reasons, the prevalence of DS has remained stable during these 16 years.

Vascular Endothelial Growth Factor (VEGF) is the most important pro-angiogenic factor, implicated in both physiological and pathological angiogenic processes. A previously published GWAS had identified four loci independently associated with VEGF levels, two on chromosome 6, one on chromosome 9 and one on chromosome 8 (Debette et al, 2011).
We sought to identify additional loci associated with circulating VEGF levels measured on ~13.000 individuals from six cohorts using genome wide association data imputed to the Phase1v3 release of the 1000 genomes. A GWAS of VEGF levels was performed in each cohort and the results were meta-analyzed using an effective sample size weighted meta-analysis approach.
Five chromosomal regions (5q14.3, 6p21.1, 8q23.1, 9p24.2, 10q21.3) containing SNPs associated at genome-wide significance with VEGF levels (p-value<5*10-8) were identified. Independence was assessed by conditional GWAS in a forward stepwise fashion, including in the association model the most significantly associated SNP at each step, and repeating this process until all SNPs independently associated with VEGF levels had been detected. Ten independent signals were identified including all four previously-reported loci as well as six novel loci.
In silico and de novo replication analysis will be carried out in ~2000 individuals from three additional independent cohorts, as well as functional validation using mRNA data and exploration of the association of these VEGF loci with various clinical endpoints.
Further, pathway analysis will be performed to look for biological processes most likely to be associated with the genes located in the identified loci and to help identify additional VEGF loci.

P18.01-S
Familial 17q12 duplication presented as SGA/IUGR and microcephaly during pregnancy: A counseling dilemma

A. Singer[1], *I. Maya*[2], *C. Vinkler*[3];
[1]*Genetic Institute, Ashkelon, Israel,* [2]*Institute of Medical Genetics, „Rabin", Petah-Tikva, Israel,* [3]*Institute of Medical Genetics, „Wolfson", Holon, Israel.*

Recurrent genomic rearrangements of chromosome region 17q12, ranging from 0.3 to 2.1 Mb, have been described to be associated with different clinical phenotypes. Patients carrying a 17q12 duplication present with intellectual disability, developmental delay of various degree, epilepsy, schizophrenia, autisim, brain abnormalities, esophageal atresia and various renal and urinary tract abnormalities. In the normal population, duplication of 17q12 is quiet rare (<0.02%) and it penetrance estimate is around 21%. Hence, prenatal counseling poses a dilemma.
We present a baby boy with prenatal and postnatal microcephaly and IUGR/SGA. He was born to a healthy nonconsanguineous couple. Late amniocentesis (32 week) because of symmetric SGA/IUGR, microcephaly and echogenic intracardiac focus found 1.4 MB 17q12 duplication. Parents' CMA showed that it was inherited from his father. During counseling the father was found to have normal HC but he has dyslexia and some speech disturbances. Counseling in this case posed a dilemma since 17q12 duplication is known to have a variable phenotype and incomplete penetrance. The parents decided to continue with the pregnancy. The boy was born at term. Examination was normal except for microcephaly (HC< -2Sd).
Prenatal microcephaly has not been previously described in 17q12 duplication syndrome. The clinical significance of this prenatal finding adds to the counseling dilemma

P18.02-M

Evaluating a digital information resource for adolescents in genetic research - adolescent and parent perspectives on information requirements

A. J. Gibson[1,2], *P. Callery*[3], *P. Clayton*[1], *I. Starling*[2], *F. Ulph*[4];
[1]*Institute of Human Development, Faculty of Medical & Human Sciences, University of Manchester, Manchester, United Kingdom,* [2]*Nowgen, Manchester Academic Health Science Centre, Central Manchester University Hospitals NHS Foundation Trust and The University of Manchester, Manchester, United Kingdom,* [3]*School of Nursing, Midwifery & Social Work, University of Manchester, Manchester, United Kingdom,* [4]*Manchester Centre for Health Psychology, School of Psychological Sciences, University of Manchester, Manchester, United Kingdom.*

There is insufficient evidence regarding adolescent participants' information needs in genetic research. Previous information interventions have yielded little improvement in understanding and confidence in participation decisions, and have not specifically addressed the needs of adolescents. UK adolescents (aged 12-17) and parents with experience of participation in genetic research discussed their knowledge, attitudes, and information needs surrounding genetic research, in focus groups or interviews. A digital information resource (website) was developed following participants' suggestions, and subsequently evaluated for its feasibility and desirability by adolescents (n=21) and parents (n=5) with and without experience of genetic research. Thematic analysis was carried out on transcripts of focus groups and interviews, and on written feedback. Predominant attitudes to genetic research were that such research is prestigious and complex, and that participation in genetic research is a relatively simple proposition, until potential outcomes are explored. The evaluation of the resource suggests participants favour comprehensive information, presented using modern technology, which is accessible and manageable. Further, participants recommend that information is ‚customisable' to accommodate individual differences in requirements, concerning specific content and information quantity. Finally, the analysis suggests participant autonomy is an integral aspect of information provision for adolescents, and should be explicitly incorporated into information design. Digital technology can satisfy participants' preferences, though information resources should be designed with the specific needs of the adolescent population in mind. Questions remain regarding the ‚minimum essential information' in genetic research, but participants should be afforded as much choice as possible.

P18.03-S

Adolescent participation in genetic research - motivations and influences on adolescent and parent participation decisions

F. Ulph[1], *A. J. Gibson*[2,3], *P. Callery*[4], *P. Clayton*[2], *I. Starling*[3];
[1]*Manchester Centre for Health Psychology, School of Psychological Sciences, University of Manchester, Manchester, United Kingdom,* [2]*Institute of Human Development, Faculty of Medical & Human Sciences, University of Manchester, Manchester, United Kingdom,* [3]*Nowgen, Manchester Academic Health Science Centre, Central Manchester University Hospitals NHS Foundation Trust and The University of Manchester, Manchester, United Kingdom,* [4]*School of Nursing, Midwifery & Social Work, University of Manchester, Manchester, United Kingdom.*

Increasing numbers of young people participate in genetic research following changes in international regulations. There is a recognised need to support children and adolescents in making informed participation decisions, yet there is little evidence concerning how to do so. Moreover, adolescents are a distinct population from children and adults because of their cognitive development and social context. A thematic analysis of focus groups and interviews with UK adolescent patients (aged 12-17) who have previously participated in genetic research (n=7), and their parents (n=7), explored participants' experiences of decisions regarding research participation. The analysis suggests that participants prioritise subjective and interpersonal factors when making participation decisions, and that genetic aspects of research are subordinate influences on decisions. Adolescents cited primarily altruistic motivations, while parents referred to their children's illness and healthcare experiences as key to participation decisions. Further, the analysis demonstrates how motivations such as altruism and personal benefit are mediated by other aspects such as trust and personal histories, and highlights differences between adolescent and parental considerations regarding participation in genetic research. The potential influences of subjective or interpersonal influences on adolescent and parent decisions should be taken into account when inviting participation, in order to support autonomous participation decisions. Further, participant information should be tailored to each group's needs to reflect adolescent and parent priorities, and to ensure that participants are properly informed concerning genetic aspects of research which may not be viewed as a priority.

Telethon Network of Genetic Biobanks (TNGB), composed of 10 members, was founded in 2008 to coordinate biobanks already supported by Telethon since 1993. Currently, TNGB stores 75,900 biospecimens from over 750 rare genetic diseases. Governed by a Coordinator and the Biobanks' Directors (Network Board), TNGB is also supported by both a Coordinator Emeritus and an Advisory Board which includes ethical-technical experts and a representative of Patients' Associations. Policies and activities are defined in the TNGB-Charter. TNGB has always focused on improving quality, visibility and catalogue access. Its interoperability is facilitated by an IT infrastructure, which greatly simplifies harmonisation and standardisation of all activities. The IT platform, managing samples' workflow, generates a centralised, continuously updated, online catalogue and also enables coordinated management and common rules for catalogue access based on a unique "Request Control Panel". Hitherto, over 300 scientific publications results from research conducted using TNGB-services. Through continued dissemination activities aimed at promoting TNGB-services, the interest for the Biobanks is also enormously increased among patients/families. Indeed, 9 agreements have been formalised between TNGB and Patients' Associations. TNGB is a member of EuroBioBank and some Biobanks are also part of Regional Nets. TNGB is a BBMRI-EU associated-member and is involved in BBMRI-IT node construction. Finally, TNGB is an associated partner of the RD-connect project. TNGB operates according to national and international regulations/recommendations and collaborates with qualified centres and regulatory bodies (Garante Privacy Authority) to review emerging ethical-legal and societal issues. General information and documents including the catalogue are available at www.biobanknetwork.org.

P18.05-S

Ethical, social and policy issues of biobanking for genomic research: a multidisciplinary and qualitative study

G. Barazzetti[1], *L. Benaroyo*[1], *A. Kaufmann*[2];
[1]*Ethics Unit, CHUV Lausanne University Hospital; Ethos - Interdisciplinary Ethics Platform, University of Lausanne, Lausanne, Switzerland,* [2]*Science-Society Interface, University of Lausanne, Lausanne, Switzerland.*

This contribution presents an ongoing study of ethical, social and policy issues of biobanking in the context of the Lausanne Institutional Biobank (BIL), a large-scale hospital-based bioresource established in January 2013 at the CHUV Lausanne University Hospital to support prospective research in genomics. Specifically, the project aims to investigate:
- motivations of patients to accept or refuse to participate in the biobank;
- participants' and non-participants' concerns about issues of collective interest related to biobanking, such as: data protection, data sharing, exploitation for research, ownership and commercialization;
- participants and non-participants' perspectives about feedback of individual findings from research.
To explore these questions, we use a multidisciplinary approach where identification and analysis of key ethical, social and policy issues is informed by qualitative research. Data are collected through follow-up of broad consent using semi-structured interviews with biobank participants and non-participants, and focus groups with personnel in charge of recruitment. A second phase of the project will include a qualitative survey of opinions of the various stakeholders concerned by the future exploitation of the biobank, e.g.: lay citizens, patients associations, researchers, health professionals, policy-makers. Study outcomes will contribute to:
- the improvement and adaptation of informed consent requirements in the context of the biobank;
- the development of a framework for participative governance of the bio-

bank, involving various stakeholders concerned;
- the definition of criteria and procedures to disclose individual findings to biobank participants, in preparing for future research on data collected.

P18.06-M
Do we still need to follow the traditional model of face to face results disclosure for BRCA predictive testing? An examination of current practice in the Republic of Ireland (ROI)

R. O'Shea, *M. Meany, N. Coady, D. Healy, A. Green, S. Lynch, C. Debaroid;*
National Centre of Medical Genetics (NCMG), Dublin, Ireland.

The traditional model of cancer predictive testing services is changing. Many genetic centres are now offering a choice to patients in how they receive their results instead of the typical face-to-face disclosure. Research has shown that it is feasible to change the current 2 visit model of initial consultation followed by results disclosure, without reducing patient satisfaction to a large degree (Sutphen et al, 2010). In view of this and the increasing demand on the ROI Breast Cancer (BRCA) predictive testing service, a 2 year retrospective study on patient preference in how to receive a BRCA predictive result was performed. The aim was to examine those who had been through the BRCA predictive process previously to study if an alternative to face-to-face result disclosure would have been an option they would have preferred. A questionnaire was used to assess this and results showed that 71.7% of respondents would have liked the option of obtaining their results by telephone or by letter. However, when asked about their actual experience of BRCA predictive results disclosure 40.6% did still prefer the face-to-face contact, while 44.9% would have preferred an alternative. Car parking and distance were the top two variables determining whether the surveyed showed a preference towards options or not, followed by sex and test result. This study shows that while the majority expressed a wish to have a choice, it is important not to underestimate the value of a face-to-face encounter. We are now reviewing our practice for BRCA predictive genetic counselling.

P18.07-S
Risk-stratified screening for cancer and response to personalised genetic information in the general population

S. Chowdhury[1], *T. Dent*[1], *A. Hall*[1], *N. Pashayan*[2], *P. Pharoah*[3], *H. Burton*[1];
[1]*PHG Foundation, Cambridge, United Kingdom,* [2]*UCL, London, United Kingdom,*
[3]*University of Cambridge, Cambridge, United Kingdom.*

There is evidence that risk-stratified population screening based on multiple factors including a polygenic risk profile has the potential to be more efficient than age-stratified screening. Therefore, genetic information is likely to be used for cancer prevention strategies in the general population in the future. To understand issues of acceptability of such genome based screening in the public, we reviewed issues of genetic risk-communication, how disease risk is perceived and the behavioural response of people to genetic risk feedback. A systematic review was conducted based on inspection of 1948 abstracts and use of 25 studies. We found that though the general population has limited genetic literacy, they are interested in being informed of their genetic risk status. They are generally positive about using genetic information in disease prevention but not about provision of this information to employers and insurers. There is evidence of positive association between perceived risk and cancer screening behaviour such as uptake and mammography, particularly when risk is communicated by categorising into high, medium and low strata. Yet genetic risk feedback particularly that conveying small increases of risk has little or no effect on lifestyle changing behaviour. Also, personalised risk-communication is effective in improving knowledge and risk perception of the population. Personalised risk information is associated with only short term psychological distress including anxiety and fear but not with fatalism. Strategies of preventing cancer using personalised genetic information may potentially be acceptable to the general public. However, before implementation of risk-stratified screening, further empirical evidence is needed.

P18.08-M
Carrier screening for recessive disorders through exome sequencing

P. Makrythanasis[1], *A. Massouras*[1], *S. E. Antonarakis*[1,2,3];
[1]*University of Geneva, Geneva, Switzerland,* [2]*University Hospitals of Geneva, Geneva, Switzerland,* [3]*iGE3 Institute of Genetics and Genomics of Geneva, Geneva, Switzerland.*

Detection of carrier status for certain recessive Mendelian disorders is a well-accepted health-care practice in several countries since the 70s and aims at the prevention of frequent severe monogenic disorders. Exome sequencing in combination with the increasing knowledge of human pathogenic variation provide the possibility to perform a carrier screening for all the known recessive Mendelian disorders. Such a screening would allow for a much more informative genetic counseling and may alter the total prevalence of the known recessive disorders. In order to test this hypothesis we have used exome sequencing data from 104 individuals of European origin and have identified the total number of likely pathogenic variants in the >1600 recessive disorders for which the responsible gene is known. The mean value was 18.2 variants per individual. Consequently we have randomly paired these exomes in order to create 5356 fictive couples. 33.14% of these couples have at least one gene for which both members are heterozygous for a likely pathogenic variant. These preliminary results exhibit an upper estimate of at risk couples but more precise knowledge and definition of the pathogenic potential of each variant will render the carrier detection more accurate and make it a potent test for family planning.

P18.09-S
Call for a Standardized Genetics Clinical Laboratory Specialty Training Across the Globe: An Initiative for Clinical Molecular Genetics Training in Turkey

H. Düzkale;
Yeditepe University, Istanbul, Turkey.

Genetics discipline is composed of several clinical laboratory specialties, as defined by the American Board of Medical Genetics (ABMG): Clinical genetics, biochemical genetics, clinical cytogenetics, and clinical molecular genetics. Except for the clinical genetics, each specialty can be practiced by scientists with PhD and an appropriate training in human genetics. ABMG mandates a two-year, highly structured specialty training for the laboratory scientists before they become lab directors who can officially sign out patient reports. The Clinical Molecular Genetics specialty training program includes a preparation of a logbook documenting contribution to the reporting of 150 cases at different levels, i.e. performance and interpretation of certain number and variety of diagnostic test results, and sharing them with physicians and patients. In addition, rotations in Clinical Cytogenetics and Biochemical Genetics laboratories ensure cross-disciplinary exposure. Didactic lectures and hands-on laboratory training provide fellows competency in skills such as variant interpretation, risk estimation, clinical test development and validation, proficiency testing and regulatory aspects of running a certified clinical laboratory. The investigator, an ABMG board certified clinical molecular geneticist, aims to discuss the training outline that can be implemented in the rest of the world, especially in an era of rapidly advancing technologies that results in accumulation of variants in clinical laboratories with an unprecedented speed. In particular, the significance of a standardized variant assessment system across different laboratories (as outlined in Duzkale et al., Clinical Genetics 2013) and transferring variant data from clinical reports to public databases such as NCBI's ClinVar will be discussed.

P18.10-M
Clinical utility guidelines covering diagnostic next-generation sequencing (NGS)

A. Dierking, *J. Schmidtke;*
Institute of Human Genetics, Hannover Medical School, Hannover, Germany.

Clinical Utility Gene Cards (CUGCs) are disease-specific guidelines authored by international expert groups. They are dealing with the risks and benefits of the application of genetic tests in the clinical setting. Each document represents a balanced summary of the analytical and clinical validity, the clinical utility and cost-benefit issues. CUGCs offer quick guidance to all stakeholders, including clinicians, clinical geneticists, referrers, service providers and payers. Each CUGC is peer-reviewed and published by the European Journal of Human Genetics. CUGCs are also freely available on the websites of EuroGentest, the European Society of Human Genetics and Orphanet.
In order to adapt CUGCs to NGS approaches we have started to build up a NGS panel data collection. It contains data from NGS providers including panel name, tested genes, disease and genetic background. The overlap of tested genes between different providers can be determined by comparison and genes deemed essential by the providers can be easily identified, serving as the first step in the establishment of CUGCs for NGS-based genetic test applications in diagnostics. In a second step we have modified the disease-specific format of the CUGC guidelines and invited experts to put it to test. We here present the state of discussion.
A prototype of our data collection is available at the EuroGentest website: https://eurogentest.eshg.org/index.php?id=668. So far we have identified 28 laboratories having launched a total of 944 clinical NGS tests covering 2882 genes. We encourage NGS providers to contact us regarding their current services and to include them in the database.

P18.11-S
Dynamic Consent - A Patient Interface for 21st Century Research Networks

J. Kaye[1], *E. Whitley*[2], *D. Lund*[3], *M. Morrison*[1], *H. Teare*[1], *K. Melham*[1];
[1]*University of Oxford, Oxford, United Kingdom,* [2]*London School of Economics, London, United Kingdom,* [3]*HW Communications Ltd, Lancaster, United Kingdom.*

Biomedical research increasingly relies on the application of novel technologies to allow data to be shared on an unprecedented scale. However, the procedures for ethical involvement of participants have not kept pace with these dramatic changes in research capability; mechanisms of informed consent remain static, paper-based, and organised around national boundaries and legal frameworks.
Dynamic consent (DC) is both a specific project and a wider concept that offers a new approach to consent, to meet the needs of twenty-first century research. It is a personalised, communication portal which allows interactions over time, enabling participants to engage in the donation of their tissue samples and personal information for research purposes, as much or as little as they choose.
The technical architecture of DC includes components that can securely encrypt sensitive data and allow participant consent choices to travel with their data and samples when shared with third parties. In addition to improving transparency and public trust, this system is of benefit to researchers by streamlining recruitment, and enabling efficient recontact of participants.
The interface facilitates two-way communication of information to stimulate a more engaged, informed and scientifically literate participant population where individuals can tailor and manage their own consent choices. To date, DC has mainly been developed in the context of biobanking, but it also has potential for use in other domains for a variety of purposes.
In this paper we present dynamic consent and show how it can be used as a tool for translational research and personalised medicine.

P18.12-M
Duty to recontact in clinical genetics: Asystematic review of the literature

E. Otten, *M. Plantinga, A. V. Ranchor, M. A. Verkerk, E. Birnie, I. M. van Langen;*
University Medical Center Groningen, Groningen, Netherlands.

Introduction Many findings from NGS diagnostic techniques cannot be interpreted yet, but may provide medically relevant information in the future. However, guidelines on recontacting former patients if new actionable information arises are lacking. **Methods** As a first step in developing such guidelines, we conducted a systematic literature search on recontacting in clinical genetics in PubMed, Embase, Web of Science, and Google Scholar. Our search strategy identified 974 articles in all four databases. Fifty full-text articles in English language met our inclusion criteria, and were included in the review. **Results** Most literature is from the US (48%), followed by Canada (22%) and Europe (22%). In the literature recontacting is usually not regarded a legal obligation in clinical genetics. Most authors do consider recontacting to be desirable. Many articles argue that the responsibility for recontacting should be shared with the patient. We found no national or international guidelines, except for the 1999 ACMG policy statement on duty to recontact. Only four of the fifty articles described practical experiences with recontacting. These showed that patients were usually positive about the renewed contact. **Conclusion** Most authors consider recontacting to be desirable. The limited empirical evidence indicates that patients appreciate recontacting. Practical problems of implementing recontacting in clinical genetics are brought forward most often as argument contra imposing a duty to recontact. One of the challenges for the future will be to create ways to overcome these. Legal issues remain important. We therefore consider it important to develop guidelines on this topic for the NGS-era.

P18.13-S
The ethical dimensions and the tools for data sharing in genetics within evolving frameworks

A. Cambon-Thomsen[1], *A. Pigeon*[1], *G. Chassang*[1,2], *L. Mabile*[1], *E. Rial-Sebbag*[1];
[1]*Inserm and University Toulouse III Paul Sabatier UMR 1027, Toulouse, France,* [2]*Inserm, US013, National BIOBANQUES Infrastructure, Paris, France.*

Data as well as biological sample international sharing is paramount in health research. While policy declarations from numerous research institutions and funders encourage such sharing a number of difficulties and needs are identified in practice to „make it happen". This movement in the context of the availability of large scale sequencing technologies for studying human genomic variation is confronted with legal and ethical aspects regarding privacy, confidentiality, clinically useful information and the duties attached. Issues related to identifiability, consent process and regulation of access challenge the existing framework. The evolving legal framework regarding exchanges of biological samples (no unified legal EU framework for research) and personal data protection (EU Directive in revision) is challenged. Examples from various consortia and projects are analysed to enlighten the different facets into play, from the P3G consortium (Public population projects in genomics and society), the international consortium on cancer genomics, European infrastructures such as BBMRI (Biobanking and Biomolecular Resources Research Infrastructure) or ESGI (European sequencing and genotyping) and other EU projects. The focus will be on Charts, Codes and tools to foster sharing, especially hSERN (human sample exchange regulation navigator) that gives information on theoretical and practical legal aspects for exchanging biological samples across borders and the BRIF initiative (Bioresource research impact factor) that aims at providing ways to recognise the efforts to make available quality bioresources and at measuring their use. Thus from policy willingness to incentives a whole culture of samples and data sharing is on its move, but not without difficulties.

P18.14-M
General practitioners and direct-to-consumer genomic tests: a survey in Emilia-Romagna region (Italy)

A. Baroncini[1], *O. Calabrese*[1], *E. Calzolari*[2];
[1]*Medical Genetics Unit, Maternal and Child Health Department, Imola, Italy,* [2]*Regione Emilia Romagna, Bologna, Italy.*

Personal genomic tests (PGT) for disease risk assessment, based on genome-wide association study variants, have been offered directly-to-consumers (DTC) by several companies since 2007. Concerns regarding their potential adverse impact include, among others, lack of counselling, dubious test quality, unnecessary anxiety and medical interventions based on erroneous/misinterpreted results. To mitigate worries professional education on PGT-DTC has been advocated and the central gatekeeper role of family physicians has been highlighted.
Relatively few studies have been published on awareness, involvement and attitudes of healthcare providers on DTC marketing of PGT and, to the best of our knowledge, none in Italy.
A 2008 CDC survey showed that 42% of healthcare providers were aware of DTC-PGT, that 42% of them had at least one patient asking questions about having such a test and 15% had at least one patient who brought test results in the past year.
The preliminary results of a 2014 survey in the Emilia-Romagna Region (Italy), involving solely general practitioners, show that slightly more than 20% of the respondents are aware of DTC-PGT and that respectively 85% and 15 % of them feel unprepared or only partly prepared to answer questions about such tests. About 45 % of them have had at least one patient asking questions on purchasing or performed DTC-PGT during 2013. These data are coherent with the limited number of Italian companies directly marketing PGT and underscore the critical need to enhance primary physicians' information on genomics tests provided outside of the clinical setting.

P18.15-S
The research policy regarding disclosure of genetic research results: A historical perspective in Japan

J. Minari[1], *K. Kato*[1,2];
[1]*Department of Biomedical Ethics and Public Policy, Graduate School of Medicine, Osaka University, Osaka, Japan,* [2]*Institute for Integrated Cell-Material Sciences (iCeMS), Kyoto University, Kyoto, Japan.*

Currently, the return of genetic research results to research participants is a hot topic of debate throughout the world, yet no consensus policy has emerged. Regarding genetic research, Japan has government guidelines, entitled Ethical Guidelines for Human Genome/Gene Analysis Research, which have been set by three ministries in March 2001. These guidelines, together with the preceding document formulated by the government in 2000, Fundamental Principles of Research on the Human Genome, set the principle that a research participant has the right to be informed of his/her genetics information resulting from the research. This means that Japan has taken a stance emphasizing the right of research participants to receive their results since 2000. In the recent revision of the 2001 government guidelines, however, the stance of disclosure in principle was also retained, but the newly added stipulations resulted in researchers' discretion playing a significantly larger role, due to the strong influence of the Act on the Protection of Personal Information. In this study, we have identified two potential ethical issues, which need to consider in the revised guidelines. One is that they do not actually require researchers to offer opportunities for participants to express these wishes and opinions. The other is that one of the exemptions, which show the situation that researchers do not have to disclose, considers only the promotion of research activity, but not the interests of research participants. Based on these findings, we discuss their implications for international research community.

P18.16-M
Recent situation about rules of sharing, reuse and circulation of personal genome data in Japan

N. Yamamoto;
Osaka University, Osaka, Japan.

Personal genome data is very important resource for biomedical researches. In very recent years, it is going to be used beyond previous research area and increasing in number with launce of a several large-scale genome cohorts. Although it has been used after acquisition of donor's informed consents and the review by the institutional ethics review boards, that are defined on the national guideline for the genome researches, ELSI (ethical, legal and social issues) are going to change rapidly in Japan. For example, discussions about broad consents and return of results issues are becoming more severe. Development of more secure technology for data-sharing and data-reuse are also desired as well as moral governance. Since Personal Information Protection Law will be revised in a several years in Japan, various experts f began to discuss how these new types of personal information should be protected. In the poster, these situations about the treatment of personal genome data will be reported.

P18.17-S
Genetic Counselling, Genetic Diagnostics, Genetic Prevention, Genetic Education in EB Centre Czech Republic in University Hospital in Brno

R. Gaillyová[1,2,3], *H. Bučková*[4], *J. Němečková*[1], *L. Fajkusová*[5], *L. Kopečková*[5];
[1]*University Hospital, Department of Medical Genetics, Brno, Czech Republic,* [2]*Masaryk University, Department of Biology, Brno, Czech Republic,* [3]*Masaryk University, Department of Laboratory Methods, Brno, Czech Republic,* [4]*University Hospital, Pediatric Clinic, Department of Pediatric Dermatology, Brno, Czech Republic,* [5]*University Hospital, Centre of Molecular Biology and Gene Therapy, Clinic of Internal Medicine – Hematology and Oncology, Brno, Czech Republic.*

Centre for patients with Epidermolysis bullosa congenita (EB) works at the University Hospital Brno since 2001, from 2012 as the highly specialized medical care centre. EB Centrum CZ is a member of the international network of EB centres and clinical experts. The Centre cooperates with DEBRA Czech Republic (member of the Czech Alliance for Rare Diseases) witch supports people with EB and their families and try for 10 years to engage people with EB to a full life. In EB Center CZ works a multidisciplinary team of health specialists which provides comprehensive care to all EB patients in CZ. The DNA analysis is performed for EB simplex (EBS) and dystrophica (EBD) (analysis of the genes for keratin 5 and 14, and collagen VII) . The mutation was found in 60% patients with EBS, in 67% patients with the dominant EBD and in all patients with the recessive EBD. In one patient was confirmed a rare form of EB caused by a mutation in the gene for plectin. Genetic counseling in our Centre was performed in more than 90 % families with the recessive form of EBD, in about 66 % families with the dominant form of EBD and in about 60 % families with EBS. EB patients from Slovakia, Russia and Ukraine are interested in consultation, genetic conselling and DNA analyse in EB Centre CZ. Activity of EB Centre CZ and DEBRA CZ are also focused on education and awereness for healthcare professionals, patients, their families and the public.

P18.18-M
Enhancing genetic counseling for Familial Alzheimer's Disease through improved phenotyping.

A. Blasimme[1], *M. Canevelli*[2], *G. Talarico*[2], *A. Confaloni*[3], *P. Piscopo*[3], *F. Troili*[2], *N. Vanacore*[4], *A. Cambon-Thomsen*[1], *G. Bruno*[2];
[1]*INSERM, Toulouse, France,* [2]*«Sapienza» University, Rome, Italy,* [3]*Istituto Superiore di Sanità, Rome, Italy,* [4]*Istituto Superiore di Sanità, r, Italy.*

Familial Alzheimer's disease (FAD), despite representing a rare condition, is attracting a growing interest. In clinical practice, we noticed that individuals with a family history of AD show considerable interest for the availability of genetic tests for early detection of the disease.
When informed about the availability of a genetic test for autosomal dominant mutations (PSEN1, PSEN2, APP genes) some individuals decide to be tested, while other refuse. Those who refuse to take the test are primarily motivated by lack of efficacious therapies. However, both those who decide to take the test and those who refuse it lament lack of clear information about the clinical development of the condition.
Indeed, we found out that, albeit rare, FAD cases are poorly phenotyped. In particular, we performed a systematic review of studies describing the phenotypic features of FAD cases sustained by PSEN2 mutations resulting in largely incomplete and low-quality data. Given the incomplete penetrance of some mutations, their variable phenotypic expressivity, and the lack of systematic and accurate phenotyping of FAD cases, the possibility of implementing genetic counseling procedures is strongly limited. This may also affect the capacity of individuals to react and cope with the communication of the test result should they turn out to be mutation carriers. Available guidelines do not clearly address this issue and thus may not provide sufficient guidance for clinicians and counselors. Based also on experience in other contexts, we propose criteria to improve FAD cases phenotyping aiming at enhancing the quality of genetic counseling activities.

P18.19-S
The efficacy of the teaching of the patients during genetic counseling session

E. E. Baranova[1], *A. S. Sergeev*[2], *L. Y. Ivanova*[3], *I. V. Zhuravleva*[3], *V. L. Izhevska*[2], *E. K. Ginter*[1,2];
[1]*Russian Medical Academy of Postgraduated Education (RMAPE), Moscow, Russian Federation,* [2]*Research Centre of Medical Genetics (RCMG), Moscow, Russian Federation,* [3]*Institute of Sociology, Moscow, Russian Federation.*

Studies evaluating the efficacy of the genetic counseling are few in number in Russia. In our study, we evaluated the efficacy of the genetic counseling for families with affected children or relatives by a number of parameters, such as change in the conversance of patients and the impact of genetic counseling on reproductive plans of the patients. The study was conducted in the outpatient department of the Research Centre of Medical Genetics (RCMG), the Russian Academy of Medical Sciences (RAMS), in 2007-2011. We interviewed 226 respondents aged 17 to 67 years. The survey was conducted before and after genetic counseling. Questionnaires have been analyzed using Statistica 10.0 software. We found that the conversance of the risk of an affected child birth after genetic counseling increased significantly (Wilcoxon test, $p < 0.05$). So did conversance of patients about the possibility of prenatal diagnostics (χ^2 - distribution, $p < 0.05$). However, when assessing the extent to which the patients increased their understanding of the causes of hereditary diseases (that was assessed by a series of test questions), we did not detect any changes in conversance of patients before and after genetic counseling. We concluded that these issues deserve a special attention when conducting genetic counseling. Also, we found no significant changes in reproductive plans of the patients after genetic counseling. Currently, there are many reasons that affect the reproductive plans of the family, in addition to an adequate understanding of the extent and meaning of genetic risk.

P18.20-M
Changes in the public's perception of clinical genetics in Cyprus: Reflections from the 20 years of experience of the Clinical Genetics Clinic (CGC)

V. C. Anastasiadou[1,2], *G. Tanteles*[1], *E. Aristidou*[1], *A. Kotti*[2], *T. Delikurt*[1];
[1]*Cyprus Institute of Neurology and Genetics; Clinical Genetics Clinic, Nicosia, Cyprus,* [2]*Makarios Medical Center; Clinical Genetics Clinic, Nicosia, Cyprus.*

Having been established in 1994, the Clinical Genetics Clinic (CGC) is a pioneer in the field of clinical genetics in Cyprus. Over the course of the last 20 years, we have had first hand experience in how people's perception and acceptance of the offer of clinical genetics and genetic counselling has evolved. While in its infancy we observed frequently that patients experienced fear of being stigmatised, characteristic of small societies, if diagnosed with a genetic condition or if they pursued genetic counselling. Some patients also considered being referred to CGC as accepting to proceed with prenatal diagnosis. There was a lack of awareness that genetic counselling would give them the opportunity to discuss their options, receive psychosocial and educational support to make autonomous decisions. As a result, the CGC embarked on (and still continuous) organising public awareness activities, as well as educating patients/families and other health care professionals on common/rare genetic disorders and the process of clinical genetics and genetic counselling. In recent years, patient referrals increased substantially from wide range of specialists (paediatricians, OBGYN, neurologist, oncologist etc).There are more informed individuals/patients compared to before, who may inquire about or instigate referral to genetic counselling themselves as well. We grew in our team as well as services including the Cancer Genetics Clinic, established in 2006, to provide tailored genetic counselling to cancer patients. In this poster, we will elaborate on these points mentioned as well as others to reflect on our 20 years experience in offering clinical genetics.

P18.21-S
Employment and professional integration of genetic counsellors in France : a new collaboration in the healthcare sector

C. Cordier[1,2,3], *H. Sobol*[4,2], *N. Philip*[5,2], *M. Voelckel*[5,2];
[1]*Hospital of Strasbourg, Strasbourg, France,* [2]*French Association of Genetic Counsellors, Marseille, France,* [3]*Hospital of Colmar, Colmar, France,* [4]*Institut Paoli Calmettes, Marseille, France,* [5]*Hospital of La Timone, Marseille, France.*

The profession of genetic counsellors was founded in Europe in the 1980's in the United Kingdom. In France, it began in 2005 under the aegis of a law, following a report on the demographic situation in the health professions. Today, after seven years, we number 122 graduate genetic counsellors who can work in a variety of settings in multiple specialty areas of human gene-

tics. How are these new non-medical practitioners integrated into the multidisciplinary services of genetics? How are they recruited and with which status? What are the responsibilities entrusted to them? How are they perceived by geneticists working with them? We performed a literature survey to trace the history of the creation of this profession. To answer the underlined questions, we used socio-epidemiological studies through the elaboration of surveys regarding the education, the role and practice of genetic counselor. Studies were addressed to both genetic counselors and geneticists. Among the 122 graduate genetic counsellors, 94 are employed (77%), with an average monthly salary of 2,001.21 €/month. They are able to manage consultations only when no medical procedures are required. However, the responsibilities are dependent on the relationship established between the genetic counsellor and the medical geneticist. Overall, this profession has been quickly established in France and is the only one governed by a specific law at European level. Although this survey emphasizes inequalities in the practice of this new profession, including discrepancies regarding the administrative aspects, genetic counsellors are increasingly being integrated into all levels of healthcare service delivery.

P18.22-M
Challenges of web-based personal genomic data sharing

M. Shabani, *P. Borry;*
KU Leuven, Leuven, Belgium.

In order to study the relationship between genes and diseases, the increasing availability and sharing of phenotypic and genotypic data has been advanced as an imperative within the scientific community. In parallel with data sharing practices by clinicians and researchers, recent initiatives have been observed in which individuals are sharing personal genomic data. The involvement of individuals in such initiatives is facilitated by the increased accessibility of personal genomic data, offered by private test providers along with availability of online networks. Personal webpages and on-line data sharing platforms such as *Free the Data*, *Consent to Research* and *Genomes Unzipped* are being utilized to host and share genotypes, electronic health records and/or family history uploaded by individuals. Although personal genomic data sharing initiatives vary in nature, the emphasis on the individuals' control on their data in order to benefit research and ultimately health care has seen as a key theme across these initiatives. In line with the growing practice of personal genomic data sharing, this paper aims to shed light on the potential challenges surrounding these initiatives. As in the course of these initiatives individuals are solicited to individually balance the risks and benefits of sharing their genomic data, their awareness of implications of personal genomic data sharing for themselves and their family members is a necessity. Furthermore, given the sensitivity of genomic data and the controversies around their de-identifiability, potential privacy risks and harms originating from unintended uses of data have to be taken into consideration.

P18.23-S
Opinion about reproductive decision-making among MMR mutation carriers of reproductive age

J. Duffour[1], *A. Combes-Petit*[2], *K. Baudry*[3], *J. Rey*[3];
[1]*ICM Val d'Aurelle cancer institute, Montpellier, France,* [2]*CHU Arnaud de villeneuve, Montpellier, France,* [3]*CHU Arnaud de Villeneuve, Montpellier, France.*

The reproductive techniques such as prenatal diagnosis (PND) or preimplantation genetic diagnosis (PGD), although debated, are often legally forbidden in case of HNPCC syndrome, without considering mutation carriers' opinion about their reproductive options
We conducted a study in 43 individuals (probands and relatives) identified as Mismatch Repair mutation carriers of reproductive age (until 40 years for women, 50 years for men) exhaustively screened during the genetic oncology consultations in our institution. All of them received a closed questionnaire focusing on socio-clinical, possible causes of distress and reproductive preferences (natural conception, PND, PDG or adoption) whose answers were ranked from 0 to 4.
Complete data were available for 29 individuals (22 relatives, 7 probands:13 males, 39±5.6 years; 16 females, 31±6.8 years).
Main reasons of distress given in first were fear of transmitting predisposition for 17 individuals (9 men, 8 women) (58%) and fear of premature death for eight (4 men and 4 women, 27.5%). For 5 persons the fear of passing on deleterious gene took second place, so more than 22/29(75%) of this population regarded this problem as very serious.
PND / PGD and natural conception were equally reported (52% and 48%, respectively).
Among the subjects afraid enough by hereditary concern (22), only 13(59%) chose in first the new reproductive techniques and 9/22(41%) gave priority to natural conception
Neither reason of distress, nor gender were associated with reproductive choices
Conclusion: Although most subjects were afraid to transmit the predisposition, all of them did not give priority to reproductive techniques.

P18.24-M
Improved hereditary recurrent fevers diagnostics resulting from participation in the European molecular genetics quality network

Y. Shinar[1], *L. Obici*[2], *I. Aksentijevich*[3], *M. E. van Gijn*[4], *I. Touitou*[5];
[1]*Sheba Medical Center, Ramat Gan, Israel,* [2]*IRCCS Fondazione Policlinico San Matteo, Pavia, Italy,* [3]*National Human Genome Research Institute/ NIH, Bathesda, MD, United States,* [4]*UMCUtrecht, Utrecht, Netherlands,* [5]*Hôpital Arnaud de Villeneuve, Montpellier, France.*

The hereditary recurrent fevers (HRF) are rare rheumatologic diseases characterized by a course of self resolving inflammatory episodes, inflicted by cells of the innate immune system, and mainly affecting connective tissue, skin and/or central nervous system. If untreated, some HRF patients may develop life threatening, secondary amyloidosis. HRF genetic diagnosis is increasingly requested for patients with recurrent inflammatory episodes of unknown origin. More than 10 HRF genes are listed in the Infevers database. An external quality assessment (EQA) program for the primary tested HRF syndromes (FMF, CAPS, TRAPS, MKD) has been provided by the EMQN since 2009. Fifty laboratories, mostly from European countries, participate in the scheme. Data demonstrating improved genetic diagnosis for HRF since 2009 will be presented; genotype error rates have dropped dramatically compared to a prior 3 year survey (2005-2008). Moreover, with low participation outside Europe, best practice guidelines for the genetic diagnosis of HRF have also been written by HRF genetic and clinical experts, addressing the scope of diagnosis and clinical significance of pathogenic, clinically debated, rare, novel or population specific variants. A simple interpretation chart concludes on the contribution of each variant type to the diagnosis of recessive or dominant HRF disease. Guidelines also addressed minimal details and indication for referral, technical quality assurance measures, variant description nomenclature and recommendation for further genetic testing. Our future goal is to expand the scheme to monogenic autoinflammatory diseases, and to implement EQA on new genetic diagnostic methods for HRF such as Next Generation Sequencing (NGS).

P18.25-S
Attitudes of genomic researchers, health professionals and students on returning incidental findings to whole genome research participants

A. Carnevale[1], *M. A. Contreras-Sieck*[2], *M. L. Granados-Riveros*[2], *S. Romero-Hidalgo*[1], *G. Saruwatari-Zavala*[1];
[1]*Instituto Nacional de Medicina Genómica, Mexico City, Mexico,* [2]*Escuela Nacional de Antropología e Historia, Mexico City, Mexico.*

At the moment, there is no consent on how to handle incidental findings (IF) in human research. We are investigating the opinions of genomic researchers, health professionals and students on returning IF to research participants using a questionnaire available on line at the Welcome Trust that was kindly sent to us for translation to spanish and application in our country. The questions explore if the severity of the health problem incidentally found, the level of risk of getting the condition and the usefulness of the information affect whether the person think the result should be returned. Also, it asks the participants to first answer based on their own professional knowledge and second to answer imagining they are the research participants. The preliminary results show that respondents agree that information on preventable conditions should be returned to participants in genomics research; however, they were more likely to receive IF regarding a life-threatening non preventable condition than to return it to participants. More than ninety percent of subjects would return IF related to drug response or that could be relevant to their children. And 80% think someone should decide which types of IF to share. Also, 80% feel it is acceptable to have a ‚flexible consent' process where research participants could update and change what information they choose to receive, and almost 50% of respondents think results should be available for ever. As whole genome research advance in Mexico, studies to develop policies on how to handle IF become important.

P18.26-M
To know or not to know: Research participants want to know about incidental findings in WES-studies

A. Jelsig, *N. Qvist, K. Brusgaard, L. Ousager;*
Odense University Hospital, Odense, Denmark.

Introduction
In the last years the ethical and legal management of incidental findings in

massive parallel sequencing have been discussed. There is a lack of literature concerning research participant's perspective. The aim of this study was to investigate whether research participants want disclosure of IF's and what kind of IF's they want to know about.
Methods: 127 research participants in a study of gastrointestinal polyps were informed about Whole Exome Sequencing and the risk of IF's. They were asked to decide whether they A) wanted disclosure on IF's no matter whether the mutations were associated with a non-treatable or non-preventable condition, B) wanted disclosure on mutations associated with treatable or preventable conditions or C) wanted no disclosure at all.
Results: Participants who wanted disclosure of all IF's (A) accounted for the majority (n=78), 45 of the participants only wanted disclosure of mutations, which could lead to surveillance or treatment (B) and four participants did not want IF's to be disclosed at all (C).
Conclusion: The study showed that almost all research participants wanted disclosure of at least some types of IF's. The answers did not depend on age or sex. We suggest that well-defined IF's are to be disclosed in research projects and that the type of IF's (non-treatable and actionable) are categorized, discussed with the participant, and incorporated in the research consent form.

P18.27-S
Disclosure of genetic information to family members: does the French legal framework solve the dilemma?

E. Rial-Sebbag[1], *C. Farnos*[1], *S. de Montgolfier*[2];
[1]UMR 1027, INSERM, Université Toulouse Paul Sabatier, Toulouse, France, [2]IRIS (Institut de Recherche Interdisciplinaire sur les enjeux Sociaux. Ehess/INSERM/CNRS) / Univ. Paris Est Créteil, Paris, France.

Genetic information is often considered as specific, among other biological information, because of its personal and family dimension. When a person is diagnosed with a serious genetic anomaly, the disclosure of this information can be relevant for other family members when prevention measures or treatment exist. The transmission of this information raises legal issues for professionals: how to preserve confidentiality and privacy of personal medical information? How to ensure the right to know of the relatives when the information to be disclosed can be of interest for their health? The French legislator tried, in 2004, to draw a balance between these principles by implementing the "genetic information procedure to family members. The lack of adoption of enforcement decrees made the law not applicable since a revision occurred in the new bioethics law (2011). This procedure tends to favor information of relatives by creating a primary legal obligation for the index subject to inform his family members. It also creates professional obligations notably in the ways this information has to be formalised and disclosed when the subject do not want to communicate it. The French legal system is almost complete) as many texts (legal and good practices) have enriched the procedure throughout 2013 In the light of these legal novelties we will make a comparative analysis to address -The equilibrium of the principles referred to in the law, -Their adequacy to the practices, -The remaining unclear points (responsibilities not to disclose, genetic information relating to minors)

P18.28-M
Gynecologic cancer is "sentinel cancer" for Lynch syndrome

I. Carnevali[1], *L. Cimetti*[2], *A. Chiaravalli*[1], *N. Sahnane*[2], *D. Furlan*[2], *A. Viel*[3], *L. Libera*[2], *T. Rossi*[4], *F. Sessa*[2], *C. Riva*[2], *M. Tibiletti*[1];
[1]Ospedale di Circolo - Polo Universitario, Varese, Italy, [2]Department of Surgical and Morphological Sciences, University of Insubria, Varese, Italy, [3]Oncologia Sperimentale I, CRO, Aviano, Italy, [4]Clinica Ostetrica e Ginecologica, Ospedale di Circolo - Polo Universitario, Varese, Italy.

Lynch Syndrome (LS) arises by a germline mutation of MMR genes. Women with LS show a risk for endometrial cancer equal or greater than colorectal cancer. Specific surveillance and risk-reducing strategy could be proposed in LS patients. MSI and IHC MMR protein expression tests in tumor samples could represent an effective strategy for identifying LS in patients with GC (Gynaecological Cancers). Clinico-pathological features, MSI and Immunoistochemical (IHC) expression of MMR proteins were investigated on 78 tumour samples (62 endometrial, 7 ovarian and 9 cervical tumours) of 75 patients affected by GC. All patients referred to genetic Counseling Service of Varese Hospital from 2001 to 2013. Somatic test including IHC and MSI revealed absence of MMR protein expression in 44/64 and MSI in 36/61 GC. Fifteen GC showing MSI and loss of IHC MLH1 expression revealed MLH1 promoter hypermethylation. The mean age at GC diagnosis in LS patients was 46 years. Endometrial cavity was the prevalent site, and 28/38 GC tumors showed a pure endometriod histotype. Twenty nine out of 35 patients show GC as first manifestation of LS. MMR germline pathogenetic mutation was identified in 20 patients (10 patients were obligate carriers), the remaining five patients showed variants with unknown significance of MSH6 gene. In conclusion IHC, MSI and MLH1 methylation in CG patients under 50 years is an efficient strategy to identify LS. In addition clinico-pathological features including site, hystotype and presence of lymphocytes infiltration help to identify an additional subset of LS patients.

P18.29-S
New genomic technologies and medical genetics: How much time is needed? A preliminary study

R. Sukenik-Halevy, *M. Ludman, A. Raas-Rothschild;*
Meir Medical Center, Kfar Saba, Israel.

Clinical genetics services are time and labor intensive, since they include both counseling meetings as well as extensive patient related activities such as administration, summary letters, and the interpretation of new genomic technologies. With increasing pressure for cost effective medical care, information is needed to evaluate the time and efforts required for providing medical genetics services. An online survey was conducted among 151 professionals who practice medical genetics throughout the world (85.75% medical geneticists, 13.12% genetic counselors). The reported average amount of time required for counseling sessions for pediatric, oncogenetic, pregnancy with a malformed fetus and preamniocentesis counseling was significantly different: ~60,42,51,27 minutes respectively. The average time required to write summary letters varied from 30 to 41 minutes. The time required for literature searches was 31-60 minutes and for patient related activities, 42 minutes. The time for patient related bioinformatics search and for test interpretation was 57 minutes . CMA requires an average of 48 minutes for analysis and for genetic counseling each. Professionals with less than 10 years' experience needed more time than those with more than 10 years' experience. Time devoted to clinical work received the highest percentage followed by administration, research and teaching. This study emphasizes the complexity and time consuming demands of the practice of medical genetics in the era of advanced genomic testing; further consideration and assessment is required in order to determine how to adapt genetic services to the demands of cost effectiveness, without compromising the quality of patient care.

P18.30-M
Project Superhero: the kids are doing it for themselves

J. M. Grey[1], *A. Metcalfe*[2];
[1]AMEND, Tunbridge Wells, United Kingdom, [2]King's College, London, United Kingdom.

Multiple endocrine neoplasia (MEN) disorders are autosomal dominantly inherited syndromes characterised by multi-glandular adenomas/carcinomas. AMEND is a patient group providing support and information resources to MEN patients. However; no information about MEN aimed specifically at children and young people currently exists. Inspired by 2011 research by Metcalfe et al(1), AMEND started 'Project Superhero!' which aims to 1) improve communication about the MEN conditions within affected families, 2) increase involvement and compliance by affected young people in their healthcare, and 3) provide families with a wider range of information about MEN to aid open discussion. A Family Focus Day (FFD) held in March 2013 involved 13 young people aged <18 [ages 8-18] from 6 families [2 MEN2a, 1 MEN2b, 2 MEN1, 1 control family]. Adults and young people completed self-assessments to test their knowledge about MEN. Adults' scores ranged from 3-5 (mean 4.3) for identifying five different glands; young people's scores ranged from 0-5 (mean 3.2). Knowledge levels (0 = no knowledge, 5 = complete knowledge): adults' scores ranged from 1-4 (mean 2.8) and young people's ranged from 1-4 (mean 2.3). Questions from the young people, included, 'Do I have cancer?' and 'Will this kill me?'. The findings were used to develop resources to answer their questions, which include MEN1 and MEN2 Medikidz™ comic books and 2 website animations. Evaluation of the resources is underway.

The Genome Clinic in Geneva: an example of a multidisciplinary task force for the clinical use of next generation sequencing

S. Fokstuen[1], *E. B. Hammar*[1], *P. Makrythanasis*[1], *M. Albarca Aguilera*[1], *M. E. Poleggi*[1], *C. Brockmann*[1], *M. Guipponi*[1], *F. A. Santoni*[1], *A. Mauron*[2], *S. A. Hurst*[2], *C. Moret*[2], *S. Gimelli*[1], *E. Stathaki*[1], *A. Paoloni-Giacobino*[1], *E. Ranza*[1], *K. Varvagiannis*[1], *F. Sloan Béna*[1], *L. D'Amato Sizonenko*[1], *M. Mostafavi*[1], *H. Hamamy*[1], *T. Nouspikel*[1], *J. Blouin*[1], *S. E. Antonarakis*[1];
[1]University Hospital of Geneva, Geneva 4, Switzerland, [2]Institut Ethique Histoire Humanités, Geneva 4, Switzerland.

The advances of next generation sequencing (NGS) technologies enable their application in clinical care. However, beside the clear benefits of NGS, such an implementation faces technical, ethical and financial challenges, in-

cluding data processing, storage and management, variant interpretation, genetic counseling (informed consent, management of variants of uncertain clinical significance, incidental findings), quality control as well as reimbursement questions. In order to optimally integrate the use of NGS into our clinical practice and to address these questions, we have created a multidisciplinary working group, the Genome Clinic task force.
This task force is composed of physicians and scientists, including clinical and molecular geneticists, bioinformaticians, bioethicists and a coordinator. During our weekly sessions, clinical cases of heterogeneous mendelian disorders that could potentially benefit from a NGS approach are presented, results and interpretation of analyzed cases are discussed, as well as issues related to bioethics, management and health policy.
During the pilot phase, we have validated 20 cases for whole exome sequencing followed by targeted bioinformatics analysis of selected genes. In addition, we have collaborated with the Swiss Federal Office of Public Health (SFOPH) in order to render NGS a reimbursable genetic test by the health insurance. We will present the results of resolved clinical cases as well as the outcomes of our interactions with the SFOPH.
In conclusion, this multidisciplinary task force has enabled us to deal with the multiple issues related to NGS in clinical practice and to ensure a high standard clinical service within this new and exciting field.

P18.32-M
From clinical suspect to molecular confirmation of Noonan syndrome; contribution of "best practice" genetic counselling

D. Varvara[1], *M. Patruno*[1], *M. Seri*[2], *C. Rossi*[2], *L. Cavallo*[3], *M. F. Faienza*[3], *A. Ventura*[3], *C. Simone*[4], *F. C. Susca*[1], *A. Stella*[1], *N. Resta*[1], *N. Bukvic*[5];
[1]*Division of Medical Genetics-Department of Biomedical Sciences and Human Oncology-University of Bari, Bari, Italy,* [2]*Laboratory of Medical Genetics, Department of Internal Medicine, Cardioangiology and Epatology, University of Bologna, Bologna, Italy, Bologna, Italy,* [3]*Department of Biomedicine of Developmental Age, University of Bari, Bari, Italy, Bari, Italy,* [4]*Division of Medical Genetics-Department of Biomedical Sciences and Human Oncology-University of Bari; National Cancer Institute IRCCS Oncologico Giovanni Paolo II, Bari, Bari, Italy,* [5]*Division of medical genetics- University Hospital Consortium of Bari, Bari, Italy.*

Noonan syndrome (NS) is AD disorder, characterized by variable expressivity of clinical features such as: postnatal growth reduction, congenital heart disease, characteristic facial dysmorphisms and development delay. In ~75% of all NS cases, germline mutations involving RAS-MAPK signaling pathway genes (PTPN11, SOS1, RAF1, KRAS, NRAS, BRAF, SHOC2, MEK1, CBL) are causative.
We reported a case of 13-year-old girl [born at 36w by CS (BW 3250 g (~95°), BL 48 cm (~75°)] referred for genetic counseling due to growth retardation, facial dysmorphisms, development delay and learning disability. After birth she presented frequent vomiting, with failure to thrive and at 5 months of age underwent surgery for intestinal malrotation. Because of short stature, Growth Hormone (GH) therapy have been introduced at age of 3yrs up to 11yrs. Negative molecular testing for PTPN11 and SOS1 genes, normal female karyotype and aCGH analysis were observed.
Objective examination: H 138 cm, (<3°); W 33 kg, (<3°), no menarche, hypertelorism, eyelids ptosis with down slanting palpebral fissures, low-set and posteriorly rotated ears, high-arched palate, micrognathia, short and webbed neck, low hairline at the back of the neck, pectus excavatum, prominent scoliosis, joint hyperextensibility, bilateral pes planus and mitral valve prolapse disclosed by US.
Phenotype of our patient was suggestive to NS, thus further mutational screening has been requested. Missense mutation in exon 2 of KRAS gene (c.40G>A; p.Val14Ile) has been identified. Even though KRAS mutations are usually associated with NS severe phenotype with cardiac involvement (hypertrophic cardiomyopathy), this finding is not present in our patient.

P18.33-S
Orphanet UK: Ensuring quality of information

I. Gomez Paramio[1,2], *R. Scholey*[1,2], *H. R. Middleton-Price*[1], *S. Ayme*[3], *O. Kremp*[3], *D. Donnai*[4];
[1]*Nowgen, Manchester Biomedical Research Centre, Manchester, United Kingdom,* [2]*The University of Manchester, Manchester, United Kingdom,* [3]*INSERM US14, Paris, France,* [4]*Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom.*

Orphanet is the largest online resource for rare diseases and orphan drugs for all audiences. It provides free and direct online access to the most comprehensive classification for rare diseases, an "assistance to diagnosis" tool, the EUCERD's newsletter, thematic studies and reports and updated information about rare diseases and specialised services in around 40 countries. Orphanet UK (www.orphanet.co.uk) has been operational since 2005. To date it lists >300 expert centres, 125 laboratories, >300 patient organisations, >130 patient/mutation registries and >580 research projects and clinical trials.
Orphanet has established strong quality standards over the years considering the different situations of the countries part of the consortium. There are defined inclusion criteria for each activity.
Information is collected from official sources specific to each country. Once published data will be checked annually by post-validators, who are professionals working in the field of rare diseases with expert knowledge in the relevant activity. Orphanet UK has established several partnerships to post-validate its information. Rare Disease UK and Genetic Alliance validate patient organisations. ERNDIM validates EQA accredited metabolic laboratories in the UK. UK centres of expertise are validated by experts that are part of the EUCERD and research activities are validated by relevant patient organisations. Orphanet UK is also working to establish new partnerships to validate data about molecular and cytogenetic laboratories and data about clinical trials too. Every effort will be made to ensure that information is accurate, comprehensive and up to date.

P18.34-M
Attitudes of adult patients and parents of children with cystic fibrosis towards carrier screening for cystic fibrosis

S. Janssens[1], **D. Chokoshvili**[2,3], *C. Binst*[4], *I. Mahieu*[4], *L. Henneman*[5], *A. De Paepe*[1], *F. De Baets*[6], *P. Borry*[3];
[1]*Center for Medical Genetics, University Hospital Ghent, Ghent, Belgium,* [2]*University Hospital Ghent, Ghent, Belgium,* [3]*Catholic University of Leuven, Leuven, Belgium,* [4]*University of Ghent, Ghent, Belgium,* [5]*VU University Medical Center Amsterdam, Amsterdam, Netherlands,* [6]*Ghent CF Reference Center, Ghent, Belgium.*

Cystic Fibrosis (CF) is a severe autosomal recessive condition with clinical symptoms such as chronic pulmonary disease and pancreatic insufficiency. CF affects approximately one in 2500-4000 Caucasians, while the carrier frequency is estimated at one out of 25 to 30. Carrier screening for CF has been available to individuals without family history of the disease since the early 1990s. However, very few screening programs have been implemented around the world to date. In order to assess social desirability of carrier screening for CF, it is important to study views and attitudes of key stakeholders, such as patients with CF and their family members.
The aim of this study was to assess views of adult patients and the parents of children with CF regarding carrier screening for CF. Participants were recruited from a register of patients at the University Hospital of Ghent. 134 questionnaires were distributed of which 112 were returned (response rate 83.5%). In overall, the attitudes towards carrier screening for CF were positive, with 80% of respondents thinking the procedure entails more advantages than disadvantages. Eighty-five percent of the respondents believe that the screening should be routinely offered to all couples planning a pregnancy, while 72.9% were of the opinion that the procedure should also be provided prenatally. Regarding future pregnancies, 46.1% would themselves choose for preimplantation genetic diagnosis, 43.6% would prefer to conceive naturally followed by a prenatal diagnosis. Others were ready to accept the risk of having an affected child, or opt for an adoption, 5% each.

P18.35-S
Predictive genetic testing in hereditary heart diseases: a single-center series of 304 subjects

C. Bordet[1], *E. Le Boette*[1], *M. Babonneau*[1], *S. Fosse*[1], *M. Garguilo*[1], *E. Gandjbakhch*[1], *V. Fressart*[1], *P. Richard*[1], *D. Héron*[2], *M. Komadja*[1], *P. Charron*[1];
[1]*Centre of reference of hereditary heart disease, Groupe Hospitalier Pitié Salpétrière, Paris, France,* [2]*Department of Genetics; Groupe Hospitalier Pitié Salpétrière, Paris, France.*

Hereditary heart diseases are typically characterized by autosomal dominant inheritance and delayed cardiac expression. Predictive genetic testing (PGT) is offered to asymptomatic relatives to allow targeted medical care with early therapeutics in order to reduce the risk of complications. Psychological issues related to PGT are complex and have been poorly studied. To evaluate our practices regarding PGT for hereditary heart diseases and study the behavior of relatives after the first information consultation, offering a waiting period before blood sampling. We retrospectively studied records from 304 consecutive relatives seen in our department and have requested PGT. Underlying diseases in the families were HCM (60%), DCM (17%), ARVC (15%), LQT (5%), Brugada syndrome (2%) and other (1%). There were 260 adults and 44 minors. At the time of the first consultation, the average age was 37 years, and 83 % of the relatives previously had a cardiac checkup. After multidisciplinary consultation, 22 relatives (8%) dropped out of procedure and 11 relatives (3%) performed blood sampling but did not come back to know their results. Blood sample was delayed for 70% of relatives and immediate for 30%. A total of 21 different genes were analyzed and most frequent ones were MYBPC3 (97), MYH7 (77), LMNA (37). A mutation was present in 36% of relatives and absent in 64%. We observed a high level of genetic uptake after initial consultation but a minority of relatives decided to stop or delay the procedure. These results suggest the benefit of a waiting period before blood sampling.

P18.36-M
Presymptomatic and predictive genetic testing in minors - a mini-review in preparation for new Danish best practice guidelines

J. B. Andersen[1], *B. R. Diness*[2], *K. Brøndum-Nielsen*[1];
[1]*Kennedy Center, Department of Clinical Genetics, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark,* [2]*Department of Clinical Genetics, Rigshospitalet, Copenhagen, Denmark.*

Aim: In preparation for the creating of Danish guidelines regarding predictive and presymptomatic genetic testing in minors, we have reviewed existing guidelines and policy papers as well as international conventions. Furthermore we have reviewed existing literature concerning the psychosocial impact of testing children.
Materials: Guidelines on the topic from four of the largest English-speaking genetic associations were reviewed. The Convention on the Rights of the Child and the Convention on Human Rights and Biomedicine were also considered.
Results: In the reviewed guidelines it is recommended to offer genetic testing if the test result will be of medical benefit to the child. In some guidelines emphasis is on *immediate* benefit. If there is no potential medical benefit it is recommended to defer genetic testing for adult-onset disorders until minors are able to decide for themselves. Some guidelines suggest that psychosocial factors in certain cases can justify genetic testing for adult-onset disorders. Requests for genetic testing for childhood-onset disorders can usually be met. Thorough genetic counseling and consideration of timing of the test is of importance in the decision-making process.
Discussion: There is a lack of knowledge about the psychosocial impact of testing children. The recommendations in the reviewed guidelines are based on the classic medical moral principles: Nonmaleficence, beneficence and respect for autonomy. The recommendations are in consistency with international conventions on the field, but statements within these conventions can be subject to interpretation. We call for increased awareness of the difficulties in defining "the best interest" of children.

P18.37-S
Presymptomatic testing in minors: Requests and pratices. Evaluation of pluridisciplinary consultations for the last 20 years

A. Jacquette, *M. Fuger, A. Durr, C. Colas, M. Garguilo, A. Herson, M. Babonneau, S. Fosse, I. Marey, S. Whalen, C. Boucher, E. Schaerrer, C. Bordet, p. Charles, E. Le Boette, J. Feingold, P. Charron, D. Heron;*
département de génétique, Paris, France.

Twenty years ago, the first presymptomatic tests (PST) began for Huntington's disease. Since then, PST have been extended to other diseases, in particular among minors. The practice of these tests is regulated by law within each European country and follows a number of principles, including respect for the «right to not know» and autonomy. In the case of children, performing such tests is complicated because all of these conditions cannot always be met. In the Department of Genetics in the Pitié-Salpêtrière Hospital, several protocols of PST are reported to the French Biomedicine Agency, in accordance with French law. We wanted to explore our practices regarding children. All patients under 18 years of age at the first consultation for a PST were included in this retrospective study. 175 children met the inclusion criteria and they were divided into 4 groups (cardiology, myology, neurology, oncology). Medical data but also access to the test or not, motivations, were collected. The average age of minors at the first consultation was 13 years. 69% of children have performed the test but this varies significantly ($p<0.05$) according to the pathology (46% in neurology and over 90 % in cardiology and oncology). 8.6% of children also said they did not want the test at the first consultation, underlying the importance of parental demand. The study by group of pathologies also notes that the reflexion time, the reasons given for doing the test vary according to the pathology and emphasize the importance of a differentiated care.

P18.38-M
Promotion of genetic services in the Slovenia-Italy cross-border region

M. Cassina[1], *F. Petrera*[2], *C. Puppin*[3], *A. Viel*[4], *P. Korošec*[5], *A. Komac*[6], *S. Bigoni*[7], *A. Savoia*[2], *G. Damante*[3], *B. Peterlin*[8], *M. Clementi*[1];

Anna, Ferrara, Italy,* [8]*Clinical Institute of Medical Genetics – University Medical Center, Ljubljana, Slovenia.*

SIGN (Slovenian-Italian Genetic Network) is a project sponsored by the European Union with the aim to implement both the accessibility and the quality of genetics services in the Slovenia-Italy cross-border region. Eight Slovenian and Italian institutions have joined the project. One of the major objective of SIGN is to raise awareness in both the general public and medical specialists on the activities of the genetic services and on the new diagnostic options patients with rare diseases may be offered. For this purpose, training courses in medical genetics for paediatricians, gynaecologists and oncologists have been organized and several workshops for high school students have been conducted. All the project partners were actively involved in these meetings, allowing the reinforcement of the genetic network and the establishment of new scientific collaborations. In addition, a specific website, in both Italian and Slovenian, has been developed in order to help patients, doctors and students to better understand human and medical genetics (www.signgenetics.eu). The section dedicated to the general public contains information on human genetics, genetic diseases and their impact on the society described in a simple, non-technical way. The section for doctors and students offers a variety of educational tools, including fact sheets on several genetic diseases, examples of clinical cases useful to recognize and correctly diagnose specific diseases, video seminars of experts and clinical protocols. Another section is devoted to updating and promoting the results achieved within the project: it includes a description of the project partners and their clinical and research activities.

P18.39-S
The French Foundation for rare diseases: accelerating rare diseases research

E. Chanudet-van den Brink;
on behalf of the French Foundation for rare diseases („Fondation maladies rares"), Paris, France.

The French Foundation for rare diseases is an innovative cooperative framework dedicated to rare diseases research. Flagship of the second French National Rare Diseases Plan, co-founded by University Hospitals, Research organisations and Patients organisations, we act as a federative and strategic hub to accelerate scientific, clinical and social innovation by stimulating cross-sector cooperation to the benefit of patients affected by rare diseases. With our headquarters at the heart of the French Platform for Rare Diseases and seven regional coordinators, in direct contact with researchers all over the national territory, our priorities are driven by grounded needs and integrated into a national strategy with an international perspective. Our active support, spanning from basic to translational and clinical research, includes enhancing the access to high throughput technologies such as NGS, promoting international collaboration via dedicated partnerships, and accelerating the translation of research into clinical development through targeted links to orphan drug experts. Since rare diseases research is tightly linked to societal challenges, we are also actively supporting studies on social, economical, ethical impacts of rare diseases. We regularly initiate national working groups, open to international perspectives, to specifically target timely issues, including professional training needs, ethical and regulatory issues around data and bio-specimen collections, as well as the impact of new technologies in genetics, patients' consent to genetic testing and their paths through diagnosis and treatment. Through this unique range of actions, we aim to contribute to acquainted national public health and research policies and to the promotion of international multi-stakeholders cooperation.

P18.40-M
Rare Diseases week in Timisoara - a campaign with a good start

M. Gafencu[1], *G. Doros*[1], *D. Dan*[2], *I. Jurca Simina*[1], *L. N. Bogdan*[1], *M. Puiu*[1];
[1]*Victor Babes University of Medicine and Pharmacy, Timisoara, Romania,* [2]*National Alliance for Rare Diseases Romania, Zalau, Romania.*

„Volunteers for Rare Diseases" was created in „Save the Children" Timis in 2007 when students from the University of Medicine Timisoara, supported by teachers, wanted to work with people with special needs. The campaign launched on the International day of rare diseases was the opportunity to spread informations about this topic in community. An extension to a whole week dedicated to this was the next step.
Increase awarenes in general population, involving the local authorities, rasing the interes in this field for medical services employees and involving our students in volunteer work were main objectives.
In all the 5 years we used internet as a tool and mass-media campaign also. Volunteers made a street march in the dedicated day with flyiers distribution in downtown and placing posters. We organised round table at the local TVs with specialised medical staff. Each year we met the children in hospitals and settled lessons for parents.
With parents we discussed the common situations of various diseases, followed by monitorization of their skills yearly. „Rare Disease Day" has taken many forms over the years: symposiums, conferences, information campaign, march (more than 200 participants/year). The childrens with rare pathologies have in this way support for their integration into society. The

authorities realise the need for social protection with different ways to support this people. All the student involved can use informations about this pathology and early diagnose cases, encouraging prevention.

P18.41-S
Respecting autonomy while reacting to change: A review of current policy and empirical evidence on re-consent in longitudinal biomedical research

S. E. Wallace, **E. G. Gourna**, *O. Shoush, L. Brewster, J. Wright;*
University of Leicester, Leicester, United Kingdom.

Background: The need to balance the autonomy of participants and their consent to participate in biomedical research with the fast pace of scientific enquiry is becoming difficult as the number of projects grows and pressure increases at national and international levels to link project resources to facilitate access and data sharing.
Methods: We undertook a literature review from the perspective of longitudinal cohort studies and biobanks. We examined existing policy statements, academic literature on re-consent, and evidence from re-consent exercises.
Results: Guidance from policy bodies is vague, suggesting that re-consent should be sought if changes are made to the original protocol or if new research falls outside the scope of the original consent. Stakeholders' attitudes showed different approaches. Broad consent, with or without an oversight body is a popular alternative, while seeking re-consent for every study was also mentioned by a minority. Several alternatives along this continuum have been suggested by commentators and as a result of empirical studies. Actual and potential research participants want re-consent when a new use presents increased risks and is for a new unrelated condition, while commentators also suggest re-consent when the research is moving beyond existing use, such as for next-generation sequencing.
Conclusion: Practical difficulties, potential loss of participants and increased costs make re-consent for every new study unpractical and in some cases unfeasible. There is a lack of studies investigating actual participants and their positions on re-consent and research is needed to inform best practice guidelines for re-consent in longitudinal studies.

P18.42-M
Willingness to participate in the research of rare diseases: general public versus patients and their family members

V. Frankova[1,2], *J. Bártl*[1], *P. Chrastina*[1], *M. Boučkova*[1], *V. Kožich*[1];
[1]*Institute of Inherited Metabolic Disorders, Prague 2, Czech Republic,* [2]*Institute for Medical Humanities, Prague 2, Czech Republic.*

Background: Development of new approaches for prevention and diagnosis of rare diseases depends on willingness of people to participate in research. In this study we compared the research participation of general public represented by mothers of newborns with the proportion of patients with rare diseases and their relatives consenting to anonymous genetic research.
Material and Methods: General public participation was assessed from an intake of a pilot study for newborn screening (NBS) expansion involving 70,818 newborns from 58 Czech maternity hospitals. The willingness of patients and/or their relatives to donate samples for research was recorded from 318 consent forms obtained by 67 physicians during genetic counselling; only 240 forms were completed with regard to research.
Results: The intake of the NBS pilot study varied considerably by the maternity hospital ranging between 11% and 93% of mothers with a median intake of 75%. The willingness to donate samples for research differed substantially by the counselling clinical geneticist and varied between 0% and 100%; 82% of patients and their relatives consented to the research use of residual samples.
Conclusions: This study shows similar and quite high willingness of both the general Czech population and patients/relatives with rare genetic disorders to participate in research. The notable difference in recruitment between maternity hospitals as well as clinical geneticists points out the major factor also documented in literature for other conditions, which is the involvement of site or person offering the research participation.
This study was supported by projects LM2010004 and PRVOUK-P24/LF1/3

P18.43-S
50 years anniversary of Smith-Lemli-Opitz Syndrome

M. Witsch-Baumgartner;
Medical University Innsbruck, Innsbruck, Austria.

50 years ago the Smith-Lemli-Opitz Syndrome (SLOS, RSH syndrome) was described for the first time in three male patients by David W. Smith, Luc Lemli and John Opitz. It was a clinical description showing microcephaly and hypogenitalism. 30 years later Tint and colleagues found the underlying defect in cholesterol biosynthesis (1994). The gene was identified by a group in Innsbruck (Fitzky et al., 1998), first mutations in SLOS patients have been detected by the same group and also by Wassif et al. (1998). Hence SLOS is a metabolic and malformation disorder caused by mutations in the DHCR7 gene. This gene encodes the α7 sterolreductase. Now more than 130 mutations are known and all reported patients are included in the DHCR7 database (http://databases.lovd.nl/shared/genes/DHCR7). Mutation spectra are different in European populations. Time since establishment of common founder mutations (c.964-1G>C, p.Trp151* and p.Thr93Met) is long enough (about 100 and 200 generations) to explain frequencies (1:100 for c.964-1-G>C) by genetic drift (Witsch-Baumgartner et al., 2007). There are modifiers of clinical severity of SLOS. Depending on SLOS patient´s maternal variants apoE 2, 3 or 4 the severity vary significantly (Witsch-Baumgartner et al., 2004). The fundamental problem of the disease is the lack of cholesterol during embryogenesis. Regarding therapies adding HMG-CoA reductase inhibitor (simvastatin) might ameliorate the severity (Jira et al., 2000; Haas et al., 2007). After 50 years the pathophysiology of SLOS is still not as clear due to multiple functions of cholesterol. To help patients it is still necessary to continue research on SLOS.

P18.44-M
Gonadal mosaicism in split-hand/foot malformation: Implications for genetic counselling

N. Martin[1], *J. Jessen*[1], *C. Barr*[2], *J. T. R. Clarke*[2,3], *K. Chong*[1], *D. Chitayat*[1,3];
[1]*Department of Obstetrics and Gynecology, Prenatal Diagnosis and Medical Genetics Program, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada,* [2]*Service de génétique médicale, Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, Canada,* [3]*Department of Pediatrics, Division of Clinical & Metabolic Genetics, Hospital for Sick Children, Toronto, ON, Canada.*

Split-hand/foot malformation (SHFM) is a congenital limb defect affecting predominantly the central rays of the hands ± feet. SHFM is genetically and clinically heterogeneous with inter and intra familial variability in the clinical manifestations. Most cases are inherited in an autosomal dominant manner and a causative genetic alteration is detected in approximately 50% of patients affected. SHFM3 accounts for 20% of cases and is caused by tandem microduplications at 10q24. We report 2 cases of recurrent 4 limb ectrodactyly with phenotypically normal parents and 1 case of a female with SHFM3 and her difficult attempts at IVF due to an abnormally high number of affected embryos. Case 1: A brother and sister presented with isolated 4 limb ectrodactyly. Microarray analysis showed a *de novo* 10q24.32 microduplication, which was 434 Kb in size. Case 2: A mother with a child with 4 limb ectrodactyly was 16.5 weeks pregnant when abnormalities of the hands and feet were identified on fetal ultrasound. Microarray analysis confirmed the 10q24.32 microduplication, previously identified in the affected sibling. Case 3: The proband was a mother with SHFM3 and a microduplication at 10q24.32, approximately 540 Kb in size. Preimplantation genetic diagnosis of 16 embryos identified the microduplication in greater than 80% of the embryos. We speculate that SHFM3 may represent a subtype of ectrodactyly that exhibits a higher chance of gonadal mosaicism. Genetic counselling in *de novo* cases should reflect this observation. Further research of the complex inheritance of SHFM is essential to providing families with accurate counselling.

P18.45-S
Regulation of genetic information

B. Tolo[1,2], *Å. Lunde*[1];
[1]*Department of Global Public Health and Primary Care, Faculty of Medicine and Dentistry, University of Bergen, Bergen, Norway,* [2]*Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway.*

Background: Genetic information in Norway is regulated by The Norwegian Act of Biotechnology (2003). One of its purposes is to protect people against discrimination and stigmatization. According to the Act § 5-8 genetic information in terms of predictive, symptomatic or carrier status shall not be released to insurance companies or employers. **Purpose**: The purpose of this study was to gain new insight and broader knowledge regarding regulation of genetic information in Norway. The focus was how people from insurance companies, medical genetics, patient organizations and the Norwegian government experience the regulation of § 5-8. **Material and methods:** A qualitative method was used with in-depth interviews of seven participants. **Results:** The participants experienced the § 5-8 to be important. They stated that genetic information is private and can easily be linked to a person's identity. Genetic information can also easily be misused, misinterpreted and can result in healthy people thinking they have a diagnosis. Despite challenges associated with enforcing the paragraph, the participants believed that it has a major role in protecting people from discrimination and stigmatization. In terms of new technology and commercial forces they also thought the paragraph will be important. **Conclusion:** The paragraph 5-8 has a high significance for the participants. It will also be important for fu-

ture perspectives to prevent people from discrimination and stigmatization. In order to protect human rights, it is important to inform patients about the regulation.

P18.46-M
Chromosomal mosaicism in chorionic villi: implications for prenatal diagnosis and genetic counseling

F. Maggi, **F. Malvestiti**, *B. Grimi, E. Gaetani, C. Agrati, F. Dulcetti, A. M. Ruggeri, G. Gallazzi, E. Niada, V. Zanatta, L. Branca, G. Simoni, F. Grati;*
TOMA, Advanced Biomedical Assays S.p.A., Busto Arsizio, Italy.

Chromosomal mosaicism in chorionic villi (CVS) can be either confined to the placenta (CPM) or generalized to the fetus (TFM). The probability of TFM depends mainly on timing and mechanism generating the mosaicism. Due to the variable distribution of the abnormal cell line, when a mosaic is detected in CVS a confirmatory amniocentesis should be performed to discriminate between CPM or TFM. We present a diagnostic experience on 52,673 CVS combining cytogenetic analysis of cytotrophoblast and mesenchyme and, in case of CVS mosaic, on amniocytes. A CV mosaicism was found in 1.81% of CVS. The stratification by category of chromosome abnormality indicate that mosaics involving 47,+mar or sex-chromosome aneuploidies have the highest risk of TFM (35.8% and 31.6%, respectively) while autosomal trisomies and 46,der karyotypes have a lower risk (6.9% and 5.2%, respectively). We will present the risk of TFM stratified by type of chromosome abnormalities distinguishing mosaic (MA) and nonmosaic abnormalities (NMA). Genetic counselling is challenging in case of CVS mosaicism and the need for data to calculate a risk of fetal involvement is vital to refine a personalized chromosome abnormality-based strategy of investigation to reduce the need for follow-up amniocentesis. While prenatal diagnosis is destined to become "molecular" with microarrays, NIPS and NGS, the large cytogenetic diagnostic experience on CVS presented in this study is helpful to evaluate limits and advantages of the new technologies that must be integrated in pretest and post-test counseling.

P18.47-S
Realising Genomics in Clinical Practice- Whole Exome Sequencing and the Patient Pathway

C. Alberg[1], *A. Hall*[1], *N. Hallowell*[2], *T. Finnegan*[1], *M. Kroese*[1], *J. Whittaker*[1], *G. Hall*[3];
[1]*PHG Foundation, Cambridge, United Kingdom,* [2]*Institute of Public Health, Cambridge, United Kingdom,* [3]*Manchester Centre for Genomic Medicine, Manchester, United Kingdom.*

Whole genome sequencing (WGS) and whole exome sequencing (WES) have been described as transformative technologies with potential to revolutionise patient care. As part of a bigger project addressing the ethical, legal, social (ELSI) and operational challenges likely to be raised by these technologies 'Realising Genomics in Clinical Practice', the PHG Foundation convened a workshop to explore the impact of these technologies on patient pathways. Key features such as the point and source of referral for sequencing will influence how WES/WGS will be translated into clinical practice. By comparing patient pathways currently in use in targeted approaches and whole exome sequencing, our aim was to illustrate the key operational differences and translational aspects that are likely to arise. In particular, we focused on three areas which seem to raise distinctive ELSI challenges: the nature and scope of consent processes and the degree to which they might need adaptation; technical aspects including the scope, construction and standardisation of data filters, and requirement for data sharing in order to validate and interpret findings; and the extent, timing and nature of disclosure of test results, including incidental or unsolicited information. We review our findings and evaluate the prerequisites for effective translation, including requirements for additional genetic counselling, and the educational and training needs of health care professionals, clinical scientists, patients and publics. These findings will be contextualised by presenting preliminary results from the entire Realising Genomics Project. Further information on the Realising Genomics project can be found at http://www.phgfoundation.org/pages/realising_genomics.htm

P18.48-M
Revisiting Hook: rates of fetal aneuploidy and other significant genetic aberrations in women presenting for prenatal care

G. Simoni[1], *J. Pinto B. Ferreira*[2,3], *F. Malvestiti*[1], *K. Bajaj*[2], *E. Gaetani*[1], *C. Agrati*[1], *B. Grimi*[1], *J. S. Hartman*[4], *F. Maggi*[1], *R. Wapner*[5], *S. Gross*[2,6], **F. R. Grati**[1];
[1]*TOMA Advanced Biomedical Assays S.p.A., Busto Arsizio, Italy,* [2]*Albert Einstein College of Medicine, Bronx, NY, United States,* [3]*Uniwersyteckie Centrum Zdrowia Kobiety i Noworodka, Warszawa, Poland,* [4]*Bryn Mawr College, Bryn Mawr, PA, United States,* [5]*Columbia University Medical Center, New York, NY, United States,* [6]*Natera, San Carlos, CA, United States.*

To date, health care providers have relied on modelled values to counsel pregnant women regarding their age-related risks for common aneuploidy syndromes, particularly in younger maternal age categories. The goal of this study was to provide a contemporary update using actual data from a single laboratory to derive specific age-related risks for common aneuploidies as well as significant non-aneuploidy fetal genetic aberrations.
QFQ-banded karyotypes from prenatal samples analyzed at a single biomedical from 1994-2012 were analyzed. Selected for study, were samples in which the only indication for karyotype was either maternal age ≥ 35 or maternal anxiety (patients <35 years) with exclusion of additional risk factors, such as maternal serum markers or ultrasound anomalies.
129,263 karyotypes from villi and AF were analyzed. As expected, autosomal aneuploidies and 47,XXY show a statistically significant positive association with maternal age while MX shows a borderline negative association only for CVS. Risk of non-aneuploid anomalies compromise a substantial share of chromosomal abnormalities in younger women. We present the rates of fetal aneuploidies and other significant chromosomal anomalies stratified by two periods of gestational age and, when applicable, by maternal age, which have been observed in real clinical practice. As standard prenatal screening strategies currently do not detect these non-aneuploidy DNA aberrations, the data presented in this study is critical for informed patient decision-making which should be a routine part of genetic counseling in the prenatal setting.

EMPAG EDUCATIONAL SESSIONS

EES1.1
Responding to guilt and shame in clinical consultations

C. Baguley;
Psychological Professions Network - Health Education North West, Manchester, United Kingdom.

Genetic medicine is an area of health care that often deals with delivering profound and difficult information; it brings clinicians directly in contact with individuals and families who sometimes have to make very difficult and life-changing decisions. Genetic counselling involves the skill of giving information, advice and support to help guide patients through this process.
Adjusting to information and assimilating new knowledge can have significant implications for the life decisions patients make. It is now recognised as normal for the course of adjustment to involve a range of emotional responses including denial, sadness, anger and guilt before the stage of acceptance is reached. This process can take time, individuals can vary in presentation and sometimes they can get 'stuck' often resulting in unhelpful behavioural consequences and increasing distress. In order to be effective clinicians need to understand this process and be equipped to recognise and respond to emotional responses that may occur within routine consultations.
This workshop looks specifically at the nature of guilt and shame in the context of genetic medicine. Drawing upon a cognitive behavioural model of emotion we will consider how the difficult and corrosive emotions of guilt and shame can be understood as an attempt by the individual to assimilate information and actions into their pre-existing belief system.
Drawing on a combination of theory, reflection on clinical examples, and illustration by video, participants will be encouraged to consider how they can develop their clinical interview skills to identify and respond to expressions of guilt and shame in routine clinical settings.

EES2.1
Qualitative and quantitative methods in psychosocial research

K. O'Doherty[1], **B. Meiser**[2];
[1]*Department of Psychology, University of Guelph, Guelph, ON, Canada,* [2]*Department of Medical Oncology, Psychosocial Research Group, Prince of Wales clinical School, University of New South Wales, Randwick, Australia.*

This presentation will provide an overview of qualitative and quantitative methods in psychosocial research in the genetics setting. In the first part of the session, we will cover three distinct types of qualitative research that have been used in psychosocial research in genetics: thematic analysis; discourse analysis; and deliberative approaches. Each approach is useful for particular kinds of research questions and problems. Case studies will be presented to illustrate the utility of each method, and the specific research questions it is able to address. Case studies will be drawn from the domains of genetic testing and counselling, popular representations of genetic risk, and research participation in biobanks.
The second part of the session will cover the key concepts and study types used in quantitative methodology, including survey studies, case control studies, cohort studies and randomised controlled trial, as well as examples of quantitative studies that may be carried out in the genetics setting to illustrate strengths and weakness of different types of designs. This will be followed by an introduction to the most commonly used validated instruments suitable for measurement of genetic counselling and testing outcomes. Finally the session will cover several health psychology theories that are particularly relevant to the genetic counselling and testing setting and may be used to provide the basis for formulation of study hypotheses and interpretation and analyses of findings.

EMPAG PLENARY LECTURES

EPL1.1
The impact of total gastrectomy upon e-cadherin carriers: experiences of eating

N. Hallowell[1,2,3], *S. Badger*[2], *S. Richardson*[2], *R. Fitzgerald*[2], *C. Caldas*[2], *J. Lawton*[1];
[1]*University of Edinburgh, Edinburgh, United Kingdom,* [2]*University of Cambridge, Cambridge, United Kingdom,* [3]*University of Melbourne, Melbourne, Australia.*

Between 30%-50% of cases of Hereditary Diffuse Gastric Cancer (HDGC) are caused by mutations in the E-cadherin gene. CDH1 mutation carriers have an earlier than average age of disease onset, and greatly increased risks of developing stomach cancer. Individuals identified as at-risk, either because of their family history or as a result of DNA testing, need to make decisions about risk management, whether they will have risk-reducing surgery (total gastrectomy - RRG) or continue screening. This retrospective study interviewed 42 patients, 27 of whom had undergone RRG. In this paper we will reflect upon the impact of surgery on bodily integrity and look at people's experiences of living without a stomach. The paper will focus upon eating post surgery, and discuss the ways in which surgery impacts upon identity. We will demonstrate that following surgery, hunger and satiety are constructed as disembodied experiences or desires that need to be re-embodied. Finally, we will argue that the process of re-embodying these supposed „physiological" states raises a number of issues about the nature of hunger and satiety. These will be interrogated using an analytic framework in which internal states are understood as grounded within public criteria.

EPL1.2
Impact of rapid genetic counselling and testing on primary surgery and psychosocial well-being in newly diagnosed breast cancer patients: Findings from a randomized controlled trial

M. R. Wevers[1,2], *M. G. E. M. Ausems*[2], *E. M. A. Bleiker*[1], *E. J. T. Rutgers*[1], *A. J. Witkamp*[2], *D. E. E. Hahn*[1], *T. Brouwer*[2], *R. B. van der Luijt*[2], *F. B. L. Rijna*[11], *J. P. Vente*[12], *S. Verhoef*[1], *N. K. Aaronson*[1];
[1]*the Netherlands Cancer Institute, Amsterdam, Netherlands,* [2]*University Medical Center Utrecht, Utrecht, Netherlands,* [3]*Diakonessen Hospital, Utrecht, Netherlands,* [4]*Antonius Hospital, Nieuwegein, Netherlands,* [5]*Meander Medical Center, Amersfoort, Netherlands,* [6]*Rivierenland Hospital, Tiel, Netherlands,* [7]*Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands,* [8]*St. Lucas Andreas Hospital, Amsterdam, Netherlands,* [9]*Tergooi Hospitals, Blaricum, Netherlands,* [10]*Gelre Hospitals, Apeldoorn, Netherlands,* [11]*Kennemer Gasthuis, Haarlem, Netherlands,* [12]*Zuwe Hofpoort Hospital, Woerden, Netherlands.*

Aims Female breast cancer patients carrying a BRCA1/2 mutation have an increased risk of contralateral breast cancer. We investigated the effect of rapid genetic counselling and testing (RGCT) on treatment decisions and psychosocial well-being. **Methods** Newly diagnosed breast cancer patients from 12 Dutch hospitals with at least 10% risk of a BRCA1/2 mutation were randomized to an intervention group (offer of RGCT) or a usual care control group (ratio 2:1). Study outcomes included uptake of direct bilateral mastectomy (BLM), cancer-specific distress, anxiety, depression, and health-related quality of life (HRQOL). Assessments took place at study entry, and at 6 and 12 months follow-up. **Results** Between November 2008 and December 2010, we recruited 265 women. Based on intention-to-treat analyses, no significant group differences were observed in percentage of patients opting for a direct BLM (14.6% (RGCT group) versus 9.2% (control group); OR 2.31; CI 0.92-5.81; p=0.08). Per-protocol analysis indicated that patients who received DNA test results before surgery (59/178 women in the RGCT group) opted for direct BLM significantly more often than patients who received usual care (22% versus 9.2%; OR 3.09, CI 1.15-8.31, p=0.03). No statistically significant differences were observed between groups over time on any of the psychosocial or HRQOL outcomes. **Conclusions** These results suggest that RGCT can be safely offered to newly diagnosed high-risk breast cancer patients. However, DNA test results need to be made routinely available pre-surgery in order to play a more significant role in surgical treatment decisions.

EPL1.3
Disclosure of psychosocial research results: a randomized study among GENEPSO-Ψ cohort participants

J. Mancini[1,2], *E. Le Cozannet*[1], *N. Resseguier*[1], *E. Bureau*[1], *A. D. Bouhnik*[1], *C. Lasset*[3], *E. Mouret-Fourme*[4], *C. Noguès*[4], *C. Julian-Reynier*[1,5];
[1]*UMR912, Aix Marseille Université, Inserm, IRD, Marseille, France,* [2]*APHM, Hôpital de la Timone, BiosTIC, Marseille, France,* [3]*Centre Léon Bérard, Lyon, France,* [4]*Institut Curie, Hôpital René Huguenin, Saint-Cloud, France,* [5]*Institut Paoli-Calmettes, Marseille, France.*

Background: The disclosure of aggregate research results to long-term cohort participants is rarely done and no recommendation specifies the best way to achieve this ethical obligation. GENEPSO-Ψ cohort follows both *BRCA1/2* carriers and non-carriers to study their psychosocial and preventive behaviour. Our aim was to study the impact of different formats of dis-

closure document.
Methods: Among the 454 respondents to the 5- and/or 10-year GENEPSO-Ψ questionnaires, 76% wished to receive "*information about the survey results*". They were randomized in a 2x2 factorial design to study the impact of adding to the psychosocial research leaflet: 1) an up-to-date medical information sheet, 2) a photography of the research team with the names of the researchers.
Findings: Providing additional medical information did not change outcome measures. On average (possible range[0-10]) the document was considered satisfactory (6.8), interesting (7.0), useful (7.3), and understandable (8.8). The information provided on medical findings was regarded as insufficient by 35% of the sample but the document was regarded as more often increasing (28%) than decreasing (2%) trust in research; average trust in medical researchers was high (75.2, possible range[0-100]). The additional photography only increased the rate of people feeling the information about the research team was sufficient (90.1% vs 80.7%, p=0.041).
Discussion: Adding medical information to the leaflet presenting the psychosocial research results did not significantly change satisfaction and trust of cohort participants. The lack of huge recent advances regarding prevention among *BRCA1/2* carriers may explain their relative disappointment. Predictors of dissatisfaction will be further studied.

EPL1.4
Prevalence and detection of psychosocial problems in cancer genetic counseling

W. Eijzenga, **E. M. Bleiker**, *D. E. E. Hahn, L. E. van der Kolk, G. N. Sidharta, N. K. Aaronson;*
Netherlands Cancer Institute, Amsterdam, Netherlands.

Introduction: Although only a minority of individuals undergoing cancer genetic counseling experience high levels of distress, many experience a range of specific psychosocial problems related to genetic counseling. The aim of this study is to evaluate the prevalence of these problems, and to investigate which method for detecting psychosocial problems is most optimal during counseling. **Methods:** Individuals undergoing genetic counseling for cancer were invited to complete a questionnaire including the Psychosocial Aspects of Hereditary Cancer (PAHC) questionnaire, the Hospital Anxiety and Depression Scale (HADS) and the Distress Thermometer (DT) prior to, or immediately following, their counseling session. **Results:** The most frequently reported problems of the 137 participants were on the PAHC-domains 'living with cancer' (84%), 'family issues' (46%), 'hereditary predisposition'(45%), and 'child-related issues'(42%). Partial correlations between the PAHC, the HADS and DT were low. Previous contact with a psychosocial worker, and a previous cancer diagnosis were significantly associated with higher distress on the HADS, but explained little variance (9%). No variables were associated with the DT. Previous contact with a psychosocial worker, and having children were significantly associated with several PAHC domains, but explained a small percentage of the variance (2-14%).
Conclusion: The large majority of counselees experience specific problems related to cancer genetic counseling. No variables were identified as important predictors of distress or psychosocial problems. To detect experienced psychosocial problems, we recommend that all counselees complete a brief problem-oriented questionnaire like the PAHC, and not only a questionnaire measuring distress, as a routine part of cancer genetic counseling.

EPL1.5
Developing a group programme for BRCA1/2 mutation carriers who underwent prophylactic mastectomy

M. den Heijer[1], *J. Gopie*[2], *A. Tibben*[2];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*Leiden University Medical Centre, Leiden, Netherlands.*

Introduction - Prophylactic mastectomy in BRCA1/2 mutation carriers reduces the breast cancer risk significantly, but may have a profound impact on body image and self-esteem. In addition, some women report feelings of isolation and stigmatisation. Other issues to face are an increased risk for ovarian cancer, potential cancer risk for offspring, intimacy with the partner, communication with family and ongoing grief. **Methods -** As a result of our long-year studies on impact of prophylactic mastecomy a group intervention was developed with regard to the supportive-expressive needs of these women. With a maximum of 10 members, a closed 8-sessions group programme was started focussing consecutively on the following themes: 1) introduction 2) body image 3) social support and coping 4) social support and loss 5) partner relationship or dating 6) ovarian cancer risk 7) communication within the family 8) evaluation and future plans. **Results -** Seven women participated in the first group aged 26-52. The older women advised the younger and vice versa, for example with regard to mother-daughter communication issues. The group members reported high satisfaction, particularly they felt they were no longer isolated and they could share their experiences and learn from each other. One woman who already had mastectomy for previous breast cancer, felt she was different from the others.
Conclusion - A next group will focus on a more homogenous population with regard to the experience of having had cancer yet or not. After refining content and structure of the programme an intervention study will be established.

EPL2.1
Ok for us, not for them: Patients and genetic counsellors' experiences of NIPT and views on wider use

A. Effa[1,2], *E. Alexander*[1], *S. E. Kelly*[3], *L. Kerzin-Storrar*[1];
[1]*Manchester Centre for Genomic Medicine, Institute of Human Development, University of Manchester and Manchester Academic Health Sciences Centre (MAHSC), Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom,* [2]*Program of Genetics and Metabolism, Winnipeg Regional Health Authority, Winnipeg, MB, Canada,* [3]*Department of Sociology, Philosophy and Anthropology, University of Exeter, Exeter, United Kingdom.*

In the UK non-invasive prenatal testing (NIPT) is now routinely offered for sex determination of pregnancies at risk of sex-linked conditions, and technology is progressing towards use for diagnosis of single gene disorders and detection of aneuploidy. We present the findings of a two-arm qualitative study investigating both genetic patients' and genetic counsellors'(GCs) experiences of NIPT for sex-linked conditions and their views on wider use of the technology. Forty (20 patients and 20 GCs) semi-structured interviews were completed and transcripts analysed using modified grounded theory methodology.
While both groups expressed that they felt positive about the use of NIPT for pregnancies at known genetic risk, they had concerns about broadening its use in the routine antenatal setting, particularly relating to the early timing in pregnancy and the apparent ease of using the technology. Shared concerns included the difficulties of ensuring informed consent, potential misuse of the technology for non-medical indications, and a diminished acceptance of disability in society. Patients articulated a strong sense of distinction from the general public, which included their use and perspectives of the technology, based on their lived experience, prior knowledge of a genetic condition and sense of 'genetic' responsibility. GCs discussed concerns about availability of necessary knowledge and time to appropriately offer NIPT in stretched routine services to provide the counselling and support they felt patients required. These findings highlight the importance of discussing and considering the issues surrounding wider implementation of NIPT including differences between those with prior genetic risk and the general population.

EPL2.2
Non-invasive prenatal testing (NIPT): opinions and interest among pregnant women in a country with relative low uptake of prenatal screening

R. V. van Schendel[1], *D. R. M. Timmermans*[1], *W. J. Dondorp*[2], *E. Pajkrt*[3], *J. H. Kleinveld*[1], *L. Henneman*[1];
[1]*VU University Medical Center, Amsterdam, Netherlands,* [2]*Maastricht University, Maastricht, Netherlands,* [3]*Academic Medical Center, Amsterdam, Netherlands.*

Objective: To study pregnant women's current uptake of prenatal screening for Down syndrome, and future interest in non-invasive prenatal testing (NIPT).
Methods: Online survey on the Dutch pregnancy Fair website, completed by n=389 pregnant women.
Results: Uptake of the combined test (33%) corresponded to the average uptake in the Netherlands. Most important reason to have this test was reassurance that the child is healthy (57%). Reasons to decline included: 'the results are just a chance' (49%), 'fear of miscarriage due to follow-up invasive diagnostics' (34%). 230 (59%) had heard of NIPT; 48% were interested in having NIPT, 24% were unsure, and 28% were uninterested. Safety (33%) and accuracy (30%) were considered most positive aspects, and 70% were willing to pay for it (average 150 euros). 41% expected that women would deliberate less before taking the test, 23% expected more women to feel obliged to take it. Testing for other diseases was considered positive, mostly because this could avoid suffering (75%). However, 38% expected that women cannot foresee the consequences of their choices, and acceptance of children with a handicap will reduce (35%). 42% found that women should be able to choose from a list of diseases, 25% preferred packages with different diseases to choose from, and 30% preferred a fixed list (no choice).
Conclusion: The results suggest that more women will have prenatal screening if NIPT is to replace the combined test. However, challenges for counselling are expected if NIPT is introduced, especially when widening the scope of testing.

EPL2.3
Received information and knowledge about Down syndrome among pregnant women and their partners coming for a first trimester combined (CUB) test? - Do they have the knowledge to make the decision

C. Ingvoldstad[1,2], *E. Ternby*[2], *G. Annerén*[3], *P. Lindgren*[1,2], *O. Axelsson*[2,4];
[1]*Center for fetal medicine, Karolinska University Hospital, Solna, Sweden,* [2]*Department of Women's and Children's Health, Uppsala University, Uppsala, Sweden,* [3]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden,* [4]*Centre for Clinical Research Sörmland, Uppsala University, Uppsala, Sweden.*

Fetal diagnostic testing for chromosomal abnormalities such as Down syndrome (DS) is frequently used in Sweden. Prior to testing expecting parents do not routinely receive information about the conditions being screened for. The aims were to assess why expecting parents choose to undergo CUB-testing (combined ultrasound and biochemistry test), their perception of information, thoughts about invasive procedures, possible termination of pregnancy and knowledge about DS.
Method: From November 2010 to March 2011, 105 pregnant women and 104 partners answered a questionnaire after completing the CUB-test, at the Fetal Medicine Unit, Uppsala University Hospital.
Results: The most common reason for choosing a CUB-test is "to get a confirmation on a healthy baby" or "because you should do it". A majority had not been given information on what it means to live with a child with DS and many requested more information. Internet is the most common source for information about DS. A substantial proportion of pregnant women and partners have little knowledge of the medical, cognitive and social consequences of DS. Twenty-four percent had not yet decided about invasive testing if increased CUB-risk and almost half had not decided what to do about the pregnancy if DS was diagnosed.
Conclusions: A majority of expecting parents attending CUB-test had not received information about DS and requested more information. A substantial proportion of expecting parents have varying and in several aspects low levels of knowledge about DS and its consequences. Many had not yet decided what to do if DS was diagnosed.

EPL2.4
Diagnosis Down syndrome: a cross-cultural study of family experiences

M. L. Van Riper;
University of North Carolina Chapel Hill, Chapel Hill, NC, United States.

Purpose: Much has been written about family-provider interactions surrounding the diagnosis of Down syndrome (DS) and substantial resources have been devoted to helping health care providers feel more prepared to deliver the diagnosis of DS. However reports of parents receiving inaccurate information continue to appear in the literature.Moreover, anecdotal reports of parents feeling pushed to make unwanted choices, such as undergoing invasive testing or terminating a pregnancy following the diagnosis of DS, are becoming more common. In addition, limited attention has been devoted to understanding how family experiences vary from one country to another. Therefore, the purpose of this presentation is to compare family experiences in four countries (Ireland, Portugal, United Kingdom, USA) where differences currently exist in terms of options for prenatal testing and options for families following the diagnosis of DS. Method: 1185 parents of individuals with DS completed a survey which includes a variety of questions concerning family-provider interactions surrounding the diagnosis. In addition, interviews were conducted with a subset of parents. Results: Findings suggest that 50% of the parents were dissatisfied with family-provider interactions and most health care providers are not following the recommended guidelines regarding how to inform parents. Additionally, important cultural differences were noted. Conclusion: Findings from this study will help in efforts to improve parental satisfaction with family-provider interactions surrounding the diagnosis of DS. In addition, they will help ensure that cultural context is considered during the informing process.

EPL2.5
Dynamics of prenatal screening: blurring boundaries between normative frameworks

W. Dondorp, *G. De Wert*;
Dept Health, Ethics & Society / Research Schools CAPHRI & GROW,Maastricht University, Maastricht, Netherlands.

Historically, distinct prenatal screening programmes are aimed at finding different types of conditions: 1) maternal/fetal diseases or markers requiring intervention or adapted care in order to secure healthy pregnancy outcomes for mother and child; 2) fetal disorders that the prospective parents may regard as a reason for abortion. Ethically, this is an important distinction. There is a widely shared consensus that for screening leading to no other possible interventions but abortion, prevention is a morally problematic category. This is why official documents define such screening in terms of what may be called the 'autonomy paradigm', where the aim is to help individual women/couples make autonomous reproductive choices. This is also reflected in counseling guidelines. Whereas some degree of professional directivity is morally acceptable (or even required) for the first type of prenatal screening, non-directivity is regarded as absolutely essential for the second. However, this distinction is increasingly under threat. It was already blurred with the introduction of 'dual purpose' ultrasound screening, but it will only be further undermined with the present dynamics of genetic technologies. Think eg. of NIPT for both serious fetal disorders and for gene expression profiles that are predictive of pregnancy complications. The expanding scope of prenatal screening will also provide more options for fetal therapy. This presentation will consist of a systematic exploration of the ethical challenges involved in this blurring of frameworks and conclude with ethics guidance recommendations for the future field of 'prenatal personalized medicine' (Bianchi).

EPL2.6
Stigma and reproduction: the place of stigma in reproductive decisions

A. J. Clarke;
Cardiff University School of Medicine, Cardiff, United Kingdom.

This paper reviews the impact of a genetic disorder on family life, reflecting its mode of inheritance, and then examines the social impact of a specific sex-linked disorder, hypohidrotic ectodermal dysplasia. The stigmatisation of HED affected males is as important in the accounts given by their womenfolk as the physical effects of the condition; this impacts on their feelings about transmission of the disorder to the next generation. Perspectives may also change over time, with grandmothers expressing more strongly their sense of guilt at having transmitted the condition, despite there being no question of moral culpability.
We then consider the broader impact of stigma on reproductive decisions. They can be impacted by stigma both (i) within families where the practical effects of a specific genetic disorder are well known, and (ii) in couples faced by decisions in pregnancy with no prior expectation of a fetus affected by a genetic disorder. In the former case, any decision made has implications for the self-esteem of affected family members. In the latter case, decisions about continuing or terminating the pregnancy may be affected by the parents' remembered past and/or imagined future responses to encountering an affected individual. In this way, parents' fantasies may shape their decisions.
The scope for parental fantasies to influence decisions is greater when technology amplifies the uncertainty attained in genetic investigations or ultrasound imaging. How will parents' fantasies of uncertainty play out in practice? What can genetics professionals do to promote respect for affected individuals?

EPL3.1
How do research participants perceive "uncertainty" in genomic sequencing?

B. B. Biesecker[1], *W. Klein*[2], *L. G. Biesecker*[1], *P. K. Han*[3];
[1]*National Human Genome Research Institute, Bethesda, MD, United States,* [2]*National Cancer Institute, Bethesda, MD, United States,* [3]*4Maine Medical Center Research Institute, Scarborough, ME, United States.*

Introduction: The scope of uncertainty in genomic sequence information has no rival in health care delivery. We present data from adults participating in an NIH genome sequencing cohort study where perceptions of uncertainty are hypothesized to be key in predicting decisions to learn and act on genomic health information. Methods: We conducted six moderated focus groups with 39 randomly selected ClinSeq® participants, varying whether they had coronary heart disease and/or prior receipt of sequence results. We elicited perceptions of the uncertainties associated with genomic sequencing using writing prompts. Results: Participants perceived the uncertainty as a quality of the information. The majority of participants characterized uncertainty of sequencing information as "changing, fluid, developing, or ground breaking." These responses led to anticipation of more optimistic future outcomes. Fewer participants described uncertainty as "questionable, less accurate, limited, or poorly understood". These perceptions seemed to undermine participants' faith in the information, leading to feelings of disillusionment. Discussion: Our findings suggest that perceptions of uncertainty are related to epistemological beliefs and thus expectation of the information. Interventions to promote realistic expectations of genomic sequencing may mitigate adverse responses to uncertainty.

EPL3.2
Discussing clinical utility; The role of patients and their families

S. van der Burg, *L. Krabbenborg;*
Radboud University Medical Center, Nijmegen, Netherlands.

These last years, many studies investigate the clinical utility of whole exome sequencing as a diagnostic method. Clinical utility is most commonly established on the basis of data that show the effectiveness or economic value of an innovation. Given that whole exome sequencing is a very new method, however, a multidimensional approach to clinical utility seems more appropriate, which also investigates its acceptability for patients .
This paper presents how patients and their families assess the utility of whole exome sequencing, and the diagnosis it produces. Our case-study is based on 20 in-depth interviews with patients and their families, who are involved as participants in a research project which aims to assess the clinical utility of whole exome sequencing as a diagnostic tool for children with hitherto unidentified developmental delay.
The case study provides insight into why these patients and their families want a diagnosis, and how they value the diagnosis that they eventually get. Their evaluations reveal not just the acceptability of WES as a diagnostic tool, but provide insight into how diagnoses are evaluated with respect to their daily caring practice and social lifeworld. We will argue that this provides important input to an assessment of the clinical utility of WES, which may inform how WES is to become part of clinical routine, and how it should be accompanied by counseling.

EPL3.3
Variants in Practice Study (VIP): High risk women's responses to receiving genetic test results for genomic variants associated with breast cancer risk

M. Young[1], *P. James*[1], *G. Mitchell*[1], *L. Forrest*[1], *S. Sawyer*[1], *N. Hallowell*[2];
[1]Peter MacCallum Cancer Centre, Melbourne, Victoria, Australia, [2]University of Melbourne, Melbourne, Victoria, Australia.

Results from genome-wide association studies (GWAS) have identified common genomic variants that form an important component of the heritability of breast cancer risk. Data from Victorian high risk breast cancer families demonstrate that testing for these genetic factors identifies a significant aetiological group known as 'polygenic families' and provides clinically important information.
It is important to investigate lay and professional understandings of novel, complex genetic test information generated by SNP testing to identify the most effective ways for genetic health professionals to communicate this information to patients and the treating medical team.
Our qualitative study aimed to **assess patient and healthcare professionals' understandings of genomic variant data. This presentation focusses upon women's expereinces of receiving SNP results following their participation in a GWAS study: Variants In Practice study (VIP).**
Forty women attended an appointment at the familial cancer clinic, Peter Mac, Australia. Women had 1. previosuly been diagnosed with breast cancer 2. undergone BRCA1/2 mutation testing (no mutation found). Subsequently they were genotyped for 22 common genomic variants from which breast cancer risks were calculated.
Analysis of interview transcripts has revealed a number of preliminary themes, including study participation is motivated by feelings of altrusim and specifically responsibility for family members. Receiving SNP information was viewed very postively, particularly by those women who had previously undergone risk-reducing surgery, who felt their decision was validated by their polygenic result. In conclusion, this study suggests that SNP results are regarded as useful information for both the research participants and their families.

EPL3.4
To Disclose, or Not to Disclose? The Context Matters

V. Rahimzadeh[1], *D. Avard*[1], *K. Sénécal*[1], *B. M. Knoppers*[1], *D. Sinnett*[2];
[1]McGill Univeristy, Montreal, QC, Canada, [2]Universite de Montreal, Montreal, QC, Canada.

Progress in understanding childhood disease using next generation sequencing (NGS) portends vast improvements in the nature and quality of patient care. Ethical questions surrounding the disclosure of incidental findings (IF) persist, as NGS and other novel genomic technologies become the preferred tool for clinical research. Thus, the need for multidisciplinary discussions and disclosure practices on the return of results in paediatric research has never been more immediate. The aim of this study is to explore the views of investigators concerning the disclosure of IFs in the paediatric oncology context. Our findings reveal at least four contextual themes underlying the ethics of when and how young participants and their families could be made aware of these unexpected results during the course of their research participation: clinical significance of the result, respect for persons, scope of professional responsibilities and implications for the healthcare/research system. Moreover, this study illustrates heterogeneity of standards and approaches within the broader researcher community, and the need to recognize the multiplicity of contextual factors that characterize paediatric cancer genetic research, specifically. As NGS increasingly becomes a centerpiece for innovative genetic research in paediatric oncology, sober thought should be given to the possibility of discovering IF, and to proactive and anticipatory management of resultant data that conforms to bioethical norms. The authors intend to broaden the scope of ethical disclosure practices for paediatric participants, their families and the investigators who recruit them.

EPL3.5
Comparing the views of Australian parents, paediatricians and genetic health professionals about disclosure of genomic results

E. Turbitt[1,2], *J. Halliday*[1,2], *D. Amor*[1,2,3], *S. Metcalfe*[1,2];
[1]Murdoch Children's Research Institute, Parkville, Australia, [2]The University of Melbourne, Melbourne, Australia, [3]Victorian Clinical Genetics Service, Melbourne, Australia.

Background: Genomic chromosomal microarray (CMA) testing for childhood investigations has increased diagnostic yields. However, CMAs also increase detection of incidental findings (IFs) and variants of unknown and uncertain clinical significance (VUS). Elucidating patient disclosure preferences may help clinicians anticipate the type of results about which patients want to be informed.
Methods: A questionnaire, using hypothetical scenarios, was designed to investigate and compare the perspectives of parents, paediatricians and genetic health professionals for result disclosure. Quantitative data were analysed using ANOVA and Kruskal Wallis tests. Open text data were analysed using content analysis.
Results: 147 parents, 159 paediatricians and 69 genetic health professionals participated and at least 89% of respondents in each category certainly or probably favoured disclosure of VUS as well as variants of certain clinical significance, with the lowest percentage being amongst parents, who were less sure of their disclosure preferences. There was consensus among respondent groups that knowledge of a variant of certain clinical significance would provide more practical and emotional utility compared to VUS. Parents demonstrated some different perspectives to health professionals; for example, they placed more emphasis on using knowledge of a VUS when considering future pregnancies (K.Wallis:$p<0.001$).
Conclusion: This study, together with a previous study investigating the opinions of a subset of these respondents for disclosure of IFs,(1) is the first Australian exploration of preferences for genomic result disclosure, with implications for clinical practice.

EPL3.6
The experiences and views of health care professionals and researchers regarding the feedback of results in the context of next generation sequencing in oncology

H. Howard[1,2,3], *A. Mahalatchimy*[1,2,4], **A. Soulier**[1,2], *A. Blassime*[1,2], *A. Cambon-Thomsen*[1,2];
[1]INSERM, Toulouse, France, [2]Université Paul Sabatier, Toulouse, France, [3]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, [4]IRDEIC Université Toulouse 1 Capitole, Toulouse, France.

Next generation sequencing (NGS) allows the production of large volumes of sequence data (and potentially genetic results) and the ethical and practical issues regarding feedback of results become particularly pertinent to address. Should (any) results be given to research participants? If so, which results and who should provide them? Within two EU funded projects in oncology (CAGEKID and EUROTARGET), in order to gather researchers' and health care professionals' views and experiences on providing results we distributed a questionnaire to attendees of genetics meetings in Europe in 2013.
Of the 95 respondents, 88% work as researchers and/or clinicians in a field related to oncology and half (52%) use NGS in some aspect of their work; 56% of respondents state that they provide specific information about NGS to participants or patients before enrolling them in a study or using their samples for sequencing. The majority, 83% had never received requests from physicians or patients for access to NGS data to inform treatment decisions. Regarding feedback of results in a research setting, 54% or respondents think that results stemming from NGS studies should be provided to individual participants and 72% think that actionable incidental findings should be disclosed to participants. Finally, 53% of respondents think that specific measures and/or limitations should be implemented for the sharing of NGS data/results with colleagues in the scientific community. Such empirical data from stakeholders is a valuable contribution to the ongoing discussion of how to responsibly handle and feedback results to patients and research subjects.

EPL4.1
Parental influences on decision making in Duchenne/Becker clinical trials

H. L. Peay[1,2], *B. B. Biesecker*[3], *J. V. Bowie*[4], *H. Scharff*[1], *K. Nagaraju*[5], *J. Piacentino*[6], *A. Tibben*[2];
[1]*Parent Project Muscular Dystrophy, Richmond, VA, United States,* [2]*Leiden University Medical Centre, Leiden, Netherlands,* [3]*National Human Genome Research Institute, Bethesda, MD, United States,* [4]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [5]*Children's National Medical Center, Washington DC, DC, United States,* [6]*Self-Advocate, Rochester, NY, United States.*

Introduction: Parents' decisions about enrolling children in Duchenne/Becker muscular dystrophy (DBMD) clinical trials (CTs) may be influenced by hopes and expectations, which when unrealistic may challenge informed consent. We explore influences on decision-making. Methods: The study team used a community-based participatory research approach. Parents of children in DBMD CTs were recruited for an online survey through Parent Project Muscular Dystrophy and clinics. Participants viewed a series of benefit and worry statements and rated each statement's influence on decision-making, and how much they expected and hoped/worried about each. Results: From the first 61 participants, CT decision-making was influenced by potential altruistic and individual benefits: learning generalizable information (97% slightly to strongly agree), CT resulting in a drug that works (82%), better future for other children (82%), improved quality-of-life for their child (82%), and parent doing everything to help their child (82%). CT worries most affecting decision-making were: child bothered by side effects (39%), eligibility for another trial (36%), and child not liking the trial (29%). Expectation and hope ratings were strongly correlated with decision-making influence ratings ($r=0.5$ to 0.8, $p<0.01$). Associations between expectations and altruistic decision-making influences yielded the highest correlation values; conversely, associations between hopes and individual-benefit influences yielded the highest values. Conclusions: Anticipated CT benefits influenced parents' decision-making more than worries. The relationships among hopes, expectations and decision-making influences for altruistic versus individual benefits will be further explored, to inform a new conceptualization of opportunities and challenges during informed consent that extends beyond knowledge-oriented concepts such as therapeutic misconception.

EPL4.2
The impact on children and parents of participation in clinical research trials for Morquio A syndrome and Sanfilippo A syndrome

D. L. Holliday[1,2], *M. Farag*[2], *C. Breen*[2], *S. Jones*[2], *T. Clancy*[2];
[1]*Yorkshire Regional Genetics Service, Leeds, United Kingdom,* [2]*Manchester Centre for Genomic Medicine, Manchester, United Kingdom.*

Clinical research trials of enzyme replacement therapy for Morquio A syndrome and Sanfilippo A syndrome are underway. This qualitative study explored the impact of participation on 7 children with Morquio A syndrome and parents (5/9 eligible families) and parents of children with Sanfilippo A syndrome (4/6 eligible families). Face-to-face semi-structured interviews were carried out, the interviews were transcribed and key themes identified through interpretative phenomenological analysis. The main questions explored were: motivations for taking part, impact on life, and views on the information received prior to the trial. Children described the key role their parents played in providing them with information and supporting them through medical procedures. They talked about what was "good" (e.g. making new friends) and "bad" (e.g. fear of needles) about taking part. Many parents felt there was no real choice as current management options are limited. Some saw the trial drug as treatment rather than potential treatment. Most felt that too much complex information was given during the consent process, but discussions with the clinical trial team facilitated understanding and provided emotional and practical support. Parents described negative impacts on employment and family life. Positive impacts include an improvement in their child's condition and a more optimistic outlook for the future. Overall, children and parents felt the advantages outweighed the disadvantages, and would recommend taking part in a similar trial to other children/families. These findings provide an insight into the impact trials have on children and parents' lives and identify potential improvements for future clinical trials.

EPL4.3
Why do parents request carrier testing in their healthy children? A comparison of genetic health professionals' and parents' views

D. F. Vears[1,2], *C. Delany*[3,2], *J. Massie*[4,5], *L. Gillam*[1,2];
[1]*Melbourne School of Population and Global Health, Centre for Health and Society, University of Melbourne, Parkville, Australia,* [2]*Children's Bioethics Centre, The Royal Children's Hospital, Parkville, Australia,* [3]*School of Health Sciences, University of Melbourne, Parkville, Australia,* [4]*Department of Respiratory Medicine, The Royal Children's Hospital, Parkville, Australia,* [5]*Department of Paediatrics, University of Melbourne, Parkville, Australia.*

Many parents want to know the carrier status of their other children following the diagnosis of a child with a genetic condition. However, the reasons behind their desires for this information have not been fully investigated.
The aim of this study was to explore the reasons parents want carrier testing performed in their healthy children and health professionals' understanding of these reasons.
Semi-structured interviews were conducted with genetic counselors and clinical geneticists (n=17), and parents (n=25) of children with one of three genetic conditions (cystic fibrosis, haemophilia and Duchenne muscular dystrophy). Inductive content and thematic analyses were used to compare genetic health professionals' and parents' accounts of the reasons parents want to know the carrier status of their healthy children.
Genetic health professionals expressed views about parents' reasons for requesting, including that parents primarily want carrier testing to reduce their own anxiety and be reassured. Several professionals indicated that some parents 'just need to know', and others acknowledged that generally parents request testing with their child's best interests in mind. In contrast, parents stated they primarily wanted genetic testing in order to convey the information to their children. Parents felt that disclosing carrier status to their children would allow the children to make informed reproductive decisions or prepare themselves for having an affected child.
This mismatch in understanding between the genetic health professionals and parents of the reasons parents want carrier testing in their healthy children has implications for genetic counselling practice.

EPL5.1
What is the role of genetic counsellors? A systematic review of evidence

H. Skirton[1], *C. Cordier*[2], *C. Ingvoldstad*[3], *N. Taris*[4], *C. Benjamin*[5];
[1]*Faculty of Health and Human Sciences, Plymouth, United Kingdom,* [2]*2. Department of Oncology and Haematology, Hospital of Strasbourg,, Strasbourg, France,* [3]*Department of Public Health and Caring Science, Uppsala University, Uppsala, Sweden,* [4]*Department of Oncology and Haematology, Hospital of Strasbourg, Strasbourg, France,* [5]*School of Health, University of Central Lancashire, Preston, United Kingdom.*

In many countries, genetic counsellors are employed in specialist genetic centres. However, in Europe, the role and practice of genetic counsellors is at a critical stage of development: in 2014 genetic counsellors will have their first opportunity to formally register via the European Board of Medical Genetics. The Board states that the genetic counsellor must fulfil a range of roles, including providing information and facilitating psychosocial adjustment of the client. To examine the extent to which genetic counsellors fulfil the prescribed roles, we conducted a systematic review of the published relevant scientific evidence using the method described by the Centre for Reviews and Dissemination. We searched five relevant electronic databases (Medline, CINAHL, SocIndex, AMED and PsychInfo) using relevant search terms and handsearched four journals for research-based papers published in English between 1 January 2000 and 30 June 2013. Of 419 potential papers identified initially, only seven satisfied the inclusion criteria for the review and all studies were conducted outside Europe. The findings indicate that where genetic counsellors are utilised in specialist genetic settings, they undertake a significant workload associated with direct patient care and this appears to be acceptable to patients. Genetic counsellors manage cases related to a wide range of conditions, predominantly where the diagnosis has been clearly established. With the increasing burden on genetic counselling services, there is an argument for the increased use of genetic counsellors in countries where they are under-utilised. However, further research on the roles of genetic counsellors in Europe is required.

EPL5.2
Referral for breast cancer genetic counseling among Turkish and Moroccan patients in The Netherlands

J. E. Baars[1], *A. M. van Dulmen*[2], *M. Velthuizen*[1], *E. B. M. Theunissen*[3], *B. C. Vrouenraets*[4], *A. N. Kimmings*[5], *T. van Dalen*[6], *B. van Ooijen*[7], *A. J. Witkamp*[8], *M. G. E. M. Ausems*[1];
[1]*Department of Medical Genetics, Division of Biomedical Genetics, University Medical Center Utrecht, Utrecht, Netherlands,* [2]*NIVEL (Netherlands Institute for Health Services Research), Utrecht, Netherlands,* [3]*Division of Surgery, St. Antonius Hospital, Nieuwegein, Netherlands,* [4]*Division of Surgery, St. Lucas Andreas Hospital, Amsterdam, Netherlands,* [5]*Division of Surgery, Slotervaart Hospital, Amsterdam, Netherlands,* [6]*Division of Surgery, Diakonessen Hospital, Utrecht, Netherlands,* [7]*Division of Surgery, Meander Medical Center, Amersfoort, Netherlands,* [8]*Division of Surgery, University Medical Center Utrecht, Utrecht, Netherlands.*

Introduction: Turkish and Moroccans are the largest minority groups in the Netherlands. Migrant breast cancer patients are underrepresented in family cancer clinics. The present study investigates the referral for genetic counseling and DNA testing among Turkish and Moroccan breast cancer patients.

Methods: Breast cancer patients were identified as Turkish or Moroccan using a name-based approach. Data were ascertained from medical registries of 6 participating hospitals in Amsterdam and Utrecht, The Netherlands. All patients had been diagnosed with a new breast cancer in the years 2007-2012. A control group included non-Turkish/Moroccan patients from the same hospitals.
Results: In total, 156 Turkish/Moroccan patients have been identified. Preliminary results show that no information about the cancer family history was found in 13 (8%) patient files, and insufficient information was found in 77 (49%) medical files (i.e. report of breast cancer family history only). Approximately 35% (n=55) of Moroccan and Turkish breast cancer patients fulfil criteria for breast cancer genetic counselling, of whom 40 (73%) were aged < 40 years at diagnosis. A total of 31 (56%) were actually referred for cancer genetic counseling and testing. These results will be compared to a group of non-Turkish/Moroccan breast cancer patients.
Conclusion: Our study shows that a large group of Turkish and Moroccan breast cancer patients is eligible for genetic counseling and testing due to a young age at diagnosis. Over half of the eligible patients are referred for genetic counselling. Attention should be paid to the completeness of the registration of cancer family history in the hospital records.

EPL5.3
Genetic counselling for Indigenous populations: an exploratory study from the perspective of Australian genetic health professionals

L. Gallacher[1], *M. Sahhar*[2,3], *I. Macciocca*[3], *E. Kowal*[2];
[1]*Oxford University Hospitals NHS Trust, Oxford, United Kingdom,* [2]*The University of Melbourne, Parkville, Australia,* [3]*Victorian Clinical Genetics Services, Parkville, Australia.*

It is well established that cultural factors impact on the provision of genetic health care in a range of populations. Indigenous populations are thought to have particularly low levels of access to genetic health services, and cultural issues may be a contributing factor. We present data from the first study of genetic health service provision to Indigenous Australians. This qualitative study aimed to identify elements of culturally-competent genetic health service provision for this population group. Twelve semi-structured interviews were conducted with genetic counsellors and clinical geneticists from around Australia who had experience delivering services to Indigenous Australians. Participants were asked to describe their experiences and comment on collective cultural needs they identified, as well as training and resources for health professionals working with Indigenous patients. Interviews were audio-recorded and transcribed with thematic analysis conducted on the data. The findings show that participants were reluctant to generalise the needs of Indigenous peoples. Some participants asserted that Indigenous peoples have needs that differ from the general population, while others felt that there were no collective cultural needs, instead advocating an individualized approach. However, being flexible and practical, taking time to build rapport, recognising different family structures and decision-making processes, as well as other socio-economic factors were all identified as important factors in participants' interactions with Indigenous patients. This research has implications for international policy, training and practice, in addressing the needs of global Indigenous populations in the field of genetic health.

EPL5.4
Attitudes toward consumer-targeted genetic testing in Japan

K. Muto[1], *A. Nagai*[1], *H. Hong*[1], *Z. Yamagata*[2];
[1]*The University of Tokyo, Tokyo, Japan,* [2]*Yamanashi University, Chuo, Japan.*

Background: Development in genomics have radically changed our self-understanding, and "we have become biomedicalized" (Pálsson 2007). In US, consumers feel the need for tools to estimate the promises and claims of genetic testing services (Green et al, 2011). Ministry of Industry in Japan is preparing best practice guidelines for consumer-targeted genetic testing, but there is no legal regulation against genetic discrimination. However, few studies on public attitudes exist in Japan. Purpose: This paper shows Japanese citizens' attitudes toward consumer-targeted genetic testing and its regulation and address broad ethical, legal and social implications in East Asia. Methods: We employed a web-based questionnaire survey to investigate general perceptions in 2012. In total, 14,718 Japanese citizens completed (RR=37.0%). Results: 14% of respondents knew consumer-targeted genetic testing and just 3.1% had purchased before. 48.6% showed interests to use susceptibility testing on life-style related diseases, 35.9% for congenital disorders and 30.8% for PGx testing. On genetic testing for children, 27-33.3% of respondents agreed to share results with schoolteachers for "personalized education". They show fewer interests in talent identification testing. 56.2% wished to ban genetic discrimination by law. Discussions: Compared with past studies in South Korea and Taiwan, Japanese respondents showed fewer interests. We could explore the reasons why Japanese haven't been "biomedicalized" in spite of its innovative position in Asian countries. We'll compare these results with newly obtained data in 2014.

EPL5.5
Predictors of adverse psychological reactions to receipt of direct-to-consumer genome-wide profiling results

K. M. Broady[1], **K. E. Ormond**[1], *N. J. Schork*[2], *E. J. Topol*[2], *A. J. Butte*[1], *C. S. Bloss*[2];
[1]*Stanford University, Stanford, CA, United States,* [2]*Scripps Translational Science Institute, La Jolla, CA, United States.*

The purpose of this study was to assess predictors of adverse psychological reactions among direct-to-consumer genomic test consumers. We analyzed data from the Scripps Genomic Health Initiative, which studied 2,037 individuals who underwent the Navigenics Health Compass, a commercially available test yielding personalized risk estimates for 28 complex diseases. The participants completed baseline and follow-up survey measures assessing demographics, personal and family health history, attitudes toward genetic testing, anxiety (STAI), test-related distress (IES), and reactions to receipt of results. One hundred thirty participants (6.4%) were defined as having an adverse psychological reaction based on changes in STAI and/or IES. These participants reported significant changes in emotions ($p<0.0005$) and the way they thought of themselves ($p=0.032$) after receipt of results, as well as differences in level of concern about their health ($p=0.024$) as compared to the rest of the study population. However, this group did not endorse a different profile of pre-test concerns at baseline, including concerns related to learning about personal disease risk or to not knowing how they would feel about their results ($p=0.785$, $p=0.902$, respectively). Further, neither were the number of conditions for which participants had elevated risks, nor the actual estimated risks disclosed significantly different in these participants ($p=0.696$, $p=0.123$, respectively). In this study population, while participants' self-report of feelings and concerns upon receipt of results align with their psychological measures, neither self-assessment of pre-test concerns nor genetic risk estimate information disclosed serve as predictors of distress upon receipt of results.

EPL5.6
"It is a very lonely path": Exploring experiences of establishing a genetic support group in Victoria, Australia

L. Di Pietro[1], *E. Swain*[2,3], *L. Forrest*[4,5], *M. Sahhar*[3,2];
[1]*Genetic Support Network of Victoria, Parkville, Melbourne, Australia,* [2]*University of Melbourne, Parkville, Melbourne, Australia,* [3]*Victorian Clinic Genetics Services, Parkville, Melbourne, Australia,* [4]*Australian Primary Health Care Research Institute, Acton, Canberra, Australia,* [5]*Australian National University, Canberra, Australia.*

The diagnosis of a genetic condition can be life changing. Genetic support groups have an important role in providing mutual or peer support, advocacy, and assisting in public and professional education for families affected by a genetic condition. People may be motivated to start a support group for a variety of reasons, but this can be difficult, and there has been little prior research conducted on the process. This research, which was part of the Master of Genetic Counselling program at the University of Melbourne, aimed to explore how members of the Genetic Support Network of Victoria (GSNV) experienced establishing or attempting to establish a genetic support group in Victoria. Seven semi-structured, in-depth interviews were conducted with nine participants. Using a narrative analytic approach, a number of concepts and themes were identified: participants found that setting up and running a support group could be lonely; they experienced being a support person for others as confronting; and felt they needed to acquire skills to help them establish their group effectively. Participants also needed mutual support and information from a genetic support group, and worked in partnership with health professionals and peak organisations to establish their group. These findings have implications for genetic counsellors who have skills in providing emotional support, training, and facilitating the running of, and access to, support groups. This research also suggests a role for the GSNV in providing practical assistance to those who wish to start a genetic support group in Victoria.

EPL6.1
Co-designing an Intervention to facilitate family communication about inherited genetic conditions (IGC).

E. Rowland[1], *S. Hutchison*[1], *C. Jackson*[1], *L. Longworth*[2], *M. McAllister*[3], *R. Macleod*[4], *C. Patch*[5], *F. Ulph*[6], *A. Metcalfe*[1];
[1]*King's College London, London, United Kingdom,* [2]*Brunel University, London, United Kingdom,* [3]*Cardiff University, Cardiff, United Kingdom,* [4]*Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom,* [5]*Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom,* [6]*University of Manchester, Manchester, United Kingdom.*

Introduction: Many parents experience difficulties in talking to their children about an IGC that affects their family. Parents often want to talk to their

children but are unsure about what to say, when to say it and are concerned about their child(ren)'s reactions. As a result, children may be given little or no information and they are often afraid of upsetting their parents by asking. The silence that occurs about the IGC can be detrimental to the long-term mental health and well-being of parents and children. Methods: To facilitate better family communication about the IGC, we designed a therapeutic intervention based on multi-family discussion groups (MFDG) used in systemic family therapy. To inform the intervention's development, a series of focus groups for parents, children, young people and genetic counsellors were held. Findings: MFDG were considered important for facilitating family communication. Families suggested MFDG should be held in welcoming environments that simultaneously facilitate involvement in group activities but also provide distraction from the emotionally challenging subject matter. MFDGs should be attended by families with similar IGC but not necessarily the same so that they could relate to and learn from each others' experiences. Parents and young people agreed that all family members should attend the MFDG although parents only, should attend the first session. Desired outcomes included: a happier home life, design of a communication tool kit for families use and the development of informal networks. Conclusion: The newly designed MFDG's effectiveness will be tested using a randomised controlled trial.

EPL6.2

A randomised controlled trial of a genetic counselling intervention to enhance family communication - the GIF study

J. L. Halliday[1,2], *S. A. Metcalfe*[1,2], *M. Aitken*[1,2], *S. M. Donath*[1,2], *C. L. Gaff*[1,3], *I. M. Winship*[4,5], *M. B. Delatycki*[6,7], *L. L. Skene*[8], *J. M. Hodgson*[1,2];
[1]*Murdoch Childrens Research Institute, Parkville, Australia,* [2]*Department of Paediatrics, University of Melbourne, Parkville, Australia,* [3]*Walter and Eliza Hall Institute, Parkville, Australia,* [4]*Genetic Medicine, Royal Melbourne Hospital, Parkville, Australia,* [5]*Department of Medicine, University of Melbourne, Parkville, Australia,* [6]*Bruce LeFroy Centre, Murdoch Childrens Research Institute, Parkville, Australia,* [7]*Department of Genetics, Austin Health, Ivanhoe, Australia,* [8]*Melbourne Law School, University of Melbourne, Parkville, Australia.*

Background: Disclosure of genetic information within families to at-risk relatives is extremely important, but often problematic. A genetic counselling intervention, delivered post consultation, may result in increased access to genetic services by family members. This Australian randomised controlled trial aimed to assess the effectiveness of intense genetic counselling follow-up on numbers of at-risk relatives utilising genetics services.
Methods: Participants (probands) (n= 95) were recruited when attending a genetic service for diagnosis or genetic testing. The intervention group (n=45) received three telephone counselling interventions while the control group (n=50) received usual care.
After 18 months, clinical files were audited to look for differences in the percentage of at-risk relatives who contacted genetics services. Analyses were adjusted for clustering within families.
Results: Overall, 142/554 (25.6%) at risk relatives in the intervention arm contacted genetic services, compared with 112/536 (20.9%) in the control arm (adj OR 1.30 95%CI: 0.70-2.42). Subgroup analyses of genetic categories revealed substantial differences in contact percentages: cancers - 28% (intervention) vs 15%(control); cardiac - 32% vs 44%; CF carriers - 10% vs 13% and 'others' (including FraX, translocation carriers, SMA, Duchenne) - 39% vs 10%.
Conclusions: The GIF genetic counselling intervention, specifically designed to enhance family communication was found to:
• remain congruent with principles of genetic counselling practice
• be delivered successfully by different counsellors
• improve the ability of clients to communicate genetic information effectively
Findings have implications for health professionals who wish to assist clients in effectively communicating new genetic information to at-risk relatives.

EPL6.3

"What would you like to know?" Patients' attitudes towards communication of incidental findings emerging from new sequencing technologies

L. Godino, *G. Rodella, G. Severi, M. Mirra, G. Lanzoni, M. Romagnoli, A. Tranchina, G. Tortora, C. Graziano, A. Wischmeijer, M. Seri, D. Turchetti;*
Medical Genetics, Bologna, Italy.

In the near future, testing of single or few genes is expected to be replaced by whole exome/genome sequencing (WE/GS). which raises controversies on communication and management of incidental findings. However, few studies have analyzed the perspectives of those expected to be more affected by WE/GS: patients undergoing genetic testing (GT). A semi-structured interview was submitted to patients undergoing clinical GT with the aim of exploring their attitudes toward communication of genetic alterations other than those specifically searched for. Eighty-two patients, 22.8% females and 77.2% males, aged 18-83 years, were interviewed between June 2013 and mid-february 2014. Only a minority (36.6%) stated they had heard of WE/GS before. The majority of interviewed (58; 70.7%) stated they would like to be informed of any alteration; this answer was not influenced by previous knowledge, marital status, gender, education, and purpose of testing, while showed a significant correlation with having children: outof 48 with no children, 22 (75%) desired to know any alteration compared to 22 out of 32 (68%) having children (p=0.04). Although less aware (only 18% reported knowledge of WE/GS), younger people (18-35 years) were more likely to want to know any alteration (86% versus 70% and 60% in people aged 36-54 and 55-83, respectively). The main reason for choosing to be informed of any alterations was the willing to have a clear knowledge of own risks (89.7%), while helplessness and fear of an unpreventable disease were the main motivations for those willing to be informed only of preventable diseases.

EPL6.4

Genomic investigations: health care professional (HCP) and family experiences of managing incidental information in clinical practice

G. Crawford[1,2], *A. Fenwick*[1], *A. Lucassen*[1,2];
[1]*University of Southampton, Southampton, United Kingdom,* [2]*Wessex Clinical Genetics Service, Southampton, United Kingdom.*

Background
The ability to analyse the genetic code in ever greater detail means that the possibility of clinically relevant findings, that are unrelated to the original reason for a test, is increased. These Incidental Findings (IFs), especially when identified in children, may not bring health consequences for many years. This greater sensitivity of genetic testing poses challenges to the clinical encounter including consent to, and disclosure of results.
Study aims
1.Identify current practice, including consent and disclosure practices, surrounding IFs in a range of clinical settings in the UK
2.Investigate family and professional experiences and views about the ethical and practical issues raised by the discovery of IFs
3.Inform policy on the consent and disclosure practices of IFs in clinical practice
Methods
The findings from 23 clinic observations and 52 in-depth interviews were analysed thematically.
Findings
4 main findings will be presented:
1.The possibility of IFs is currently not discussed in any systematic way at the time of genetic testing
2.More results with uncertain clinical significance are being reported. HCPs communicate these to families in different ways
3.There is no clear consensus from HCPs and families on what and how incidental information should be disclosed
4.HCPs believe that current systems do not facilitate the follow up of IFs long term
Conclusion
Further debate is required to integrate genomic technologies into medicine whilst addressing the ethical challenges, particularly as genetics is mainstreamed.

EPL6.5

„Very often the answer's not black or white": Exploring communication in paediatric clinical genetic consultations

J. Paul[1,2], *S. Metcalfe*[1,2], *L. Stirling*[2], *J. Hodgson*[1,2];
[1]*Murdoch Childrens Research Institute, Melbourne, Australia,* [2]*The University of Melbourne, Melbourne, Australia.*

Background: A large proportion of clinical geneticists' workload includes investigations for children with developmental delay where the underlying cause often remains unknown. New diagnostic technologies provide hope for a diagnosis for many of these children. However, results generated through use of these technologies increases the complexity of communication and uncertainty during genetic consultations. To date there has been limited research into the process of paediatric genetic consultations. This project investigates the process and experiences for clinicians and parents during these consultations.
Methods: This qualitative project investigated consultations across four Australian states. Theoretical framework: Symbolic Interactionism - meaning is derived, created and modified through social interactions. Data: audio-recorded consultations (n=32), parent pre-consultation surveys (n=32), and post-consultation interviews with parents (n=32) and clinicians (n=11). Detailed microanalysis (content, thematic and discourse) was completed

across data sets for enhanced understanding, triangulation and analytical rigour.
Results: Overall, the content of the consultations was similar although clinicians appeared to have different 'styles' of communicating and interacting with families. Parents largely understood the information and had realistic expectations regarding diagnoses. Where expectations were not met, parents were often disappointed. Clinicians described many professional challenges working in this area, both practical and emotional, especially the frustration of frequently being unable to answer parents' questions regarding the cause of the child's delay.
Conclusion: Detailed analysis of three complementary data sources provided rigorous and unique perspectives on impacts of new genetic technologies for clinicians and parents. Findings from this study will inform best practice in this area of medical communication.

EPL6.6
Communicating oncogenetic information: do gastroenterologists and surgeons discuss heredity with their patients and, if so, what and how?

K. F. L. Douma, E. Dekker, E. M. A. Smets, **C. M. Aalfs***;*
Academic Medical Center, Amsterdam, Netherlands.

Background: Doctors need to investigate if there is an indication for DNA-testing and provide their patients with information. We aimed to gain insight in discussion of cancer genetic topics by gastroenterologists and surgeons as part of an intervention study, comprising a checklist for doctors, intending to optimize referral to genetic counselling of patients visiting the Gastro-Intestinal Oncology Centre Amsterdam. Insight into physicians' performance can improve referral and optimize patient understanding.
Methods: Following a pre-post design, both before and after introduction of the checklist, 40 consecutive, new patients completed a short questionnaire assessing the discussion of cancer genetic topics during the initial consultation. Additionally, after introduction of the checklist, initial consultations were audiotaped for a qualitative analysis of the discussion of cancer genetic topics. Data on family history and referral was collected from medical files.
Findings: Discussion of cancer in the family increased from 78% before, to 90% post-intervention (p=0.11). However, doctors infrequently asked about second-degree family members (pre: 50%; post: 65%; p=0.19) and age at which family members got cancer (pre: 57%; post: 70%; p=0.29). Qualitative analysis of the audiotapes indicated the use of multi-interpretable and vague questions.
Discussion: Contrary to expectations, cancer in patients' family members was discussed in most intake consultations. However, the suboptimal quality of the discussion hampers optimal referral for genetic counselling. Development of an alternative intervention might help better discussion of cancer genetic topics. Education for doctors is needed to improve knowledge and discussion of cancer genetic topics.

EPL7.1
Consent and confidentiality in clinical genetics: a qualitative study

S. Dheensa*, A. Fenwick, A. Lucassen;*
University of Southampton, Southampton, United Kingdom.

Background: Should healthcare professionals (HCPs) have a responsibility to ensure patients' relatives are aware of genetic risk? What kind of consent is required before genetic information is shared? And how might sharing information affect patient confidentiality? The UK has national guidelines regarding these matters. We explored HCPs' and patients' views.
Method: We conducted 13 HCP focus groups (n=60) and 31 patient interviews in the UK. Data were analysed thematically.
Findings: HCPs and patients felt genetic information should ideally be confidential to families, not individuals. Keeping individual confidentiality could constrain relatives' comprehension of risk and ability to make informed decisions about testing. But familial confidentiality and sharing information was difficult for HCPs to put into practice, due to limited time and practical resources and concerns about disrupting family dynamics. Sharing information across genetic services was also problematic, because of variations in how consent was documented and what it entailed, e.g. some genetic services gave patients an explicit choice of whether HCPs could share information with relatives, while others used an opt-out system where permission to share was assumed. Few patients remembered consenting and the options given.
Conclusion: Sharing information and familial confidentiality were viewed positively by most participants, but not consistently put into practice by HCPs. We therefore show that guidelines are not yet fully integrated into clinic. These issues will become more pertinent as increasing amounts of data about patients' relatives are produced though genome-wide testing. Ethical tensions warranting further research will be highlighted.

EPL7.2
Autonomy and emotions: Professional challenges in seeking consent to genetic testing

H. E. Shipman*, A. J. Clarke;*
Cardiff University, Cardiff, United Kingdom.

Informed consent is the ethical and legal bedrock of clinical practice and research involving humans. This paper investigates consent in practice by exploring how professionals account for consent to microsatellite instability and immunohistochemical testing for features of Lynch Syndrome and biobanking for research purposes.
Twenty eight semi-structured interviews were undertaken with professionals responsible for seeking consent. Thematic mapping was carried out on transcribed data, which led to the identification of themes for more detailed analysis. Data were examined from a rhetorical discourse analysis perspective, which involved micro-examination of the discursive devices drawn on by participants in their talk.
Two themes encompass the communicative difficulties that were described: Autonomy (enabling choice) and handling emotional responses in interaction. Challenges pertaining to enabling choice involve different forms of opposition to respecting the autonomy of the person giving consent, both within and beyond the individuals involved in communication. Issues concerning handling emotional responses in interaction involve accounts of strong emotions both of those asked to consent and also of the professionals involved. These two themes were unevenly balanced between the settings with challenges of handling emotional responses almost entirely confined to bio-bank settings. This is likely to reflect the contexts of current and previous family experiences. In both settings, enabling autonomy becomes complex when the professional is not involved in a face-to-face interaction with the person asked to give consent. This work brings an alternative perspective to accomplishing consent, as an interactive process involving complex moral negotiations within relationships.

EPL7.3
Randomized controlled trial of a telephone-based peer support program for female carriers of a BRCA1 or BRCA2 mutation: Impact on psychological distress

B. Meiser[1]*, V. White*[2]*, M. Young*[3]*, A. Farrelly*[2]*, M. Jefford*[4,5]*, S. Ieropoli*[2]*, J. Duffy*[6]*, I. Winship*[7]*;*
[1]*Prince of Wales Hospital, Randwick, Australia,* [2]*The Centre for Behavioural Research in Cancer, Cancer Council Victoria, Carlton, Australia,* [3]*Familial Cancer Centre, Peter MacCallum Cancer Centre, East Melbourne, Australia,* [4]*Strategy and Support Division, Cancer Council Victoria, Carlton, Australia,* [5]*Sir Peter MacCallum Department of Oncology and Faculty of Medicine, Melbourne, Australia,* [6]*Hereditary Cancer Clinic, Prince of Wales Hospital, Randwick, Australia,* [7]*Genetic Medicine, Royal Melbourne Hospital, University of Melbourne, Parkville, Australia.*

Objective: To assess the effectiveness of a telephone-based peer-delivered intervention, in reducing distress among female *BRCA1 or BRCA2* mutation carriers. The intervention consisted of trained peer volunteers contacting women multiple times over a four month period to provide informational, emotional and practical support.
Methods: 337 participants completed the baseline questionnaire and those reporting interest in talking to other mutation carriers were randomized to either usual care group (UCG) (n = 102) or intervention group (IG) (n = 105). Two follow-up questionnaires were completed: i) four months after randomization (Time 2, intervention end for IG) and ii) two months later (Time 3). Outcomes included breast cancer anxiety (primary outcome), unmet information needs, and cognitive appraisals about mutation testing.
Results: Over the study period, there was a greater decrease in breast cancer anxiety in the IG than UCG (p<0.01) and at Time 2, the IG's mean breast cancer anxiety scores were significantly lower than the UCG's. There was a greater reduction in unmet information needs in the IG than UCG (p<0.01), with unmet needs lower in the IG than UCG at Time 2 (p<0.01). There was a greater reduction in cognitive appraisals-stress in the IG than UCG (p<.01) with significantly lower scores found at Time 2 for the IG compared to UCG (p<.01). However cross-sectional differences were not found at Time 3 for any outcome measure.
Conclusion: The intervention is effective in reducing breast cancer related anxiety and unmet information needs in the short-term. Identifying strategies for prolonging intervention effects is warranted.

EPL8.1
Women's experiences following a prenatal diagnosis of fetal abnormality: The PeTALS project

J. M. Hodgson[1]*, M. A. Menezes*[2]*, S. A. Metcalfe*[1]*, J. L. Halliday*[1]*, J. Fisher*[3]*, K. Petersen*[4]*, C. Hickerton*[5]*, B. J. McClaren*[5]*;*

Melbourne, Australia, [4]LaTrobe University, Melbourne, Australia, [5]Murdoch Childrens Research Institute, Melbourne, Australia.

Introduction In Victoria, Australia, following prenatal diagnosis of a fetal abnormality, women and their partners are commonly offered a choice about whether to have an abortion or continue their pregnancy.
Objectives The PeTALS project aims to explore the psychosocial impact of prenatal diagnosis and identify professional and social supports utilised and needed at this time.
Methods This study is being conducted at 3 sites including two tertiary metropolitan hospitals and a private ultrasound clinic. A longitudinal case study approach is being used to collect questionnaire and qualitative data from women at three different time points – 6 weeks post definitive diagnosis of fetal abnormality, 6-9 months later, and 2 years post-diagnosis.
Findings 39 women were interviewed at the first time-point, regarding their experience of receiving a prenatal diagnosis (27 had various chromosomal aneuploidies, 6 had cardiac anomalies, 6 had other structural anomalies), and choosing to have an abortion (n=33), or continue their pregnancy (n=6). Women commonly experienced significant grief and overwhelming sadness; many described intense feelings of isolation from their partner, family and friends. Women who had an abortion described feeling negatively 'judged' and reported that their partners also experienced significant emotional impact.
Conclusions Women describe variable and sometimes inadequate levels of follow-up bereavement care and support. There is a need for increased support and counselling for couples following prenatal diagnosis. Providing prenatal testing and abortion in the absence of a full range of supportive options may be considered unethical; this is an important area for ongoing research.

EPL8.2
Experiences of young Huntington's disease carriers and their partners solliciting a prenatal and/or pre-implantation genetic diagnosis: a qualitative study

A. J. Van Tongerloo, *A. M. De Paepe;*
University Hospital Ghent, 9000 Ghent, Belgium.

Introduction: Huntington's disease (HD) is an autosomal dominant, incurable, late onset neurodegenerative disorder. There is an increasing demand for prenatal or pre-implantation diagnosis by couples in which one partner is a HD carrier and who want to avoid transmission of the disorder to their children. This exploratory qualitative study aims to gain insight into the decision-making process regarding reproductive options by young HD carriers and their partners, and into the way prenatal testing is being experienced. Materials and methods: Using thematic analysis, ten semi-structured interviews were conducted in HD carriers aged between 18 and 30 years, to document their attitude on and experience with the decision-making process that preceded their request of a prenatal or pre-implantation genetic diagnosis. Following topics were addressed: 1/ Which issues arose in the decision to have children?; 2/ Which issues arose in the decision to have prenatal testing (PD or PGD); 3/ How did you experience the actual procedure ?; 4/ How do you see the future with your children? Results: For young HD carriers not to choose for prenatal testing is not an option, nor is refraining from offspring. With regard to the emotional impact, major differences in the lived experience of PD and PGD are reported: the prospect of a termination of pregnancy causes great distress in women. Conclusions: With this exploratory study we gain understanding in the complex psychological process linked to procreative decision-making of young HD carriers and their partners that opt for a prenatal or pre-implantation diagnosis.

EPL8.3
Difficult decisions in prenatal diagnosis - patients' experiences of decision-making under uncertainty, and the implications for expanding the offer of prenatal testing.

S. Leonard;
University of Bristol, Bristol, United Kingdom.

The practice of fetal anomaly detection has progressed tremendously from the first diagnoses of anencephaly by x-ray to modern 4-D imaging techniques and chromosomal microarrays. Although these new technologies will increase the range of abnormalities that can be detected prenatally, the amount of uncertain findings will also increase.The current practice of fetal anomaly detection has largely developed as the result of rapid transfer of research developments to practice with limited prior ethical reflection. To date, although "uncertainty" is often cited as a potential drawback to more detailed genetic testing in the prenatal setting, there has been little study of the impact of uncertainty on the decision-making process of patients. In order to gain insight into these processes and to better understand how to approach the ethical evaluation of new fetal anomaly detection technologies, a qualitative study was undertaken. In-depth interviews of 26 participants who had received an uncertain prognosis in their pregnancies were conducted. These interviews identified a number of key themes including managing information, values and decisional context, and trust. The findings raised a number of questions, regarding for example the usefulness of the notion of autonomy as a primary ethical principle in the prenatal context where parents must make decisions based on unclear and often changing information. These findings have implications for how new fetal anomaly detection technologies are evaluated and put into practice to ensure that the maximum benefit is achieved with the minimum harm.

EPL8.4
Offering a choice between 5 Mb and 0.5 Mb prenatal whole genome SNP array analysis: are pregnant couples able of making informed decisions?

S. L. van der Steen[1], *K. E. M. Diderich[1], S. R. Riedijk[1], J. Verhagen-Visser[1], L. C. P. Govaerts[1], M. Joosten[1], M. F. C. M. Knapen[1], F. A. T. de Vries[1], D. Van Opstal[1], M. I. Srebniak[1], A. Tibben[2], R. H. Galjaard[1];*
[1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands.

Background: We implemented whole genome SNP array instead of conventional karyotyping (CK) for prenatal diagnosis (PND). Array detects more clinically relevant anomalies and more genetic anomalies of yet unquantified risk for neurodevelopmental disorders, so-called susceptibility loci (SL). Using SNP array ensues the question whether pregnant couples want to know more and oversee the possible consequences. We explored whether pregnant couples at increased risk for aneuploidies were capable of informed decision-making when offered a choice between the clinical outcomes of a SNP array analyzed at 5 Mb resolution (comparable to CK) and a SNP array analyzed at 0.5 Mb resolution with or without SL. **Methods:** Consenting pregnant couples (N=143) received genetic counseling by phone and filled out the Measure of Informed choice (MIC) designed for this study. Choices based on sufficient knowledge and congruent with attitude were considered informed. **Results** *:* The MIC had sufficient internal consistency (Knowledge α=.74; Attitude α=.80). Median MIC knowledge score was 5, range 0-7. We considered a score ≥5 on the MIC knowledge scale as sufficient. Based on this criterion, 66% of the couples had sufficient knowledge and thus made an informed decision. However, 82% found it difficult to reproduce knowledge about SL. **Discussion:** Our results show that the majority of couples were capable of making an informed choice. However, the most complicated possible outcome of array, SL, was least understood. More research is necessary to assess what the psychological impact of SL is when couples have not well anticipated this possible outcome.

EPL8.5
SNP Array in prenatal diagnosis; first impressions on the psychological impact of receiving a susceptibility locus s a test result

J. Visser[1], *L. P. C. Govaerts[1], S. L. van der Steen[1], K. E. M. Diderich[1], M. Joosten[1], M. F. C. M. Knapen[1], F. A. T. de Vries[1], D. Van Opstal[1], M. I. Srebniak[1], A. Tibben[2], S. R. Riedijk[1], R. H. Galjaard[1];*
[1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands.

Background: Genomic SNP array as a first-tier prenatal cytogenetic test for all indications has been implemented in our laboratory. Array may also detect susceptibility loci (SL) for neurodevelopmental disorders, with an unquantifiable risk for the fetus. SL may psychologically challenge the couple in their decision whether or not to continue their pregnancy. Since we implemented SNP array in September 2010, our policy was to disclose the presence of SL. We conducted this study to explore the psychological impact of receiving a SL. **Methods** In our pretest counseling was no emphasis on the possibility of receiving a SL. Twelve pregnant couples whose fetus was affected with a SL were asked for participation postnatally. Two couples and six men refused participation. Consenting participants (*N*=13, four men and nine women) were interviewed by phone. The interview was structured with a fixed set of questions. **Results** Receiving their SL was shocking to 10 out of 13 participants. Postnatally, all participants considered their child healthy without concern about the SL. They stressed the importance of a pre and posttest counseling and their wish for a choice regarding SL disclosure. Eleven participants indicated they wished to learn about their SL again. **Conclusions** Although our group is small, it is one of the first studies providing a preliminary insight into how couples experienced receiving a prenatal SL. Further studies have to be carried out in order to investigate the (dis)advantages of reporting SL in a prenatal setting, from medical as well as from psychological point of view.

EPL8.6

Professional views about prenatal aCGH-testing

S. Shkedi-Rafid[1], *A. Fenwick*[1], *D. Wellesley*[2], *A. M. Lucassen*[1];
[1]*Clinical Ethics and Law, University of Southampton, Southampton, United Kingdom,* [2]*Wessex Clinical Genetics Service,Princess Anne Hospital, Southampton, United Kingdom.*

Background: Array-comparative-genomic-hybridization (aCGH) in pregnancy allows a higher detection rate and shorter turnaround time compared to karyotyping. However, the test can also reveal findings that are (a) not related to the reason for which the test was done (b) relevant only much later in life, and (c) uncertain. Little empirical data exist on health care professionals' (HCPs') views about these issues.
Aims: To explore the views of UK HCPs about: the type of information that should be sought and disclosed; timing of disclosure (i.e. during-pregnancy/after-birth/when the information is medically-actionable); and who should decide about these issues.
Methods: Q-methodology, which combines qualitative and quantitative approaches, was used to explore the views of 45 HCPs (Genetic-health-professionals, lab-scientists, fetal-medicine-experts).
Results: Preliminary data suggest that: HCPs either prioritise parental-choices, or their own judgements about clinical relevance to determine disclosure.
Most HCPs support aCGH testing in pregnancies for further investigations of abnormalities found on scans, but would not currently wish to offer it otherwise.
Where aCGH uncovers adult onset predispositions, many argue that these should be disclosed because (a) they might be relevant to one or other parent, and (b) they are not confident that systems can be set-up to delay disclosure to nearer the time of clinical relevance.
Conclusion: HCPs support the introduction of prenatal aCGH into clinical practice in certain circumstances, but are concerned that consent procedures, education of professionals outside of genetics and national-guidelines are not yet in-place to address all the ethical issues.

EPL9.1

Predictive testing for Huntington Disease: Lessons learned from 24 years' experience

F. H. Richards, *M. J. Wilson;*
Children's Hospital at Westmead, Westmead, Australia.

Predictive testing for Huntington disease commenced in Sydney, Australia, in 1990, at one genetics service. The same counsellor (a social worker) has coordinated and provided counselling for predictive testing at this service for 24 years. Over this time 554 people have been seen through the predictive testing process, with additional provision of social work assistance to the 19% of mutation carriers who have become symptomatic. This long term perspective has provided some valuable insights into dealing with the challenges of the process and impact of predictive testing. This paper presents our recommended procedures, based on lessons learned, for various aspects of the process including pre-result assessments, timing of test clinicians' knowledge of result, testing of minors, testing of siblings, protocol flexibility and the therapeutic relationship versus duty of care, and follow up. Utilisation of these procedures, together with expert counselling skills, is likely to achieve the aim of maximising client support and autonomy while minimising harm arising from the outcome of predictive testing for Huntington disease and similar late-onset neurogenetic conditions.

EPL9.2

Patient views on the delivery of predictive test counselling services for Huntington's Disease

M. E. Jones[1,2], *R. MacLeod*[1,2];
[1]*Manchester Centre for Genomic Medicine, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom,* [2]*Manchester Centre for Genomic Medicine, Institute of Human Development, Faculty of Medical and Human Sciences, University of Manchester, Manchester Academic Health Science Centre (MAHSC), Manchester, United Kingdom.*

Huntington's disease (HD) is a progressive neurodegenerative disorder characterised by involuntary movements, cognitive impairment and psychological symptoms and is inherited in an autosomal dominant manner. Predictive testing by direct mutation analysis for individuals at risk of HD has been available since 1993. Internationally agreed guidelines for predictive testing have been published and recently updated but variability exists in *how* testing is delivered between centres. Whilst a substantive literature exists on the impact of predictive testing, few studies have looked at how the predictive test counselling process is received by tested individuals. This evaluation study sought the views of individuals who had a predictive test for HD at our centre over a 5 year period (2007-2012). 44 of 100 eligible individuals completed and returned a questionnaire designed for the purpose of the study. Descriptive statistics were used to present the quantitative data and a thematic analysis was conduced on the free text comments. Overall, participants were positive about their experience and valued getting information and support as well as building a good relationship with their genetic counsellor. However, 14/44 participants found the testing process too long and for 7/44 participants the journey time to the hospital took > 2 hours. Proposals for improving the service included a more tailored approach that took greater account of prior experience. In addition participants welcomed the inclusion of information resources such as video clips highlighting a range of testing experiences, and also advocated more focus on post test follow up and support.

EPL9.3

Quality issues in genetic counselling practice for presymptomatic testing: a European Delphi study

M. Paneque[1,2], *J. Sequeiros*[1], *H. Skirton*[2];
[1]*IBMC-CGPP, Porto, Portugal,* [2]*School of Nursing and Midwifery, Plymouth University, Plymouth, United Kingdom.*

Genetic counselling for presymptomatic testing is complex, bringing both ethical and practical questions. There are protocols for counselling but a scarcity of literature regarding quality assessment of such counselling practice. Generic quality assessment tools for genetic services are not specific to presymptomatic testing. Our aims were to identify aspects of effective counselling practice in presymptomatic testing for neurodegenerative disorders as a basis for developing a quality assessment tool. We used the Delphi method to ascertain the views of relevant European experts in genetic counselling practice. Ethical approval was obtained and panelists were anonymous to other contributors. Questionnaires were sent by electronic means to a list of 45 experts, who each contributed to 1-3 rounds (Medical Doctors, Geneticists, Genetic Counsellors, Genetic Nurses, and others). In the first round, we provided a list of relevant indicators of quality of practice from a literature review. Experts were requested to evaluate topics in four domains: a) professional standards; b) service standards; c) consultand's perspective; d) protocol standards. We then removed items receiving less than 65% approval and added new issues suggested by experts. The second round was performed for the refinement of issues and the last round was aimed at achieving final consensus on high standard indicators of quality, for inclusion in the assessment tool. The most relevant indicators were related to (1) consultand-centred practice and (2) advanced counselling and interpersonal skills of professionals. High standard indicators are being used to develop a new tool for quality assessment of presymptomatic testing counselling practice.

EPL9.4

Experiences and implications of young women undergoing predictive BRCA testing under the age of 30

K. Brunstrom[1,2], *A. Murray*[3], *M. McAllister*[1];
[1]*Institute for Cancer & Genetics, University of Cardiff, Cardiff, United Kingdom,* [2]*Clinical Genetics, Manchester Centre for Genomic Medicine, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom,* [3]*Cancer Genetics Service for Wales, Cardiff and Vale University Health Board, Cardiff, United Kingdom.*

Background: This qualitative study focuses on experiences of a sample of young female BRCA carriers who had predictive genetic testing before the age of 30 and explores their motivations for testing and implications of receiving a positive (bad news) result.
Methods: Following appropriate informed consent procedures participants were recruited through the Cancer Genetics Service for Wales. Semi structured interviews were conducted face-to-face with seven participants. Interviews were transcribed in full and analysed using thematic analysis.
Results: The motives for testing and perceived advantages described by participants were similar to those identified in previous studies with older participants, such as increased awareness and knowledge, and feeling more in control. However some of the perceived disadvantages described by participants were specific to young women. These included feeling pressured to make important life decisions earlier than they would have liked, for example decisions about when/if to have children, and about risk reducing surgery. Participants also reported feeling abandoned or forgotten because of the loss of ongoing clinical contact or feeling 'stuck waiting' for screening to begin. None of the participants however, felt that these disadvantages were sufficient reason to regret having had the test at a young age.
Conclusions: Findings in this small study suggest that having BRCA predictive testing can have positive outcomes for young women. However they should be encouraged during pre test counselling to explore the decisions and choices they may be faced with in the event of a bad news test results and may benefit from ongoing support/follow up.

EPL9.5
The experiences of BRCA1/2 mutation positive women in Northern Norway

N. Strømsvik[1,2,3], *M. Myklebust*[4], *E. Gjengedal*[5,6];
[1]*Nothern Norway Familial Cancer Center, Department of Medical Genetics, University Hospital of North-Norway, Tromsø, Norway,* [2]*The Arctic University of Norway, Department of Clinical Medicine, Psychiatry Research Group, Tromsø, Norway,* [3]*The Arctic University of Norway, Department of Health and Care Sciences,, Tromsø, Norway,* [4]*Department of Public Health and Primary Health Care, University of Bergen, Norway, Bergen, Norway,* [5]*Department of Public Health and Primary Health Care, University of Bergen, Bergen, Norway,* [6]*Faculty of Health and Social Care, molde University College, Molde, Norway.*

This qualitative study explores how women who have been diagnosed with a mutation in BRCA1 or BRCA2 experience living with risk of cancer development, as well as their need for psychosocial and informative follow-up. The study also investigates whether learning and coping seminars (LCS) contribute to a greater sense of coping. Focus group interviews were performed with female BRCA1 and BRCA2 mutation carriers when they attended LCS. The interviews were performed immediately before and after the LCS. 17 women participated in two focus groups in two different LCS seminars (10+7). The following themes were discussed: Their personal reactions after being identified as mutation carriers, experiences with the risk management program, decision making and experiences regarding risk reducing surgery. In addition, the participants expectations and experience with participating at the LCS were discussed. They were also encouraged to expound upon any other issues important to them. The data were analyzed using content analysis as described by Knodel.
Preliminary results indicate that the participants had experienced random and different information regarding risk reducing surgery. They regarded the LCS as a valuable source for information and psychosocial support, and suggested that future LCS should be available for female BRCA1/2 mutation carriers shortly after receiving their unfavourable test results. Other themes as feelings of loneliness and fear of cancer development were also identified in this study.

EPL9.6
Genetic test declining and high personal colorectal cancer risk perception in DNA mismatch repair gene mutation families

L. Flander[1], *A. Ugoni*[1], *L. Keogh*[1], *H. Niven*[1], *A. Rutstein*[1], *A. Ko Win*[1], *D. Ait Ouakrim*[1], *C. Gaff*[2], *M. Jenkins*[1], *I. Winship*[3];
[1]*University of Melbourne, Parkville, Australia,* [2]*Royal Melbourne Hospital, Parkville, Australia,* [3]*Royal Melbourne Hospital, Melbourne, Australia.*

Purpose: About half of people from mutation-carrying families do not undergo genetic counselling and/or testing to identify their mutation status and risk of colorectal cancer (CRC). We studied perceived CRC risk and qualitative analysis of reasons for declining in this group.
Patients and Methods
We studied 26 participants (mean age 43.1 years, 14 women) in the Australasian Colorectal Cancer Family Registry who were relatives of mismatch repair gene mutation carriers; who had not been diagnosed with any cancer at the time of recruitment and who had declined an invitation to attend genetic counselling and/or testing at the time of interview. Bounded estimates of perceived CRC risk over the next 10 years, understanding of genetic testing and CRC risk, reasons for declining testing and self-reported colonoscopy screening were elicited during a face-to-face semi-structured interview.
Results: A sub-group of decliners (31%) unconditionally rejected genetic testing compared to conditional decliners who would consider genetic testing in the future. Mean perceived 10-year risk of CRC was 54% [95% CI 37, 71] in unconditional decliners, compared with the mean perceived 10-year risk of CRC of 20% [95% CI 5,36] in people who conditionally decline genetic testing. This difference remained after adjusting for potential confounding factors (age, gender and reported screening colonoscopy).
Conclusions: The unconditional decliner group perceive themselves to be at 3.26 times higher risk than conditional decliners. Novel interventions in general practice clinics may improve genetic testing uptake and/or appropriate colonoscopy screening for this high-risk and under-serviced group.

EP01-S
Counselling issues arising from microarray in prenatal testing

M. Graetz;
Mercy Hospital for Women, Melbourne, Australia.

Microarrays have replaced conventional karyotyping for the detection of chromosomal imbalance for the large majority of cases in the prenatal setting. Our clinic began to offer microarray in 2010. The test was initially restricted to women found to carry a fetus with a structural abnormality on ultrasound, in accordance with studies that suggested an increase in detection rate of a chromosomal imbalance not detected by karyotype. More recent studies have examined offering microarray to all women undergoing invasive procedures for reasons such as advanced maternal age, increased risk on screening and parental anxiety. In our clinic, a large proportion of our clients are referred for increased risk counselling post screening. Within this group, many women undergoing invasive testing to exclude chromosome abnormalities have opted to have microarray with the view of greater detection of syndromes that have a significant clinical impact. Our counselling includes the risk of detecting a CNV of unknown or uncertain significance. Case examples will illustrate the complexity of information, coping with uncertainty, counselling issues and implications for practice.

EP02-M
Factors affecting PGD decision making in Israeli BRCA1/2 mutation carriers

E. Dagan[1], *E. Friedman*[2], *B. Feldman*[3];
[1]*Department of Nursing, University of Haifa, Haifa, Israel,* [2]*The Susanne-Levy Gertner Oncogenetics Unit, Sheba Medical Center, Tel Aviv, Israel,* [3]*The Danek Gertner Institute of Human Genetics, Sheba Medical Center, Tel Aviv, Israel.*

Aim: In 2006, the Israeli Ministry of Health issued directives to expand PGD to encompass hereditary breast-cancer syndrome. This study aimed to decipher the factors affecting PGD decisions among Israeli BRCA1/2 mutation carriers or a spouse of a carrier.
Methods: We used a qualitative-phenomenological approach. Participants were 19 Jewish Israeli women, who requested PGD for BRCA1/2 mutation detection for their future embryos, at the Sheba Medical Center. All women were either carriers (n=14) or spouses of a male carrier (n=5), of one of the three Ashkenazi founder mutations in BRCA1/2. Of carriers, six were diagnosed with breast cancer. All women are married, and all but three had at least one child. We invited the women to narrate what motivated their choice to opt for PGD. Thematic analysis was used to unveil experiences and preferences related to the issue.
Results: Three significant factors were found to be associated with PGD: Prior infertility treatment (n=12); The existence of frozen embryos after fertility preservation treatment, done before chemotherapy (n=5); and Family history of ovarian and/or early-onset breast-cancer (n=10). Although most women underwent PGD (n=16), the majority (n=12) ended by declining the selection process, primarily for clinical, bureaucratic and financial difficulties.
Discussion: This study details factors associated with the choice to undergo PGD, in order to prevent the passing on of the `bad` BRCA1/2 mutation. Although, PGD for BRCA1/2 mutation is allowed in Israel, it is not funded by the Israeli healthcare insurance.
This study was funded by the Israel Cancer Association grant.

EP03-S
Prenatal genetics service: the service users' perspective

C. Eddy, *T. Homfray, S. Mansour, V. Tripathi;*
South West Thames Regional Genetics Service, St. Georges Hospital NHS Trust, London, United Kingdom.

Prenatal Genetics is about to become yet more complex with the advent of array comparative genome hybridisation with some centers already having implemented this approach. Various research studies looking into the process of the prenatal genetic diagnosis interaction highlight that clinicians' and service users' can have different goals, purposes and values regarding prenatal testing. Informed patient decision making requires that information provision is responsive to patient interests. Clinical audit is one method to elucidate the needs of these service users. An advocate in the UK for this approach of information provision, support and care that is responsive to the current needs of service users is the national charity Antenatal Results and Choices (ARC), which provides non-directive support to expectant and bereaved parents throughout and after the antenatal testing process. ARC provides guidance on the principles of good practice when supporting parents through a diagnosis of fetal abnormality. The South West Thames Regional Genetics service is responsible for a population of 2.2 million people and undertakes approximately 400 prenatal appointments annually. To assess the ongoing needs of our prenatal service users, a clinical audit was conducted through the use of a questionnaire which was sent to 150 families. The responses were then corroborated with data from the clinical genetic notes. The collated results were annonymised for the purpose of analysis. This retrospective clinical audit will present areas of good practice already in existence and others which may provide opportunities to improve patient experience with the advent of emerging new genetic technologies.

EP04-M
An easy test but a hard decision: non-invasive prenatal testing and emerging ethical issues

L. Goldsmith, **H. Skirton**, *L. Jackson, A. O'Connor;*
Plymouth University, Plymouth, United Kingdom.

Non-invasive prenatal testing (NIPT) using cell-free fetal DNA in maternal serum can be used to test for specific genetic disorders. The aim of this study, part of the RAPID project, was to explore ethical issues around NIPT for single gene disorders. We used a qualitative cross-sectional design and recruited carriers of four autosomal recessive conditions: cystic fibrosis, thalassaemia, spinal muscular atrophy and sickle cell disease. Data were collected via focus groups or telephone interview and analysed thematically.
Parents were overwhelmingly in favour of NIPT: those with deceased children were especially keen to reduce the chance of fetal loss, while many valued knowledge of fetal status in the first trimester. Obtaining written consent was considered important to emphasise the potential impact of the results on the pregnancy and to avoid possible routinisation of the test, as parents reflected that although the test was easy, subsequent decisions could be hard. Parents felt that giving the mother time to discuss the test with her partner was required before blood was taken. Where fathers declined carrier testing, participants felt that mothers should be able to request a test, but the father should be aware the result might convey potentially unwanted information about his carrier status if the fetus was affected. While many of the ethical issues echo those for invasive testing, due to the ease of non-invasive testing, it is important that it does not become routine and that informed decision-making by parents is supported by professionals.

EP05-S
The phenotype and genotype of Bartter syndrome in Maltese patients

V. Said Conti[1], *V. Benoit*[2], *S. Attard-Montalto*[1], *R. Parascandalo*[1], *J. Torpiano*[1], *P. Hilbert*[2], **I. Borg**[3];
[1]*Department of Paediatrics, Mater Dei Hospital, Msida, Malta,* [2]*Département de Biologie Moléculaire,Institut de Pathologie et de Génétique, Gosselies, Belgium,* [3]*Department of Medical Genetics, Mater Dei Hospital, Msida, Malta.*

We describe the clinical phenotype and genotype in a Maltese cohort with Bartter's syndrome.
Children with a genetic diagnosis of Bartter's syndrome until December 2013 were included. Gender, gestation, birth weight, occipitofrontal circumference (OFC), age at presentation,age and clinical phenotype at diagnosis, were documented.
Three female and one male were identified with age range of 2-15 years. All pregnancies were complicated by polyhydramnios and prematurity. Median gestational age was 33 weeks. Birth weight ranged from 1.5kgs-2.1kgs. All OFC measurements were above P90. Two children were diagnosed clinically at birth, one child at 2 years and one at 6½ years. One child has severe spastic diplegia from complications of prematurity and one child has delayed speech. All have a small triangular face, small chin and body weight along a low percentile. Two children have been diagnosed with nephrogenic Diabetes Insipidus. All have borderline low-normal potassium levels, normal eGFR and parathyroid hormone, and bilateral nephrocalcinosis. Molecular genetic analysis in the coding region of the KCNJ1 gene revealed a homozygous c.277T>G mutation in all patients; all parents are heterozygous for the same variation. A random sample of 100 Maltese and a 100 Belgian DNA samples, revealed the heterozygous state in 1 Maltese sample and none in the Belgian samples.
To our knowledge the c.277T>G mutation is reported once, in a compound heterozygote Italian patient. It would appear that the c.277T>G variation is a Maltese mutation since it presents in the homozygous state in all patients. Some phenotypic features are shared by all patients.

EP06-M
Attitudes of pregnant women and male partners towards non-invasive prenatal testing (NIPT) and widening the scope of prenatal screening

R. V. van Schendel[1], *J. H. Kleinveld*[1], *W. J. Dondorp*[2], *E. Pajkrt*[3], *D. R. M. Timmermans*[1], *K. C. A. Holtkamp*[1], *A. M. A. Lachmeijer*[1], **L. Henneman**[1];
[1]*VU University Medical Center, Amsterdam, Netherlands,* [2]*Maastricht University, Maastricht, Netherlands,* [3]*Academic Medical Center, Amsterdam, Netherlands.*

Non-invasive prenatal testing (NIPT) and its potential to test for multiple disorders has received much attention. This study explores women's and men's attitudes towards NIPT, and their views on widening the scope of prenatal testing in a country with a low uptake of prenatal screening (the Netherlands). Five focus groups with low-risk pregnant women (n=28), three focus groups with men (n=19) and 13 interviews with high- and low-risk pregnant women were conducted. Participants felt that current prenatal screening has great disadvantages such as uncertain results and risk of miscarriage from follow-up diagnostics. Characteristics of NIPT (accurate, safe and early testing) could therefore diminish these disadvantages of prenatal screening and help lower the barrier for participation. This suggests that NIPT might allow couples to decide about prenatal testing based mostly on their will to test or not, rather than largely based on fear of miscarriage risk or the uncertainty of results. The lower barrier for participation was also seen as a downside that could lead to uncritical use or pressure to test. Widening the scope of prenatal testing was seen as beneficial for severe disorders, although it was perceived difficult to determine where to draw the line. Participants argued that there should be a limit to the scope of NIPT, avoiding testing for minor abnormalities. The findings suggest that NIPT could enable more conscious decision-making for prenatal screening. However, to ensure voluntary participation, especially when testing for multiple disorders, safeguards on the basis of informed decision-making will be of utmost importance.

EP07-S
Case Ilustrations of the utilization and uptake of NIPT-counselling and management issues

J. Kelley;
Mercy Hospital for Women, Melbourne, Australia.

Non invasive prenatal testing (NIPT) for aneuploidy using cell free DNA in maternal circulation has had a dramatic impact on prenatal screening and diagnosis. In Melbourne, Australia, NIPT is offered by several different service providers with out-of-pocket costs ranging from $500 - $1,200. Testing is largely performed in the USA and turn around times vary from 10 days to 3 weeks. Some centres provide clients with genetic counselling. At present, clients attending our public hospital may access NIPT as a first tier screening option or after first or second trimester screening. We have observed that many women who receive an increased risk result for Trisomy 21 will utilize NIPT before committing to an invasive test such as amniocentesis. Personal experiences that appear to influence this decision include IVF pregnancies, history of infertility, advanced maternal age, religious/spiritual beliefs and a desire to further clarify their risk. Counselling for this group of women requires significant time to explore the various pathways and possible outcomes, and the limitations and benefits of each.
Case examples will be used to illustrate our experiences with clients taking up NIPT, including management of false positive results, inappropriate use of NIPT and failure to achieve results. Decision making processes and counselling issues arising from NIPT will be explored.

EP08-M
Monitoring of congenital anomalies in the population of the Republic of Moldova

V. V. Egorov, *N. I. Barbova, E. A. Halabudenco, M. S. Stratila;*
National Center of Human Reproduction and Medical Genetics, Chisinau, Moldova, Republic of.

In the Republic of Moldova, the monitoring of the CA using since 1991, and from 2009 we are working to incorporate our registry in the EUROCAT. Were studied the prevalence and sharing of CA on the basis of genetic monitoring for the period from 2008 to 2012. The overall prevalence of the CA for the 5-year period amounted to 18.92 per 1000 newborns. The maximum frequency of the CA was noted in 2008 - 20.3 per 1000 births, the lowest in 2009 - 18.36 to 1000 newborns. Prenatal screening of pregnant women using non-invasive and invasive diagnostic techniques has allowed to reduce the average frequency of the birth of children with CA for 7.2% to 17.56 per 1000 newborns. In the structure of the CA by prevalence leading place is occupied by CA of the musculoskeletal system (22.5 ± 2.58%), multiple malformations (22.02 ± 2.98%) and the CA of the circulatory system (19.12 ± 4.48%). The prevalence of individual nosological forms of CA (esophageal atresia, cleft lip/palate, omphalocele, Down syndrome) are consistent with those of the international register of EUROCAT. Results of questionnaire of 158 women given birth to children with CA showed that 85.6% of women do not take folic acid in the first trimester of pregnancy. 74.5% of the mothers drank alcohol during pregnancy. Influence of the teratogenic factors noted at 22.2% of cases.Monitoring data allow to plan and carry out preventive measures to reduce the birth rate of the children with CA in Moldova.

EP09-S
The impact of the perceived severity of genetic conditions on the attitudes towards genetic testing and termination of pregnancy

A. M. Ciucă, *R. Moldovan;*
Babeș-Bolyai University, Cluj-Napoca, Romania.

Introduction: It is known that different factors (e.g. education, religion, severity of genetic conditions) may influence decisions regarding genetic testing and/or termination of pregnancy.
Objective: The aim of the present study was to investigate the extent to which the perceived severity of various conditions moderates the decision to opt for genetic testing and/or termination of pregnancy.
Methods: The study was conducted on adult couples from the general population in Romania. Participants were asked to complete questionnaires assessing the perceived severity of 30 conditions, the attitudes towards genetic testing and the attitudes towards termination of pregnancy.
Results of the study are being analyzed and presented in detail.
Discussion & Conclusions: This study was aimed at integrating these three concepts in order to have a better understanding of the factors associated with the decision to opt for genetic testing or terminate a pregnancy, in the general population. Implications of the impact of perceived severity of genetic conditions on the decision to opt for genetic testing and termination of pregnancy are being discussed.

EP10-M
Development of Myriad Individualized Medicine Units

N. Bosch, *E. Iglesias, C. Peel, C. Perez, N. Angulo, C. Moretones, C. Zapatero, E. Albiñana, F. Iglesias;*
Myriad Genetics, Madrid, Spain.

Since its foundation 20 years ago, Myriad genetics has become a leading molecular diagnostic company dedicated to making a difference in patient's lives. Through the discovery and commercialization of transformative tests to asses a person's risk of developing disease, guide treatment decisions and assess risk of disease progression and recurrence. These test services achieve top-quality assessment enabling top-quality information for the patient based on test results. Myriad laboratory operates under the highest standards of lean efficiency allowing result reporting much faster than average. In its aim to improve patient's quality of live and deliver top-quality information to the patients, Myriad Spain has developed a plan to create Individualized Medicine Units (IMUs). These multidisciplinary units located into the health system offer professional cancer counseling services. Different professionals including nurses, geneticists, genetic counselors, oncologists and psychologists will provide genetic testing education to patients and medical specialists. Thus, IMUs will become single organization structures which will permit a degree of coherence in providing genetic tests to counseled individuals. With the creation of IMUs access to an integral service with added value will benefit individuals affected of cancer as well as individuals at risk to develop it. IMUs are patient centered structures which intend to implement equal opportunity, help specialists to interpret genetic test results as well as to get genetic guided medical and preventive options closer to patients.

EP11-S
The disclosure of direct to consumer genetic testing: how to regulate them?

S. Oliveri[1,2], *A. Gorini*[1,2], *C. Lucchiari*[1,2], *M. G. Hansson*[3], *G. Pravettoni*[1,2];
[1]*Interdisciplinary Research Center on Decision Making Processes IRIDe, Department of Health Sciences, University of Milan, Milan, Italy,* [2]*Applied Research Unit for Cognitive and Psychological Science, IEO Istituto Europeo di Oncologia, Milan, Italy,* [3]*Centre for Research Ethics & Bioethics CRB, University of Uppsala, Uppsala, Sweden.*

Direct to the consumer genetic test (DTC GT) service is an indisputable and increasing phenomenon which portray internet society. It lets hypothesize that common people search for more health information and more sense of responsibility on their health behaviors. Indeed, proponents of DTC GT argue that making consumers able to calculate the relative risk of developing certain diseases may result in improved compliance with health-screening practices and more healthful lifestyle choices. The advertisements have a tendency to highlight these benefits and minimize any possible limitations. Moreover, consumers purchase these tests without the obligatory involvement of the health care provider, leaving free interpretation and use of genetic data. Despite these aspects, no concrete evidence about the attitudes towards, knowledge and use of DTC GT tests by members of the general population exist. Findings of previous researches indicate a low level of awareness of direct-to-consumer genetic testing impact, because of the hypothetical nature of many studies, use of not representative samples of the population and too little evidence from users. It is necessary to provide a theoretical framework of DTC tests use and to collect systematic data on

cognitive and behavioral DTC GT effects in the general population, in order to achieve progress in the policy arena, regulatory oversight, insights for consumers to make aware decisions and reduce the potential for misinterpreting genetic test results.

EP12-M
From NICE guidance to clinical practice: the challenge of setting up a service for Familial Hypercholesterolaemia

M. S. Watson;
Wessex Clinical Genetics Service, Southampton, United Kingdom.

In 2008 NICE published guidelines for the identification and management of Familial Hypercholesterolaemia (FH). A key priority was the identification of people with FH using DNA cascade testing.
This led to a scoping exercise in how to implement this service in the south central region. This included who, where, when & what kind of service. More importantly who would pay? The Wessex FH Cascade Testing is about to be launched in April 2014, commissioned by 12 Clinical Commissioning Groups (CCGs) within the new NHS structure with pump priming by the South Central Cardiovascular Network (SCCVN) and support from the British Heart Foundation (BHF) This is a narrative on how this was achieved, including the challenges of commissioning a new service and the opportunities afforded and how this has impacted thus far on the Genetic Service as a whole.
In March 2013, the Cardiovascular Disease Outcomes Strategy (CVDOS) specifically highlighted the need to improve the detection and management of people with Familial Hypercholesterolaemia (FH).
Action 5: The NHS Commissioning Board will take the lead, working with the Chief Coroner as appropriate; to improve the processes for identifying inherited cardiac conditions. The National Clinical Director for Heart Disease will work with all relevant stakeholders to develop and spread good practice in relation to FH and sudden cardiac death.

EP13-S
Developing genetic counselling in Portugal: education, practice and the growing of the profession

Á. Mendes[1,2], *J. Sequeiros*[1,3], *M. Paneque*[1,3];
[1]*UnIGENe and Centre for Predictive and Preventive Genetics, Institute for Molecular and Cell Biology - University of Porto (CGPP.IBMC-UP), Porto, Portugal,* [2]*Family, Health and Community research group, Department of Health Sciences - University of Aveiro, Aveiro, Portugal,* [3]*ICBAS - University of Porto, Porto, Portugal.*

As high-throughput genomic technologies became widespread and genetic healthcare workload expands, there is a call for education and training professionals to translate this changing landscape into appropriate care as well as for the health education of general population. In that sense, genetic counsellors are fully skilled professionals that could play an important role on the provision of safe and ethically adequate practice.
The first Portuguese genetic counsellors have completed their formal training in 2012. The Portuguese course in genetic counselling is accredited by the European Board on Medical Genetics (EBMG), in accordance with the proposed standards for education and core competences for professional practice, and in line with the harmonizing efforts of professional's education across different countries and healthcare settings. Moreover, a national association of genetic counselling professionals have been created. With this report we aim to provide evidence on the development of genetic counselling in Portugal, its educational program and current challenges on the establishment of the profession.
A growing body of research focusing diverse settings of the genetic counselling provision has been undertaken recently in Portugal. This includes the professionals' training needs for effective practice, quality issues of counselling, or the set of constraints affecting service delivery. Emergent challenges to continue the development of genetic counselling in Portugal are the recognition of the genetic counsellor profession, the harmonization of practice at national level, and the development of a clinical and counselling supervision network.

EP14-M
Reaction of maternity generations to human genetics in Japan

H. Moriya[1], *S. Izumi*[1], *M. Mizoguchi*[2], *S. Mori*[1], *R. Inoue*[1], *N. Terayama*[1], *H. Jono*[1], *R. Aoki*[3], *K. Takahashi*[1], *I. Inoue*[4];
[1]*Tokai University, Kanagawa, Japan,* [2]*Akita Red Cross Nursing College, Akita, Japan,* [3]*Soka University, Tokyo, Japan,* [4]*National Institute of Genetics, Shizuoka, Japan.*

Background:Demand for prenatal genetic testing has been increasing in general citizens, despite that they have less literacy on human genetics. This study aimed to educate human genetics to maternal generations and evaluate the reactions to the education and their understandings. Method: We recruited 10 mothers of pre-school children who accepted the program. We designed a lecture program, followed by focus group interviews (=FGI), which were conducted twice. After having an event on genetics with children, further planning and operation were carried out together with the mothers, then FGI were conducted again. Main theme of this program was to understand and accept a concept, "*everybody is different therefore everybody is valuable*". The transcript data were qualitatively analyzed. The study protocol was approved by the ethical committee of the affiliated institution. Results: After series of genetic education, participants naturally accepted "*everybody is different*". Accordingly, some of them changed their attitude to have more confidence to themselves, and some have more tolerance to the children. Most importantly, participants start thinking that learning genetics is useful for children to stop bullying and discrimination, and want nearby friends to learn about it.Discussion: Through genetic education, negative images of heredity that originally participants possessed were drastically disappeared. Therefore, it is important to educate human genetics and to give messages to recognize human diversity simultaneously.

EP15-S
And if I announce a genetic rare disease,are there particular recommendations? That must I know?

K. M'Bailara[1], **E. Toussaint**[2], *D. Lacombe*[2];
[1]*University, Bordeaux, France,* [2]*Hospital, Bordeaux, France.*

For some people, the disease announce is a shock. This announcement is going to change the course of life of the patient and its perception of the future. We know that is not only the subject which is going to receive the impact of the announcement but a whole family system. Numerous measures implemented have encouraged the improving how the disease is announced to the patient. Indeed, in our presentation, we shall see in what an announcement of genetic rare disease is a particular announcement. We speak about: the representation of the disease rare genetics, the extreme rarity of these diseases, the absence of „name" for many, the notion of orphan disease, the consequences of the dysmorphology, the difficulty giving of the information. It's essential that the doctors who announce the genetic rare diseases know what is has the work psychically for a patient, a family confronted with the genetic rare disease. It will be there a facilitator for the announcement and the care of the families.

EP16-M
Informing best practice in presymptomatic genetic testing for Huntington disease

K. K. Barlow-Stewart[1], *A. Howat*[1], *J. Conaghan*[2];
[1]*University of Sydney, Sydney, Australia,* [2]*Hunter Genetics, Newcastle, Australia.*

Introduction: International guidelines for offering pre-symptomatic genetic testing for Huntington disease (HD) first developed in 1994 have been recently reviewed (MacLeod et al, 2012). In light of these recent recommendations, the experience and views of clients who had undergone testing at an Australian HD genetics service operating since 1991 were explored. Method: Semi-structured telephone interviews with 14 participants were transcribed, de-identified and coded for thematic analysis using NVivo data management software. Results: Six main themes were identified: (1) motivations for testing; (2) access to services; (3) information and client-centred care; (4) perspectives on the guidelines; (5) support person role and impact; and (6) the afterwards. Motivations for testing were similar to previous studies including reducing uncertainty, family planning and to inform risk status of existing children. Participants felt they were seen promptly by the service, that they were provided with sufficient information about testing, their care was client-centred and their needs were met at the time of testing. Some participants wanted testing immediately, but understood the rationale in the guidelines for delaying testing until the second counselling session. Involvement of a support person varied, and those who involved their support person only at the results-giving session described a greater emotional impact of the result on the support person. Some individuals reported a significant long-term psychological impact after receiving a negative test result. Conclusion: Recommendations for practice include the involvement of support person/s from the initial session, and to provide long-term follow-up to all individuals undergoing pre-symptomatic testing, regardless of result.

EP17-S
Myotonic dystrophy type 1 families: anticipation as a decision making behavior for presymptomatic DNA testing of asymptomic children

A. Shopova[1], *S. Shopova*[2], *S. Bichev*[3], *A. Savov*[3];
[1]*Department of Neurology, Universiry Hospital „Alexandrovska", Sofia, Bulgaria,* [2]*Department of Neuropsychology, University Hospital „St. Naum", Sofia, Bulgaria,* [3]*National Genetic Laboratory, Sofia, Bulgaria.*

Myotonic dystrophy (dystrophia myotonica, DM) is the most frequently inherited neuromuscular disease of adult life. The classical DM, known as

Steinert disease or DM type1, is a multisystem disorder with an autosomal dominant inheritance associated with the presence of abnormal expansion of CTG trinucleotide repeats in DMPK gene on chromosome 19q13.3. Anticipation is a well known phenomenon in DM1. The greater size of the expansion of CTG repeats is associated with earlier onset and more severe symptoms in the following successful generations. This study presents different decision making choices of parents for presymptomatic -DNA testing of their asymptomatic children in DM1 families. This decisions are defined by the following medical and psychological aspects: genetically verified DM1 diagnosis in one of the parents, family history data for a relative with DM1 symptoms, making a choice about the asymptomatic sibling after receiving an information for affected fetus in second pregnancy of DM1 patient.

EP18-M
Ten years' experience of pre-symptomatic genetic testing for late onset neurodegenerative diseases

F. Rodrigues;
Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal.

Introduction: Pre-Symptomatic genetic Testing (PST) for late onset monogenic neurodegenerative diseases, such as Familial Amyloid Polyneuropathy (FAP), Machado-Joseph Disease (MJD) and Huntington's Disease (HD), is available to at-risk healthy individuals. The aims of this study were: 1) to analyze the motivations for a PST; 2) to access the present clinical situation of the subjects; 3) to inquire about the individual treatment and preventive options; 4) to evaluate the reproductive options; 5) to analyze feelings of regret after PST.
Methods: This retrospective study consisted of telephone interviews of 168 carriers who underwent PST at our Medical Genetics Unit between 2000 and 2013 (145 FAP, 11 MJD, 12 DH).
Results: Most subjects failed to formulate, retrospectively, a motivation for PST, either than mentioning a positive family history (46%). From all patients that tested positive for FAP, 45% present peripheral neuropathy, 19% have undergone liver transplantation and 10% are medicated with *Tafamidis*. 11/23 patients with MJD and HD have psychiatric illness. From 43 pregnancies were reported - 6 patients underwent prenatal genetic testing and 5 couples pre implantation genetic diagnosis. 24 subjects mentioned having decided not to have children because of the test result. 18 subjects presented feelings of regret after performing PST.
Conclusion:
The complexity of PST calls for discussions about testing that are tailored to the testing context and the individual's needs and preferences. Hence, it might be useful to access the long-term psychosocial consequences of PST, as well as to ensure that adequate health and reproductive care are accessible.

EP19-S
Educational-support groups for daughters of BRCA mutation carriers: a valuable addition to patient care

N. van den Boogaard - van der Put, *S. Stehouwer, M. G. E. M. Ausems;*
Division of Biomedical Genetics, University Medical Center Utrecht, Utrecht, Netherlands.

Introduction: The social workers of the department of Medical Genetics of the University Medical Centre Utrecht twice a year organize educational-support groups for young woman at risk for hereditary breast and ovarian cancer (either yet untested daughters of BRCA1/2 mutation carriers or mutation carriers)
We started these group sessions in 2008 because we noticed:
- parents with a BRCA mutation worrying about their daughters <25 years
- young womens' need to be in contact with peers
Although there is no medical benefit of knowing one's mutation status before the age of 25, the risk and uncertainty of (not) knowing are usually hard to deal with.
Methods: The group meetings are separated two-hour psycho-educative support sessions with 5-8 participants. Themes include:
-Timing of the DNA testing
-Family influence on decision making
-Talking about BRCA carriership and breast cancer within your family, with friends, at work or school
Results: We have conducted 11 group sessions. Over 60% of the participants joined more than once. Participants experienced positive effects such as an increase in knowledge and nuance. Their feelings are recognized by their peers and thereby contributing to normalization and sense of release. The participants and their reactions endorsed us to continue these meetings.
Conclusion: The purpose of the educational-support groups is that participants feel recognized in their particular situation and can share their experiences with peers. This helps them in learning how to deal with the (possible) genetic predisposition and being able to make their own decisions thoughtfully.

EP20-M
Living with uncertainty: the experiences of young healthy Italian women who have undergone genetic testing for hereditary breast and ovarian cancer

M. Franiuk[1], *N. Rania*[2], *M. T. Ricci*[3], *C. Bruzzone*[1], *P. Buda*[4], *O. Puricelli*[5], *L. Battistuzzi*[6], *P. Bruzzi*[7], *L. Migliorini*[8], *L. Varesco*[1];
[1]*IRCCS AOU San Martino-IST, Unit of Hereditary Cancer, Genoa, Italy,* [2]*University of Genoa, School of Social Sciences, Department of Education Sciences, Genoa, Italy,* [3]*IRCCS AOU San Martino-IST - Unit of Hereditary Cancer, Genoa, Italy,* [4]*IRCCS - AOU San Martino-IST, Unit of Hereditary Cancer, Genoa, Italy,* [5]*IRCCS AOU San Martino-IST, Unit of Clinical Psychology and Psychotherapy, Genoa, Italy,* [6]*University of Genoa, Section of Forensic Medicine and Bioethics, Department of Health Sciences, Genoa, Italy,* [7]*IRCCS AOU San Martino-IST, Unit of Clinical Epidemiology, Genoa, Italy,* [8]*University of Genoa, School of Social Sciences, Department of Education Sciences, Genova, Italy.*

Introduction. Testing of the BRCA1 and BRCA2 genes can identify inherited mutations that predispose to breast and ovarian cancer, and thus provides those women with the opportunity to engage in risk-reducing behaviors and programs. The information derived from the test, however, also exposes women to the responsibility of making difficult decisions and raises important new issues that may affect how they manage their lives.
Aims and methods. The aim of this qualitative study was to explore, through in-depth interviews, the experiences and behaviors of 22 young Italian women (11 mutation-positive, 11 mutation-negative, mean age: 35.21) who participated in BRCA testing. All the women had a known BRCA mutation in the family but no personal cancer history. Interview data were collected and analyzed in accordance with the grounded theory approach.
Results and conclusions. The following psychosocial themes were found to be affected by the results of BRCA testing: childbearing intentions, future projects, family support, feelings towards children and partners, risk perception, attitudes towards risk management strategies. Test results appeared to have a definite but generally not severe impact on the participants' lives although, in some cases, negative emotions were denied in words but expressed through behaviors. The results also showed that the main predictor of negative feelings was a previous experience of cancer in the family. These findings may help clinicians better understand women's experiences of BRCA testing and thus develop adequate, culturally and ethically sensitive interventions in the areas of effective communication, support and care.

EP21-S
The initiator and timing of referral to breast cancer genetic counselling; an exploration of everyday person-centered practice

E. van Riel[1], *J. Hubers*[1], *A. Witkamp*[1], *S. van Dulmen*[2,3,4], *M. Ausems*[1];
[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*NIVEL, Utrecht, Netherlands,* [3]*Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [4]*Buskerud University College, Drammen, Norway.*

Objective: The referral process for genetic counselling in breast cancer patients may be compromised by patient-related factors, like patient's age, referral initiative or cancer history. This study aimed to characterize this referral process in daily clinical practice.
Methods: During genetic counselling a checklist was filled in for each consecutive counselee affected with breast cancer assessing educational level, the initiator for referral and the ethnic background as reported by the counselee. Chi-square tests were used to assess associations between patient-related factors and initiator of referral and timing of genetic counselling.
Results: Included were 96 consecutive breast cancer patients referred to cancer genetic counselling: 52% of them were referred on their own initiative versus 48% on their doctor's initiative. There was no significant relationship between initiator of referral and time elapsed since diagnosis, age at time of diagnosis, number of first-degree female relatives and number of first degree relatives affected by any cancer.
Discussion: Patients' interest in genetic testing is not clearly related with time elapsed since diagnosis. Family history seems to play a role in the timing for referral.
Conclusion: One out of two breast cancer patients plays an active role in the referral for genetic counselling. However, we did not establish a relationship between initiative for referral and time since diagnosis.

EP22-M
The impact of objective versus subjective risk on emotional distress in breast cancer women

R. Moldovan, *A. Sabau;*
Babes Bolyai University, Cluj Napoca, Romania.

Objective: The aims of this study were to assess the impact of objective versus subjective risk on emotional distress and to investigate the extent to which cognitions mediate the impact of risk perception on emotional distress in a sample of breast cancer women. **Method:** In a retrospective quasi-experiment, a convenience sample of 53 breast cancer women (mean

age 51.92 years, SD=10.33) completed questionnaires assessing subjective and objective risk emotional distress and cognitions. **Results:** Subjective risk and objective risk are positively correlated (p<.01). Both subjective risk and objective risk cannot to predict emotional distress. No association was found between subjective or objective risk and cognitions. Alternatively, cognitions are an important predictor of emotional distress. Moreover, cognitions were found to mediate the relationship between risk estimation and the emotional distress. **Conclusions:** Results suggest that risk estimates (both subjective and objective) have a limited capacity to predict emotional distress in breast cancer women. The impact of risk estimates is mediated by cognitions which are an important predictor of emotional distress. Collective findings in this area will provide a better understanding of the mechanisms responsible for emotional distress in breast cancer women and will suggest potential psycho-social intervention

EP23-S
Predictive TP53 testing in adolescence and young adults: a case series

A. Lewis, *K. Thompson, L. Holland, M. Young;*
Peter MacCallum Cancer Centre, East Melbourne, Australia.

The growing awareness of the contribution of genetics in cancer has resulted in increasing numbers of young people (16-27) at risk of Li Fraumeni syndrome (LFS) presenting to the Peter MacCallum Familial Cancer Centre for predictive testing. The unique needs of young people in combination with the complex and unpredictable nature of cancers associated with LFS has led to a considered method of genetic counselling practice being employed when supporting these young people through predictive testing. The methodology adopted by genetic counsellors at the Peter MacCallum Familial Cancer Centre incorporates many of the recommendations made in a locally developed model for the provision of genetic counselling to young people. This yet to be published model, was developed by a group of Melbourne based genetic health experts and adolescent health experts in response to the growing number of young people seeking advice from Familial Cancer Centres. It aims to counter the apprehension had by many genetic health professionals in working with young people by providing practical evidence based strategies.[1] The strategies employed aim to engage and empower the young person throughout the process and include mandating direct contact with the consultand prior to the consultation. Ensuring one on one time is had for a period of the consultation to allow for unrestricted discussion and overt discussion with the young person about the level of involvement of their parents. Ten consultations with young people requesting LFS predictive testing utilising this methodology will be reviewed and discussed. [1]Duncan RE, Young MA. *J.Pers.Med*. 2013.10(6),589-600

EP24-M
Attitudes of women at high risk of ovarian cancer to population-based risk prediction and stratification

B. Rahman[1], *S. Meisel*[2], *L. Fraser*[1], *L. Side*[1], *S. Gessler*[1], *J. Wardle*[2], *I. Jacobs*[3], *A. Lanceley*[1];
[1]*Institute for Women's Health, University College London, London, United Kingdom,*
[2]*Health Behaviour Research Centre, University College London, London, United Kingdom,*
[3]*Faculty of Medical and Human Sciences, The University of Manchester, London, United Kingdom.*

Ovarian cancer is the fifth most common cancer amongst women in the UK, and accounts for more deaths than all the other gynaecological cancers combined. As early stage symptoms are few and non-specific, ovarian cancer is often diagnosed at an advanced stage and survival rates remain low. There is an opportunity to improve outcomes through advances in risk stratification, early detection and diagnosis. A population-based ovarian cancer risk prediction and stratification program incorporating genetic testing is being developed. A previous focus group study with individuals from the general population identified a need and support for the proposed program. This qualitative interview study was undertaken to explore attitudes of women at high risk of ovarian cancer (strong family history or BRCA1/2 mutation carriers). Eight women participated in one-on-one semi-structured interviews to explore their experiences of learning about ovarian cancer risks and attitudes towards the proposed program. Overall women had very positive attitudes towards the introduction of a population-based risk prediction and stratification program for ovarian cancer. Women felt that it would be of interest to other women in the general population and would raise awareness of the disease. Women drew on their own experiences of genetic testing, screening, risk-reducing surgery and interactions with health professionals to offer suggestions for the successful implementation of the program. Suggestions included providing counselling before and after receiving risk estimates, different formats for presenting risk estimates and providing information regarding ovarian cancer symptoms, effectiveness of screening, preventive options and lifestyle factors to reduce cancer risks.

EP25-S
Genetic counselling for inherited cardiac conditions in Wales: A service evaluation

H. A. Jolley[1,2], *S. Sarangi*[1], *D. Kumar*[3];
[1]*Cardiff University, Cardiff, United Kingdom,* [2]*Manchester Centre for Genomic Medicine, Manchester, United Kingdom,* [3]*Cardiff and Vale University Health Board, Cardiff, United Kingdom.*

The management of Inherited Cardiac Conditions (ICCs) is one of the most rapidly evolving areas in cardiology. The last decade has seen major changes in the diagnosis and management of ICCs. These were previously thought to be rare isolated disorders; however, it is now recognised that collectively they are common and are associated with the tragedy of sudden arrhythmic death syndrome.

A service evaluation was designed to investigate service users and Genetic Counsellors' experiences of genetic counselling at the time of a funding freeze for genetic testing for ICC's in Wales. Information was sought about service user's reactions and responses to information about genetic testing restrictions, psychosocial issues, and service improvements. A qualitative study which used in depth semi structured interviews with three service users and two genetic counsellors; a theme orientated discourse analysis was used to extract meaning from the data.

The service users' accounts supported existing theory that effective communication in genetic counselling is partially dependent on believing that the GC is interested in service users' personal circumstances. In this sample the unavailability of genetic testing contributed to feelings of uncertainty and concern for at risk family members.

As a result of this study, clinicians may wish to consider re-contacting service users who agreed to have a DNA sample stored during a freeze in NHS funding for ICC mutation screen testing. Service users with DNA banked for a prolonged period may require additional information or support to cope with the implications for their family.

EP26-M
Does and should breast cancer genetic counselling include lifestyle advice?

M. Ausems[1], *A. Albada*[1], *M. Vernooij*[2], *L. van Osch*[3,4], *A. Pijpe*[5], *S. Van Dulmen*[2,6,7];
[1]*University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Netherlands Institute for Health Services Research, Utrecht, Netherlands,* [3]*Maastricht University, Maastricht, Netherlands,* [4]*Maastricht University Medical Centre, Maastricht, Netherlands,* [5]*Netherlands Cancer Institute, Amsterdam, Netherlands,* [6]*Radboud University Medical Center, Nijmegen, Netherlands,* [7]*Buskerud and Vestfold University College, Drammen, Norway.*

Introduction: To optimally inform counselees about their and their relatives' risks, information about lifestyle risk factors, e.g. physical activity and alcohol consumption, might be discussed in breast cancer genetic counselling. This study explored lifestyle discussion in consultations during breast cancer genetic counselling. *Method:* First and follow-up consultations with 192 consecutive counselees for breast cancer genetic counselling were videotaped and coded for discussion of lifestyle topics (e.g. physical activity, diet, alcohol, smoking). Counselees completed online questionnaires before the first and after the final consultation. *Results:* With 52 (27%) counselees lifestyle was discussed, either in the first or final consultation, or both. Counselees mostly raised the topic (60%). Counsellors provided information about lifestyle risk factors to 19% and lifestyle advice to 6% of the counselees. Discussion of lifestyle was not associated with counselees' characteristics or causal attributions. Post-counselling, more affected counselees considered lifestyle as a factor contributing to their breast cancer (29%) compared to pre-counselling (15%; p=.003). *Conclusions:* Information and advice about lifestyle risk factors is infrequently provided, both with breast cancer unaffected and affected counselees and with those who did and did not consider their lifestyle as a cause of their breast cancer. A debate is recommended on how to incorporate lifestyle information in breast cancer genetic counselling. Modifiable lifestyle factors could be discussed more frequently to optimally inform counselees about possible ways to reduce their risk. Counsellors should be educated about effects of lifestyle and studies are needed on how to best integrate lifestyle information in breast cancer genetic counselling.

EP27-S
What ethical and legal challenges are associated with implementing risk-stratified screening for common cancers?

A. E. Hall[1], *N. Hallowell*[2], *S. Chowdhury*[1], *N. Pashayan*[3], *T. Dent*[1], *P. Pharoah*[4], *H. Burton*[1];
[1]*PHG Foundation, Cambridge, United Kingdom,* [2]*Institute of Public Health, University of Cambridge, Cambridge, United Kingdom,* [3]*Centre of Applied Health Research, University College, London, London, United Kingdom,* [4]*Department of Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom.*

The prospect of using multiple common genetic variants for population-

wide genotyping and personalised screening for common cancers raises some significant ethical, legal, social and organisational challenges. Whilst risk-prediction modelling performed as part of the Collaborative Oncological Gene-Environment Study (COGS) suggests that genotyping can effectively target screening and treatment, questions remain about the optimal age for sampling, analysis and reporting. Ethical guidance relating to the genetic testing of children generally focuses on highly penetrant variants which are strongly predictive of future ill health. In contrast, the multiple common variants identified through the COGS project are less predictive, and much more work needs to be done to assess the utility of this genetic knowledge particularly in children, when combined with lifestyle factors over a lifetime.
With these caveats in mind, the ethical, legal and social challenges associated with two alternative models for managing genotypic information in a personalised screening programme are presented: a targeted database in which data and samples are accessed solely for genotyping for risk prediction for a single type of cancer; and a generic database in which samples and data are retained indefinitely for multiple conditions. These ethical, legal and social challenges are discussed in terms of the potential implications for the ethical principles of autonomy, beneficence, and justice. These also inform relevant recommendations from the COGS project which illustrate some of the translational challenges of moving from modelling into practice.

EP28-M
Impact of genetic counselling in women undergoing invasive prenatal diagnosis for advanced maternal age

L. Godino, E. Pompilii, F. D'Anna, **D. Turchetti***;*
Medical Genetics, Bologna, Italy.

A cross-sectional survey using a self-administered questionnaire was performed with the aim of exploring the impact of genetic counselling in women undergoing invasive prenatal procedures because of advanced maternal age.Out of 637 questionnaires mailed to women who underwent prenatal diagnosis 1 -6 weeks before, 221 (34.69%) were returned; of those, 52.9% belonged to women counselled through an individual session, while 47.1% women had attended a group session.The majority of women (85.5%) defined the information received during counselling as clear (with 15.4% considering it as „extremely clear", regardless of the type of counselling received) and helpful (overall 99.1%).Twenty-two (10%) stated their expectations about CVS/LA had changed after counselling.Out of 192, 140 (72.9%) reported satisfaction about the counselling process regardless of the type of counselling received. Although more women (52.6%) stated they preferred, or would have preferred, individual counselling, the highest satisfaction rates were reported by women attending group sessions.

EP29-S
Cancer genetic counseling in Iceland

V. Stefansdottir[1], *O. T. Johannsson*[1], *C. Chapman*[2], *L. Tryggvadottir*[3], *H. Skirton*[4], *H. Tulinius*[5], *J. J. Jonsson*[1,6];
[1]*Landspitali - The National University Hospital of Iceland, Reykjavik, Iceland,* [2]*Women Hospital NHS Trust, Birmingham, United Kingdom,* [3]*Icelandic Cancer Registry, Reykjavik, Iceland,* [4]*Faculty of Health, Education and Society, Plymouth University, Plymouth, United Kingdom,* [5]*The Genetical Committee of the University of Iceland, Reykjavik, Iceland,* [6]*Department of Biochemistry and Molecular Biology, Faculty of Medicine, University of Iceland, Reykjavik, Iceland.*

Cancer genetic counseling was formally set up at Landspitali - The National University Hospital of Iceland in 2007. Clinical genetics use the services of the Genetical Committee of the University of Iceland the Icelandic and the Cancer Registry to make accurate electronic pedigrees and risk assessment. Biobanks allow for up to 60-70 years old samples to be tested. Icelandic founder *BRCA* mutations are the 5193G>A in *BRCA1* and 999del5 in *BRCA2*. The latter has been traced back several hundred years. The prevalence of the *BRCA2* mutation is 0.6-1% in a population of 320.000 and the estimated number of carriers is 12-1500 at screening age; 25-70 years. We have identified 40 *BRCA2* and three *BRCA1* founder mutation families. A counselee not found in the pedigree database, does usually not belong to a *BRCA* family. A little over 750 individuals have been tested for the founder mutations identifying 200 carriers of the *BRCA2* mutation, 15 of the *BRCA1* mutation and 2 with a new *BRCA1* mutation. The number, age of onset and types of cancers vary considerable in the *BRCA2* families. The 45 pedigrees, with 38-1250 individuals each, showed that 38 female carriers had been diagnosed once with breast cancer, two with bilateral breast cancers, two had been diagnosed with three or more breast cancers and 11 with ovarian cancer. Seven males have had prostate cancer and eight breast cancer. Other cancers were pancreatic, kidney, colon and thyroid. For prevention, 15 females and one male have had mastectomy and 7 had oophorectomy.

EP30-M
Is communication with relatives discussed in the final consultation for breast cancer genetic counselling?

I. Wieffer[1], *A. Albada*[1], *S. van Dulmen*[2,3], *M. G. E. M. Ausems*[1];
[1]*UMC Utrecht, Utrecht, Netherlands,* [2]*Buskerud University College, Drammen, Norway,* [3]*Radboud University Medical Centre, Nijmegen, Netherlands.*

Background Counselees in cancer genetic counselling are responsible for discussing possibilities for DNA-testing, risk estimations and surveillance advice with their relatives. We describe whether communication with relatives is discussed in final genetic counselling consultations, whether counsellors provide advice and whether counselees share their intention. *Methods* Consecutive new female counselees who were the first of their family to seek breast cancer genetic counselling were included from 2008 to 2010. We report on counselees whom received an indication for DNA-testing for themselves or an affected relative and/or a follow-up consultation. Final consultations were videotaped (n=152). Questions, information and advice about family communication were coded. Counselees' reactions to the counsellor's advice were scored on the level of agreement. Furthermore, counselees' intentions were transcribed. *Findings* Communication with relatives was discussed in 73.0% of the final consultations. In 33.6% the counsellor provided advice about family communication and a large majority (n=47, 92%) of the counselees responded with agreement. Almost half of the counselees (46.3%) expressed an intention about discussing risk information and most explicitly stated which relative they would inform (42.7%). Few counselees expressed when (9.2%), how (5.9%) or where (1.3%) they intended to discuss information with relatives. *Discussion* Almost half of the counselees expressed an intention to share risk information with one or more relatives. However, most counselees were vague about how and when they intended to do this. As risk information may be poorly transferred within families, counsellors could explore counselees' intentions and discuss how best to discuss risk information with relatives.

EP31-S
Genetic counselling in post-genomic era

N. Bukvic[1], *M. Maurizio*[2];
[1]*Azienda Ospedaliero Universitaria Consorziale Policlinico di Bari, Bari, Italy,* [2]*Servizio di Genetica Medica Dipartimento, di Scienze Biomediche Azienda Ospedaliero, Universitaria di Foggia, Foggia, Italy.*

With the surge of genetic tests and technologies, genetic counsellors are faced with the challenge of translating emerging scientific knowledge into practical information for patients, clinicians and public health policy makers. The new tests and technologies also are associated with new psychosocial and ethical considerations. New guidelines are needed for each new discovery of the genomic impact on phenotype, pathology and disease while "old" syndromes and "old" pathology, continue to require attention. In the new post-Human Genome Project era, genetic counsellors will be an integral part of translating genomic discoveries into beneficial impact on human disease, health care, and medical benefits. The needs for genetic counselling should be designed into genomic research at the onset. Genetic counsellors need to handle old while rapidly assimilating new information and the principal challenge is to be up to date and updated. [World J Med Genet 2013 May 27; 3(2)]

EP32-M
Attitude toward genetic testing of children for common disease risk in Japan

Z. Yamagata[1], *K. Muto*[2], *I. Ishiyama*[3];
[1]*University of Yamanashi, Yamanashi, Japan,* [2]*University of Tokyo, Tokyo, Japan,* [3]*Teikyo-Gakuen Junior College, Yamanashi, Japan.*

[Purpose] The purpose of this study was to assess the attitude of Japanese general public toward genetic testing of children for common diseases, and to clarify factors related to the attitude by nationwide opinion surveys conducted in 2009 and 2013. **[Methods]** In the survey in 2009, 4,000 people (age, 20-69) were selected from the Japanese general population by a stratified two-phase sampling method. In 2013, 2000 people were selected in the same way. They were queried about the following topics in a mail survey: attitudes toward genetic testing for disease susceptibilities of children for common diseases, interest in medical genomic studies, level of genomic literacy and awareness of the benefits and risks of medical genomic studies. The factors related to the attitude were examined using logistic regression analysis. **[Results]** The response rate was 52.5% (2,009/3827) in 2009 and 60.3% (1161/1925) in 2013. The genetic testing for disease susceptibilities of children was favored by 58.8% people in 2009 and 58.4% in 2013. The interest in medical genomic studies did not so change between in 2009 and 2013; belief of "scientific development has more advantage than disadvantage" was a little increased. Interest in medical genomic studies, belief in science and awareness of risks were significantly related to favorable attitudes

in each survey. It was suggested that interest, belief and awareness of risks were the factors related to the outcome of positive attitude change toward genetic testing for children. We will also show the attitude toward informed assent to children in genetic research.

EP33-S
Opinions Of Hearing Parents About The Causes Of Hearing Loss In Their Deaf Children Compared With Gjb2 (Cx26) Genetic Testing Results In Three National Republics Of Russia

Hereditary hearing impairment (HI) caused by GJB2 mutations is frequent sensory disorder. The results of research on molecular basis of HI are widely used in practice as various genetic test systems. However, primary subjective opinions of parents about causes of HI in their children should be taken in to account at the interpretation of genetic testing results especially in regions where genetic testing has not yet been widely used in public health. We conducted the first sociological research based on surveys of hearing parents of deaf children in three national Republics of Russia: Sakha (n=101), Tuva (n=61), and Bashkortostan (n=21) for analysis of subjective opinions of parents about causes of HI in their children followed by comparison with results of genetic testing of GJB2 gene. Most of respondents (73.8%-86.1%) chose answer "non-hereditary" for question about presumptive causes of HI of children and their opinions are more likely based on the absence of deaf relatives. Subjective opinions of parents are inconsistent with genetic testing results, despite different contributions of GJB2 mutations (16%-71%) in studied regions, and in many cases the announcement of testing results may have severe psycho-emotional influence on parents.

Study was supported by RFBR (#12-04-00342_a, #12-04-98520_r_vostok_a, #12-04-97004_r_povolzhye_a, #14-04-01741_A), SBRAS Integration project #92 «Ethnogeny of indigenous peoples in Siberia and North Asia: comparative, historical, ethno-social and genomic analysis», the Sakha Republic President grant for Young Researchers for 2014 (RP#80), RAS Program «Fundamental Sciences for Medicine» (#30 for 2013-2015), and «Scientific and Educational Foundation for Young Scientists of Republic of Sakha».

EP34-M
State anxiety as an affecting factor to the perception of the information during the genetic counseling and the reproductive decision making process

E. Zayakova[1]*, S. Shopova[1], A. Savov[2];*

[1]Department of Neuropsychology, Universiry Hospital „St. Naum", Sofia, Bulgaria, [2]National Genetic Laboratory, Sofia, Bulgaria.

This paper will show the results, part of longitudinal study /more than 5 years/, of the factors that influence the perception of the information during the GC and the reproductive decision making process. Till now we explored the effect of: type of diagnostic procedures, advanced maternal age, family reproductive history. This study focuses on the pathologic rates of the SA. SA is inducted and is a result of the concrete situation, not a typical personal trait. Purpose: Analyzing the anxiety rate during the GC and the reproductive decision making process. Task: Examination of the SA rate with State-Trait Anxiety Inventory (STAI). The object of the study are 100 women, who were pointed for GC because of biochemical screening results and risk pregnancy. Hypothesis: The need of making reproductive choice after the GC can increase the rates of SA. Results: In most of the cases of women without higher rates of trait anxiety pathologic rates of the anxiety during the process of GC are observed. Conclusions: Through the GC process the SA is increased and this affects the subjective perception of the information and the reproductive decision making process. This suggests creating an algorithm for good practices for psychological support in the process of genetic counseling.

EP35-S
Content analysis of informed consent for whole-genome-sequencing offered by direct-to-consumer genetic testing companies

E. Niemiec[1,2]*, P. Borry[1], H. C. Howard[2,3];*

[1]Department of Public Health and Primary Care, KU Leuven, Kapucijnenvoer 35 BOX 7001, B-3000 Leuven, Belgium, [2]IQhealthcare, Medical Ethics, Radboud University Medical Centre, P.O. Box 9101, 6500 HB Nijmegen, Netherlands, [3]Centre for Research Ethics and Bioethics, Uppsala University, PO Box 564, SE-751 22 Uppsala, Sweden.

Due to rapid development and a decrease in the price of high throughput sequencing technologies, whole genome sequencing (WGS) has become increasingly available in the research and clinical settings and is also being offered commercially by direct-to-consumer (DTC) companies. This offer amplifies the already identified concerns regarding informed consent for both WGS and the DTC offer of genetic tests. The aim of this project is to study the websites of companies advertising WGS DTC to analyze whether they address the recommended elements outlined by Ayuso and colleagues (2013) regarding consent for WGS in the clinic, which include, among others, pre-test counselling, description of the test process, expected benefits, possible risks, voluntary nature of participation, confidentiality and privacy, informing relatives or not, the storage and future use of samples, management of incidental findings and specific informed consent. Preliminary analysis reveals that the consent information on the websites of Illumina and Gentle, at least mention the majority of these items. Furthermore, both companies require consumers to obtain the test and/or results through a physician. However, involving a physician, and addressing these aspects on their website do not ensure an adequate informed consent process. Indeed, challenges of informed consent include, among others, the potential overload and complexity of the information regarding the process and the potential results, the (limited) ability of individuals to completely understand the information given, and biased understanding. This empirical study contributes valuable information toward the ongoing debate on the responsible offer of WGS in the commercial realm.

EP36-M
Return of whole-genome sequencing results in paediatric Research: a Statement of the P3G international Paediatric Platform

K. Sénécal, *B. M. Knoppers, D. Avard, M. H. Zawati;*

Centre of Genomics and Policy, McGill University, Montreal, QC, Canada.

Background: Whole-genome sequencing (WGS) is expected to have a significant impact on the field of human genetics in the near future. The sheer volume of information generated by WGS raises the question of whether or not to return such results. This dilemma is exacerbated in the context of paediatric research as particular issues are raised: the rights of parents to access their child's genetic information; the best interests of the child; the right (not) to know; the utility of information; consent, and counseling.
Objective: The aim of this research was to develop guidance on how to address the return of WGS results in paediatric research. We worked with the P^{3}G International Paediatric Plateform to build a common tool.
Methods: To formulate the Statement, we: (a) reviewed the legal and ethical norms applicable to the European and Canadian research communities and the relevant literature to identify both existing and emerging guidance; (b) conducted a qualitative study of stakeholder groups; (c) developed recommendations; and (d) validated the recommendations through consultations with a large number of stakeholders (e.g. genetic researchers, community-based organizations).
Results: We propose a Statement to address the issues of when WGS results: i) should be returned; ii) should not be returned (and identify exceptional circumstances); and iii) described the procedures for the communication of results.
Conclusion: It is anticipated that the Statement will not only provide a template for paediatric research using WGS, but also guide researchers and ethics committees.

EP37-S
Disclosure of genetic information within the family: evaluation of the model letter accompanying a new French decree

L. Monteil[1]*, E. Haquet[2], N. Taris[3], L. Akloul[4], L. Pasquier[4], C. Zordan[5], C. Cordier[6];*

[1]Department of Medical Genetics, CHU Toulouse, Toulouse, France, [2]Department of Medical Genetics, CHU Montpellier, Montpellier, France, [3]Department of Oncology and Haematology, CRCC Strasbourg,, Strasbourg, France, [4]Department of Medical Genetics, CHU Rennes, Rennes, France, [5]Department of Medical Genetics, CHU Bordeaux, Bordeaux, France, [6]Department of Oncology Genetics, CHU Strasbourg, Strasbourg, France.

In France, the recent publication of the decree of June 20th 2013 (n° 2013-527) modifies professional practices in medical genetics. It suggests a protocol regarding the transmission of information to relatives after a genetic diagnosis of a serious condition with the possibility of preventative or care measures. If a mutation carrier refuses to directly inform other members of

the family, one option is to call on the services of a genetic professional for the transmission of this information. This decree includes a specific model letter that can be sent to relatives by genetic professionals to invite them to make an appointment at a genetics center to access genetic counselling.
As part of a group comprising a geneticist and six genetic counsellors, we aimed to study the impact of this letter, both in terms of patient understanding and feelings. Evaluation was based on a brief interview after reading the model letter. Two groups were recruited either from "classical" genetics consultations or from "the general population".
We present here the results of 148 questionnaires. Overall, this type of letter appears to be an acceptable procedure for the majority and participant understanding was satisfactory, nevertheless two paragraphs were frequently read twice to be understood. The relevance of a third paragraph was frequently questioned. The main feeling is concern, while anxiety appears to occur with lower frequency. In light of these results, we discuss the need to formulate a new model letter accommodating as many people as possible to standardize practices.

EP38-M
Experiences of being a carrier and mother of a child with hemophilia

C. von der Lippe[1], *J. Frich*[2], *A. Harris*[3], *K. N. Solbrække*[4];
[1]*Centre for Rare Disorders, Oslo University Hospital, Oslo, Norway,* [2]*Institute of Health and Society, University of Oslo, Oslo, Norway,* [3]*Technology and Society Studies Department, Maastricht University, Maastricht, Netherlands,* [4]*Dep. of Health Sciences, University of Oslo, Oslo, Norway.*

We have conducted a qualitative study to explore women's experiences of being a carrier of the X-linked disorder hemophilia. We collected data through in-depth interviews with 16 women who were carriers and mothers of a child with hemophilia. In analysing these narratives, we adopted an interpretative approach to highlight the personal experience of being a carrier of an X-linked disorder, how meaning is negotiated, communicated and lived out within a wider social context. Preliminary analysis suggests that carriers experience feelings of worry and guilt after having a son with hemophilia. A striking feature in our study is that those who already knew they were a carrier, and thought this knowledge would prepare them, still experienced the event of having a child with the diagnosis distressing. Those who were diagnosed as carriers after having a son with hemophilia seemed to go through a different trajectory, focussing primarily on the child and not so much on their own carrier status. Although open communication about hemophilia and inheritance within the family makes coping with the disease easier, it might not hinder distressing feelings. More nuanced knowledge into experiences and challenges of mothers of children with X-linked disorders could prepare genetic counsellors, clinical geneticists and other professionals to understand their situation and facilitate an empowering approach.

EP39-S
The parenthood and the child rare disease: there is specificities?

E. Toussaint[1], *K. M'Bailara*[2];
[1]*Hospital, Bordeaux, France,* [2]*university, Bordeaux, France.*

About 3 million people are concerned by in France and even if the media and the French Foundation of Rare Disease are proactive in discussing these diseases, their increased number and specifications are difficult to keep up with.
A preexisting child presenting with a rare genetic disease will also be a source of psychological disturbances. An overview of the current literature showed that many dimensions are involved in parents with children diagnosed with rare genetic disease: social, financial, familial, professional, educational, medical and psychological. However this analysis was done on a little number of studies and very little is detailed on the specificity of the rare genetic disease. Also these elements are usually studied to individual levels and not necessarily at the family level. And, if a child is diagnosed with a rare genetic disease, the whole family will be concerned, will suffer and will need to adapt to this new situation. It seems that parents are showing signs of psychic weakness but no prediction can be made on the impact this will have on the family system nor on the factors of protection of weakness.
But are there specificities in the rare genetic diseases?

EP40-M
The impact of carrier identification on children's wellbeing from parents' and children's perspectives

M. Noke, *S. Peters, A. Wearden, F. Ulph;*
The University of Manchester, Manchester, United Kingdom.

The identification of sickle cell disorder carriers is routinely reported to parents following newborn screening in England. Although parents express intentions to provide carrier results to children in late childhood, little is known about when carrier status is provided or how children adapt to knowledge of their status. This is despite advice from European guidance that testing be deferred to avoid negative psychosocial detriment in childhood. This study explored the impact of disclosure of sickle cell carrier results on children's wellbeing via separate semi-structured interviews with 8 mothers and their children (M = 9.50 years, range = 6.92 - 14.56 years). Thematic analysis explored themes within and between each parent-child pair. Parents provided partial carrier information to children at around age 7; some parents acknowledged children's residual anxiety yet others did not report adverse effects following disclosure. By contrast, children reported significant anxiety, nightmares, withdrawal, distraction in school and feared negative responses from peers, which they had not discussed with parents or others. Parents and children reported the desire to have more developmentally appropriate information to improve understanding. Poor parental communication and lack of understanding of a carrier status caused children's maladaptive adaptation to results. Greater emphasis should be placed on aiding discussion between parents and children following carrier status disclosure acknowledging how difficult it can be for children to have these discussions, the availability of resources for families and further research regarding the long-term impact of carrier status on children's wellbeing.

EP41-S
Impact of Hemophilia on the Psychological Health of Hemophilia Patients

L. M. Hogea[1], *B. Georgiana*[2], *M. Rodica*[3];
[1]*"V. Babeş" Medicine and Pharmacy University, Timisoara, Romania,* [2]*"Oncomed" Medical Center, Timisoara, Romania,* [3]*"V. Babeş" Medicine and Pharmacy University;"Oncomed" Medical Center, Timisoara, Romania.*

Purpose: Psychological factors have a significant impact on quality of life for patients with chronic diseases such as haemophilia. The aim of this study was to evaluate psychological aspects of haemophilia. Sf-36 is one of the most beneficial instruments for assessment of life quality in haemophilic patients. Methodology: The study included 60 patients with A and B severe haemophilia, with the age between 16-40 years old, during 2012-2013. The results of SF-36 questionnare were examined on the whole group, on age group respectively 16-25 years old and 26-40 years old. The health condition declared by the haemophilic patients was correlated with Beck depression parameter. Results: Evaluation on the whole group showed the lowest scores on the domains D4=45,2+/_19,4 of the pain, D1=35,1+/36,6 physical performed functionality and vitality D7=44,2+/38,1. There were statistically significant differences between the two groups on D1 and D4 ($p<.0.1$). We observed significant differences in social relationships, mental health and the general state of health between the two groups ($p<.05$). The correlation between health score and Beck depression parameter is not significant. Conclusions: Knowledge of the psychological characteristics of haemophilia patients are useful in developing a plan for social integration and finding a healthy balance.

EP42-M
Creation and started by a therapeutic patient education for gaucher's disease patients: the french experience

E. Toussaint[1], *F. Camou*[1], *I. Raymond*[1], *F. Eyquard*[2];
[1]*Hospital, Bordeaux, France,* [2]*Hospital, Libourne, France.*

Therapeutic patient education (TPE) is an essential part of chronic disease care, enabling to achieve autonomy in health-related decisions, a better quality of life and better health outcomes. In order to elaborate an educational program adapted to patients, a working group* was made up including physicians, nurses, psychologists and the patient's association.
The first step was an evaluation of the patient's needs based on patients and professionals' interviews. This investigation brought to light a plurality of representations and real-life experience of the disease as well as numerous repercussions on the working life, the social life, the balance of the couple and the family.
Several preferential themes have been identified to design the educational program which contains:
-A personalized consultation in order to identify the patient needs (educational diagnosis) and to organize his educational training
-Three educational group sessions of approximately 2 hours. The choice of sessions for a given patient will be negotiated by the physician and the patient together. They concern the following themes:
a) Better understanding of Gaucher's disease and its consequences (definition, symptoms, natural evolution, follow-up and complications)
b) Living with the disease in everyday life (real-life experience, fatigue and pain management, identification of available resources)
c) Better appropriation of his (her) treatment (criteria of choice of the specific treatment, additional treatments, oral treatment and drip administration)

-A follow-up consultation, support and evaluation of patient's progress
The program is based on interactive educational methods meeting quality criteria of adult's training and it is accompanied by varied educational tools.

EP43-S
Psychological support of BRCA1/2 carriers: audit of patient satisfaction with clinical psychology appointments, issues discussed and the offer of psychological support for women considering risk reducing mastectomies

C. Firth, *L. Izatt, C. Hammond, C. Compton, S. Wells, H. Hamed, J. Farhadi, C. Jacobs;*
Guys and St Thomas' NHS Trust, London, United Kingdom.

BRCA1 and BRCA2 carriers who live in the south east of England are offered an appointment in a one-stop BRCA clinic at Guy's hospital following identification of a gene mutation. Carriers are offered a choice of appointments with specialists in genetics, breast surgery, gynaecology, oncology and psychology. In addition regular support groups and patient education days are provided. Dedicated psychological support is provided by a clinical psychologist. We will discuss the types of interventions offered and the range of issues addressed.
In addition we will present data from a satisfaction survey carried out with patients who opted to see the Clinical Psychologist in the BRCA follow up clinics between January and March 2014. This survey found that 92% of patients felt completely listened to and understood, 85% felt completely able to talk about the things they needed to and 85% felt that the appointment helped them feel they could move forward a great deal or to some extent with their issues.
UK guidelines recommend that all women considering risk-reducing mastectomy are offered psychological support. The local protocol is that all women seen in the BRCA multidisciplinary clinic are offered an appointment with the Clinical Psychologist. An eighteen month audit of the offer of these appointments (by the psychologist) to the women is currently underway. Preliminary data show that 46% (12) of the total number of women eligible for an appointment (26) were offered an appointment. Possible reasons for this discrepancy and tentative recommendations for practice will be discussed.

EP44-M
Using Patient Reported Outcome Measures in clinical genetics services: Pilot studies in six UK clinical genetics centres.

M. McAllister[1,2], *A. Clarke*[1], *N. Bowen*[1], *G. Scott*[3], *S. Watts*[4], *C. Eddy*[5], *A. Melville*[6], *A. Bruce*[7];
[1]*Cardiff University, Cardiff, United Kingdom,* [2]*Cardiff & Vale University Health Board, Cardiff, United Kingdom,* [3]*NHS Greater Glasgow & Clyde, Southern General Hospital,, Glasgow, United Kingdom,* [4]*Guy's & St Thomas's NHS Foundation Trust,, London, United Kingdom,* [5]*St George's Healthcare NHS Trust, London, United Kingdom,* [6]*NW London Hosiotals NHS Trust, London, United Kingdom,* [7]*St George's Hospital for Children NHS Trust, London, United Kingdom.*

Background: Patient Reported Outcome Measures (PROMs), short self-completion questionnaires capturing aspects of health or health-related quality of life, have recently gained prominence in healthcare evaluation worldwide. Historically, the quality of UK clinical genetics services has been evaluated using process measures e.g. patient waiting times, numbers of patients seen. Whilst current approaches to quality are important, little attention has been paid to patient outcomes because these have been difficult both to specify and to measure. This paper reports on pilot studies using a new clinical genetics-specific PROM, the Genetic Counselling Outcome Scale (GCOS-24) in six UK clinical genetics centres.
Methods: Patients were asked to complete GCOS-24 before and after clinic attendance. Satisfaction data were also collected in some centres. Data were analysed using analysis of variance and bivariate correlation. Centres provided feedback on feasibility of PROMs data collection and lessons learned.
Results: Five centres demonstrated statistically significant improvement in patients' GCOS-24 scores following clinic attendance with usable samples sizes of 42, 45, 54, 55 and 74 patients respectively ($p<0.001$). One centre had insufficient matched pre-clinic and post-clinic questionnaires to enable a useful analysis. GCOS-24 improvement scores correlated significantly with patient satisfaction.
Conclusions: Findings demonstrated that participating clinical genetics centres can deliver significant measurable patient benefits and that GCOS-24 has potential to be a useful supplement to existing methods of evaluating quality of routine clinical genetics services. Useful next steps could include developing methods for optimising patient response rates and for integrating PROMs information into continuous quality improvement cycles in clinical care.

EP45-S
Fitting the Pieces Together - Adoption Issues in Genetic Counselling

M. J. Boon;
Genetic Health Queensland, Brisbane, Australia.

Adoption is a unique situation which can present a number of challenges within a genetic counselling session. Primarily, adoption may limit the communication of information between at-risk relatives, with difficulties in notifying either a child who was adopted out at birth, or the biological family of an adopted individual, of genetic risk information. However, many other clinical and psychosocial issues can also be raised in these cases which likewise need to be addressed.
In Queensland, Australia, the adoption process is regulated by a single State Government organisation. The current *Adoption Act 2009* legislation came into effect in February 2010 and aims to balance the privacy of those individuals who do not want to be contacted with people's right to access information about their birth parents or a child who was adopted. For new couples wishing to express interest in adopting a child, multiple assessments are required to determine their suitability as parents, including close examination of their medical history.
Three cases will be presented which highlight some of the various challenges that adoption can present within a cancer genetic counselling context. The outcome of each case will be discussed, including the specific clinical and psychosocial issues that were raised. These include the assessment of eligibility for genetic testing, provision of accurate risk management advice, facilitating communication of genetic risk, addressing psychosocial issues and the potential discrimination an individual with a genetic condition may face if they are wishing to become an adoptive parent.

EP46-M
„BRCA isn't all about boobs"...or is it? Lessons from a BRCA support group

M. M. J. Bradford[1], *S. M. A. Goodman*[1], *A. Charles*[2];
[1]*Peninsula Clinical Genetics Service, RD&E NHS Foundation, Plymouth, United Kingdom,* [2]*Mustard Tree Macmillan Centre, Plymouth, United Kingdom.*

Within the Plymouth region of the Peninsula Clinical Genetics Service we identified 71 women who had tested positive for a BRCA1 or BRCA2 mutation. Letters were sent to these, inviting them to attend a support group. Twenty-seven women responded with twenty-five attending the group. Numbers were almost precisely equal between BRCA1 and BRCA2, with age ranging from early twenties to over 65. Most attendees had known about the gene change in their family for 4+ years. Motivation for attending focused on sharing experiences and meeting other women in a similar position. Reporting of beneficial aspects of the group tallied with this, with women particularly appreciating the chance to see the outcome of surgery. While distressing stories were shared, all participants reported feeling positive about the event. It was noted that, with appropriate facilitation, groups achieved an effective balance; sharing personal stories while also appreciating individual circumstances. Professional concerns about causing distress to those earlier in their journey were not realised, as participants took an active role in reassuring and supporting one another. Some women listed "helping others" as their main motivation for attending. Discussion at the end of the session helped provide a plan for future groups. It was identified that group support should be two-fold; combining continuity through consistent small groups, as well as the opportunity to divide according to stage of treatment / topic of interest. It is notable that, while women with cancer felt well supported, those undergoing prophylactic mastectomy felt that they lacked a clear pathway.

EP47-S
Differential binding of CREB, USF, and c-Myc to the Calreticulin Human Specific -220C may be linked with the evolution of higher brain functions in human

S. Farashi, *H. Bayat, M. Banan, S. Mohammadparast, M. Ohadi;*
Genetic Research Center, Tehran, Islamic Republic of Iran.

We have previously reported a human-specific nucleotide in the promoter sequence of the calreticulin (CALR) gene at position -220C, which is the site of action of valproic acid. Reversion of this nucleotide to the ancestral type, -220A, co-occurs with severe deficit in higher brain cognitive functions. This mutation has since been reported in the 1000 genomes database at an approximate frequency of 0.0009 in humans (rs138452745). In the current study, we compare the pattern of protein binding between -220C and -220A using electrophoretic mobility shift assay (EMSA) by oligonucleotide probes representing 24 base pairs encompassing -220C>A. Antibodies reactive against transcription factors CREB, USF, and c-Myc were used to identify the specific proteins involved in complexes with DNA. Significant increase was observed in the overall protein complexes binding to the -220C allele vs. -220A. The transcription factors, CREB, USF, and c-Myc, were differentially bound to -220C, represented by supershifts. We propose that differential binding of CREB, USF, and c-Myc to CALR nucleotide -220C may be linked with the evolution of higher brain functions in human.

EP48-M
Association between COMT Val158Met genotype and personality traits in healthy female subjects

L. D'Onofrio[1,2], *F. Cieri*[1], *M. Sergi*[1], *M. Balsamo*[3], *L. Picconi*[3], *M. Tommasi*[3], *M. Franzago*[1], *A. Grilli*[3], *A. Saggino*[3], *L. Stuppia*[2,3], *V. Gatta*[2,3];
[1]*Department of Neuroscience and Imaging, "G. d'Annunzio" University, Chieti, Italy,* [2]*Functional Genetics Unit, Center of Excellence on Aging, (Ce.S.I.), Chieti, Italy,* [3]*Department of Psychological, Humanities and Territorial Sciences, School of Medicine and Health Sciences, "G. d'Annunzio" University, Chieti, Italy.*

Dopaminergic genes are associated with a broad range of behaviors. The enzyme catechol-O-methyltransferase (COMT) is involved in extrasynaptic dopamine degradation in prefrontal cortical areas. The relatively common methionine (Met) for valine (Val) substitution at codon 158 of the COMT gene (Val158Met) results in an enzyme with 3-4 times lower rates of catabolism, increasing dopamine levels in prefrontal cortical regions. Among the characteristics of dopamine is important to mention the brain reward systems, infant attachment and adult human personality, particularly higher scores in Val carriers were reported for the Extraversion scale of the NEO Five-Factor Inventory and the Novelty Seeking and Persistence scales from Cloninger's-TCI questionnaires. The aim of the study was to compare the COMT Val158Met functional genetic variant with personality traits, assessed using self-reported Big Five Questionnaire (BFQ-2) and Temperament and Character Inventory-Revised (TCI-R). We tested a possible interaction among these variables on a cohort of 154 healthy female students, recruited at the "G. d'Annunzio" University, Chieti. A significant correlation has been observed between Val carriers and the BFQ-2 Dynamism subscale ($r=-.17$; $p<.05$). Moreover we observed significant correlations among Val carriers and two TCI-R's temperament traits: Reward Dependence ($r = -.16$; $p < .05$) and Persistence ($r = -.16$; $p < .05$). We found a significant correlation ($r = -.22$; $p<.01$) between the Val carriers and Cooperativeness, a factor of the character side of the personality, measured through the TCI-R.

EP49-S
Psychological aspects of living with EDS.

P. De Wilde, *F. Malfait, A. De Paepe;*
Centre for Medical Genetics, Gent, Belgium.

EDS patients suffer from a loss of control (body, time, environment, emotions). Inevitably this results in a loss of identity. Four elements stand out: the danger of living a restricted life, the risk of social isolation, the feeling of uselessness and the problem of being discredited. Especially the latter is very hard to endure. Patients are caught in a typical paradox: successful coping, often at the expense of superhuman efforts, makes other people doubt about the gravity of the illness. Yet, they have no other choice but to do their very best. There is always this pending and lurking question: "Are you really trying enough?" The underlying assumption is that effort always yields positive outcomes. If someone does not get any better he is being held responsible. It is this social response that makes a disease stigmatizing and tiring, not the disease in itself. We take a social psychological stance: not a person's character is determining his behavior, it is the context. As a consequence: we should reconsider our notion of empowerment. The traditional medical belief that 'rational' communication of information and compliance in following treatment regimens form the basis for patient empowerment is in line with a social discourse that propagates mastery and responsibility. It overlooks some important elements of illness experience. By listening to and talking with our patients we, practitioners, by definition, legitimize their experiences. This is where authority meets vulnerability. Only then are patients capable of moving forward.

EP50-M
Psychosocial outcomes and uptake of testing in non-pregnant and pregnant women offered carrier screening for fragile X syndrome (FXS)

S. A. Metcalfe[1], *M. Martyn*[2], *J. Emery*[3,4], *J. Halliday*[1], *S. Donath*[1], *J. Cohen*[5], *& FaXeS study team*[6];
[1]*Murdoch Childrens Research Institute and Dept Paediatrics, University of Melbourne, Parkville, Vic, Australia,* [2]*Murdoch Childrens Research Institute, Parkville, Vic, Australia,* [3]*Dept General Practice, University of Melbourne, Parkville, Vic, Australia,* [4]*The University of Western Australia, Perth, Australia,* [5]*Fragile X Alliance and Monash University, Melbourne, Vic, Australia,* [6]*Murdoch Childrens Research Institute, University of Melbourne, University of Western Australia and Deakin University, Melbourne and Perth, Australia.*

Population carrier screening for FXS identifies women at increased risk of having an affected child, and provides information about their own health risk. Debate surrounds educational and counselling complexities inherent in such screening. We assessed aspects of decision-making, in non-pregnant and pregnant women offered FXS carrier screening. Women were approached through general practice, obstetric or ultrasound clinics, received written information and telephone pre-test counselling with consent. At home, women decided about testing, and completed a questionnaire (Q1), returned with their buccal sample if tested. Premutation (PM) or grey zone (GZ) results were discussed by telephone and women offered genetic counselling; test-negative results were mailed. 1237 women (702 non-pregnant and 535 pregnant) initially consented; 71% and 59% were tested, respectively: PM (0.4%); GZ (2.0%). 85% had good knowledge (≥7/10 correct). 77% non-pregnant and 67% pregnant women had positive attitudes. Pregnant women were less depressed and less stressed than non-pregnant women on Depression Anxiety Stress Scale; no differences between tested and non-tested. Only a few women had scores outside of the normal range. Decisional conflict (DC) scores were subtly different between groups. Most significant differences were seen in the DC uncertainty subscale: non-tested less certain than tested women ($p< 0.0001$); pregnant less certain than non-pregnant women ($p< 0.0001$). The majority of women offered screening had good understanding with minimal psychosocial impact, possibly related to pre-test counselling embedded within this study, an important element for consideration in screening programs. Overall, women supported availability of being offered screening, although testing before pregnancy is preferred.

EP51-S
Post-mortem genetic testing requested by a family member: challenges for genetic counseling

V. Cina, *D. Hersch, S. Unger;*
Service of Medical Genetics, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.

We report a family where post-mortem genetic testing identified a predisposition to melanoma and pancreatic cancer. The index case referred to genetic counseling presented a cancer of unclear origin (pancreatic/ovarian) at age 58. A sister had died of pancreatic cancer at 59, the mother had died of melanoma at 48 and an aunt was diagnosed with melanoma at 32 and breast cancer at 52 and died of a head and neck cancer at 60. Analysis of *BRCA* 1 and 2 genes was normal. Analysis of *CDKN2A* gene was discussed but declined by the patient for different reasons among which were the lack of efficacy of surveillance measures and clear guidelines. The patient gave consent for DNA storage for further analysis and research. After her death, one sister requested genetic testing of *CDKN2A* through a Canadian genetic team. With the consent of the patient's husband, the medical authority in Switzerland and the ethical committee in Canada, analysis of *CDKN2A* was performed in Canada and a pathogenic mutation was identified. Subsequently, the patient's adult children who live in Switzerland requested genetic counseling and opted for testing. Post-mortem genetic testing is commonly performed in the setting of forensic autopsy (for example following sudden cardiac death) but it presents some specific challenges when requested by a family member and performed on a stored DNA sample. This case raised legal and ethical questions about consent, practical questions regarding reimbursement of the test and awareness of psychological aspects of genetic counseling for offspring.

EP52-M
Reciprocity among genetics professionals in Europe - A UK:Dutch experience.

A. S. Matadeen[1,2];
[1]*Oxfordshire Regional Genetics Service, Oxford, United Kingdom,* [2]*Leiden University Medical Centre (LUMC), Leiden, Netherlands.*

Recent literature has highlighted that collaborations among genetics professionals in different countries can help to facilitate genetic counselling practice development. Reciprocity is one manner of achieving this. Reciprocity has been identified by the Transnational Alliance for Genetic Counselling (TAVC) as a useful entity in allowing for progression of the international genetic counselling community as it allows for reflection on current methods of genetic counselling in one's own and other countries. Furthermore, the December 2013 issue of the Journal of Genetic Counselling was dedicated as a special issue concerning a global perspective of genetic counselling, in particular highlighting the value and drawbacks of student exchange experiences as a component of study programs. Currently this seems to be the most common method of gaining such experience. Here, I present the experience of a UK trained and registered genetic counsellor visiting a Netherlands based genetics service and I reflect on the benefits and drawbacks for staff from genetics centres engaging in these opportunities. This is the first report of this kind and it is hoped that it may help to facilitate future reciprocity among these two countries. Furthermore, a Dutch perspective of a UK based service is also provided.

Cytogenetic analysis of first trimester missed abortions

S. Grigore[1], *R. Cretu*[1], *L. Neagu*[1], *M. Malageanu*[1], *D. Albu*[1], *D. Mierla*[1], *L. Bohiltea*[2];
[1]*Life Memorial Hospital, Bucharest, Romania,* [2]*Carol Davila University of Medicine and Pharmacy, Department of Genetics, Bucharest, Romania.*

BACKGROUND: Approximately 15% of all clinically recognized pregnancies are spontaneously aborted and ~60-70% of these are attributable to detectable chromosome abnormalities . Cytogenetic analysis is an important component in the assessment of human malformation in early failed pregnancies. **METHODS:** A total of 32 patients with missed abortion between 7-11 weeks gestation underwent cytogenetic analysis of chorionic villi, using R-banding cytogenetic techniques. **RESULTS:** Among 32 examined cases, 14 (43,75%) were with abnormal karyotype and rest of 18 (56,25%) were normal. Of the 14 cases with an abnormal karyotype, there were 3 structural abnormalities and 11 numerical aberrations. When analyzed by maternal age, the rate of abnormality for first-trimester losses was 38,88% in women younger than 35 years, and 42,85% in those 35 years or older. **CONCLUSIONS:** A total of 43,75% of the cases with missed abortion had an abnormal karyotype and the percentage was a little higher at advanced maternal age. Karyotyping of spontaneous losses in the first trimester beginning with the patient's second loss provides clinically important etiologic information and decreases the number of evaluations necessary for recurrent pregnancy loss.

J01.02
An analysis of the cells of trophectoderm with the use of aCGH within the scope of PGS, pregnancy rate and the effect of maternal age

I. Slamova[1], *V. Horinova*[1], *K. Okenkova*[2], *L. Pracharova*[2], *K. Texlova*[1], *S. Kloudova*[3], *E. Matejickova*[2], *P. Texl*[2];
[1]*Sanatorium Helios ltd., IVF Centre, Laboratory of Medical Genetics, Brno, Czech Republic, Brno, Czech Republic,* [2]*Sanatorium Helios ltd., IVF Centre, Laboratory of Embryology, Brno, Czech Republic, Brno, Czech Republic,* [3]*Sanatorium Helios ltd., IVF Centre, Laboratory of Andrology Genetics, Brno, Czech Republic, Brno, Czech Republic.*

Chromosomal abnormalities are a major cause (in 70 %) of miscarriages in the early stage of pregnancy and in the failure of an embryo implantation. Many aberrations are of maternal origin. The number of aberrations increases with the age of the woman.
530 embryos were analysed from 299 patients with the use of aCGH within the scope of PGS, from that 256 embryos from 158 patients with the heartbeat of fetus were used for the calculation of pregnancy rate. The results of IVF cycles of 247 patients withouth PGS was used as a control group. The group of women was further divided into the group A) women younger than 35 years and group B) women over the age of 35. 34,6 % of embryos with aberrations was found in the group A, and 48,1 % of embryos with aberrations was found in the group B. Total pregnancy rate in both groups with PGS was 63 %. The pregnancy rate was 25,8 % in the group of women older than 35 years without PGS. The percentage of pregnancy rate increased to 68 % in group B. This represents an increase of 42,2 % for IVF success in the group B.
The increase of aberrations is obvious after the age of 35, here are the chromosomal aberrations a clear cause of the failure of IVF. It was confirmed that the exclusion of embryos with chromosomal aberrations can eliminate the effect of the age of woman on the success of IVF.

Array CGH in prenatal diagnosis

K. Najafi, *R. Kariminejad, A. Kariminejad, K. Najafi, N. Sadatian, G. Abbasi, A. Moshtagh, N. Nabavinia, F. Azimi, M. Kariminejad;*
Kariminejad-najmabadi pathology and genetic center, Tehran, Islamic Republic of Iran.

Following confirmation of array cgh as first tier diagnostic test for individuals with intellectual/ developmental delay, multiple congenital anomalies and autism spectrum disorders there has been a lot of discussions regarding using this test for prenatal diagnosis. In different countries there has been different approach to this case. Considering the possibility on finding CNVs of unknown significance leading to counseling dilemmas the general trend has been to use this technique in cases of ambiguity identified in routine chromosomal karyotype or where a normal karyotype is reported in a sonographic report of congenital anomalies. In the period of 24 months starting December 2011 till December 2013 we performed array CGH for 32 amniotic or chorionic villi samples. From these 32 samples, 3were inconclusive and of the 29, 5 showed a significant CNV. 3 of the 5 had problems in their sonography and 2 were being studied for de novo markers. It appears that array CGH Is an instrumentAl tool in clarifying complicated karyotypes and a significant test for fetuses with abnormal sonography findings.

J01.04
The AZFc region: crossroad between male infertility and recurrent pregnancy loss in women

M. Kerachian[1], *A. Mojtabanezhad Shariatpanahi*[2], *A. Torkamanzehi*[2];
[1]*Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran,* [2]*University of Sistan and Baluchestan, Zahedan, Islamic Republic of Iran.*

Introduction: Male factor infertility comprises approximately 30-50% of all infertilities. A great proportion of these patients have spermatogenesis failure with a genetic cause. After Klinefelter syndrome, Y chromosomal microdeletions (YCM) in AZF regions are the most frequent cause of male infertility. There are evidences that male factors can potentially affect fertilization, human embryo development and viability and placental proliferation. According to the recent studies, there is a potential association between Y chromosome microdeletion and recurrent pregnancy loss (RPL). Screening for Y chromosomal microdeletion in AZF region in men with non-obstructive infertility and spouses of women with RPL was the focus of this study.
Material and Methods: This study was carried out with a total of 65 male samples which included 35 non-obstructive infertile men, 15 males from couples with RPL and 15 fertile males as a control. Genomic DNA was extracted from blood lymphocytes. Screening of AZF deletion was performed by multiplex polymerase-chain reaction using 19 sequence tagged sites (STS) sets of primers.
Results: In 35 men with non-obstructive infertility only 1 subject was detected to have Y chromosome microdeletions in SY254 and SY157 and SY255. Results showed no Y chromosome microdeletion in 15 males of couples with RPL and their controls.
Conclusion: Amongst the various regions of AZF, often only microdeletion in the AZFc region could end up with fertility, thus mutation screening at the AZFc region is strongly recommended in males whose spouses have recurrent pregnancy loss after ruling out other RPL causes.

J01.05
Chromosomal abnormalities and Y chromosome microdeletion amongAzosperima/Oligospermia Saudi Patients

M. A. Al Balwi[1], *F. Al Salman*[1], *C. Jimenea*[1], *I. Alabdulkareem*[2];
[1]*King Abdulaziz Medical City, Riyadh, Saudi Arabia,* [2]*King Abdullah International Medical Research Center, Riyadh, Saudi Arabia.*

A prospective cytogenetic and molecular study was conducted on 123 Saudi men with azoospermia to estimate the prevalence of common genetic abnormalities associated with male infertility. Routine cytogenetic studies were performed to screen for chromosomal abnormalities whereas multiplex PCR methods were employed to screen for submicroscopic microdeletions of the AZFa, b and c regions located on the long arm of the Y-chromosome. Chromosomal abnormalities were detected in 21 patients (17%). Among the 21 patients with cytogenetic abnormalities, 15 (71%) had the Klinefelter's syndrome 47,XXY karyotype, 4 patients showed different large deletions of the long arm of the Y-chromosome with or without 45,X cell line mosaicism, one patient showed low 47,XXY/46,XY mosaicism and one patient had a chromosomal translocation between chromosomes 2 and 5. The molecular studies revealed submicroscopic microdeletions of the Y-chromosome in 3 (3%) of the 102 patients with a normal male karyotype. These Y-chromosome microdeletions involved regions AZFc in all three cases and AZFb in two cases.
Our studies revealed that the prevalence of chromosomal abnormalities in azoospermic Saudi patients is similar to that of major international studies. However, the prevalence of submicroscopic Y-chromosome microdeletions in patients with a normal karyotype was noticeably lower than what have been reported internationally but consistent with a few studies performed in Arab countries including Saudi Arabia. Our findings therefore strengthen the assumption that other genetic and/or non-genetic factors may play a major role in male infertility in Arab patients.

J01.06
The Relationship Between The Index and the Blood Disease Thalassemia and a Sample Report

N. Ghazavi, *F. Hosseini, M. Behnam, A. Hejazifar, A. R. Salehi Chaleshtori, M. Salehi;*
Genome Medical Genetics Laboratory, Isfahan, Islamic Republic of Iran.

Background and Aims: Thalassemia is a severe hemoglobin disease, recognizing by CBC and hemoglobin electrophoresis primarily. At first, CBC and hemoglobin electrophoresis was performed for the index case recognized as α-Thalassemia but finally experimental studies clearly demonstrated that it was different type of thalassemia. In the present study, we report a case of β-thalassemia mutations which is called -101 C>T relative to the transcription start site of β-globine gene, and is a β+-Thalassemia case, but it has been observed with different indices.
Methods: The patient was admitted based on hematologic indices as

α-Thalassemia, and diagnostic tests for α-Thalassemia, including GAP PCR, ARMS-PCR for α-Thalassemia were performed and all examinations were normal. For increased confidence, sequencing for patient's β-globins' gene was performed. We also observe more cases with the same index.
Results: Our findings, present the incidence of mentioned mutation in β-globin gene in β+ patient, in contrast to the hematologic indices for β-Thalassemia heterozygote. Moreover, this case has no resemblance to other β+-Thalassemia cases and it can be mistaken as α-Thalassemia. (For example: The - 88 C> A mutation relative to the transcription start site, which several of our indices present beta-Thalassemia).
Conclusion: As mentioned above, our outcomes are extremely similar to the results of CBC and hemoglobin electrophoresis of α-Thalassemia, but the patient was β-Thalassemia. Such conditions as cited above are hazardous and end to affected neonates if the other partner is β-Thalassemia patient. In this condition, Sequencing of β-globins for one of the couples could be helpful.

J01.07
Comprehensive carrier screening for severe recessive pediatric disorders in Chinese population by next-generation sequencing

Q. Li[1,2], *S. A*[1], *Y. Yi*[1], *T. Liu*[1], *H. Du*[1], *S. Zhao*[1], *X. Yi*[1,2];
[1]BGI-Tianjin, Tianjin, China, [2]BGI-DX, Shenzhen, China.

The global birth prevalence of single gene disorders is as high as 16.9%,among which recessive disorders account for 43.7%. Of 7719 disorders with suspected Mendelian inheritance, more than 1000 are recessive with an established molecular basis. Preconception genetic testing and counseling has led to significant declines in the incidence of Tay-Sachs disease and other several severe recessive diseases. And extension of preconception screening to more severe disease genes has also been attempted in some developed countries.
Here, we report a preconception carrier screen for 658 severe recessive childhood diseases in Chinese population. All the exons and their flanking sequences (±30bp) of 546 target genes were enriched by hybrid capture, sequenced by next-generation sequencing (NGS). At a resultant 160x average target coverage, 93% of nucleotides had at least 20x coverage, and mutation detection/genotyping had ~95% sensitivity and ~100% specificity for substitution, insertion/deletion, splicing, and gross deletion mutations and single-nucleotide polymorphisms.
In 199 DNA samples (91 males and 106 females), the average genomic carrier burden for severe pediatric recessive mutations was 1.47 and ranged from 0 to 6. The distribution of mutations among sequenced samples appeared random. Among the 199 individuals,118(59 couples) had once or more times adverse pregnancy outcomes such as miscarriage. The carrier burden of these individuals was 1.89, which is higher than general population.
Preconception carrier screening by NGS is feasible to the general population, especially the individuals with adverse pregnancy outcomes. And it may be an economical way to reduce the incidence of severe recessive pediatric disorders.

J01.08
Non-invasive prenatal diagnosis of fetal sex using multiplex-PCR

A. Saffar Moghadam[1,2], *D. Hamedi*[1,3], *T. Majidi Zadeh*[1,4], *F. Davari*[1], *F. Asle Rousta*[1], *T. Asle Rousta*[1], *Z. Karami*[1], *M. Kamali*[1], *M. Soleimani Dodaran*[1];
[1]Mehr Pathobiology laboratory, Hashtgerd, karaj, Tehran, Islamic Republic of Iran, [2]Hormozgan university of Medical Sciences, Bandar Abbas, Islamic Republic of Iran, [3]Qazvin university of Medical Sciences, Tehran, Islamic Republic of Iran, [4]Division of Medical Biotechnology ,National Institute of Genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran.

The uncovering of cell free fetal DNA (cffDNA) in maternal serum of pregnant women (1997) has provided an approach for applying of cffDNA as a non-invasive method for prenatal diagnosis (PND). The determination of fetal gender is the first step of the PND. It is especially important in fetuses at risk of sex-linked disorders and in conditions associated with ambiguous development of the external genitalia.
Peripheral blood sample (10 ml) was obtained from 100 pregnant women that referred to the diagnostic laboratory for routine pregnancy tests during 6th to 10th weeks of gestational age. Cell-free fetal DNA was extracted from the maternal serum. The cffDNA was not enriched. The conserve sequences of SRY and GAPDH genes as a marker for fetal gender and for internal control respectively were amplified by Multiplex-PCR using specific primers for their reigns. We considered; amplification of just internal control indicates female fetal gender and amplification of internal control and SRY conserve sequence indicates male fetal gender. Latterly, all the collected results were compared with the real gender of the newborns.
Early determination of fetal gender provides the opportunity of deciding and employing early treatment designed for fetuses at risk. However, this study aims to validate a simple, reliable and applicable method for non-invasive prenatal diagnosis of fetal gender. In this presentation we will demonstrate our data regarding fetal gender. Furthermore, we will present sensitivity and specificity of this study.

„Filling the gap" : the prenatal phenotype of two cases of rare microdeletion syndromes

R. Pitta[1], *S. Boito*[2], *R. Fogliani*[2], *B. Zaina*[2], *B. Ischia*[2], *T. Rizzuti*[3], *D. Quagliarini*[2], *S. Guerneri*[4], *M. Baccarin*[4], *B. Gentilin*[5], *F. Lalatta*[5];
[1]Medical Genetics, University of Catania, Azienda Ospedaliera Universitaria Policlinico-Vittorio Emanuele di Catania,, Catania, Italy, [2]Prenatal Diagnosis Unit Department of Woman, Child and Infant Health Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy, [3]Pathology Unit Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy, [4]Medical Genetics Laboratory Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy, [5]Clinical Genetic Unit, Fondazione Cà Granda Ospedale Maggiore Policlinico, Milan, Italy.

We describe two cases of prenatal detection of unexpected interstitial deletion syndromes that were recognized by CGH-Array after evidence of ultrasound fetal anomalies and normal karyotype
Case 1: A 43 years old woman in her fourth pregnancy referred for genetic counseling because of cystic hygroma with normal fetal biometry measurements at the first trimester. Level II ultrasonography: micrognathia, low-set ears, lower limb abnormalities. CGH-Array was performed revealing a deletion syndrome of 10,6 Mb on chromosome 6 (locus 6q11q14.1). After termination the fetal pathology showed frontal hypertricosis, small nose, long filtrum, macrostomia, thin lips, micrognathia, and low-set ears with abnormal lobes.
Case 2: A 41 year old woman in her third pregnancy. During the second trimester the pregnancy was complicated by intrauterine growth restriction and unilateral fetal club foot. A microdeletion of 496 kb at 17q21.21 was detected by CGH- Array. This mutation has been reported in only a limited number of families and with a variable phenotype. After termination the physical examination of the fetus demonstrated high forehead, hypertelorism, bulbous nose, thin lips, pointed chin, low-set simplified ears, camptodactyly, tales equinovarus, and reduced musculature in the lower limbs.
Both deletions were shown to be de novo. Understanding the pathogenesis of fetal anomalies and correlations between the pre- and post-natal phenotype is difficult and limited because of a lack of prenatal data from cases reported after birth. The clinical spectrum of microdeletion syndromes could be expanded greatly if more prenatal cases would be described and published in the open literature.

J01.10
Chromosomal abnormalities in couples with reproductive failures and/or those included in ART programs

K. Kovacheva[1], *M. Simeonova*[1], *E. Konova*[2], *R. Kotzev*[3], *Z. Kamburova*[1], *P. Angelova*[1];
[1]Section of Medical Genetics, Medical University, Pleven, Bulgaria, [2]Clinical Institute for Reproductive Medicine, Pleven, Bulgaria, [3]Urology Clinic, Medical University, Pleven, Bulgaria.

Chromosomal abnormalities (CA) are among the major genetic causes of reproductive disorders. A**im:** to investigate the prevalence and profile of CA among couples with deferent type of reproductive failures, as well as to assess the value of karyotyping in the routine work-up of couples, referred for ART. **Material and methods:** The study included a total of 947 individuals with reproductive failure. They were divided into the following groups: (1) 273 couples with two or more spontaneous abortions; (2) 193 women and 208 men from couples with infertility +/- one or more unsuccessful IVF procedure. All patients were analyzed cytogenetically for detection of major chromosomal abnormalities.
Results: Chromosomal abnormalities were found in 26 (2.74%) of all investigated individuals, 10 (2.08%) males and 16 (3.43%) females. The determined prevalence of CA was - 4.76% among couples with recurrent abortions (4 times more frequently in women than in men) and 3.24% in individuals (more frequently men) with infertility. The most common type of CA in group (1) (92% of these cases) are balanced structural rearrangements, carried mainly (83%) by female; in group (2) – CA of sex chromosome (62% of these cases), more frequently (62%) in male. **Conclusion:** The results of current study demonstrate the significance of chromosomal pathology in etiology of reproductive failure and emphasise the need for thorough genetic work-up in couples referred for infertility. Karyotype analysis should be an integral part of diagnostic work up in couples with reproductive problems especially those undergoing assisted reproductive procedures.

J01.11
Study of chromosomal abnormalities involved in couples with reproductive failure

D. M. Mierla[1], *R. Cretu*[1], *D. Albu*[1], *M. Malageanu*[1], *S. Grigore*[1], *D. Neagos*[2];
[1]*Medlife, Bucharest, Romania,* [2]*Carol Davila University of Medicine and Pharmacy, Department of Genetics, Bucharest, Romania.*

BACKGROUND Infertility is a medical problem affecting a significant proportion of the population, up to 15.0% of couples of reproductive age. Genetic pathology is an important part of the general human pathology due to the increasing number of genetic diseases. The purpose of this study was to establishing a correlation between the presence of structural and numerical chromosomal abnormalities in one of the partners and their reproductive development.
METHODS During the period from August 2007 to December 2011, 2195 patients with reproduction problems, who had received in our hospital, were investigated for this retrospective study, and the frequency of chromosomal abnormalities was calculated. The control group consists of 83 fertile couples who had one or more children in history, was investigated by karyotype.
RESULTS Of the 2195 patients investigated by classical cytogenetic techniques 91.12% had normal karyotype and 8.88% had chromosomal abnormalities, the most common chromosomal changes are polymorphisms. Numerical chromosomal abnormalities were detected in the proportion of 0.65% in infertile men and 0.62% in infertile women in the study group.
CONCLUSIONS: Recently a possible association between infertility and chromosomal abnormalities have been reported with a significant statistically association. Our study shows that there is not association between chromosomal abnormalities and infertility problems,but this study needs to be confirmed with further investigations on a larger control group to establish the role of chromosomal aberrations in the etiology of infertility.

J01.12
FISH assessment of chromosomal aneuploidies in infertile males

S. Farcas[1], *M. Cosma*[1], *A. Belengeanu*[1], *M. Stoian*[2], *N. Andreescu*[1], *M. Puiu*[1];
[1]*Victor Babes University of Medicine and Pharmacy, Timisoara, Romania,* [2]*Personal Genetics, Bucuresti, Romania.*

Background. Reproductive failure is one of the most important issues for the population at the age of procreation and approximately 15% of the couple encounters reproductive difficulties. In the last years it was taken in consideration the hypothesis that not only somatic chromosomal anomalies but also germ cells chromosomal aberrations could lead to reproductive failure.
Aim: In this study we used multicolor FISH probes for chromosome 13, 18, 21, X and Y to evaluate the aneuploidy incidence in sperm cells from infertile males.
Methods: The study lot included 35 males with infertility and oligoasthenoteratozoospermia (OAT) and 20 males with normal fertility and normal semen characteristics for which the conventional cytogenetic investigation using peripheral blood revealed a normal karyotype. The fluorescent signals for these chromosomes, were analysed at least 10000 cells/patient.
Results: The overall chromosome disomy and nulisomy in OAT group was higher than the one identified in the control group. By comparing the incidence of the disomy in the OAT group, the highest incidence was the sex chromosome disomy, followed by the disomy of chromosomes 13, 21 (equal values) and then 18. The nulisomy incidence in the OAT group was higher for sex chromosomes, followed by the nulisomy of autosomes 13, then 21 and 18.
Conclusion: During these days, for patients with OAT, intra cytoplasmic sperm injection (ICSI) is frequently used, and it is important to inform the patients that the use of spermatozoa for fertilization could be associated with an increased risk of aneuploidies in embryos.

J01.13
Cleidocranial Syndrome with Premature Ovarian Failure

N. Almadani, *H. Gourabi;*
Department of Genetics at Reproductive Biomedicine Research center,Royan institue for Reproductive biomedicine,ACECR, Tehran, Islamic Republic of Iran.

Our patient family had twenty members that five of them (three brothers, One sister and father) suffered from oligodontia , enamel hypoplasia , dental decay, Mild proportionate short stature , frontal bossing , Hx of recurrent upper respiratory infections , sinusitis, bilateral clavicle bone hypolplasia , pectus carinatum , short & tapering fingers , lumbar lordosis and thorasic scoliosis.
My proband was a 33 years old female with premature ovarian failure and chromosomal abnormality in peripheral blood (%40 mosaicism of deletion of 6p2 and %4 45 XO in fifty metaphase) , other family members had not any fertility problem and chromosomal abnormality.
We gussed Our diagnosis in this case is Cleidocranial Dysostosis and ocurrance chromosomal abnormality and this syndrome probability resulted frome location of this gene (CBFA1) in short arm of chromosome 6 and varibilty of mosaicism 45 XO phenomenon in ovarian tissue.

J01.14
Mutations in cyp21ohb gene of women with reproductive dysfunction

A. Nagimtaeva, *A. Borovikova, D. Zhumazhanova, G. Abildinova;*
National Research Center Maternal and Child Health, Astana, Kazakhstan.

The interest in non-classical forms of congenital adrenal hyperplasia (CAH) and its impact on human reproduction was increased. The vast majority of all cases of CAH (95%) was due to deficiency of the enzyme of 21-hydroxylase. Defect of this enzyme is able to lead a miscarriage.
In aim to determ the ratio of the number of gene replica (b) and pseudogene (a) on exon 3 in CYP21OHB was conducted molecular genetic testing at 46 women, among them 26 women with infertility and 20 women- control group. The presence or absence of the mutation in the test region was determined by PCR using a specific primer.
In result of analyses was determined that equal ratio of the number of gene replica (b) and pseudogene (a) on exon 3 (b=a) was detected in 20 patients, representing 76,9% as compared with a group of fertile women (95%). In the group of women with the disorder generative function there are in 6 patients noted an altered replica of the gene «b» and pseudogene «a» on exon 3 (b<a) towards the control (23.1% and 5% respectively).
The present changes in the ratio of the number of replica gene and pseudogene were due to deletion a gene (b) and in this case, probably, it is a mutation which leads to development of reproductive disorders in the homozygous condition.

J01.15
Genetic counselling for pregnant woman with CPT II deficiency - a case report

A. Kondo[1,2], *M. Shibata*[1], *M. Murakami*[1], *M. Morine*[1], *K. Hinokio*[1], *S. Izumi*[2], *M. Ito*[1], *K. Maeda*[1];
[1]*National Hospital Organization, Shikoku Medical Center for Children and Adults, Zentsuji, Japan,* [2]*Tokai University School of Medicine, Isehara, Japan.*

Carnitine palmitoyltransferase II (CPT II) deficiency is a autosomal recessive disorder of long-chain fatty-acid oxidation. The three clinical presentations are: lethal neonatal form, severe infantile hepatocardiomuscular form, and myopathic form. While the former two are severe multisystemic diseases characterized by liver failure with hypoketotic hypoglycemia, cardiomyopathy, seizures, and early death, the latter is characterized by exercise-induced muscle pain and weakness.
The lady aged 27 was referred to our hospital at 18 weeks of gestation. Her first child was dead at 9 months old triggered by infection. Postmortem revealed that the boy had CPT II deficiency. Hence she and her husband had genetic test for CPT II and both of them were diagnosed as carrier. At the genetic counselling at previous hospital, they decided not to have prenatal test in the future. We talked about that again and confirmed their will.
At 39 weeks of gestation, she delivered a boy, 2650g, Apgar score 9(1)/9(5). We monitored the boy in Growing Care Unit to avoid low glucose level which could cause catabolism, and the cord blood was sent for genetic test. The genetic test showed the boy is carrier as well as his mother.
If the mutations have been identified in an affected family member, molecular genetic testing of at-risk relatives can reduce morbidity and mortality through early diagnosis and treatment. In this case, the patient did not choose to take prenatal test, however, it would be worth to know if the fetus is affected to prepare neonatal care.

Reduced fertility and sperm DNA fragmentation

M. Mazilina[1], *E. Shilnikova*[1,2], *I. Fedorova*[2], *A. Gzgzyan*[2];
[1]*St. Petersburg State University, Saint Petersburg, Russian Federation,* [2]*Ott's Institution of Obstetrics and Gynecology, Saint Petersburg, Russian Federation.*

Conventional semen analysis is widely used to assess man's reproductive potential, giving no information about sperm genome. Sperm DNA integrity assessment is not a routine diagnostic, requiring specific markers that may indicate that sperm DNA fragmentation assay is needed. The aim of this study was to investigate possible markers of sperm DNA damage. Semen analysis was performed for 75 men and 8 sperm donors. According to WHO criteria all patients were divided into groups: normozoospermic, teratozoospermic and asthenozoospermic. Terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) assay used to assess sperm DNA fragmentation. Sperm DNA fragmentation rates in normozoospermic group (0,47±0,17) and control group (0,21±0,04) were equal (p=0,17). Sperm DNA fragmentation rate in teratozoospermic group (0,62±0,1) was

significantly higher compared to control (p=0,02). No difference was found between DNA fragmentation rate in group with reduced sperm motility (p=0,30). Sperm DNA fragmentation had no effect on sperm motility. Patients were also divided into groups on the basis of predominant sperm head morphology: amorphous (n=27), bulb (n=20), vacuolated (n=6) and others (n=22). The level of sperm DNA fragmentation (1,31±0,30) among patients with vacuolated sperm head as a predominant morphological form was higher compared to control (p=0,02). No significant differences were found between sperm DNA fragmentation level among patients with amorphous or bulb sperm heads and control group. In case of teratozoospermia sperm DNA fragmentation assessment should be recommended. Sperm head vacuoles may be a possible marker of DNA damage. Supported by Carl Zeiss, RF President's scholarship and RFBR.

J01.17
Association of MTHFD and RFC1 polymorphisms with the risk of Down syndrome in Romanian population

D. Neagos[1], *D. Albu*[2], *D. M. Mierla*[2], *S. Grigore*[2], *M. Malageanu*[2], *R. Cretu*[1];
[1]*Carol Davila University of Medicine and Pharmacy, Department of Genetics, Bucharest, Romania,* [2]*Life Memorial Hospital, Bucharest, Romania.*

Introduction Down syndrome (DS or trisomy 21) is a genetic disease resulting from the presence of an extra copy of chromosome 21. Although advanced maternal age represents the major risk factor for DS, most of DS children are born from women less than 30 years of age and is seems that different mechanisms are responsible for chromosome 21 nondisjunction in young women compared to older ones, each of them potentially affected by an impaired folate/Hcy metabolism. The objective of this study was to evaluate the correlation between gene polymorphisms MTHFD G1958A and RFC1 G80A and the risk of Down syndrome. **Materials and methods** Our study included 26 women that gave birth to DS babies and 46 control mothers of healthy children. Genomic DNA was isolated from whole blood, using peqGOLD blood DNA mini kit (ATP Biotech) following the manufacturer's instructions. The MTHFD G1958A and RFC1 G80A mutations were investigated by polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) analysis. **Results** The combined RFC-1 80(GA or AA)/ MTHFD1958GG genotypes compared with the reference RFC-180GG/ 1958GG genotype was associated with increased DS risk (OR 0.18 [0.02-1.41] P= 0. 08), but not statistically significant. **Conclusions** This is the first study in a cohort of Romanian mothers of DS children in comparison with control mothers, analyzing RFC1 G80A and MTHFD G1958A polymorphisms as a maternal risk factor for meiotic nondisjunction of chromosomes 21, causing DS.

Genetic deletion of Pelota in mice leads to embryonic lethality at an early post-implantation stage

P. Raju, *G. Nyamsuren, I. M. Adham;*
Institute of Humangenetik, Göttingen, Germany.

Pelota (*Pelo*) is ubiquitously expressed, and its genetic deletion in mice leads to embryonic lethality at an early post-implantation stage. In our study, we conditionally deleted *Pelo* after the establishment of embryonic stem cells (ESCs) and showed that PELO depletion did not markedly affect the self-renewal of ESCs or their capacity to form teratomas. However, *Pelo*-null ESCs differentiation into extraembryonic endoderm (ExEn) was severely compromised during embryoid body (EB) formation studies. Failure of *Pelo*-deficient ESCs to differentiate into ExEn was accompanied by the retained expression of pluripotency-related genes and alterations in expression of components of the bone morphogenetic protein (BMP) signaling pathway. Further experiments have also revealed that attenuated activity of BMP signaling is responsible for the impaired development of ExEn in *Pelo*-deficient cells. Collectively, our results convincingly show that PELO plays an important role in the differentiation of ESCs, into ExEn through activation of BMP signaling. Hence, the observed early embryonic lethality in conventional *Pelo*-deficient embryos could be attributed to the defects in ExEn formation during early embryonic development.

J01.19
Gene variation of TLR4 in patients with Endometriosis

Z. Sina Foomani, *M. Shahhoseini, F. Ramazanali, P. Afsharian, R. Aflatoonian;*
Royan Institute, Tehran, Islamic Republic of Iran.

Endometriosis, defined as the presence of endometrial tissue outside of the uterus, is an estrogen-dependent chronic inflammatory condition associated with degrees of pelvic pain and infertility. Toll-like receptors play a key role in immune response, by regulating inflammatory reactions and activating adaptive immune response to eliminate infectious pathogens and cancer debris. Polymorphisms in TLR4 have been shown to be associated with increased susceptibility to diseases such as inflammation and cancer. Ectodomain of TLR4 protein consists of 21 leucine-rich repeats (LRRs) that are crucial for its dimerization and signaling. The aim of this study was to determine gene variations of TLR4 in patients with endometriosis.
Sixty three blood samples were recruited from endometriosis patients referring to Royan Institute along 2012-13, who have been confirmed by laparoscopic surgery. Ethical approval forms were obtained prior to the samples collection. The control group was consisted of fertile women who had no history of inflammatory disease or using any related drugs.
DNA was extracted by kit, special primers were designed, the LRR coding region was amplified by PCR and products were analyzed by sequencing. among 63 patient, 6 of them had a heterozygote single nucleotide polymorphism (SNP) (rs120475167) G/A which changes aa E to K, and 4 patients had heterozygote SNP (rs120475108) G/A (aa R to K), and 2 patients had heterozygote SNP (rs120475032) G/A(aa D to N).
According to our finding we suggest that the three aforementioned new SNPs in TLR4 gene can be associated with endometriosis.
Key words: Endometriosis, gene variation, polymorphism, TLR4.

The association between endothelial nitric oxide synthase gene Glu298Asp polymorphism and spontaneous pregnancy loss

S. Yalcintepe[1], *O. Ozdemir*[1], *S. O. Haciveliogluˆ*[2], *C. Akurut*[1], *T. Kumcular*[3], *D. Uysal*[1], *K. Yucesoy*[4], *A. Uludag*[1], *E. Cosar*[4], *F. Silan*[1];
[1]*Department of Medical Genetics, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey,* [2]*Department of Obstetrics and Gynecology, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey,* [3]*Gynecology and Obstetrics, Kastamonu Inebolu State Hospital, Kastamonu, Turkey,* [4]*Department of Gynecology and Obstetrics, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey.*

Aim: The endothelial nitric oxide synthase gene (eNOS) polymorphisms have been associated with reduced vascular NO production or increased level of homocysteine and related to pregnancy losses. In the current case control study it was aimed to find out the possible role of eNOS E298D polymorphism in spontaneous pregnancy loss. Material and Methods: Twenty-three spontaneously aborted fetal materials, 22 mothers who had these abortions and 86 healthy control cases were enrolled in the current results. The genomic DNAs were isolated from aborted materials and peripheric blood samples and genotyping for target polymorphic allele was done by real time PCR technique. Results: Current results showed that eNOS (Glu298Asp) polymorphisms were significantly associated with spontaneous abortion (p=0.011). Conclusion: The present study identified the strong association between eNOS gene polymorphisms and spontaneous pregnancy loss risk.

J01.21
18p partial trisomy with fetal ascites inherited from a mother with familial 18p deletion syndrome

K. MIN JEONG, *K. Myungshin;*
The Catholic University of Korea, Kyunggido, Korea, Democratic People's Republic of.

The deletion 18p syndrome is one of the most common chromosome abnormalities characterized by dysmorphic features, growth and mental retardation with a poorer verbal performance. Until now, no reliable phenotype map for the characteristic clinical findings such as mental retardation, post-natal growth retardation and typical facial features has been established yet.
Molecular karyotyping holds the promise of improving genotype-phenotype correlations for frequent chromosome conditions such as the 18p-syndrome. Until now, there have been 9 reported families with transmission of del (18p) from a mother to a child (including our study).
We describe a female baby, 46,XX,der(18)t(18;20)(p11.32;p11.2) with fetal ascites, transmission of deletion 18p from a mother and her affected families with partial monosomy 18p of different sizes owing to unbalanced translocations.

Structure of prenatally-identified polyploidies - a retrospective study

C. GUG[1,2], *R. Mihaescu*[1], *R. Patrascu*[1], *V. Gorduza*[3], *M. Militaru*[4], *A. Trifa*[4];
[1]*University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania,* [2]*Private Medical Practice and Genetics Laboratory Dr. Cristina Gug, Timisoara, Romania,* [3]*University of Medicine and Pharmacy "Grigore T Popa", Iasi, Romania,* [4]*University of Medicine and Pharmacy "Iuliu Haţieganu", Cluj, Romania.*

Objective: The objective of this study was to identify the frequencies and types of prenatally-identified polyploidies through amniocentesis or chorionic villus sampling (CVS), and to compare them with polyploidy identified in terminated pregnancies. Materials and Methods: Fetal karyotypes were investigated from cell cultures and banded with GTG. Amniocytes were also screened with FISH and QF-PCR was used in the CVS cases. Results: We report here prenatal diagnostics through amniocentesis for 3 triploid fetuses.

Classical anomalies were observed during ultrasound scans: severe oligoamnios, intrauterine and placental growth retard with morphologic modifications. Each case presented with biochemical risk (trisomy 21 or trisomy 18). Fetal karyotypes post-amniocenteses showed 69,XXX (66.66%), and 69,XXY (33.33%). These represent 0.27% of the amniocentesis investigations. There were 75 CVS investigations performed, and one case (1.33%) of 69,XXY triploidy was identified through QF-PCR and subsequently confirmed by karyotype. Cytogenetic investigations were also performed in 172 cases of terminated pregnancies, and 17 instances of polyploidy were discovered (9.88%). Eleven of these were triploidy, and the most common karyotypes were 69,XXY (63.63%), followed by 69,XXX (27.27%) and 69,XYY (9%). Six cases of tetraploidies were discovered: 92,XXYY (50%), 92,XXXX (33.33%), 92,XXYY/46,XY (16,66%). The maternal age was between 22-32 years old in cases with triploidy as compared to 28-43 years old in cases with tetraploidy. Conclusions**:** Polyploidies are relatively frequent in terminated pregnancies, but can also be present the first or second semester of pregnancy in live fetuses. Obtaining fetal karyotypes in all cases which present severe fetal abnormalities can elucidate the etiology.

J01.23
First Trimester Combined Screening in a General Pregnancy Population in Voronezh Region Russia

T. V. Fedotova, *E. V. Kolpakova, M. I. Klimova, E. Y. Mashneva, G. V. Kireeva, E. P. Povalyaeva, V. P. Fedotov;*
1 Regional Clinical Hospital Genetic counseling, Voronezh, Russian Federation.

Early diagnosis of chromosomal abnormalities shall be secured by means of mass prenatal screening of pregnant women in the first trimester. The frequency of chromosome trisomy 21 (Down syndrome) constitutes 1:680 in Voronezh Region.
A general screening population of pregnant women presenting in their first trimester underwent combined screening for fetal trisomy 21 and 18 using serum markers and nuchal-translucency (NT), nasal bone (NB) measurement.
Pregnancy outcome was determined by invasive testing or phenotypic evaluation of the newborn.
During the 2012-2013 in Voronezh Region we examined 36 566 expectant mothers (86.5% out of women registered in first trimester).
As a result of prenatal screening, 451 women were selected to high-risk group of chromosomal anomalies (CA) (1.2% of all examined at a cut-off level at 1: 100). The PAPP-A; free ß-HCG was carried out on Delphia. The calculation of risk was evaluated with the FMF software. These women are recommended to pass the invasive diagnostics. We carried out 284 invasive procedures for karyotyping of fetal cells. In 97 cases (34.2%) CA was diagnosed by cytogenetic methods, including FiSH. Trisomy 21 was the most common among the detected fetal CA (47 cases). Trisomy 18 was detected in 13 cases; trisomy 13 - 9; triploidy syndrome - 10; Turner syndrome - 8 cases. Other CA was detected in 10 fetuses.
The expected number of trisomy 21 in the studied cohort is 54 cases. Thus the «Prenatal Diagnostics» program allows effectively diagnosing 87% trisomy 21 and preventing the birth of children with CA.

J01.24
Prenatal diagnosis of unbalanced translocation 11,18 - pitfalls of FISH rapid prenatal diagnosis

M. Souto[1], *P. Botelho*[1], *R. Almeida*[1], *R. Nogueira*[2,3], *M. Martins*[1], *O. Moutinho*[1], *R. Pinto Leite*[1];
[1]*Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal,* [2]*Centro Genética Clínica, Porto, Portugal,* [3]*Universidade do Minho, Braga, Portugal.*

FISH screening in uncultured amniocytes, is a standard procedure for the rapid detection of chromosomal aneuploidy in prenatal diagnosis, in order to detect the most common aneuploidies, involving chromosomes 13, 18, 21, X and Y. It is easy to perform, don't need cell culture, the risk for misdiagnosis is low (~0.4%) and, principally, allow results in less than 24 hours.
We report the case of a young pregnant woman with an abnormal ultrasound scan, revealing a foetus with multiple anomalies, including cardiopathy, short femur and clenched hands. It was the first pregnancy of this young, health, non-consanguineous couple with a normal family history.
Amniocentesis was performed and FISH aneuploidy technique, in uncultured amniocytes, was applied, with normal results. Cytogenetic analysis of amniotic fluid revealed an unbalanced translocation involving chromosome 11 and 18, with deletion of 11q24-qter and trisomy of 18q11.2-qter, confirmed by FISH.
The foetus had several anomalies consistent with trisomy 18 phenotype.
The FISH rapid prenatal aneuploidy test is, taken in account its possibilities and limitations, a powerful tool for the clinician in the care of pregnant women. It's limitations, it cannot detect cytogenetic abnormalities such as mosaics, translocations or rare aneuploidies, do not allow this technic to be used as an independent, stand-alone technology and must be performed in conjunction with standard cytogenetic testing for clinical diagnosis.
So, it seems likely that, for the foreseeable future, banded chromosomes will remain an indispensable tool in the genetic diagnostic laboratory.

J01.25
Analysis of association between the number of CGG repeats in FMR1 gene with IVF failure

V. Arab[1], *M. Noruzinia*[2], *Z. Amirkhani*[1];
[1]*Islamic Azad University, Medical Tehran branch, Tehran, Islamic Republic of Iran,* [2]*Tarbiat Modares University, Tehran, Islamic Republic of Iran.*

Infertility is a common clinical problem. It affects 13% to 15% of couples worldwide. In Vitro Fertilization is a common medical treatment which fails in some cases. IVF is not successful for several reasons. FMR1 Gene (Xq27.3) with CGG repetitive sequence -through their impact on autoimmunity - is one of the genetic factors influencing IVF failures. In normal subjects, the number of iterations is 5 to 54 and in relation to normal ovarian function the number of CGG repeats in the FMR1 gene are 26 to 34. The occurrence of these three repetitive sequences is three genotypes as normal, homozygous, and heterozygous. Heterozygous genotype has 2 modes: with the occurrence one of two alleles greater than 34 sub-genotypes creates het-norm/high and less than 26 sub-genotypes creates het-norm/low. In this study, correlation studies are of case - control and long PCR method. Samples are peripheral blood of 50 women with a history of at least 3 failed IVF, karyotype and normal MTHFR gene and 50 matched controlled group. Total Lab Quant software was used to determine the number of iterations and SPSS 17 software was used in data analysis. Analysis done using frequency tables and coefficients determined by measuring the number of iterations shown by p-value equal to 0.002 indicates a significant relationship between het-norm/low sub genotype in FMR1 gene and IVF failure.

J01.26
Analysis of association between the number of CGG repeats in *FMR1* gene with recurrent abortion in Iranian patients

S. Beiranvand[1], *M. Noruzinia*[2], *M. Ahmadvand*[3];
[1]*Sarem Cell Reasearch Center-SCRC, sarem Women's Hospital, Tehran, Islamic Republic of Iran,* [2]*Department of Medical Genetics, Tarbiat Modares University, Tehran, Islamic Republic of Iran,* [3]*Department of Hematology, Tarbiat Modares University, Tehran, Islamic Republic of Iran.*

Most frequent anxieties in pregnant women is recurrent abortion with prevalence of 1 per 300 pregnancies which is occasionally caused through autoimmunity disorder. Recurrent abortion has been observed in pregnant women with autoimmune antibody such as Anti-phospholipids and Anti-TPO. The number of CGG repeats in *FMR1* gene correlates to autoimmunity. Increasing in *FMR1* repeat number is correlated to fragile X syndrome. Normal range is considered 5-54 repeats. The Normal function of ovarian is correlated to (26-34) CGG repeats in 5'UTR-*FMR1*. Accordingly two distinct types of ovarian sub genotypes are *Het-norm/low*, *Het-norm/high* with fewer 26 and more than 34 repeats respectively. Autoimmunity has been reported to be associated to *Het-norm/low* sub genotype. This study was designed to evaluate the relationship between the number of CGG repeats with recurrent abortion in Iranian patients. In this investigation, 50 women with normal karyotype and normal MTHFR genotype (with at least two kids) were compared to 50 women with 3 or more recurrent abortions for the number of *FMR1*-CGG repeats. Long Range PCR was performed to amplify the 5'UTR of *FMR1* gene and results were analyzed using the TOTAL LAB software. In conclusion our finding shows that 14 normal persons and 10 patients with recurrent abortion have high correlation with *Het-norm/low* sub genotype. So there was a statistically significant difference in the number of CGG repeats of women without abortion compared with women with 3 or more recurrent abortion (P-value <0.05). This is the first report to show the correlation of *FMR1*subgenotypes and recurrent abortion.

J01.27
Hereditary thrombophilia and pregnancy loss

O. Miljanovic[1], *Z. Magic*[2], *S. Teofilova*[1], *T. Ostojic*[1], *D. Likic*[3], *T. Dakic*[1];
[1]*Centre for medical genetic and immunology, Clinical centre of Montenegro, Podgorica, Montenegro,* [2]*Institute for medical research – Military Medical Academy, Belgrade, Serbia, Belgrade, Serbia,* [3]*Institute for Public Health of Montenegro, Podgorica, Montenegro, Podgorica, Montenegro.*

Pregnancy loss and adverse pregnancy outcomes (APO) result from a complex interaction of environmental and inherited factors. Although the etiology of more than half of such events remains unclear, gene mutations leading to a hypercoagulable state, such as factor V Leiden, factor II prothrombin, methylenetetrahydrofolate reductase (MTHFR) mutation, are often found associated with pregnancy loss.

Polymorphisms in genes for factor II prothrombin (20210G→A), factor V Laiden (1691 G→A) and MTHFR (677C→T), were determined in 121 women with history of pregnancy losses and in 51 women with healthy offspring and no history of APO (control group).
Mutations in investigated genes were found in 25.6% women of study group. Analyses showed that inherited thrombophilias were found in women with 2nd and/or 3rd (50%), rather than those with 1st trimester recurrent pregnancy loss. Women with a history of 3rd pregnancy loss showed the highest prevalence of examined thrombophilic genotypes. Group of women with the history pregnancy loss, as well as fetal chromosomal abnormalities and congenital malformations, also showed a significantly higher presence of thrombophilic genotypes than the control group. Mutation 677C→T in MTHFR gene was the most frequently found polymorphism among the examinees form the study group. Odds ratio analyses showed that women with thrombopilic genotypes have 5 – 10 times greater risk for APO.
Established association of inherited thrombophilias, especially 677C→T mutation in MTHFR gene, to late pregnancy loss, and fetal malformations and chromosomal abnormalities implies that these mutations might be significant risk factors for a broad spectrum of APO.

J01.28

The importance of appropriate genetic counseling and informed consent before beginning IVF procedures: two case reports

D. Serapinas[1,2], **J. Juškevičius[2]**;
[1]Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

In the Hospital of Lithuanian university of health sciences were counseled two couples which in the past used unsuccessfuly intensive infertility treatment regimen. The first couple was unable to conceive for 7 years: they applied two unsuccessful IVF procedures, however gave birth to a healthy boy. The second couple applied two IVF procedures and did not conceive for four years.
After the karyotype testing a chromosome translocation was identified: in the case of the first couple to a female, in the case of second couple to a male. The karyotypes of the first couple were the following: 45 XY, der(13;14)(q10;q10)of a male and 46XX of a female. The karyotypes of the second couple were respectively 46XY and 45 XX , der(13;14)(q10;q10)
The possibility of miscarriage and of anomaly were explained and further recomendations to couples were provided. After the counseling families are better able to decide on further family planning and prenatal diagnostics, if necessary. These cases present the importance of quality of health care services for the adjustment of the diagnosis, and the need of genetic counseling and appropriate genetic testing before ART because the main requirements for the informed consent include rationality, sufficient and clear information, free will and the form of consent conforming to the legal acts

J01.29

Prenatal genetic tests of pregnant women who were exposed to psychoactive drugs

D. Serapinas[1,2], **D. Burkojus[1]**;
[1]Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

Backround: The effect of psychoactive substances on fetal developement has recently become a great concern. There's not enough data regarding this subject.
Methods: A retrospective study of cases from year 2009-2010 included 20 cases of pregnant women who were exposed to psychoactive drugs during their pregnancy. A control group of 30 cases of pregnant women who were not exposed to any psychoactive substances was randomly selected. Out of these cases the data of the use of drugs during pregnancy, prenatal utrasound evaluation (nuchal translucency thickness, morpho-pathologic alterations of organs), biochemical prenatal tests (markers indicating the risk of Down's syndrome and spina bifida) was collected.
Results and conclusions: No pathologic fetal ultrasound findings were observed in the control group of 30 pregnant women who didn't use antipsychotic drugs during pregnancy. Pathological fetal ultrasound findings (minor) were observed in 3 out of 20 pregnant women treated with psychoactive substances. The strongest associacion was observed between neuroleptics and ultrasound changes, $p<0.01$. Pathological fetal ultrasound findings were observed in 3 out of 13 pregnant women exposed to neuroleptics during pregnancy. The relationship between exposure to antidepressants and pathological ultrasound findings was statistically significant, $p<0.038$. Pathological fetal ultrasound findings were observed in 2 out of 8 cases of antidepressant treatment during pregnancy. The relationship between exposure to psychoactive substances during pregnancy and biochemical markers indicating the risk of Down's and Edward's syndromes and spina bifida was statistically insignificant. No increased risk of spina bifida was observed in any group of patients.

Polycystic Ovary Syndrome and MTHFR C677T polymorphism in mexican women

I. M. Salazar-Dávalos[1], *N. Suárez-Magaña[2], J. P. Mena[3,4], M. Salazar-Páramo[5,6], E. Chávez[5,6], M. A. Aceves-Aceves[1], N. O. Dávalos-Rodríguez[1], M. G. González-Mercado[3,4], F. Grover-Páez[5,6], I. P. Dávalos-Rodríguez[3,4];*
[1]Instituto de Genética Humana, DGH, Facultad de Medicina, CUCS, Universidad de Guadalajara, Guadalajara, Mexico, [2]UMAE, HGO, IMSS, Guadalajara, Mexico, [3]Doctorado Genética Humana, IGH, CUCS, Universidad de Guadalajara, Guadalajara, Mexico, [4]Centro de Investigación Biomédica de Occidente, IMSS, Guadalajara, Mexico, [5]Depto. Fisiología, CUCS, Universidad de Guadalajara, Guadalajara, Mexico, [6]Div. Investigación, UMAE, HE, CMNO, IMSS, Guadalajara, Mexico.

Introduction: Polycystic ovary syndrome (PCOS) is a common endocrine disorder in reproductive age patients, high homocysteine level has been reported in PCOS, the MTHFR-C677T gene polymorphism have been associated with hyperhomocysteinemia and decrease of folic acid. **Objective:** To determine MTHFR C677T polymorphism frequency in Mexican women with polycystic ovary syndrome. Material and methods: We included 64 patients with PCOS diagnosis according to Rotterdam criteria and 101 Mexican mestizos as reference group (M). The genotyping was performed by PCR/RFLP technique. The M group presented Hardy-Weinberg equilibrium. **Results:** In the PCOS group (n=64) the MTHFR C677T genotypic frequencies %(n) were distributed as follows: CC 33 % (21), CT 48 %(31) y TT 19 %(12). The allelic frequency of the C allele was 57 %(73) and T was 43 %(55). The genotypic frequency in the reference group (n=101) were CC 31 %(31), CT 50 %(51), TT 19% (19) and allelic frequency for C allele 56 %(113) and for T allele 44 % (89). The allelic frequency comparison between both groups were no statistically different ($p>0.05$). Conclusion: In PCOS group the MTHFR-C677T genotypic frequency was 19 % and the allelic frequency for T allele was 46%. The genotypic and allelic distribution between both groups (group-PCOS vs group-M) was similar. This study showed no association between MTHFR C677T polymorphism and PCOS.

Multilocus methylation defects at imprinted genes in miscarriages from women with recurrent and single pregnancy loss

E. A. Sazhenova, *M. V. Lepshin, I. N. Lebedev;*
Institute of Medical Genetics, Tomsk, Russian Federation.

Genomic imprinting is an epigenetic phenomenon, which is involved in regulation of embryonic development and placental function. Previously we have reported that the multilocus methylation defects (MLMD) at imprinted genes may be among molecular processes, which are responsible for dysfunction of imprinted loci in pathology of early embryonic development. We hypothesize that MLMD at imprinted genes may cause karyotypically normal miscarriage, particularly among women experiencing recurrent miscarriage.Differential methylation of 51 imprinted genes were examined in first-trimester spontaneous abortions (SA) from women who have recurrent (group RPL, from 9 (data of GoldenGate Methylation Cancer Panel) to 105 (Methylation-specific PCR (MSP) SA) and single (group SPL, from 6 (data of GoldenGate Methylation Cancer Panel) to 114 (MSP) SA) pregnancy loss. Sixty induced abortions were investigated as a control group. All spontaneous and induced abortions had the normal karyotype.
Our results provide evidence that MLMD at imprinted genes in the group RPL was more frequent than that in SPL ($15x10^{-2}$ and $5.2x10^{-2}$, respectively, $p<0.01$) with predominance of somatic epimutations ($10x10^{-2}$ and $3.9x10^{-2}$ respectively, $p<0.01$) and multiple hypomethylation ($9x10^{-2}$ and $4.4x10^{-2}$ respectively, $p<0.01$). Frequency of MLMD in both groups at maternal loci was higher than that at paternal one ($12x10^{-2}$ and $6.4x10^{-2}$, respectively, $p<0.05$ for RPL; $3.6x10^{-2}$ and $1.4x10^{-2}$, respectively, $p<0.01$ for SPL). Therefore, the RPL is characterized by multilocus somatic hypomethylation of imprinted genes and MLMD at imprinted genes on maternal loci that associated with abnormal maintenance of maternal imprinting in somatic cells.

Genetic association of phase II detoxification genes with recurrent pregnancy losses among Moldavian women

V. A. Hlistun[1], *N. Sirocova[1], N. Usurelu[1], V. Egorov[1], A. Parii[2], A. Muntean[2], A. Muntean[2], V. Racila[2], V. Racila[2], V. Sacara[1];*
[1]Institute of Mother and Child, Chisinau, Moldova, Republic of, [2]Centre of Reproductive Health and Medical Genetics, Chisinau, Moldova, Republic of.

Background:
Recurrent pregnancy loss (RPL) is a multifactor and distressing disease. In this study, we aimed to investigate the relationship between the polymorphism of GSTM1, GSTT1, GSTP1 and the pregnancy loss.

Methods: A case-control study of 100 women with RPL and 100 healthy women was conducted. Have been investigated DNA of 100 healthy children aged up to 17 years for comparative analysis of GST polymorphisms in Moldova with other countries. PCR, PCR/RLFP methods have been used for polymorphisms of GSTM1, GSTT1 and GSTP1 genotyped.
Results: We found that 57% of the cases with RPL and 47% of the controls had the GSTM1 null genotype (OR= 0.72, 95%CI = 0.49-1.07). On the other hand, 28% of the cases and 35% of the controls had the GSTT1 null genotype (OR = 0.72; 95%CI = 0.47-1.10). The frequency of GSTP1 gene of the cases and control is the following: GSTP1 Ile/Ile - 49% and 51%; GSTP1 Ile/Val - 42% and 43%; GSTP1 Val/Val - 9% and 6%. No significant difference have been established (p>0.05) The comparative analysis performed in the healthy population of the RM and other states have found that the frequency of GSTM1 null genotype in Moldova was similar to that in Ukraine, Italy , Russia, Egypt and Brazil (p>0.05), whilst the frequency of GSTT1 null genotype and GSTP1 polymorphism was significantly different to that countries (p<0.05).
Conclusion: The polymorphism of GSTM1, GSTT1, GSTP1 cannot be associated with the risk of recurrent pregnancy loss of Moldovan women.

Alpha globin gene mutations in Kurdistan and Kermanshah provinces, Iran

L. Mohammadpour[1], *M. S. Fallah*[2,3], *F. Keshavarzi*[4], *S. Azadmehr*[2], *R. Akramipour*[5], *S. Zeinali*[6,2];
[1]*Science and Research branch, Islamic Azad University, Kurdistan, Islamic Republic of Iran,* [2]*Kawsar Human Genetics Research Center (KHGRC), Tehran, Islamic Republic of Iran,* [3]*Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [4]*Sanandaj branch, Islamic Azad University, Kurdistan, Islamic Republic of Iran,* [5]*Kermanshah University of Medical Sciences, Kurdistan, Islamic Republic of Iran,* [6]*Department of Molecular Medicine, Biotech Research Center, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran.*

Alpha thalassemia is one of the most common hemoglobin disorders in the world and its severe clinical form (e.g. H disease) could be transfusion dependent. In this study we genotyped cases with history of blood transfusion or suspicious to H disease who referred to blood transfusion centers and or hospitals in Kermanshah and Kurdistan provinces. Alpha thalassemia was diagnosed on the basis of hematologic index and hemoglobin electrophoresis of patient (before blood transfusion) or patient's parents. DNA was extracted using salting out method and alpha globin mutations were investigated using multiplex Gap-PCR for common deletions and direct sequencing for point mutations. One hundred and ten thalassemia patients were recruited and screened using hematologic index and hemoglobin electrophoresis. 10 patients with diagnosis of alpha thalassemia were tested. --Med mutation was most common allele that was found in 5 chromosome (25%), followed by -α3.7 in 4 (20%), -α20.5 in 3 (15%), polyA1 in 3 (15%), -αIVSI (-5nt) in 3 (15%) and -αcd59 in 2 (10%). Deletional H disease (-α/--) was diagnosed in 4 cases (40%) and non-deletional H disease (--/αTα) in 4 cases (40%). Two cases (20%) showed αTα/αTα genotype. Two patients were blood-transfusion dependent, from which the first one received regular monthly blood showed --Med/αcd59genoyype. The second cases with -α20.5/α3.7α genotype received blood occasionally. This survey indicated diversity of alpha globin mutations and also different clinical manifestation of the H-disease.

J01.34
Holt-Oram syndrome as result of prenatal exposure of valproic acid

D. Serapinas[1,2], **E. Puisyte**[3];
[1]*Department of Pulmonology and Immunology, Lithuanian university of Health sciences, Kaunas, Lithuania,* [2]*Mykolas Romeris university, Vilnius, Lithuania,* [3]*Lithuanian university of health sciences, Kaunas, Lithuania.*

Holt-Oram syndrome (HOS) is caused by TBX5 gene mutation and it is estimated to affect 1 of 100 000 individuals. This condition is inherited in an autosomal dominant pattern, but most cases result from new mutations in the gene. HOS is characterized by skeletal abnormalities of the hands and arms (upper limbs) and heart problems. The diagnosis of HOS can be established clinically. Clinical signs include upper limbs malformations, anomalous heart structure (eg. atrioseptal and ventriculoseptal defects or Fallot tetrada) and cardiac conduction disease, which can cause bradycardia or tachycardia. HOS can be confirmed through TBX5 gene mutation molecular genetic testing - DNA sequence analysis or array comparative genomic hybridization (array CGH). A case report of Holt-Oram syndrome in 6 month girl is represented from Kaunas hospital of LUHS, when mother has been taking a valproic acid 500mg/day during pregnancy for epilepsy treatment. The antiepileptic drug valproic acid has teratogenic side effect and is a potent inducer of neural tube defects and other abnormalities, such as cardiac, skeletal and limb deffects. When valproic acid cannot be avoidened in pregnancy, the lowest possible effective dose should be prescribed. Also it is recommended to use folic acid to 5 mg/day. A usage of folic acid should be started before pregnancy, so family planning and prenatal consultation is recommended for women with epilepsy.

Stage-dependent expression of HomeoboxA10 gene in human endometrium

Y. Samadieh[1,2], *M. Shahhoseini*[2], *S. Mahdian*[3], *R. Aflatoonian*[3];
[1]*Faculty of Basic Sciences and Advanced Technologies in biology at University of Science and Culture, ACECR, Tehran, Islamic Republic of Iran,* [2]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran,* [3]*Department of Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, Tehran, Islamic Republic of Iran.*

HOXA10 gene belongs to Homeobox gene family and encodes DNA-binding transcription factor that regulates variety of downstream genes. HOXA10 gene has a well-characterized role in uterine organogenesis during embryonic development and functional endometrial differentiation and growth in adults. It is actively involved in cell proliferation through the regulation of hundreds of genes.
To evaluate the expression profile of HOXA10 gene during menstrual cycle, endometrial tissues were collected from 21 healthy fertile women undergoing laparoscopy for tubal ligation surgery, in menstruation, proliferative and secretory phases. For this respect ethical approval and informed patient consent was gained for the use of tissue sample. Total RNA was extracted from tissues using TRIzol reagent and cDNA was subsequently synthesized. Quantitative expression analysis was performed using the real-time PCR system.
Results showed stage-dependent manner of HOXA10 gene expression in endometrium tissues as notably increase of expression level in the secretory phase in comparison to the menstruation and proliferative phases.
This finding suggests that HOXA10 gene may have an important role in regulating endometrial cells proliferation and development in menstrual cycle and it is important for establishing conditions necessary for implantation. Up-regulation of HOXA10 in secretory phase during the window of implantation may be one of the potential molecular mechanisms of fertility .This gene can be noted as one of the candidate genes that its aberrant expression may contribute to the etiology of infertility and gynecological disorders.

J01.36
No alteration in PRLR gene in Iranian women with idiopathic hyperprolactinemia

Z. Mansouri[1], *A. Amiri Yekta*[1], *H. Gourabi*[1], *R. Hosseini*[2], *T. Madani*[2], *S. Zari Moradi*[1], *A. Mohseni Meybodi*[1];
[1]*Department of Genetics at Repproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine ACER., Tehran, Islamic Republic of Iran,* [2]*Department of Endocrinology and female Infertility at Repproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine ACER., Tehran, Islamic Republic of Iran.*

Hyperprolactinemia is seen in a group of infertile women .These women are treated for this problem because high amounts of prolactin can affect fertility by changing LH and FSH quantity.The increase in prolactin levels could be due to a disorder in the prolactin receptor, so investigating the geneome of this receptor which is located on chromosome 5 might be useful in finding the reason for this problem.
In this study, the infertile women referred to Royan infertility institute, diagnosed with idiopathic hyperprolactinemia whose pituitary MRI results were normal, were compared with the control group who were fertile women, for any changes in their prolactin receptor gene. The techniques used in this study were PCR-SSCP and Sequencing .the DNA was extracted from the blood samples by salting out method and then amplified by the polymerase chain reaction .The purified PCR products, were sequenced by the sanger sequencing technique in order to confirm the SSCP result.No change in any of the eleven exons of the prolactin receptor gene was detected neither in control group nor in the patients group, consequently it can be concluded that idiopathic hyperprolactinemia in the affected infertile women, is not in association with any change in the genome of the prolactin receptor.To our knowledge this is the first study on this gene in this group of patients.

J01.37
The role of ID gene family in transformation of endometrial lining of uterus during menstrual cycle

M. Ashini[1,2], *M. Shahhoseini*[2], *S. Mahdian*[3], *R. Aflatoonian*[3];
[1]*Faculty of Basic Sciences and Advanced Technologies in biology at University of Science and Culture, ACECR, Tehran, Islamic Republic of Iran,* [2]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran,* [3]*Department of Endocrinology*

and Female Infertility at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, Tehran, Islamic Republic of Iran.

The inhibitor of DNA binding family members (ID1,ID2,ID3,ID4) inhibit activity of basic helix-loop-helix transcription factor and have an important role in cell growth ,differentiation and angiogenesis.
Due to the high proliferation and angiogenesis in the endometrial lining of the uterus during the menstrual cycle, it seems that this gene family may be involved in the occurrence characteristics of this tissue.
This study focused on expression of ID gene family by real-time PCR in 21 healthy fertile women undergoing tubal ligation surgery, between 20-45 years old to investigate the possible role of this gene family in endometrial tissue changes during three phases (menstrual ,proliferative , secretory) of menstrual cycle. For this respect ethical approval and informed patient consent was gained for the use of tissue sample.
Data revealed high levels of mRNA expression for ID1, ID2, ID3 and ID4 in proliferative phase. Also, all members of this gene family showed more significant expression levels during the secretory phase than the proliferative phase of the menstrual cycle.
These results suggest for the first time that ID gene family has a dynamic role in the proliferation and angiogenesis of endometrial cells. We propose that changes in expression pattern of this family can be reviewed in gynecologic disorder and infertility that related to embryo implantation.

J01.38
Polymorphisms of *Toll Like Receptor* 2, 3 and 4 in patients that do and do not enter labour spontaneously at term

T. Özlü[1], *Z. Ocak*[1], *S. A. Simavlı*[2], *A. Karataş*[1];
[1]*Abant İzzet Baysal University Medical Faculty, Bolu, Turkey,* [2]*İzzet Baysal Maternity and Children Hospital, Bolu, Turkey.*

To assess the association of polymorphisms of *Toll Like Receptors (TLR's)2,3 and 4* with the delay in onset of labour at term pregnancies, patients delivering at >37 weeks and without preeclampsia, IUGR or a history of preterm delivery were prospectively evaluated. *TLR*2 Arg753Gln, *TLR3* (c.1377C/T) and *TLR4*Asp299Gly and Thr399Ile polymorphisms were genotyped by using PCR-RFLP. Patients labouring spontaneously before the 41st week were compared with those who did not labour spontaneously until this week in terms of baseline characteristics, *TLR* 2, 3 and 4 polymorphisms. The same comparisons were also performed by using 40th week cut-off. Chi-square test, two sample T test or Man-Whitney U test were used for comparisons as appropriate. 79 patients delivering after 37 weeks were evaluated. All had CC genotype for *TLR*2 Arg753Gln and *TLR*4 Thr399Ile. There were no significant differences for *TLR*4Asp299Gly GA and *TLR*3 (c.1377C/T) polymorphisms between patients spontaneously entering or not entering labour until the 41st week; the same was true when the 40th week cut-off was used. Delay in onset of labour at term pregnant patients does not seem to be affected by presence of *TLR* 2, *TLR* 3 or 4 polymorphisms. Further studies are needed.

J01.39
Prenatal diagnosis of AIPL1 related Leber Congenital Amaurosis (LCA) in the Iranian population: application of novel informative markers rs11658369 and rs8066853

A. Karimi[1], **S. Vallian**[2,1];
[1]*Isfahan Medical Genetics Center, Isfahan, Islamic Republic of Iran,* [2]*University of Isfahan, Isfahan, Islamic Republic of Iran.*

Leber congenital amaurosis (LCA) shows clinically and genetically heterogeneous disorder which is caused by a large number of mutations in at least 17 different genes. In the present study the application of two genetic markers including rs11658369 and rs8066853 markers located in AIPL1 genetic region were genotyped and their application were investigated in prenatal diagnosis of the disease in the Iranian population. The markers were genotyped using newly designed specific primers by Tetra-primer ARMS PCR in 150 unrelated healthy individuals in the Iranian population. Analysis of the genotyping data using GenPop program, indicated the presence of informative haplotypes (>5%) with strong linkage disequilibrium for the markers and the AIPL1 gene. The efficiency of these haplotypes as a suitable tool in prenatal diagnosis of LCA was evaluated in two Iranian families with one affected child with an already diagnosed W278X mutation in the AIPL1 gene, through an APEX microarry screening and sequencing analysis. The transmission of the normal and affected alleles form parents to their affected child and the fetus was confirmed by using the haplotypes obtained by genotyping of rs11658369 and rs8066853 markers. Interestingly, in line with the mutation results, the genotyping data also confirmed the transmission of normal alleles to fetuses. The families now were given birth to children with normal vision as confirmed by ophthalmic diagnosis. The data suggested that rs11658369 and rs8066853 could be suggested as novel informative markers for linkage and prenatal diagnosis of AIPL1 associated LCA in the Iranian population.

J01.40
Analysis of pedigrees of families with reproductive losses

B. Ginzburg;
Regional Hospital of Kaluga, Kaluga, Russian Federation.

Given the important role of genetic factors in the genesis of reproductive losses in families with miscarriage, we analyzed taking into account the reproductive disorders in families. When analyzing families accounted reproductive losses and infertility among relatives of the 1st, 2nd, 3rd and 4th degree of consanguinity. Analysis was conducted among 226 families with one miscarriage, 277 families with two miscarriages, 117 families with three miscarriages in history. The comparison group consisted of 201 families in history, which marked the birth of a healthy baby. Conducted under the EBM calculations showed that the presence of relatives in the pedigrees of families of women with reproductive losses is IP = 2,47 (CI- 95% 1,62:3,75) . Among the male relatives of the families of miscarriage, this indicator was IP = 2,18 (CI- 95% 1,27:3,59). In general, the odds ratio for relatives with reproductive disorders, excluding sex pedigrees in groups with reproductive losses and in the comparison group was IP = 2,79 (CI- 95% 1,95:3,98). Thus, in families with reproductive losses 2.5 times more relatives with reproductive disorders, compared with the families of the comparison group. This indicates a hereditary component, leading to reproductive losses. Availability unspecified hereditary factors, both by women and by men contributes to further research to find genetic markers defining gender reproductive disorders.

J01.41
Methylenetetrahydrofolate reductase C677T and A1298C polymorphism is not associated with oligozoospermic and azoospermic infertile male patients in the Turkish population

H. Gurkan, *H. Tozkir, E. Goncu, S. Ulusal, M. Yazar;*
Trakya University, Medical Faculty, Department of Medical Genetics, Edirne, Turkey.

Folate pathway plays significant role in the cell phsiology by participating in the DNA repair, methylation and genomic stability. Optimal function of the pathway is essential for high metabolic activity of the testicles. Methylenetetrahydrofolate reductase (MTHFR), the key enzyme of folate metabolic pathway, was reported to be five times more active in the testicles compared to other organs in a study with adult mice. This is the first study researching the association of MTHFR 677C>T (rs1801133) and 1298A>C (rs1801131) polymorphisms with infertility of the idiopathic nonobstuctive azoospermic and oligozoospermic patients. Study population included nonobstuctive 75 azoospermic and 62 oligozoospermic nonconsangiuonous infertile patients referred to Department of Medical Genetics of Trakya University between 01.03.2012-01.06.2013 due to the infertility who had been diagnosed based on the clinical examination and spermiograms (World Healh Organisation standarts, 2010) .All patients had normal karyotype without Y microdeletion. Melting curve analysis with labeled probes and primers designed by the manufacturer's (NLM Diagnostics, Italy) and Real Time Polymerase Chain Reaction method (Qiagen, Rotor Gene) have been used. There was no statistically significant association of MTHFR C677T and A1298C polymorphisms and infertility in the study population (p>0.05). The differences in the dietary folic acid intake between populations, even between the different regions of the same geographical area may cause the different results. The similarity of our results with other studies on Caucasian population can be explained by the patients included in this study live in the Trakya region of Turkey and they were being exposed to similar enviromental factors.

J01.42
The association study of MSH5 C85T and MLH3 C2531T polymorphisms in infertile men with non-obstructive azoospermia

H. R. Heidari-Rostami[1], *R. Mirfakhraie*[1], *A. Movafagh*[1], *N. Salsabil*[2];
[1]*Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Introduction: Genetic factors cause about 10% of male infertility. However, the etiology of the majority of male infertility cases including non-obstructive azoospermia remains idiopathic. Defects in DNA repair during spermatogenesis are thought to underlie some types of testicular failure. Evidence is accumulating the mismatch repair proteins MSH5 and MLH3 play a crucial role in spermatogenesis. In the present study, we investigated the association between MLH3 C2531T and MSH5 C85T polymorphisms and developing non-obstructive azoospermia.
Methods: In a case-control study, peripheral blood samples were obtained from 110 non-obstructive azoospermia patients and 102 proven fertile men. DNA was extracted by using salting out method. Y chromosome

microdeletions were studied using Multiplex PCR. MLH3 C2531T variants were analyzed using the tetra-amplification refractory mutation system-PCR (4P-ARMS-PCR) method in the patients and controls. MSH5 C85T variants were determined by PCR-RFLP assay in the studied groups. SNPSTAT program was used for the detection of allelic and genotype frequencies and the association between non- obstructive azoospermia and the mentioned polymorphisms.
Results: 14 patients (12.7%) showed Y chromosome microdeletions and therefore were excluded from our study. No association was detected between MLH3 C2531T and MSH5 C85T polymorphisms with developing non-obstructive azoospermia in Iranian patients.
Conclusions: Our results suggest that these polymorphisms may not be considered as a genetic risk factor for non-obstructive azoospermia at least in Iranian population. Variability of the results in other populations may be explained due to differences in the ethnic backgrounds.

J01.43
Effect of oxidative stress on *KDM5D* expression in mature mouse testis

P. Mokhtari[1,2], *H. Gourabi*[2], *A. Mohseni-Meybodi*[2];
[1]*Biology department, Pharmaceutical Sciences branch, Islamic Azad University, Tehran, Islamic Republic of Iran,* [2]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran.*

Male factors are important causes of infertility. Two major causative factors of male infertility are oxidative stress (OS) and genetic factors. OS damages the sperm plasma membrane, the genome integrity and expression profile of genes involved in spermatogenesis. *KDM5D* or *SMCY* is one of these genes which its alteration is associated with male infertility.
In this study the expression profile of *KDM5D* gene was evaluated in testis tissues of infertile after OS induction.
Oxidative stress in adult mice testis was induced by injection of the 1:10 concentration of tertiary-butyl hydroperoxide (TBHP). Adult male Balb/c mice were randomly selected. Case group included treated mice by TBHP for 2 weeks and control group treated only by injection of dH_2O. Induced ROS levels in testes tissue samples of all mice measured by flow-cytometry. Consequently the expression of *KDM5D* gene was quantitatively measured in samples of both groups by real-time PCR.
According to Flow-cytometry results, an increase of oxidative stress in ROS treated mice in comparison to control group was observed. Moreover, the expression level of *KDM5D* gene was lower in TBHP treated mice than that of in control mice.
Oxidative stress can have detrimental effects on testicular tissue and alters the expression of some genes which are involved in spermatogenesis.

J01.44
The case of prenatal diagnosis Pallister-Killian syndrome in Sverdlovsk region (Russian Federation)

S. S. Deryabina, *N. V. Nikitina, N. V. Konopleva, V. V. Voroshnin, I. A. Sevostyanova; Clinical-diagnostic Center, Yekaterinburg, Russian Federation.*

Pallister-Killian syndrome or Tetrasomy 12p is an uncommon aneuploidy, which may present in the prenatal period with an ultrasonographically detected fetal abnormality.
A 30-year-old woman was referred to our center for evaluation of a frontal edema in her fetus. The pregnancy was uncomplicated and there was no significant medical history of the family. The initial screening scan was performed at 13 weeks gestation and an increased nuchal translucency (3, 8 mm) was obtained. At 14 weeks gestation, the expert ultrasound examination demonstrated increased nuchal translucency (4,1mm) and heart defect (tricuspid regurgitation). The couple was counseled concerning the options of invasive tests for karyotyping of fetus.
The parents accepted to perform a placental biopsy at 15 weeks gestation.
The cytogenetic analysis has shown that all cells of placental villus had a supernumerary, metacentric marker chromosome.
Prenatal molecular assay for detecting aneuploidies and microdeletion syndromes (Prenatal BoBs™), that was obtained in parallel with cytogenetic analysis has defined a gain of chromosomal copy number in group autosomal probes (region 12p13).
Using the method fluorescence in situ hybridization (FISH) we have confirmed that the extra chromosome was derived from chromosome 12.
The parental karyotypes were subsequently checked and were both normal.
On the basis of this, given the poor prognosis for Pallister- Killian syndrome and after counseling, the couple elected to terminate the pregnancy at 17 weeks gestation.

J01.45
Association FBLN5 gene polymorphism with pelvic organ prolapse.

M. B. Khadzhieva[1], *I. V. Volodin*[2], *A. G. Chumachenko*[1];
[1]*N.I. Vavilov Institute of General Genetics, Russian Academy of Sciences, Moscow, Russian Federation,* [2]*Lomonosov Moscow State University, Moscow, Russian Federation.*

Pelvic organ prolapse - multifactorial disorder characterized by a loss of pelvic floor support leading to the herniation of the uterus into or through the vagina. One of the most important genes encoding proteins of elastic fiber matrix assembly and function is *FBLN5.* We used tagged SNP approach to increase the genetic coverage of the *FBLN5* gene (Haploview 4.2 software). The genotyping of all eleven selected SNPs was performed using a PCR-CTPP (polymerase chain reaction with confronting two-pair primers) and real-time PCR. The study sample set included patients (n=210) diagnosed with stage III-IV prolapse based on the Pelvic Organ Prolapse Quantification (POP-Q) examination, and controls (n=292) were women without prolapse and no prior history of prolapse surgery. Multiple logistic regression analysis adjusted for age, body mass index and vaginal parity was applied to evaluate the associations between *FBLN5* SNPs and POP in the entire set and in the strata with/without perineal trauma and fetal macrosomia. The top association signal was found for SNP rs2018736 (protective effect for the minor allele A; recessive model) in the entire set: P =0.0026, OR=0.42, 95% CI:0.24-0.75; in the strata with perineal trauma: P =0.0018, OR=0.27, 95% CI:0.11-0.64; and in the strata with fetal macrosomia: P=0.013, OR=0.14, 95% CI:0.03-0.71. The results of the haplotype analyses were consistent with the single SNP analysis. The results are clinically important providing a rationale for fibulin-5-targeted therapy in women combining genetic and clinical determinants of higher risk for POP.

Preimplantation genetic diagnosis (PGD) for beta thalassemia and birth of a healthy boy after 4 times of therapeutic abortion

P. Fouladi[1], *S. Sabeghi*[1], *K. Fatemi*[1], *F. Rahiminejad*[1], *S. Kianfar*[1], *A. saadat*[1], *T. Shirzad*[1], *S. Zeinali*[1,2];
[1]*Medical Genetics Lab of Dr. Zeinali, Kawsar Human Genetics Research Center, Tehran, Islamic Republic of Iran,* [2]*Dep't of Molecular Medicine, Biotechnology Research Center, Pasteur Institute of Iran, Tehran, Iran, Tehran, Islamic Republic of Iran.*

A couple who was referred to us for prenatal diagnosis (PND) for beta thalassemia had experienced 4 consecutive pregnancies with diagnosis of thalassemia major. After four times of therapeutic abortions, the couple decided to have healthy child using preimplantation genetic diagnosis (PGD).
Ovulation induction and ovum fertilization were performed in Erfan Hospital, Tehran, Iran. In the 3rd day, a single blastomere from each embryo (in total 8) was removed and given to us. For molecular PGD, a multiplex nested PCR, using several STRs markers linked to HBB gene and also amplifying part of the β-globin gene, was done. Out of 8 tested cells, 3 blastomers were thalassemia minor, 2 homozygous normal and one thalassemia major. Also two embryos did not give us conclusive result on being affected or normal due to allele dropout (ADO).
The family decided to transfer 3 embryos. Three weeks after embryo transfer, pregnancy test was positive and a single pregnancy was continued up to the 11th week gestation. The family agreed on fetal testing. CVS was followed. Genetic testing for beta thalassemia and chromosomal aneuplidies showed a healthy boy who was carrier of thalassemia minor. A healthy boy was born on the Feb 4, 2014 by cesarean section. Similar test on placental sample confirmed our findings.

Genomic variability study: CNVs analysis in women with premature ovarian failure (POF)

C. Viaggi[1], *M. Malacarne*[1], *M. Pierluigi*[1], *S. Cavani*[1], *C. Baldo*[1], *M. Mogni*[1], *D. Coviello*[1], *M. Piccione*[2];
[1]*EO Ospedali Galliera Laboratorio di Genetica Umana, Genoa, Italy,* [2]*AO Ospedali Riuniti Villa Sofia Cervello Dipartimento Materno Infantile, Palermo, Italy.*

Premature ovarian failure (POF) is defined by amenorrhea of at least 4 to 6 month duration, occurring before 40 yr of age, with two FHS levels in the postmenopausal range. Genetic basis for POF are FMR1 gene premutation and chromosomes anomalies detected by karyotype but its etiology remains unknown in more than 80% of cases. Copy Number Variation (CNVs) form an important class of human genetics variants. Array Comparative Genomic Hybridization (Array-CGH) analysis ia able to detect submicroscopic chromosomal rearrangements with a higher genomic resolution.
In this study we selected 32 women affected by POF, with normal FMR1 premutation and normal karyotype. This cohort have been analysed by Array-CGH 8x60K Agilent platform with a resolution of 100Kb, to identify an association between CNVs and POF. We observed 23 CNVs in 12 patients (37.5%): 3CNVs on the X chromosome and 20 on autosomal chromosomes; 14 duplications and 9 deletions; the rearrangements size were between

122Kb and 91.26Mb. In conclusion our data, accordingly with already published data, confirm the utility to use array-CGH to detect CNVs genome-wide for POF diagnosis and to identify new possibly pathogenetic genes.

J01.48
Expression of HIF and VEGF genes and pregnancy loss

E. Mashkina, *K. Kovalenko;*
Research Institute of Biology, Southern Federal University, Rostov-on-Don, Russian Federation.

15% of human pregnancies are known to end in spontaneous abortion before 12 weeks of gestation. A disbalance of cytokines and growth factors can affect negatively early stages of human embryogenesis. The aim of the study is to determine the expression level of the growth factors genes in miscarriage patients.
Study was performed on the RNA samples from two groups of women. The first group included of women with a missed abortion or spontaneous abortion. The control group included women with normal pregnancy. The samples of RNA were extracted from decidua and chorion. The level of the gene expression was assessed using the two-step reverse transcription probe-dependent fluorescent real-time polymerase chain reaction.
Hypoxia inducible factor (HIF) is the primary molecular sensor responded to oxygen tension changes. HIF as transcription factor regulated many cellular processes, for examples angiogenesis, invasion, cell survival. HIF in hypoxia condition provides a potent stimulus for VEGF synthesis and is essential for development of maternal and placental vasculation in early human pregnancy. In the case of miscarriage the level of HIF-1 gene expression was reduced in the chorion. Analysis of gene expression vascular endothelial growth factor in physiological pregnancy showed that mRNA levels of this gene was significantly lower in decidua compared to the chorionic tissue ($P = 0.032$). In case of miscarriage the level of VEGF gene expression in chorionic tissue was not different from decidual tissue and significantly lower compared with the level of gene expression in the control.

J01.49
Paternal and maternal origin of Primary ovarian insufficiency (POF/POI) caused by FMR1 gene premutation - using Repeat Primed PCR (RP-PCR) method

A. Beke[1], *V. Karcagi*[2], *B. Nagy*[1], *H. Piko*[2], *M. J. Molnar*[1], *J. J. Rigo*[1];
[1]*Semmelweis University, Budapest, Hungary,* [2]*National Institute of Environmental Health, Budapest, Hungary.*

Patients and methods: Early ovarian depletion criteria were consistent with international protocols: secondary amenorrhea, ovarian failure up to the age of 40 years, levels of FSH≥ 40 IU/L, and low estrogen levels. We investigated the CGG trinukleotide repeats in the FMR1 promoter region by hybridization with radiolabeled DNA probes. The premutation CGG repeat number was 55-200, and the gray zone was between 45-54 repeats. **Results:** In a 38-year-old woman suffering from premature ovarian exhaustion we found deviations on both alleles of FMR1 gene during the Repeat Primed PCR (RP-PCR) tests. On one allele the CGG repeat number was 76. On the other allele the CGG repeat number was located in the so-called gray zone (CGG 52). Given that on both alleles deviations were found, we examined the family. We found a 29/52 CGG repeat number in her mother, and a 76 CGG repeat number in her father. The menopause of the mother occurred at the age of 46, the neurological examination of the father for the Fragile X Associated Tremor Ataxia Syndrome is in progress. In the brother of the female patient, a CGG repeat number 29 was detected. **Conclusions:** The genetic examination of the premature ovarian failure is very important for the patient and her family also, because the genetic results have serious influence on the reproductive possibilities and family planning of the premutation carriers.

J01.50
Maternal variant gene RHD and clinical effects during pregnancy and at birth

E. Guinchard[1], *P. Bricca*[2];
[1]*EFS Rhône-Alpes site de Lyon-GHE, 69677 Bron Cedex, France,* [2]*EFS Rhône-Alpes site de Lyon-GHE, 69677 BRON Cedex, France.*

During her second pregnancy, a 35 year old patient known with RH:1 status surprisingly has an anti-RH1 allo-immunization at 24 weeks of pregnancy. Prenatal non-invasive RHD genotyping on fetal maternal plasma was performed using real-time PCR (TAQMAN technology) studying three regions of the RHD gene (exons 4, 5 and 10) and shows amplification of the 3 exons. The maternal DNA sequencing allows to identify the type IVa RHD variant characterized by lesions of exons 2, 3 and 7 : RH1 corresponding antigen exposed the patient to the risk of anti-RH1 immunization. The titer of the anti-RH1 increases dramatically in late pregnancy (maximum title 1024), however, without sonographic fetal anemia. At birth, the child is RH:1 and has a minor anemia 120 g / l but a positive direct antiglobulin test (due to maternal anti-RH1 antibodies on the surface of his erythrocytes). But at the 12th day, the child presents a deep hemolytic anemia at 52 g / l; requiring 4 CGR transfusions (12th day, 13th day and 30th day). The sequencing of the RHD gene of the child at birth can highlight the two copies of the RHD gene: an allele with the standard RHD gene inherited from the father, and the other with RHD variant (type 1 DIV) identical to mother's. This case shows the possible clinical consequences of anti-RH1 alloimmunization in a mother carrying a variant of the RHD gene.

Diagnostic algorithm for differential diagnosis in high-risk pregnancies identified by prenatal ultrasound screening: two case reports

R. Pourová[1], *J. Drábová*[1], *R. Vlk*[1], *M. D. Libik*[1], *P. Peldová*[1], *N. Ptáková*[1], *A. Holubová*[1], *Z. Mušová*[1], *P. Hedvičáková*[1], *M. Vlčková*[1], *D. Chudoba*[1], *M. Trková*[2], *Z. Hrubá*[3], *L. Fajkusová*[3], *A. Křepelová*[1], *D. Novotná*[1], *M. Havlovicová*[1], *M. Macek sr.*[1], *M. Macek jr.*[1];
[1]*University Hospital Motol, Prague, Czech Republic,* [2]*Gennet, Prague, Czech Republic,* [3]*Center of Molecular Biology and Gene Therapy, Brno, Czech Republic.*

Hereby, we present 2 case reports of pregnancies with an initially high risk of congenital anomalies, detected by 1st and 2nd trimester prenatal ultrasound screening (US), that was significantly reduced by a complex follow up approach. Case 1: a 34-year-old woman (12th week-of-gestation: w.g.) was referred due to increased nuchal translucency (NT: 4.5 mm) and suspected hygroma colli cysticum detected by 1st trimester US. Following CVS we performed examinations comprising standard karyotyping, QF-PCR, arrayCGH, MLPA of subtelomeric regions and SMN1 gene, sequencing of DHCR7 gene and TORCH serology with normal outcomes. US performed in the 16th w.g. proved regression of NT and absence of other congenital anomalies, except for hyperechogenic bowel (CFTR negative). Fetal ECHO and 3D US were normal. In Case 2 a 30-year-old woman (22nd w.g.) was examined due the absence of nasal bone and renal pelvic dilatation on 2nd trimester US. Following AMC and cordocentesis we utilized identical diagnostic algorithm (except MLPA) and furthermore sequencing of FMR1 and FGFR3 genes with negative results. Both families were reassured and thus opted for continuation of their pregnancies, which resulted in the in term delivery of apparently healthy children (male and female). Our complex diagnostic algorithm allowed exclusion of the most of severe prenatal affections that were suspected by US screening and substantially decreased their risk. These case reports substantiate the diagnostic utility of our algorithm and underscore the importance of multidisciplinary approach to high-risk pregnancies. Supported by NT13770-4, FNM 00064203 and OPPK CZ.2.16/3.1.00/24022.

J01.52
The utility of conventional cytogenetics and aCGH analysis in the diagnosis of the products of conception

M. Stoian[1], *C. Ionescu*[1], *I. Ceauşu*[2], *H. Rahimian*[3], *F. Nedelea*[4], *A. F. Anca*[5], *A. Rodewald*[1,6], *G. Cardoş*[1];
[1]*Personal Genetics-Medical Genetics Center, Bucharest, Romania,* [2]*University of Medicine and Pharmacy „Carol Davila", Department II of Obstetrics and Gynecology, Dr. I. Cantacuzino Hospital, Bucharest, Romania,* [3]*Regina Maria Hospital, Bucharest, Romania,* [4]*Filantropia Clinic Hospital, Bucharest, Romania,* [5]*Clinic of Obstetrics and Gynecology, Bucharest Emergency University Hospital, Bucharest, Romania,* [6]*Institute of Human Biology, University of Hamburg, Hamburg, Germany.*

During November 2012-January 2014, 42 samples were analyzed by conventional cytogenetic methods and 5 cases by aCGH technique (Array Comparative Genomic Hybridization). The analyses were performed for early miscarriages or for induced pregnancy termination due to severe fetal ultrasound abnormalities. The samples evaluated were from products of conception between 7 and 23 weeks of pregnancy, in patients aged between 24 and 41 years.
Depending on the biological sample received, either, chorionic villi, epithelial tissue, amniotic fluid or fetal cord blood was used for analysis. The karyotyping was successfully achieved in 40 cases and the aCGH analysis for all 5 cases.
Of the 40 cases analyzed by conventional cytogenetics, 23 (57.5%) had abnormal karyotype and in 17 cases (42.5%) no structural or numerical chromosomal abnormalities were identified.
Among the abnormal cases we identified: 13 homogeneous autosomal trisomies, 3 mosaic abnormalities, 2 unbalanced structural chromosomal abnormalities, 1 trisomy and unbalanced structural chromosomal aberration, one triploidy, one monosomy X, 2 double autosomal trisomies, one clonal chromosomal instability.
ArrayCGH analysis identified trisomies of chromosomes 21 and 22. In one case genomic aberrations were identified, including genes involved in embryonic development. For two cases with high gestational age the abnorma-

lities identified were correlated with the severe changes in ultrasound for which the decision of termination was taken, namely cardiac malformation in one case and sacral tumor formation for the second.
The results of our study sustain the importance of cytogenetics analysis for miscarriages, and aCGH may bring important information for pregnancies with ultrasound anomalies.

Qf-pcr in Prenatal Diagnosis: preliminary evaluation of advantages and pittfalls

A. Innoceta, *A. Pragliola, S. Brioschi, C. Caporale, A. Turci, M. Toschi, S. Ghezzo, A. Sensi; Laboratorio Unico AVR Romagna U.O. Genetica Medica, Pievesestina di Cesena, Italy.*

Quantitative fluorescence PCR (QF-PCR) is widely used for the rapid prenatal diagnosis of common aneuploidies by the analysis of short tandem repeats (STR). The amount of each allele is quantified by calculating the ratio of the peak height or area. In our laboratory for standard risk pregnacies (screening by combined test or maternal age) we replace the Short Time Culture (STC) chromosomal analysis of chorionic villi (CV) by (QF-PCR) while we hold STC+LTC for different indications (parental chromosomal abnormalities, uncommon aneuploidy in previous pregnancy, ultrasonographic abnormalities, included NT>3,5). In all QF-PCR positive and when structural or mosaic anomalies are suspected we perform STC too. We also support the karyotype analysis of amniotic fluid (AF) by QF-PCR in > 19th weeks pregnancies. 5% of the 417 CV and 10% of the 95 AF gave an aneuploid result, consistent with the classical karyotype of both STC and LTC. In case of poor sample QF-PCR allowed to resolve maternal contamination dubts (14 cases). One case of vanishing twin, 9 mosaic karyotype cases, zygosity of 6 twins, a dubt Array-cgh on Y chromosome ring duplication also were supported by the QF-PCR results. We further analyzed 13 parental Periferal Blood (PB), to investigate Primer Binding Site Polymorphism (PSP) vs Sub Microscopic Duplications (SMD) or Somatic Microsatellite Mutation (SMM) for D13S1492, D18S386, D21S1442, DXS1187, DXS981, DXS2390, DXYS267, DXYS218, TAF9/TAF9L, BRAF/BRAFP1)and others microsatellites.

QF-PCR: our experience in prenatal diagnosis and recurrent miscarriages

I. Isidori[1], *C. Ardisia*[1], *C. Spapperi*[2], *C. Gradassi*[1], *M. Schippa*[1], *A. Mencarelli*[1], *E. Donti*[1]; [1]*Medical Genetics Unit, University of Perugia, Perugia, Italy,* [2]*University of Perugia, Perugia, Italy.*

Our center is responsible for invasive prenatal diagnosis from the 90s, every year we process by conventional cytogenetic analysis about 1200 samples between amniotic fluid (AF) and chorionic villi (CVS), and about 70 samples from recurrent miscarriages. In 2010 we introduced the QF-PCR analysis for the most common aneuploidies (chromosome 21, 18, 13, X and Y) as support to cytogenetics in :
1. AF samples: when there is a need to for a rapid response in cases of advanced maternal age, clinical suspicion of fetal anomaly or in amniocentesis performed late (more than 20 weeks)
2. CVS samples: in all cases, in conjunction with cytogenetic analysis of cytotrophoblast by direct preparation (STC) or to exclude maternal contamination in chorionic villus DNA used in molecular studies. Over the last three years, we extended QF-PCR analysis to recurrent miscarriages because traditional cytogenetic testing is labour-intensive and has a significant failure rate, especially when the sample quality is poor. In this case we investigate a greater number of chromosomes: 13, 15, 16, 18, 21, 22, X and Y, whose aneuploidies are the major cases of miscarriage.
In this work we report a summary of our experience, using CE-IVD QF-PCR systems CY5- labelled. In prenatal diagnosis QF-PCR system proved to be an effective and specific support to cytogenetic analysis, and a useful and reliable tool to diagnose aneuploidies in spontaneous miscarriages, reaching a pathology's diagnosis in 45% of cases and we're considering to replace cytogenetic analysis with this molecular system.

J01.55
The correlation between sperm DNA fragmentation and recurrent abortion in Iranian population

A. Dehghanifard[1], *M. Noruzinia*[2];
[1]*Sarem Cell Research Center- SCRC, Sarem Women's Hospital, Tehran, Islamic Republic of Iran,* [2]*Sarem Cell Research Center- SCRC, Sarem Women's Hospital, Thran, Islamic Republic of Iran.*

Background: as previous studies have mentioned that sperm DNA quality may be related to unexplained recurrent abortion, this association study was designed to evaluate the degree of sperm DNA fragmentation using the SCSA (Sperm Chromatin Structure Assay) on sperm from couples with unexplained recurrent abortion compared to sperm from men of the general population without evidences of infertility, as control group. **Method:** After collection of ejaculated sperm from 60 couples with recurrent abortion and 30 couples with proven fertility, semen specimen were freezed by placing aliquots immediately under neat freezing conditions using liquid nitrogen. After thawing at approximately 37°C, sperm cells were stained with fluorescent intercalating dye, Acridine orange, after exposure to acidic conditions. Flow cytometry analysis was used to separate ssDNA as fragmented DNA from dsDNA as integrated DNA reported as DFI (DNA Fragmentation Index). Current references indicate that DFI more than 27% correlates with poor fertility potential. **Results:** In this study significant relationship between DFI over 27% of couples with recurrent pregnancy loss (43.3%) compared to normal group (13.3%) was observed (p<0.05). **Discussion:** The SCSA technique is considered to be the most time and cost effective, precise and repeatable technique for sperm DNA fragmentation assay. Due to the noticeable rate of abortion cases in iranian population, sperm DNA fragmentation analysis should be considered as a contributing factor in this incidence, as a screening test. Therefore treatment of DNA fragmentation may be important in reducing abortions.

J01.56
The Y chromosome gr/gr subdeletion is not associated with recurrent pregnancy loss

Z. Sarraf[1], *M. Salimi*[1], *R. Mirfakhraie*[1], *M. Amin-Beidokhti*[1], *G. Modabber*[2];
[1]*Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Tadbir Fan Azma laboratory, Tehran, Islamic Republic of Iran.*

Recurrent pregnancy loss (RPL) is defined as the miscarriage of two or more consecutive pregnancies in the first or early second trimester of gestation. RPL may be associated with several factors including endocrine, anatomical, psychological, infectious, thrombotic, genetic, or immunological causes. Approximately 50% of cases remain unexplained, Thus, treatments are only marginally successful. The majority of the testing for RPL assesses the woman, however, male factor is rarely discussed and has been poorly evaluated in RPL. The Y chromosome partial microdeletions including gr/gr microdeletion have been associated as a risk factor for infertility. The aim of the present study was to investigate whether Y chromosome gr/gr microdeletions was associated with RPL in a Iranian population.
Methods: The subjects were 88 male partners of couples where the female partner had experienced t or more RPLs. Fifty proven fertile males from the general population were also analysed as a control group. DNA extracted from peripheral blood was tested for Y chromosome gr/gr microdeletion using a multiplex PCR.
Results: gr/gr deletion was detected in 7 (8.64%) patients and 2(4.16%) fertile controls. However, the difference was not statistically significant (p>0.05).
Conclusion: gr/gr microdeletion in the Y chromosome does not appear to be important in the aetiology of RPL. However, ethnic variations may result in different consequences in other populations.

J01.57
An apparently balanced Robertsonian translocation rob(13;14) associated with a small chromosome marker identified in prenatal period

E. Gorduza[1], *T. Liehr*[2], *V. Martiniuc*[3], *M. Gramescu*[1], *C. Bujoran*[4], *L. Caba*[1], *D. Nemescu*[5];
[1]*University of Medicine and Pharmacy „Grigore T. Popa" Iasi, Medical Genetics Department, Iasi, Romania,* [2]*Universitätsklinikum Jena, Institut für Humangenetik, Jena, Germany,* [3]*"Cuza Voda" Maternity, Prenatal Diagnosis Department, Iasi, Romania,* [4]*"Sfanta Maria" Pediatric Hospital Iasi, Department of Cytogenetic, Iasi, Romania,* [5]*University of Medicine and Pharmacy „Grigore T. Popa" Iasi, Obstetrics and Gynecology Department, Iasi, Romania.*

We present a de novo balanced Robertsonian translocation (13;14) identified in prenatal period. The women, aged 32 years, asked the prenatal diagnostic because she had a previous pregnancy with 21 trisomy. The chorionic villous sampling made at age of 12 weeks of amenorrhea was followed by prenatal analysis by FISH technique, using Aneuvysion® kit and confirmed a 46,XX chromosomal formula. Cell culture indicated an apparently balanced Robertsonian translocation rob (13;14) and a small chromosome marker. The chromosomal analysis in both parents was normal. We repeated the prenatal analysis after amniocentesis at age of 17 weeks of amenorrhea. The G banding confirmed the presence of both anomalies: an apparently balanced Robertsonian translocation rob (13;14) and a small chromosome marker. The C banding indicated a possible derivative chromosome der (13;14) with two centromeres. To identify precisely the chromosomal anomalies we asked the help of Prof. Thomas Liehr, and the FISH analysis, made at University of Jena, with probes for centromeres of chromosomes 13/21 and 14/22, and probes for all acrocentric p-arms confirmed that one break appeared in the short arm of chromosome 13 and the second one in the centromere of chromosome 14. The latter leads to alphoid DNA derived from chromosome

14 being present on both derivative chromosomes. Thus, fetus has the chromosomal formula: 46,XX,t(13;14)(p11.2;p11.1)dn. The immunohistochemistry attested one active centromere on the chromosome marker and two active centromeres on the large derivative chromosome. We gave to parents the genetic counseling and they decided to keep the baby, which is normal.

J01.58
Premature chromatid separation in a woman with unexplained recurrent pregnancy loss; A case report

*F. Silan[1], **H. Has**[1], M. Urfali[1], A. Uludag[1], E. Ari[1], M. Gencer[2], O. Ozdemir[1];*
[1]Canakkale Onsekiz Mart University Faculty of Medicine Department of Medical Genetics, Canakkale, Turkey, [2]Canakkale Onsekiz Mart University Faculty of Medicine Department of Gynecology and Obstetrics, Canakkale, Turkey.

The current case reports show an increased frequency of lymphocyte cells with premature chromatid separation (PCS) involving all methaphase chromosomes in blood cultures of a woman with RPL. Heparinised peripheral blood cell culture was made for the current couple with RPL. We analysed metaphase spreads from a couple with RPL using a rigorous GTG banded protocol to score the affected chromosomes. No structural and/or numerical chromosome abnormalities were detected in the current couple but multiple PCS was detected in mitotic spreads from 38-year-old mother. These findings from a proband case provide evidence for a possible association of PCS and RPL.

J01.59
Sex chromosome rearrangements and implications for the phenotype

E. Margarit[1,2], *A. Sánchez[1,2], M. Papiol[1], A. Serra[1], C. Castelo-Branco[3], C. Ros[3], A. Soler[1,2];*
[1]Biochemistry and Molecular Genetics Dep., Hospital Clínic, Barcelona, Spain, [2]IDIBAPS, Barcelona, Spain, [3]Clinic Institute of Gynaecology, Obstetrics and Neonatology, Hospital Clínic, Barcelona, Spain.

Sex chromosome structural abnormalities are frequently found in individuals with reproductive failure or disorders of sexual development. X-chromosome rearrangements are identified in patients with Turner' syndrome, usually in a mosaic form. The most frequent structural abnormality in these cases is the X isochromosome for long arms, although a ring X-chromosome or other variants can also be found. Additionally, other X-rearrangements are detected in patients referred for reproductive failure, infertility or even in woman with no clinical indication, including X translocations, partial deletions or duplications. In balanced X-autosome translocations, breakpoint position and replication behavior may influence phenotypic outcome. Rearrangements on the Y chromosome include: X-Y translocations, Y-autosome translocations, isochromosomes, rings, partial deletions and inversions. Dicentric Y isochromosomes for the short arm or ring Y chromosomes are the most frequent abnormal Y chromosomes found in infertile patients and in Turner syndrome, in mosaic with 45,X cells. In all these cases, it is important to well characterize the derivative chromosomes in order to establish a good genotype-phenotype correlation, to provide information about the role of different X/Y chromosome regions or loci in the clinical manifestations of patients.
For this purpose, we have collected patients with different sex chromosome rearrangements detected with karyotyping: X-autosome translocations (3); X isochromosome (3), X deletions (4); ring X (1); X inversion (1); Y-autosome translocations (4); Y isochromosome (1). The rearranged chromosomes have been analyzed using FISH, MLPA or aCGH when appropriate. After a detailed clinical assessment, genotype/phenotype correlations have been performed.

Management of sex differentiation disorders at University Hospital Hassan II Fes

I. El Otmani;
Chu Hassan Ii Fes, Fes, Morocco.

Sex differentiation disorders represent all the abnormalities in development of the gonads, the genital tracts, and the external genitalia. Disorders of sexual differentiation are due to genetic defects or endocrine imbalance. Sex-determining genes (SRY gene) dictate the gonadal sex whereas the fetal testicular hormones determine the somatic sex during sex differenciation. Abnormal sexual development causes unconformity between gender identity and gender role.
The aim of this study was to evaluate the frequency, the genital anatomy appearance, the diagnostic and the surgical management of disorders of sex development (DSD) discovered during the neonatal period and the enfance
Between September 2009 and Marsh 2013, 30 patients with abnormal sexual development were identified in our unit. First-line testing included biology measurement and imaging. A surgical management was offered for some patients. Sexual dimorphic with genital ambiguity was the first reason of consultation. One patient had male breast development. All clinical evaluation suggested genital ambiguity.
This presentation points out the need of an accurate diagnosis of sexual differentiation disorder during the neonatal period. The intervention of a multidisciplinary team is essential as well for assignment of sex as for therapeutic guidelines.

Polymorphic locus 820AG of IGF-2 gene as a possible marker of fetal development disorders

B. Tretjak, *H. Makukh, D. Zastavna;*
Institute of Hereditary Pathology NAMN of Ukraine, Lviv, Ukraine.

Insulin-like growth factor-2 (IGF-2) is a mitogen, growth and differentiation modulator for many cell types. It is mainly expressed during the prenatal development, and its activity strongly depends on the genomic imprinting. Genomic imprinting in the chorionic tissues of spontaneously eliminated human embryos has been studied on the model of 820AG (Apa1) of the IGF-2 gene locus. Methods. Isolation and purification of DNA and RNA, PCR-RFLP, RT. Results. Molecular and genetic analysis was performed of the polymorphic locus 820-AG IGF2 in 107 samples of DNA extracted from the chorionic tissues of spontaneously eliminated human embryos within 5-10 weeks of gestation. The loss of imprinting of the IGF2 gene was analyzed in 41 samples of the chorionic villi cells in human. In 90% of cases, the loss of imprinting was detected. Presence of AG genotype of SNP 820AG of IGF2 gene was shown to cause more than a 7-fold increase in the risk of embryo elimination (OR = 7.72, CI 95% 3.31-18.04). Conclusion. The loss of genomic imprinting of the IGF2 gene may be an important cause of the miscarriages in human.

Decreased expression level and chromatin incorporation of histone acetyltransferase CDY1 in testicular biopsies of infertile men with non- obstructive azoospermia

N. Heydarian[1], *M. Sahhoseini[2], Z. Eelaminejad[1], R. Favaedi[2], M. Sedighi Gilani[3];*
[1]Department of Biology, Science and Research Branch, Islamic Azad university, Tehran, Islamic Republic of Iran, [2]Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran, [3]Department of Andrology at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran.

Background:
Many cases of male infertility associated with a severe impairment of spermatogenesis. During the last stage of spermatogenesis (spermiogenesis), haploid spermatids endures complex changes to differentiate into spermatozoa, this process includes chromatin modifications mediated by different histone modifying enzymes. Chromodomain Y (CDY) proteins encoded by the CDY family of genes, are characterized by two functional motifs, a chromodomain and a histone acetyltransferese catalytic domain. A testis specific CDY protein, named CDY1, binds to methylated histone regions through its chromodomain, and then causes hyperacetylation of genes involved in sperm chromatin condensation. This study aimed to investigate the relative mRNA expression and chromatin incorporation of chromodomain Y1 (CDY1) protein in the testis tissues of infertile men.
Material & Method:
Local ethical approval was gained for this study and informed consent was given by patients. Testicular biopsies were collected from 31 infertile men referred to Royan Institute and underwent testicular sperm extraction (TESE). These samples distributed into 4 groups: obstructive azoospermia (positive control), severe oligoasthenoteratozoospermia, non- obstructive azoospermia and sertoli cell only syndrome.
Using qRT-PCR and nucleosome-ELISA methods, the mRNA levels and chromatin incorporation of CDY1 was evaluated in the tissue samples.
Result(s):
Our data significantly showed lower expression and chromatin incorporation of CDY1 in all 3 sample groups with spermatogenesis defect in comparison to positive control.
Conclusion(s):
This data demonstrated that the defective epigenetic role of the histone acetyltranferase CDY1 may be associated with male infertility.

J01.63
Conventional CGH vs FISH and karyotyping in detection of chromosomal abnormalities in first-trimester spontaneous abortion

M. Minzhenkova, *N. Shilova, Z. Markova, Y. Kozlova, T. Zolotukhina;*
Federal State budgetary Institution 'Research Centre for Medical Genetics' under the Russian Academy of Medical Sciences, Moscow, Russian Federation.

Approximately 10-15% of clinically recognized pregnancies terminate with spontaneous abortions. Half of them are associated with chromosome abnormalities (CA). Cytogenetic analysis of chorionic villi has limitations such as high rate of culture failure, maternal cell contamination and poor chromosome morphology. FISH method with target probes doesn't allow to receive full information about fetal genome. CGH is the only DNA-based screening method that can detect chromosomal imbalances in a single experiment. In this study 60 abortion specimens were analyzed by G-banding, FISH and CGH (Table). Overall, CA were detected in 25 specimens. Karyotyping was unsuccessful in 31 samples, while CGH and FISH analyses were successful in all cases. G-banding analysis showed normal karyotype in 21 cases and detected abnormalities in 8 cases (32% of CA). FISH using probes targeting chromosomes 13, 18, 21, X and Y detected CA in 15 samples (60% of CA), but in two of these cases wasn't able to find double trisomies which were revealed by CGH. CGH detected CA in 21 samples (84% of CA) but missed triploidy in 4cases. Aneuploidies detected only by CGH were all confirmed by FISH with corresponding probes. CGH showed the highest detection rate of CA in comparison with karyotyping and FISH. CGH is a suitable technique for the detection of CA in spontaneous abortion with the exception of polyploidy that can be detected by FISH.

Comparison of karyotyping, FISH and conventional CGH analysis (n=60)

№	Karyotype results	FISH results	CGH results
1-9	46,XX	XX	Normal
10-21	46,XY	XY	Normal

Objective: Apolipoprotein E has three major isoforms (Apo E epsilon2, epsilon3 and epsilon4) and has important functions in nerve development and repair. To evaluate the association of Apo E polymorphisms and spontaneous abortion we studied the genotypes of spontaneously aborted fetuses, their mothers and control cases. Methods: In the current case control study, three different groups of aborted materials, mothers and healthy control were compared. Target gene of Apo E2/E3/E4 alleles were analysed by real time PCR. Results: The E2 and E4 alleles showed high prevalence in aborted materials comparing both with their mothers and healthy control group (p=<0.0001). The E4 allele was higher in fetuses comparing with their mothers (p=<0.0001). Conclusion: Apo E2 and E4 alleles seem to be contributing to the thrombophilic risk factors as a seconder parameter to spontaneous abortions.

Parental idendification of aborted materials for chimerism and other molecular etiological parameters by microsatellite STR profilling

F. Silan[1], **A. Uludag**[1]*, C. AKURUT[1], D. Kankaya[1], M. GENCER[2], M. Urfali[1], S. Yalcintepe[1], O. Ozdemir[1];*

[1]Canakkale Onsekiz Mart University School of Medicine Department of Medical Genetics, Canakkale, Turkey, [2]Canakkale Onsekiz Mart University School of Medicine Department of Obstetrics and Gynecology, Canakkale, Turkey.

Aim:Structural and/or numerical chromosomal abnormalities are responsible for 50-60% of the first trimester miscarriages, 20-25% for seconder and 5-10% for the third trimester miscarriages.In the current study it was aimed to use the microsatellite STR markers for the parental identifying of aborted materials.***Materials and Methods:*** Sixteen aborted materials and their parents were included in the current study.Thin skin biopsies from aborted materials and peripheral blood-EDTA samples from parents were used for total genomik DNA isolation. All samples were identified by using AmpF*ℓ*STR(®) Identifiler (Applied Biosystems) PCR Amplification Kit that provides15 different STR markers and compared.***Results:***One maternal originated trisomic (trisomy 13) aborted material and one is maternal and the other is paternal originated triploidic aborted materials were identified. One aborted material was showed maternal heterodisomic profile in the current results. ***Conclusion:***These results suggest that it is possible to identify the disomy, chimeric profiles and parental originated molecular cause of abortion by Identifiler Kit that provides specific microsatellite STR markers.

Beta globin gene mutations in Kurdistan provinces, Iran

A. Darabi[1]*, M. Fallah[2,3], F. Keshavarzi[4], B. Sedaghatikhayat[2], S. Azadmehr[2], P. Salehifar[5], S. Zeinali[2,6];*

[1]Science and Research branch, Islamic Azad University, Kurdistan, Iran, Tehran, Islamic Republic of Iran, [2]Kawsar Human Genetics Research Center (KHGRC), Dr. Zeinali's Medical Genetics Lab, Tehran, Iran, Tehran, Islamic Republic of Iran, [3]Cellular and Molecular Endocrine Research Center, Research Institute For Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran, [4]Sanandaj branch, Islamic Azad University, Kurdistan, Iran, Tehran, Islamic Republic of Iran, [5]Blood Transfusion Organization, Kurdistan, Iran, Tehran, Islamic Republic of Iran, [6]Department of Molecular Medicine, Biotech Research Center, Pasteur Institute of Iran, Tehran, Iran, Tehran, Islamic Republic of Iran.

Introduction: More than 95% of beta-thalassemia mutations are point mutations in the beta-globin gene in global population. This study was performed to determine beta globin gene mutation in blood transfusion dependent patients with in Kurd ethnicity in Kurdistan province in west of Iran.
Materials and Methods: Transfusion dependent patients were enrolled into the study. Diagnosis of beta thalassemia was confirmed using patients' parents' hematologic index and Hb electrophoresis. DNA was extracted from 5 ml of patient's blood using standard salting out method. Common mutations in Kurdish population were investigated by ARMS-PCR method. Unknown cases were investigated by direct sequencing of beta globin gene. Genotype frequency and allele frequency were calculated.
Results: Sixty eight transfusion dependent beta thalassemia patients (35 male and 34 female) with mean age of 16±6.89 years old were entered in the study. IVSII-1 had most common allele frequency in 37 (27.21%) chromosomes following by Fr8-9 in 22 (16.18%), IVSI-1 in 13 (9.56%), C36/37(-T) in 11 (8.09%) and IVSI-110 in 7 (3.67%).
Conclusion: IVSII-1 and Fr8-9 were the most common mutations in beta globin gene in Iranian Kurd thalassemia patients, which is in alignment with previous studies among Kurdish population.

Results of prenatal tests in pregnancies after assisted reproductive technologies

V. Obrikyte[1]*, D. Serapinas[1,2];*

[1]Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

In vitro fertilisation (IVF) and other assisted reproductive technologies (ART) are effective treatments for infertility and are widely provided in developed countries. However recent scientific publications suggest that there is an elevated risk of major structural malformations, imprinting defects and such syndromes as Prader-Willy, Angelman, Wiedeman-Beckwith. The aim of the study was to analyse if ART are associated with increased risk of genotoxicy for chromosomal nondisjunction in meiosis. Study included analysis of 50 families that prenatally were diagnosed chromosomal anomalies (Down, Turner, Klinefelter, Edwards, Patau syndrome). And control group included 70 families with healthy children. The results of present study showed, that in chromosomal anomalies group three cases of children with chromosomal anomalies were conceived after ART. In control group all healthy children were conceived naturally (p 35 years old) and the occurrence of trisomy (p<0.05). The number of observed pathological cases is not so big to make exact conclusions, but results of present study supports hypothesis, that ART are associated with greater risk of chromosomal anomalies in conceived children.

J01.68

Associations of prenatally detected choroid plexus cysts with biochemical risk for congenital disorders

P. Bardzilauskas[1]*, D. Serapinas[1,2];*

[1]Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

Background: The choroid plexus cysts are one of the fetus ultrasonography

findings which concerns parents about their child's health. Usually cysts are found in an estimated number 1 % all performed ultrasonographies. The aim of the study to evaluate the risk of Down, Edwards syndromes and neural tube defect when choroid plexus cyst is found.
Materials and Methods: There were calculated risks of Down, Edward's syndromes and neural tube defect (NTD) by using second trimester biomarkers (alpha fetoprotein, human choriongonadotropin, free nonconjugated estriol) for patients with choroid plexus cysts. A control group was selected randomly with calculated risks and without any abnormal ultrasonography findings. These risks were compared between these two groups.
Results: 12 pregnancies with diagnosed CPC were included in this study during the year 2012. By comparing calculated risks for chromosomal abnormalities and NTD between test and control groups, we found out that there are no statistical significant difference.
Conclusion: There is no statistically significant data that choroid plexus cysts increases the risk of Down, Edwards syndromes and neural tube defect.

J01.69
Frequency of miscarriages twins

E. Ginzburg, *B. Ginzburg;*
Regional Hospital of Kaluga, Kaluga, Russian Federation.

Conducted a study to determine the frequency of twins in the structure of abortion among 968 families with miscarriage. Families with one miscarriage were 40.74 %, with 2 miscarriages 41.82 %, with 3 or more miscarriages 14.4%. Frequency of miscarriages twins was 0.88 %, which corresponds to the population frequency of 0.82 % of the Kaluga region. Comparative analysis showed that the differences are not significant at OR = 1,08 (CI- 95% 0,40:2,97). Thus, the recorded rate of reproductive loss miscarriage consisting of twins does not exceed the prevalence of twin births. This allows us to assert that the twin has no effect on the incidence of reproductive losses in the early stages of pregnancy and is comparable with the frequencies of registrable live births.

J01.70
Molecular management of 46,XX testicular DSD: About four North African cases

F. T. Dammak, *R. Louati, R. Frikha, O. Trabelsi, O. Kaabi, T. Rebai, N. B. Abdelmoula;*
Medical University, Sfax, Tunisia.

The XX male syndrome (OMIM 400045) now termed Testicular DSD (Disorder of Sexual Differentiation) is a rare genetic condition (1:20,000 to 25,000 male newborns) characterized by a spectrum of clinical presentations, ranging from ambiguous to normal male genitalia. In males without genital ambiguity, the diagnosis is often made during investigation of infertility or delayed puberty with a frequency of 0,9% among azoospermic males.
Here, we report four observations of 46,XX men detected in our genetic counselling during genetic evaluation of infertility with azoospermia, hypergonadotrophic hypogonadism and testicular hypotrophy. Chromosomal abnormality revealed by two karyotypes in different laboratories was refined by molecular investigation of SRY gene using FISH (n=2) and PCR amplification (n=2) as well as AZF loci by multiplex PCR protocol.
The prevalence of XX male syndrome among our azoospermic men serie is 0,97% (4/412). Molecular analyses demonstrated the presence of Yp SRY gene in the four patients with absence of Yq AZF loci.
Review of literature shows that SRY positive Testicular DSD is the common variety (85%) and that PCR amplification of SRY is more appropriate, than FISH, to detect a small amount of Y chromosome translocated on to the X chromosome and to detect the Y-chromosome material in mosaic forms: XX-SRY positive/XX-SRY negative. Moreover, SRY-negative cases (15%) should undergo further molecular testing to explore the presence of SOX9, SOX3 or Sox3 promoter microduplication or microdeletion, or cryptic mosaicisme for Y chromosome. Recently, RSPO1 gene seems to be implicated in Testicular DSD associated with hyperkeratosis.

J01.71
Fluorescence in situ hybridization (FISH) on interphase nuclei in the uncultured chorionic villi samples from spontaneous abortions

I. Tkach[1], *N. Huleyuk*[1], *T. Liehr*[2];
[1]*Institute of Hereditary Pathology, NAMS of Ukraine, Lviv, Ukraine,* [2]*Institut für Humangenetik Universitätsklinikum Jena, Jena, Germany.*

Background: Approximately 15% of all clinically recognized pregnancies end in spontaneous miscarriage. The most frequent cause of spontaneous miscarriage is fetal chromosome abnormalities such as autosomal trisomy, monosomy X and polyploidy. Molecular cytogenetic technique has been introduced in the genetic analysis of miscarriages in addition to the conventional karyotyping and provides new insights into this field. The present study displays frequency and spectrum of chromosomal abnormalities in embryos derived from spontaneous abortions in the western regions of Ukraine.
Methods: The study population consisted of 100 embryo tissues from women with the final diagnosis spontaneous abortions. Cytogenetic analysis was performed in the uncultured chorionic villi samples (CVS), using interphase FISH: CEP 13/21, CEP14/22, CEP22, CEP15, CEP 16, CEP17, CEP 18, CEP Y, CEP X, BACs RP11-2P5, RP11-89H21,RP11-973L24.
Results: Among the abortions the gonosomal constitution of XX prevailed (n = 58), followed by XY (n=42). Chromosomal abnormalities were found in 39 cases (39%): autosomal trisomies in 19 cases (49%), gonosomal monosomy X in 14 cases (36%), polyploidy in 6 cases (15%) (5 cases 69, XXN and 1 case 92, XXYY). Autosomal trisomies involved chromosome 14 (one case), 15 (4 cases) 16 (8 cases), 18 (3 cases), 21 (2 cases) and 22 (one case).
Conclusions: The present study demonstrates the value of FISH on CVS as an adjunct for understanding the etiology of SAs for cases in which karyotype is not available with conventional methods of cytogenetic studies. Autosomal trisomies was predominant followed by a gonosomal trisomy and polyploidy.

J01.72
A rare case of prenatal diagnosis of partial trisomy 14q co-existing 9p deletion from familiar translocation, with Arnold-Chiari malformation

A. Pedicini, *L. Cuomo, M. Ventruto, C. Ciccone, G. Spadea, C. Rosania, S. Morrone, N. De Stefano, M. Police;*
aosgmoscati, avellino, Italy.

We report a case involving a familiar translocation between chromosomes 9 and 14 resulting in an unbalanced chromosome complement, with partial monosomy 9p (9p23->pter) and trisomy 14q (14q32->qter),in prenatal diagnosis.
A 40-year-old woman, after a miscarriage, underwent amniocentesis at the 17th week of gestation because fetal ultrasound revealed spina bifida and malformations. The dosage of the alpha fetoprotein in the amniotic fluid is >360000 UI/ml
RHG banded chromosome analysis on cultured amniocytes showed additional chromosomal material on short arm of chromosome 9.
Father's karyotype was normal. Mother's karyotype showed an apparently balanced reciprocal translocation between chromosomes 9 and 14. Fluorescence in situ hybridization (FISH) using WCP and subtelomeric probe confirmed the suspect.
Mother's karyotype is 46,XX,t(9;14)(p23;q32)
Fetal karyotype is 46,XY, der(9),t(9;14)(p23;q32)mat, which results in a monosomy of part of the short arm of chromosome 9 with a concomitant trisomy of the distal portion of the long arm of chromosome 14.
Fetal autopsy revealed a fetus with: lumbosacral myelomeningocele, mycrognathia, nose insellato, clubfoot, hypertelorism, ears low-set, diaphragmatic hernia, hydrocephaly, cerebral and posterior cranial fossa malformations compatible with Arnold-Chiari II syndrome.
Cytogenetic analysis is extended to the whole family and her brother, who presents fertility defects, shows the same traslocation.
There are the features clinical of chromosome 9p deletion syndrome, and neural tube defects due at a rare partial trisomy 14q. The peculiarity of the case is to find an Arnold-Chiari malformation associated with chromosomes aberration.

J01.73
Identification of the novel mutation c.618 C > A in HSD17B3 gene in four additional Tunisian patients with 46, XY DSD and molecular confirmation of a specific founder haplotype in the Tunisian population

B. Ben Rhouma, *Neïla Belguith1-2, Fatma Abdelhedi1-2, Mouna Mnif3, Hassen Kamoun1-2, Leila Keskes1, Faiza Fakhfakh1;*
Faculty of medicine of sfax, Tunisia, Sfax, Tunisia.

HSD17B3 isoenzyme is present almost exclusively in the testes and converts delta 4 androstenedione to testosterone. Mutations in the HSD17B3 gene cause HSD17B3 deficiency and result in 46, XY Disorders of Sex Development (46, XY DSD). This study aimed to search for mutations in HSD17B3 gene in six Tunisian patients with 46, XY DSD by DNA sequencing.
Polymerase chain reaction (PCR) amplification and subsequent sequencing of all the coding exons of HSD17B3 gene were performed on genomic DNA from all the patients and some available families members and revealed the presence of the novel nonsense mutation in the exon 9 (c.618 C > A) leading to the substitution p.C206X. the mutation was present in a homozygous state in two patients and in heterozygous state in four patients. The mutation p.C206X abolished a HhaI site, this propriety was used to confirm the mutation's presence in the patients and families members and its absence in 50 controls. The mutation p.C206X was found in six patients who belonged

to different families raising the possibility of a common founder. Genotyping using microsatellite flanking the HSD17B3 gene was performed and haplotype study showed that the c.618 C > A mutation occurred in a specific founder haplotype in the Tunisian population. The identification of this founder mutation has important implications towards genetic counseling in relatives of these families and the antenatal diagnosis. Our results showed also that HSD17B3 deficiency could not be a rare etiology of 46, XY DSD in the Tunisian population.

J01.74
Prenatal diagnosis of trisomy 5 mosaicism

L. Cuomo, *A. Pedicini, M. Ventruto, C. Ciccone, G. Spadea, N. De Stefano, I. Capone, S. Raimondi, O. Masucci, A. Colucci, M. Police;*
aosgmoscati, avellino, Italy.

We report a case of prenatal diagnosis of a fetus with trisomy 5 mosaicism, a rare cytogenetic anomaly. These cases were very rare but pose a definite problem in prenatal cytogenetic diagnosis
A 37-year-old woman, after two miscarriages, underwent amniocentesis at 18 weeks of gestation because of advanced maternal age. Cytogenetic analysis revealed 26 clones with normal female karyotype and 2 clones from two culture vessels with trisomy 5.
The fetus karyotype was a mosaic: 47,XX,+5[2] / 46,XX[26].
A diagnosis of trisomy 5 mosaicism in amniocytes indicates an increased risk for fetal abnormalities, a confirmatory placental sampling may be helpful, whereas a fetal blood sampling have a very limited value.
Trisomy 5 mosaicism may be another example of tissue-limited mosaicism; then the fetal blood sampling could be falsely reassuring.
No further invasive testing was performed until 21 weeks gestation and level II ultrasound examination showed a fetus with intrauterine growth retardation (2°c), tetralogy of Fallot and hypertelorism. The rest of the fetal anatomy was within normal limits.
The couple interrupted the pregnancy.
The autopsy showed hypertelorism, saddle-backed nose. Exploration of the thoracic viscera showed heart disease complicated by characters of the tetralogy of Fallot. No further malformations were found in abdominal viscera. At the opening of the skull there was brain colliquation.

J01.75
Reduced gene expression and chromatin incorporation of histone demethylase JMJD1A in testicular biopsies of infertile men

Z. Eelaminejad[1], *M. Shahhoseini*[2], *N. Heidaryan*[1], *R. Favaedi*[2], *M. SedighiGilani*[3];
[1]*Department of Biology, Science and Research Branch, Islamic Azad university, Tehran, Islamic Republic of Iran,* [2]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran,* [3]*Department of Andrology at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran.*

Background:
Spermatogenesis is a unique process in male reproductive system, which requires precise epigenetic regulation of gene expression. JMJD1A is a critical epigenetic modifier element that highly expresses in male germ cells and activates expression of genes by demethylation of H3K9me2/me1 modification. This study aimed to evaluate the expression and chromatin incorporation of JMJD1A protein in testicular biopsies of infertile men.
Material &Method:
Ethical approval and informed patient consent was gained for the use of tissue samples. Testicular biopsies were collected from 31 infertile men referred to Royan Institute and underwent testicular sperm extraction procedure. These samples were classified into the following four subgroups: obstructive azoospermia (as positive control, n=8), severe oligoasthenoteratozoospermia (n=7), complete maturation arrest (n=8), and sertoli cell only syndrome (n=8). The expression pattern and chromatin incorporation of JMJD1A in testicular biopsies were measured by quantitative real-time PCR and chromatin-ELISA techniques, respectively.
Result(s):
Our finding revealed that the expression and chromatin incorporation of JMJD1A were significantly decreased in severe oligoasthenoteratozoospermia, complete maturation arrest, and sertoli cell only syndrome groups in comparison to obstructive azoospermia patients.
Conclusion(s):
This study indicates that JMJD1A deficiency in testis tissues can result in defective spermatogenesis in human infertile males.

J01.76
Sperm head morphology as a predictive mark of DNA fragmentation

E. Shilnikova[1,2], *M. Mazilina*[1], *I. Fedorova*[2], *A. Gzgzyan*[2];
[1]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation,* [2]*Ott's Institution of Obstetrics and Gynecology, Saint-Petersburg, Russian Federation.*

In case of teratozoospermia the most appropriate spermatozoa from those with abnormal morphology have to be chosen. It seems very important to know if there is any relationship between sperm morphology and its genome quality. The objective of this study was to investigate whether specific sperm head abnormalities predict sperm DNA fragmentation. Semen analysis was performed for 84 patients attempting IVF clinic for spermogramm and 8 sperm donors according to WHO criteria. Sperm head morphology was assessed using strict Kruger's criteria. The following sperm head forms were analyzed: normal, big, small, bulb, amorphous, round, double, with vacuoles. The terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) assay used to assess sperm DNA fragmentation. Sperm DNA fragmentation rate was significantly higher in patients than in control (0,64±0,08 vs. 0,21±0,04; p<0,05). The correlation between sperm DNA fragmentation and vacuolated sperm heads was found (r=0,32; p=0,005). The sperm DNA fragmentation was not associated with the frequency of the spermatozoa with other head abnormalities. Vacuolated sperm head should be treated as a marker of sperm DNA integrity abnormalities and might be considered a useful trait for more efficient selection of appropriate sperm used in fertilization. Supported by Carl Zeiss, RF President's scholarship and RFBR

Chromosomal pattern in 256 Indian children presented with congenital malformation and mental retardation

S. Mandal[1], *B. B. Ganguly*[1], *N. N. Kadam*[2];
[1]*MGM Centre for Genetic Research & Diagnosis, MGM Hospital, Navi Mumbai, India,* [2]*Paediatric Department, MGM Medical College, MGM Institute of Health Sciences, Navi Mumbai, India.*

Chromosomal abnormalities are reported in 1 of 150 live born and 50% of the spontaneous abortion. Chromosomal aberrations cause major alterations at molecular level resulting in rearrangement and/or deletion of nucleotides, which pose serious impact on clinical manifestation. All such aberrations are not well characterized into syndromes; however, cause malformation and mental retardation. We describe chromosomal pattern in 256 children presented with congenital malformation, growth and mental retardation. Peripheral blood samples were processed for conventional G-banding analysis. Numerical and structural abnormalities are presented in the table below. A total of 106 children (41%) were detected predominantly with Down (65%) and rarely with Edward (3%) and Patau syndrome (1%). Among sex chromosomal abnormalities, Turner syndrome (12%) was higher than Klinefelter syndrome (1%). Down syndrome and Turner syndrome were of both classic and variant pattern. One child had both trisomy 21 and XXY pattern presenting Down syndrome and Klinefelter syndrome together, which might reflect a complex growth pattern at pubertal age. Structural abnormality was detected in 18% where autosomes were involved in 14% children. Phenotypic expression of these cases was not always straightforward for diagnosis of a typical syndrome and thus, a phenotype-karyotype correlation was essential for understanding clinical management. The detail data on 256 children highlights the necessity of routine karyotyping for clinical understanding, and also for genetic counseling of parents for introducing a preventive module.

Sex		Chromosomal aberrations detected in 106 of 256 children

Association of H3K9ac and H3K9me2 modifications with impaired spermatogenesis

R. Favaedi[1], *M. Shahhoseini*[1], *M. A. Sadighi- Gilani*[2];
[1]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran,* [2]*Department of Andrology at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran.*

During post-meiotic stages of spermatogenesis, histones of sperm chromatin are replaced by transition proteins (TNPs) and protamines (PRMs). Expression of TNPs and PRMs rise at final stages of spermatogenesis to compact chromatin for normal function of sperm. Any failure of their expression is associated with impaired spermatogenesis. Epigenetic factors such as histone actyle transferases and histone demethylases are involved in regulation of these genes. Therefore evaluation of relative modifications

such as H3K9ac and H3K9me2 in regulatory regions of mentioned genes in testicular biopsies of infertile men can represent better insight into molecular mechanisms of infertility.
In this study based on spermogram and pathological features of infertile men referred to Royan institute, testes tissue samples were collected from four groups including sever oligoasthenoteratozoospermia, complete maturation arrest, sertoli cell only syndrome, and hypospermatogenesis group as positive control. Expression of TNPs and PRMs were evaluated by qRT-PCR. Also, chromatin immunopercipitation coupled with real time-PCR was performed to evaluate the incorporation of H3K9ac and H3K9me2 into regulatory regions of mentioned genes. Consent was obtained from patients according local ethical approval.
Results showed significant decrease in expression of TNP and PRM genes in all groups compared to positive control. These findings also confirmed by ChIP data revealed decreased incorporation of H3K9ac (activating mark) and increased incorporation of H3K9me2 (repression mark) into regulatory regions of above genes in all groups vs. positive control.
The finding implies significant association of histone modifications with altered expression of sperm chromatin condensing genes and impairment of spermatogenesis in male infertility.

A Prenatal Ring chromosome 13 with CIR and abnormal genitalia

M. García-Castro[1], S. Alcalá LLorente[2], F. Jiménez[2], E. Abarca Cidón[3], **L. Rodríguez**[1]*;*
[1]Laboratorio AbaCid-Genética.Grupo Hospital de Madrid,, Madrid, Spain, [2]Departamento de Obstetricia y Ginecología. Grupo HM Hospitales. Hospital Montepríncipe., Madrid, Spain, [3]Laboratorio AbaCid-Genética. Grupo Hospital de Madrid,, Madrid, Spain.

Ring chromosomes are unusual chromosomal alterations that occur in 1/50,000 human fetuses, although they have been found from nearly all human chromosomes. Mostly, they are consequence of two breakpoints in both arms, followed by fusion of the proximal ends generating a ring with loss of the distal genetic material and resulting in clinical features mimikking terminal deletion syndromes. Here we report a "de novo" prenatal male case with a ring chromosome 13 [r(13)], which was diagnosed after an amniocentesis performed because a suspicious of ambiguous genitalia and CIR (Intrauterine Growth Retardation). There was no family history of chromosomal anomalies, and the pregnancy evolution was normal with a "non-invasive prenatal DNA test on maternal blood" performed on the 13th gestational week, informed as a normal male. In the 19th gestational week an amniocentesis was performed because a suspicious of ambiguous genitalia and CIR and although the QF-PCR was informed as a normal male, the karyotype showed a r(13) and the array-CGH showed a terminal 13q deletion (chr13:104,727,326-112,193,513) involving 48 genes, including the EFNB2 gene. Deletion of the EFNB2 gene (OMIM:600527) has been already reported to be implicated in genital malformations and growth retardation, which helped in the prenatal counseling of the couple, who decided to interrupt the pregnancy.

Introduction: The relation between microdeletions in the Y chromosome and developing male infertility has been studied in several populations. The majority of published studies were designed according to the European Academy of Andrology (EAA) and European Molecular Genetics Quality Network (EMQN) guidelines for the better detection of AZF (Azoospermic factor) microdeletions. However, there are several reports indicating that using the EAA and EMQN suggested sequence-tagged site (STS) markers will result in false positive and false negative results at least in detection of AZFa microdeletions. The aim of the present study was to evaluate the accuracy of recommended STS markers for detection of AZFa microdeletion in Iranian patients with non-obstructive azoospermia.
Methods: A total of 100 Iranian non-obstructive azoospermic infertile men and 100 proven fertile men were selected for the molecular study of Y chromosome microdeletions in the AZFa region according to the EAA and EMQN guideline using sY84 and sY86 STS markers. In addition, the presence of sY176 and sY182 STS markers was investigated using multiplex polymerase chain reaction (M-PCR).
Results: Using sY84 and sY86 primers, we found only one patient who had AZFa microdeletion. However, with the use of sY176 and sY182 markers three new patients were detected with AZFa microdeletion.
Conclusion: It seems that the primers and STS markers recommended by the EAA and EMQN guidelines may not apply to all populations and it is recommended to design a population based STS panel at least for the study of AZFa region for better detection of microdeletions.

J01.81
An NGS-based test for the identification of individuals carrying recessive genetic mutations

L. Armengol[1]*, B. Rodriguez-Santiago[1], A. Abulí Vidal[2], M. Boada[3], B. Coroleu[3], A. Veiga[3], X. Estivill[2], P. N. Barri[3], L. A. Pérez-Jurado[4];*
[1]qGenomics, Ltd, Barcelona, Spain, [2]Unidad de Medicina Genómica y Personalizada, Departamento de Obstetricia, Ginecología y Reproducción, Hospital Universitario Quirón Dexeus, Barcelona, Spain, [3]Servicio de Medicina de la Reproducción, Departamento de Obstetricia, Ginecología y Reproducción, Hospital Universitario Quirón Dexeus, Barcelona, Spain, [4]Grup de Genètica. Universitat Pompeu Fabra, Barcelona, Spain.

We developed qCarrier, an NGS-based approach targeting +4000 known mutations in over 200 genes causing recessive diseases, for testing couples undergoing assisted reproductive treatments in order to reduce the odds of passing a recessive or X-linked disorder to the offspring.
In contrast to SNP-genotyping platforms, NGS technologies are not limited to detecting previously known or certain types of mutations (i.e. point mutations or small indels), and can efficiently detect a wider range of disease-causing mutations. The qCarrier is based in sequence capture, followed by high-throughput sequencing Bioinformatic analysis is keystone in the process, as it combines algorithms optimized for the identification and annotation of different types of mutations (point mutations, indels, copy-number and balanced rearrangements).
For analytical validation of the test, we obtained DNA from 57 unrelated individuals: 39 patients and 18 previously genotyped controls. The validation set was composed of 49 different known mutations, including 29 SNVs, 13 indels and 25 CNVs causing diseases such as cystic fibrosis, phenylketonuria, spinal muscular atrophy, hypothyroidism, thalassemia, or Duchenne muscular dystrophy. All but one (48/49) different mutations were correctly scored in the blinded study and only one deletion-type mutation remained undetected. This information allowed us to finely tune the algorithm to reach maximum sensitivity. All single nucleotide changes were validated and no known recessive mutations were called in the control samples.
After initial deployment in the clinical setting we assessed the presence of disease-causing recessive mutations in 52,1% of the analyzed samples (11/21).

Association between Cytochrome P450 2C19 (CYP2C19) gene polymorphism and the risk of endometriosis in Iranian population

S. Abolghasemi[1]*, F. Mashayekhi[1], A. Ebrahimi[2];*
[1]University of Guilan, Rasht, Islamic Republic of Iran, [2]Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.

The aim of current study was to investigate the association of rs11592737 (A/G) polymorphism of CYP2C19 gene with the risk of endometriosis in Iranian women. 100 patients with endometriosis and 100 controls with no laparoscopic evidence of endometriosis were included in this study. Samples were analyzed for rs11592737 (A/G) single nucleotide polymorphism (SNP) in CYP2C19 gene using Amplification Refractory Mutation System-Polymerase Chain Reaction (ARMS-PCR).Our data revealed a significant difference in the distribution of rs11592737 genotypes between endometriosis patients and controls (P=0.002). Despite GG genotype, AG Genotype was more frequent in patients than the control samples (P<0.001, OR=3.14, 95% CI 1.66-5.96). Significantly, those cases with A allele showed an increased risk of endometriosis compared to the control group (P=0.02, OR=1.63, 95%CI1.08-2.44). No significant difference in the allele frequency has been seen in the different stages of endometriosis (P value=0.59). The results of this study suggest that rs11592737 (A/G) SNP of CYP2C19 may be associated with a higher risk of endometriosis among Iranian population.

Prevalence and distribution of somatic genomic variations in placental tissues from anembryonic pregnancies

A. A. Kashevarova, *N. A. Skryabin, T. V. Nikitina, E. A. Sazhenova, I. N. Lebedev;*
Institute of Medical Genetics, Russian Academy of Medical Sciences, Tomsk, Russian Federation.

High incidence of somatic mutations is a hallmark of abnormal embryogenesis. Recent data indicate the significant impact of copy number variations (CNV) into etiology of early pregnancy loss. However mechanisms of their origin are still poorly investigated. We aimed to estimate the somatic CNV incidence in placental tissues - cytotrophoblast (CT) and (EM) from 6 anembryonic pregnancies (AP) with normal karyotype using SurePrint G3 Human CGH+SNP 4×180K Microarray Kit (Agilent Technologies). Altogether 84 CNVs were found. Twenty-four rearrangements (21 polymorphic and 3 unique, which are absent from the Database of Genomic Variants) were de-

tected in both tissues indicating their meiotic or early mitotic origin before the germ layers divergence. On the other side, 34 (including 2 unique) and 26 (including 16 unique) variations appeared to be tissue-specific for EM and CT, respectively, originating from mitotic errors after the tissues divergence. So, at least 60 (71%) CNVs appeared de novo in somatic cells and 18 (30%) of them were unique. Sixteen CNVs from 18 were deletions. Eight of these variations were larger than 1 Mb and all of them were confined to the CT (del4p12, del4q13.1-q13.2 - 2 cases, del7q21.11, del10q21.3 - 2 cases, del17q21.33-q22 - 2 cases). The most interesting potentially pathogenic affected genes were GABRG1, GABRA2, GABRA4, GABRB1 (GABA family is responsible for implantation and endometrial decidualization, dysregulation of which is associated with AP), EPHA5 (may help to organize developing body plan), and CTNNA3 (controls trophoblast invasion). This study was supported by Russian Foundation for Basic Research, grant 14-04-32047.

J01.84
Detection of MED12 exon 2 gene mutations in Iranian women with Leiomyomas

S. Sadeghi, *R. Mirfakhraie, M. D. Omrani;*
Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.

Introduction: Uterine leiomyomas are non-cancerous tumors arising from the smooth-muscle layer of the uterus that may grow as a single tumor or in clusters. Despite their benign nature, fibroids can cause a variety of health problems including, abnormal menstrual heavy bleeding, pelvic pressure and pain, pregnancy complications and reproductive problems. It has been suggested that mutations clustered in exon 2 of the MED12 gene, located on Xq13.1, are responsible for a majority of uterine leiomyomas. According to the role of ethnicity in developing fibroids, the aim of the present study was to investigate the frequency of MED12 exon 2 mutations in uterine leiomyomas of Iranian patients.
Methods: Genomic DNA was extracted from 50 fresh uterine leiomyomas tissue samples by a phenol-chloroform method. PCR-SSCP was used to detect mutations in the MED12 exon 2 and the flanking intronic regions. Fragments with altered banding patterns were sequenced on an ABI 3730XL automated DNA sequencer.
Results: Five type of MED12 gene heterozygous mutations were detected in 24 (48%) of the leiomyomas samples including, 12 (24%) missense mutations, 5 (10%) in-frame deletions, 4 (8%) single nucleotide variants affecting splicing,1 (2%) deletions/insertion-deletions spanning the intron 1-exon 2 boundary resulting in exon skipping, and 2 (4%) frame shift deletions. No mutation was detected in normal myometrial tissue.
Conclusion: Our study confirms the role of MED12 mutations in the pathogenesis of uterine leiomyomas, regardless of ethnicity. Therefore the gene could be an appropriate therapeutic target for uterine leiomyomas.

J01.85
Epigenetic analysis of regulatory region of CYP19A1 in granulosa cells of patients with polycystic ovarian syndrome

S. Ghazisaeidi[1,2], *M. Shahhoseini[2], R. Favaedi[2], L. Karimian[3], M. Shiva[4], P. Afsharian[2];*
[1]Faculty of Basic Sciences and Advanced Technologies in biology at University of Science and Culture, ACECR, Tehran, Islamic Republic of Iran, [2]Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran, [3]Department of Embryology at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran, [4]Department of Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, Tehran, Islamic Republic of Iran.

Polycystic ovarian syndrome (PCOS) is a complex genetic endocrine disorder among the women of reproductive age. Hyper-androgenemia is one of the main clinical features of PCOS. Aromatase, the key enzyme for estrogen biosynthesis, is encoded by CYP19A1 which is comprised of an unusually large regulatory region including 10 tissue-specific promoters. In human cells CYP19A1 is expressed in gonads via promoter PII.
The aim of this study is to evaluate the acetylation and methylation levels of lysine 9 of histone 3 (H3K9ac and H3K9me2), in PII promoter region of CYP19A1 in granulosa cells of PCOS patients referred to Royan Institute for in vitro fertilization (IVF).
Six women under ovulation induction treatments for IVF consisting of three PCOS patients and three controls (women without ovulation problems; non-PCOS) groups were selected. For this respect, ethical approval form was filled before any experiment. We sequenced PII of CYP19A1 to confirm no genetic variations. After ovary puncture, follicular fluid was collected and granulosa cells were extracted via Sil-Select Plus gradient. Specific histone modifications were quantified via chromatin Immunoprecipitation (ChIP) coupled with real-time PCR.
Our results clearly demonstrate that in PCOS patients, incorporation of H3K9ac in PII of CYP19A1 is significantly higher than non-PCOS patients, whereas, the level of H3K9me2 in PCOS patients is decreased compared with the control group ($p<0.05$).
For the first time our experiments suggest that epigenetic alterations via histone modification in PII promoter of CYP19A1 can play a critical role in the development of PCOS.

J01.86
Epimutation of RB1 gene promoter is accompanied by hypermethylation of repeated genome sequences in human miscarriages with aneuploidy

E. N. Tolmacheva, *S. A. Vasilyev, A. A. Kashevarova, I. N. Lebedev;*
Research Institute of Medical Genetics, Tomsk, Russian Federation.

High level of chromosomal mosaicism is observed during global epigenetic reprogramming in early human embryogenesis. Previously, we have shown a high incidence of epimutations at RB1 gene (16.4 x 10-2) in placental tissues of aneuploid embryos with mosaicism. Moreover, hypermethylation of RB1 promoter was associated with smaller size of aneuploid clone. It was suggested that epimutations of RB1 are signs of global disturbance of epigenetic landscape in aneuploid placenta. To attend this question we analyzed level of retrotransposon LINE-1 promoter DNA methylation in the extraembryonic mesoderm and the cytotrophoblast cells of embryos with complete and mosaic aneuploid karyotype with (n = 14) and without (n =20) RB1 promoter epimutation, euploid miscarriages (n = 17) and induced abortions with normal karyotype (n = 19). There were no differences of LINE-1 methylation between extraembryonic mesoderm and cytotrophoblast cells in all studied groups. DNA methylation index of LINE-1 was significantly higher in group of mosaic aneuploid embryos with RB1 epimutation (58%) in comparison with complete and mosaic aneuploid embryos without RB1 epimutation (53%), euploid miscarriages (42%), and induced abortions with normal karyotype (52.5%) ($p<0.01$). Thus, for the first time we have shown that epimutation of RB1 gene promoter is accompanied by hypermethylation of repeated genome sequences in first trimester miscarriages with aneuploidy. This study was supported by Russian Foundation for Basic Research, grant 14-04-01003.

The evaluation of adiponectin and its receptors (AdipoR1 and AdipoR2) genes expression in rat polycystic ovary syndrome models

Z. Daneshian[1], *A. Zadeh-Vakili[1], M. Zarkesh[1], F. Ramezani Tehrani[2], M. Noroozzadeh[2];*
[1]Cellular and Molecular Endocrine Research Center, Obesity Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran, [2]Reproduction Endocrinology Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran.

Background: Strong association between hypoadiponectinaemia and the occurrence of poly cystic ovary syndrome (PCOS) suggests a pathogenic role for adiponectin. We aimed to evaluate the expression of the adiponectin and its receptors (AdipoR1 and AdipoR2) genes in immature and mature PCOS rat model that were exposed prenatally to androgen excess.
Methods: Four pregnant Wistar rats in the experimental group were treated by subcutaneous injection of 5 mg free testosterone on day 20 of pregnancy while the controls (n=4) received only 500 ml of solvent. Female pups (14 cases and 18 controls) of each mother were randomly divided into 3 groups and sacrificed at 3 stages of life: day 0 (new born, n=10), day10 (10-day-old, n=10), and day 75-85(adult, n=12). RNAs were extracted from ovarian tissues and relative expression levels for adiponectin and its receptors genes were measured using TaqMan Real-Time PCR.
Results: The expression levels of investigated genes were not significantly elevated in newborns (Adiponectin: 1.119, AdipoR1: 1.594, AdipoR2:1.112 fold), while a significant decrease was detected in 10-day-old rats (Adiponectin 0.292, AdipoR1 0.26, and AdipoR2 0.161 fold ($p\leq0.05$)). We also observed a marginally significant increase in adiponectin gene expression at puberty (2.682 fold, $p=0.08$).
Conclusion: The results of this study showed that the expression of adiponectin and its receptor genes is changed in prenatally androgenized rats. These changes may alter the normal expression of steroidogenesis regulatory genes and consequently impair the normal development of ovaries and follicles.

The Role of Early Development in Intra-individual Genetic Variation of Normal Human Fetuses

M. Bazrgar[1], *H. Gourabi[1], A. Karimpour-fard[2], P. Borjian[1], M. Zamani Esteki[3], T. Voet[3], N. A. Davani[3], K. Anisi[1], M. Banai[4], Z. Kuroshli[1], B. Movaghar[4], S. Borna[5], M. R. Valojerdi[4], J. R. Vermeesch[3];*
[1]Department of Genetics at Reproductive Biomedicine Research Centre, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran, [2]Departments

of Pharmacology, School of Medicine, University of Colorado, Aurora, CO, United States, [3]Centre for Human Genetics, University Hospital Leuven, KU Leuven, Leuven, Belgium, [4]Department of Embryology at Reproductive Biomedicine Research Centre, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran, [5]Department of Gynecology and Obstetrics, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Age-related events is one of origins of midlife copy number variations (CNVs) between tissues in non-genetic diseases; however mosaicism is prevalent in preimplantation stage and misscarriages. We aim exploring fetal mosaicism and its origins in apparently normal fetuses aborted due to maternal indications.
DNAs from 22 tissues of each fetus were studied by array Comparative Genomic Hybridization (array CGH) using 195000 probe slides in simple loops separately designed for each of two studied fetuses. Reciprocal CNVs as high confidence CNVs validated by qPCR. Functional analysis was performed by Gene Ontology (GO).
About 60 CNVs was observed in each fetus. The frequency of reciprocal CNVs varied from 2 to 18. Analysis of CNVs by array CGH and qPCR showed that changes were not mostly integer multiples. Some of CNVs were shared between both fetuses, some were found in the same tissues and some in different tissues. GO showed that altered genes are mostly involved in embryonic development. Tissues clustering according to CNVs revealed those from the same embryonic origin in some cases are close together in a cluster; however, there were large disagreements with clustering of embryonic layers derivatives.
According to distribution pattern of frequent CNVs their origin should be early development, some preimplantation and some postimplantatation. CNVs with low frequency seem to be occurred in later stages. Each organ inherits CNVs with a unique pattern regarding extensive cell mixing/migration in embryonic development. Shared CNVs between fetuses are mostly known hotspots; those occurred in same tissues might have functional role.

J01.89
Prenatal detection of fetal aneuploidy on the Ion Torrent Proton Platform

T. Zwiefelhofer, *P. Whitley, K. Roy, M. Saha, T. Burcham, D. van den Boom, M. Ehrich; Sequenom Laboratories, San Diego, CA, United States.*

Noninvasive prenatal testing (NIPT) for fetal aneuploidy detection via massively parallel sequencing has been successfully implemented in a number of high throughput clinical laboratories. Automation and parallelization of the complex workflow has reduced turnaround time and labor while maintaining high sensitivity and specificity. As these developments have improved workflow issues, the availability of new sequencing platforms on the market has introduced additional flexibility in implementation. Platform flexibility should encourage competitive pricing, foster innovation and ultimately, improve patient satisfaction.
We examined the performance of the MaterniT21™ assay using the Ion Torrent™ Proton Sequencer (Life Technologies™, San Diego California). One hundred and fifty-four patient samples, including sixteen from women carrying a known trisomy 21 fetus, as determined by fetal karyotyping, were analyzed. Libraries were prepared and sequenced according to manufacturer's recommendations. Sequenced reads were aligned, filtered for quality and normalized for GC bias. Robust statistics were then applied to identify positive samples with a z-score greater than 3.
Fetal aneuploidy status was correctly determined for 154/154 pregnant females, including 16 carrying a T21 fetus. Though the current Proton workflow requires more labor than is optimal for a production environment, significant improvements in that respect are anticipated in the launch of the Ion Chef template preparation system. Sequencing time was brief at < 3 hours and data analysis consistent with standard platforms. In summary, the performance of the MaterniT21™ assay on the Ion Torrent Proton platform in this limited study suggests the possibility of its suitability for implementation in a clinical environment.

J01.90
DNA methylation and demethylation patterns in human spermatogenesis

A. A. Pendina[1,2], *I. A. Galembo*[2,3], *O. A. Efimova*[1,2], *A. V. Tikhonov*[2,1], *I. D. Fedorova*[1], *T. V. Kuznetzova*[1,2], *V. S. Baranov*[1,2];
[1]*D.O.Ott Research Institute of Obstetrics and Gynecology, St. Petersburg, Russian Federation,* [2]*St. Petersburg State University, St. Petersburg, Russian Federation,* [3]*Stem Cell Bank Pokrovski, St. Petersburg, Russian Federation.*

We studied the distribution of 5-methylcytosine (5mC) and 5-hydroxymethylcytosine (5hmC) in human spermatogenic cells from testicular biopsy and ejaculate samples. Among analyzed dividing cells several types were detected: mitotic diploid and polyploid spermatogonia and meiotic spermatocytes at the pachytene, diplotene and diakinese stages. Chromosomes were identified by QFH/AcD staining. Cytosine modifications were detected by indirect immunofluorescence.
The distribution of 5mC in mitotic chromosomes from spermatogonia was band-specific: R-bands and pericentromeric heterochromatin of chromosomes 1, 9 and 16 were enriched in 5mC. Pachytene chromosomes showed less obvious 5mC-banding, with the most intensive DNA methylation in the peritelomeric regions. Diplotene and diakinese cells demonstrated high, but almost homogeneous DNA methylation with increased intensity of signal in chiasmas and heterochromatic regions. Mature spermatozoa contained 5mC.
5hmC was completely absent in mitotic and meiotic chromosomes of spermatogenic cells. Hydroxymethylation was identified in 8.8% of post-meiotic (haploid) spermatid nuclei and in up to 13.89% of spermatozoa, suggesting that they are actively demethylated.
Thus, mitotic chromosomes from spermatogonia and meiotic chromosomes from spermatocytes demonstrate band-specific methylation patters, but lack 5hmC. The presence of 5hmC in some post-meiotic spermatids and spermatozoa suggests that genome of these cells undergoes active DNA demethylation.
Supported by RFBR, Administration of St.Petersburg, OPTEC grant and stipend from RF President.

Elucidation the chromosomal aberration impact on ovarian reserve: A retrospective clinical report

H. Kalantari[1], *A. Mohseni Meybodi*[1], *N. Almadani*[1], *T. Madani*[2], *H. Gourabi*[1];
[1]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive, Tehran, Islamic Republic of Iran,* [2]*Department of Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, Tehran, Iran, Tehran, Islamic Republic of Iran.*

Constitutional chromosome abnormalities are among the major contributors to the genetic causes of reproductive disorders. Despite all of worldwide efforts have been made so far, prognosis for mosaic X chromosome aberration below 30% of aneuploidy has yet to be established. The purpose of this study was to assess the quantity and quiddity of chromosomal aberrations that may negatively affect ovarian health causing premature ovarian failure (POF) and diminished ovarian reserve (DOR). In this purpose, retrospective observational study of clinical features and biological parameters was performed. A total of 531 individuals who were referred to our ward from 2007 to 2014 because of amenorrhea and poor responders to gonadotropins were selected. High resolution chromosome analysis by GTG banding was carried out on peripheral blood lymphocytes cultures. Supplementary tests also were performed when required. Of the 531 cases who were assessed for chromosomal defects, 52 showed abnormal karyotype. 22 cases were found to have cell lines with different level of X chromosome variation. Seven cases who were sex reverse sex determining region Y (SRY) negative, five cases with abnormal X chromosomes, three cases with structurally abnormal autosomes and four individuals carrying X-autosome translocation were diagnosed. The overall prevalence of chromosomal abnormalities was 9.8% which 2.1% of it belongs to normal variable chromosome features. The frequencies of chromosomal alterations were 5% and 1.7% in POF and DOR females, respectively. The results confirm previous observations and emphasis on the critical role of chromosome abnormalities as one of the possible etiologies for ovarian follicular attrition.

Unique case of fertility in SRY-positive female

V. B. Chernykh, *N. Y. Kuzina, L. F. Kurilo, Y. O. Kozlova, M. E. Minzhenkova, N. V. Shilova, T. V. Zolotukhina, O. P. Ryzhkova, A. L. Chukhrova, A. V. Polyakov;*
Research Centre for Medical Genetics of Russian Academy of Medical Sciences, Moscow, Russian Federation.

We report a unique case of fertility in 29-years-old female with cryptic Y chromosome mosaicism. At the birth the patient presented female genitalia with clitoral hypertrophy, which was corrected surgically. Moderate virilization of female genitalia and high level of 17-OHP allowed to diagnose of congenital adrenal hyperplasia resulting from 21-hydroxylase deficiency. DNA analysis found heterozygous CYP21B V281L mutation. From newborn to present time the patient is under the supervision and treatment by an endocrinologist. Menstrual cycle appeared at the age of 13 years after the hormonal stimulation. At the age of 23 years she married and after 4 months of unprotected sexual intercourse pregnancy appeared naturally. Pregnancy ended in a birth of a healthy boy by caesarean section at 38 months. Subsequently, the patient was observed by a gynecologist because of ovarian cysts, and surgical laparoscopy with biopsy was performed. Histolopatology of right gonad showed disgerminoma. On this occasion, the patient was aimed at cytogenetic and molecular-genetic examinations. Chromosome analysis of cultured lymphocytes showed mosaic 46,XX[47]/45,X[2]/46,XY[1]

karyotype. FISH analysis with CEPX and CEPY probes on peripheral blood lymphocytes and buccal cells confirmed complex sex chromosome mosaicism. Following cell clones were found in lymphocytes and buccal cells, respectively: 45,X (5% and 0%), 46,XX(94% and 75%), and 46,XY (1% and 25%). QF-PCR analysis, performed for chromosomes 13, 18, 21, X and Y, and multiplex PCR for 18 Yq STSs confirmed minor Y chromosome mosaicism with a presence of SRY, ZFY and AMELY loci, and not detected a chimerism and Y-microdeletions.

Angiotensin-converting enzyme (ACE) I/D and alpha-adducin (ADD1) G460W gene polymorphisms in Turkish patients with tinnitus

S. Yuce[1], E. Sancakdar[2], S. Koc[3], **G. Bagci**[4]*, H. K. Kurtulgan[4], M. M. Seker[5], I. O. Uysal[1];*
[1]Department of Otorhinolaryngology, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey, [2]Department of Biochemistry, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey, [3]Department of Otorhinolaryngology, Faculty of Medicine, Gaziosmanpasa University, Tokat, Turkey, [4]Department of Medical Genetics, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey, [5]Department of Medical Oncology, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey.

Objective: Tinnitus is the perception of experience of sound in the head or ears in the absence of external source. A number of factor influences tinnitus like hearing loss, age, noise exposure and hypertension. Angiotensin-converting enzyme (ACE) insertion/deletion (I/D) and alpha-adducin (ADD1) G460W polymorphisms have been associated to hypertension previously and this polymorphisms may be related to tinnitus. Therefore we aimed to investigate the relationship between tinnitus and angiotensin-converting enzyme (ACE) I/D and alpha-adducin (ADD1) G460W gene polymorphisms Methods: The patient group was composed of 89 individuals and the control group was composed of 104 individuals. ACE I/D polymorphism was carried out using polymerase chain reaction (PCR) method and ADD1 G460W gene polymorphism was analyzed by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) technique. Results: ACE I/D polymorphism did not show any difference between the patient group and the controls. There was a significant difference in genotype ($p<0.01$) and allele frequencies ($p=0.0212$) of ADD1 G460W gene polymorphism between patients group with tinnitus and controls. The odds ratio for the (GW) genotype was 2.56, 95% CI=(1.39-4.71) ($p<0.01$). Conclusion: Our results demonstrate for the first time an association between ADD1 G460W gene polymorphism and susceptibility to tinnitus. ADD1 G460W polymorphism may play an important role in the pathophysiology of tinnitus.

A novel mutation of SGK1 gene in central serous chorioretinopathy

M. Akyol[1]*, M. K. Erol[2], D. T. Çoban[3], A. B. Bilgin[1], E. S. Sarı[4], G. Erdoğan[1], E. B. Türkoğlu[1];*
[1]Akdeniz University, Antalya, Turkey, [2]Antalya Training and research hospital, Antalya, Turkey, [3]Gazi State Hospital, Samsun, Turkey, [4]Balikesir University, Antalya, Turkey.

Purpose: Central serous chorioretinopathy(CSCR) is a mystery characterized by leakage of fluid under the retina that has a propensity to accumulate under the central macula. SGK1 which has an important role in many epithelial ion transport system may have a role in retinal pigment epithelial pump function whose disturbance is one of the main mechanism in development of CSCR. The aim of this study is to investigate whether SGK1gene variants are associated with CSCR
Materials and methods: We enrolled patients who were diagnosed with chronicCSCR (n=32) and unrelated individuals as a control group (n=32). For DNA extraction and PCR amplification followed standard methodologies. SGK1 gene was sequenced using BigDye® Terminator v3.1chemistry.
Results: We identified a novel mutation M32V (2/32) in the patient group (6, 25 % and AF.0,031). rs1057293 (p:0,68) is located in the encoder region of the SGK 1 gene but not associated with CSCR. An intronic rs1743966 (p.028) is also, not associated. We have also identified 3 more intronic mutations; 143951C>A(1/32; AF: 0,015), 147117A>T(1/32; AF: 0,015) and 145725 del TTAC(1/32; AF: 0,015).
Discussion: M32V is located on the region of 1-60 amino acids which is necessary for localization to the mitochondria. This mutation is probably important for the energy metabolism and plays an important role in the cellular response to hyperosmotic stress and other stress stimuli. Both rs1057293(p.0,68) and rs1743966(p.0,27) are not associated with CSCR. Probably these 7 snp are promising but it's difficult to conclude the association between these intronic mutations; 143951C>A, 147117A>T, 145725del TTAC- and CSCR.

The occurrence of the rs61749246, the c.*2G>T of the FZD4 gene, in Slovak patients with retinopathy of prematurity

Z. Lasabova[1]*, K. Matasova[2], A. Stanclova[3], S. Smolarova[4,2], L. Lucanova[2], P. Lukac[5], A. Calkovska[4], M. Zibolen[2];*
[1]Comenius University in Bratislava, Jessenius Faculty of Medicine, Dept. of Molecular Biology, Martin, Slovakia, [2]Comenius University in Bratislava, Jessenius Faculty of Medicine, Clinic of Neonatology, Martin, Slovakia, [3]Comenius University in Bratislava, Jessenius Faculty of Medicine, Dept. of Pathological Anatomy, Martin, Slovakia, [4]Comenius University in Bratislava, Jessenius Faculty of Medicine, Dept. of Physiology, Martin, Slovakia, [5]Comenius University in Bratislava, Jessenius Faculty of Medicine, Clinic of Gynecology and Obstetrics, Martin, Slovakia.

Retinopathy of prematurity (ROP) is a complex disease affecting the development of retinal vasculature in premature infants. The International classification of ROP divides the development of the disorder into 5 stages. The environmental factors can influence the development of ROP, so the appropriate care may decrease its incidence. However, a genetic predisposition to ROP is suggested. Recently, mutations in genes FZD4, LRP5, TSPAN12, and NDP, were ide identified in 3 to 12% of the cases with ROP. Nowadays, our cohort consists of 11 premature newborns with different stages of ROP (stage 1 -3) treated at the Clinic of Neonatology in Martin. We performed the sequence analysis of the coding exons of the three genes - FZD4, TSPAN12 and NPD an identified rs61749246 (c.*2G>T of the FZD4 gene) in 3 patients with ROP. Two were heterozygous in stage 1, and one was homozygous in stage 2 (T allele frequency 0.18). The control group (n=50) of premature newborns without ROP contains two heterozygotes for rs61749246 (T allele frequency 0.02). The rs61749246 (MAF = 0.008 in dSNP) is the polymorphisms of the second G after the TAA stop codon of the FZD4 gene. It has been shown, that there are preferred nucleotides around the stop codon necessary for efficient translational termination. We suggest that this SNP is involved in the pathogenesis of ROP, probably based on gene expression changes during the eye development. We will enlarge our cohort focusing on higher stages of ROP and develop in-vitro translation assay for this SNP.

Case report of a patient with sensorineural hearing loss due to compound heterozygosity of 35delG and G200R mutations in gene GJB2

O. Sterna[1]*, I. Grinfelde[2], L. Volozonoka[1];*
[1]DNA department, Laboratory, University Children's Hospital, Riga, Latvia, [2]Medical Genetics Clinic, University Children's Hospital, Riga, Latvia.

Hearing loss is the most common birth defect and the most prevalent sensorineural disorder and affects about one in 1,000 neonates. More than half of prelingual deafness cases are due to genetic factors. About 70% of all hereditary hearing loss cases are classified as nonsyndromic and recessive. Mutations in the genes GJB2 and GJB6, that are located in the locus DFNB1 and encode gap junction protein connexim 26 and connexin 30, are the main cause of nonsyndromic sensorineural autosomal recessive hearing loss. DFNB1 has digenic patterns of inheritance. The 35delG mutation in gene GJB2 is the most common mutation in DFNB1 in many European populations. We describe the case of 18 months-old boy attended genetic counsellor due to profound sensorineural hearing loss. Bidirectional sequencing analysis of gene GJB2 showed two mutations: c.35delG and p.Gly200Arg. The condition of heterozygous carrier of G200R mutation was found also in mother, father found to be a heterozygous cariier of 35delG mutation. Patient with compound heterozygosity of 35delG and G200R mutations in gene GJB2 that we found has never been described before. Precise genetic diagnosis is crucial for genetic counselling.

J02.05

Detection of mutations in selected regions of genes GJB6, MT-RNR1 and MT-TS1 in Slovak population associated with non-syndromic deafness

L. Šebest[1]*, M. Vaváková[1], M. Baldovič[1], L. Kádaši[1,2];*
[1]Department of Molecular Biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia, [2]Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia.

Hearing loss represents frequent heritable disease that can be transmitted by all known types of inheritance. More than 50 genes are responsible for deafness. The gene GJB6 has high sequence and function similarity to the gene GJB2, which causes 50% of autosomal recessive non-syndromic deafness. Possibility of a bialelic heritability of these genes requires a detection of the presence of mutations in the gene GJB6. Detection of mutations that cause non-syndromic hearing loss in mitochondrial genome offers valuable information about their prevalence in Slovak deaf patients. Due to uniparental inheritance, information about frequency and occurence of these mutations is valuable for professional genetic counseling. In present study we

analyzed the coding sequence of the gene GJB6 and selected regions of genes MT-RNR1 and MT-TS1 of mitochondrial genome of 321 Slovak patients with non-syndromic hearing loss. In this group, not more than one mutation in the gene GJB2 was detected per person. In the gene GJB6 were detected three types of polymorphisms and two different frameshift mutations in heterozygote state. Also a 309 kb deletion in this gene was detected in one patient. Presence of the 309 kb deletion in the gene GJB6 was detected in Slovak population for the first time. In the gene MT-RNR1 was detected one type of pathogenic mutation (A1555G) and four types of potential pathogenic mutations. No pathogenic mutations in the gene MT-TS1 were detected.

Genetic background of hearing loss among group polish CI patients

A. Pollak[1], *U. Lechowicz*[1], *A. Podgorska*[1], *M. Mueller-Malesinska*[1], *M. Oldak*[1,2], *L. Korniszewski*[1], *H. Skarzynski*[1], *R. Ploski*[3];
[1]World Hearing Center, Institute of Physiology and Pathology of Hearing, Kajetany/Warsaw, Poland, [2]Department of Histology and Embryology, Medical University of Warsaw, Warsaw, Poland, [3]Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland.

Hearing loss (HI) is a significant medical problem in Poland and worldwide. The cause of hearing loss can be genetic or environmental. Currently the background of genetic hearing impairment is an area of intensive research conducted by many groups. Recently worldwide intensive studies are conducted to clarify the genetic basis of hearing loss. To date, more than 60 non-syndromic deafness genes and more than 1000 deafness-causing mutations have been described. The most common variants responsible for an isolated HI with recessive type of inheritance are mutations in the GJB2 gene (in particular the deletion of guanine at position 35 (35delG)) and therefore the search for genetic basis of hearing loss for diagnostic purposes usually includes only analysis of GJB2 gene, whereas mutations in each of the remaining genes associated with the process of hearing which can also cause hearing loss are not investigated.
According to the preliminary functional analysis, pathologic changes (caused by mutations of GJB2 and GJB6 genes) did not comprise spiral ganglion cells, which are crucial for the results of cochlear implantation.
The aim of our study was to estimate the prevalence of genetically related HI among patients with cochlear implants (CI). We have analyzed 1218 patients diagnosed with congenital hearing loss who received CI. Search for mutations was performed by various molecular methods. Our results shows that genetic defects of various genes are the most common reason of HI among patients with cochlear implants.

J02.07
KCNQ4 mutation spectrum in Slovak patients with non-syndromic hearing loss

K. Ottonellova[1], *M. Pecimonova*[2], *A. Soltysova*[2], *A. Ficek*[2], *L. Kadasi*[2];
[1]Faculty of Natural Sciences, Department of Molecular Biology, Bratislava, Slovakia, [2]Faculty of Natural Sciences, Department of molecular biology, Bratislava, Slovakia.

Non-syndromic deafness is one of the most common sensory impairment in humans. Most forms of non-syndromic deafness are associated with permanent hearing loss caused by damage to structures in the inner ear. The severity of hearing loss varies, can change over time and can occur at any age. The cause of non-syndromic deafness is complex, with more than hundred genes so far identified; however, some of these genes have not been fully characterized. Different mutations in the same gene can be associated with different types of hearing loss All this aspects contribute to the complexity of the disease and markedly hamper DNA diagnostics.
In this study we focused on gene KCNQ4, whose mutations lead to DFNA2, a subtype of autosomal dominant non-syndromic deafness that is characterized by progressive sensor-neural hearing loss across all frequencies. The KCNQ4 gene encodes protein called potassium voltage-gated channel KQT-like protein 4, which is part of a protein family that forms channels to transport positively charged potassium atoms between neighboring cells.
In our work we analyzed 324 NSHL patients without mutations in Gjb2 gene, which is most prevalent disease gene. Up to now we found one new deletion in gene KCNQ4 in exon 10 that causes frame shift, some pathological mutations and also several frequent polymorphisms.

J02.08
Mutational analysis of MIR184 in Iranian Keratoconus patients

A. Farzadfard[1], *E. Elahi*[1], *N. Nassiri*[2], *H. Paylakhi*[3];
[1]School of Biology, College of Sciences, University of Tehran, Tehran, Islamic Republic of Iran, [2]Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran, [3]School of Biology, Damghan University, Damghan, Islamic Republic of Iran.

Keratoconus is a noninflammatory corneal thinning disorder and the major cause of cornea transplantations in the Western countries. Despite intensive biochemical and genetic investigations, its underlying cause(s) remains poorly understood. It has been suggested that mutations in *VSX1* and *SOD1* may contribute to disease presentation in some cases. Linkage analysis in an affected Irish pedigree ultimately in 2011 led to identification of a mutation in the seed region of *MIR184* (+57C>T) as the putative cause of keratoconus in the pedigree. In a subsequent screening of 790 patients of European or Indian descent, two novel causative mutations (+3A>G, +8C>A) in *MIR184* were identified. Notably, mutations in *MIR184* have recently been reported in two pedigrees, each affected with ocular diseases that affect the cornea. MiRNA 184 is the most abundant miRNA of the cornea. Here, *MIR184* was screened in 47 unrelated Iranians affected with keratoconus by direct Sanger sequencing. Only one variant allele (+39G>T; rs41280052) was observed in one patient. The same variation has previously been observed in control and keratoconus affected individuals at similar frequencies, suggesting that it is not a cause of keratoconus. Although the sample size was small, it is evident that mutations in *MIR184* are not a common cause of keratoconus among Iranian patients. They were not observed among the 94 chromosomes of the patients screened.

J02.09
Comprehensive analysis of keratoconus genetic factors

D. M. Nowak[1,2], *J. A. Karolak*[1,2], *M. M. Kubicka*[1], *M. Gajecka*[1,2];
[1]Department of Genetics and Pharmaceutical Microbiology, Faculty of Pharmacy, Poznan University of Medical Sciences, Poznan, Poland, [2]Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland.

Keratoconus (KTCN) is a thinning and anterior protrusion of the cornea resulting in altered refractive powers, and loss of visual acuity. KTCN is a multifactorial disorder in which both environmental and genetic factors are involved. Among the environmental factors, frequent eye rubbing and contact lenses wearing are mentioned. Family form of the disease and the coexistence with other genetic disorders indicate genetic factor involvement. Genetic studies have led to the identification of several loci on different chromosomes, linked to KTCN. However, only few reports indicated causative genes in these loci. Such examples are DOCK9, and MIR184. For most of the remaining KTCN loci, single genes were analyzed. Additionally, majority of previous reports concentrated on sequences variants in exons only. This leaves a gap in the studies of KTCN genetics.
The aim of this project was to analyze the DNA sequence information available in the databases of SNVs located within known KTCN loci. Previous studies in KTCN focused on protein-coding sequences. We extended the analyzes to include miRNA genes located in analyzed loci to investigate another genetic factor toward assessment of KTCN complexity. Additionally, sequencing of mitochondrial genome in KTCN patients from Polish population was performed and the data was incorporated into genetic analysis.
The KTCN development does not depend on a single change in the gene, but on the accumulation of numerous sequence variants. The complexity of KTCN etiology causes the need to find appropriate approach to investigate this disease.

Megalocornea should be suspected in cases with hypotonia, mental retardation and macrocephaly: neuhauser syndrome an easily missed diagnosis

T. Atik[1], **S. Atik**[2], *O. Cogulu*[1], *F. Ozkinay*[1];
[1]Ege University Faculty of Medicine, Izmir, Turkey, [2]Katip Celebi University, Izmir, Turkey.

Neuhauser syndrome, also known as Megalocornea-mental retardation syndrome (MMR), is a very rare autosomal recessive disorder. It can be diagnosed via clinical features: megalocornea, developmental delay, hypotonia and some dysmorphological signs. Genetic etiology is still unknown. About 40 cases have been reported in the literature. Here we report a further MMR case. Proband is a 13 month-old girl. Because of macrocephaly, motor and mental retardation, hypotonia and facial dysmorphic features, she was referred to pediatric genetics subdivision for genetic counseling. She was the fifth child of nonconsanguineous parents from small village and born at 35 week of gestation. In the newborn period she was hospitalized for prematurity. At 9 and 11 month of age, she was rehospitalized because of feeding problems and bronchopneumonia. On admission, her weight was 6,6kg(<3centile), height 76cm(25-50centile) and head circumference 46cm(97centile). Macrocephaly, broad forehead, hypertelorism, megalocornea, strabismus, low set ears, short columella and long philtrum were present. Corneal diameters were higher than 13,5mm bilaterally and intraocular pressures were normal. Laboratory tests revealed hypogammaglobulinemia. Echocardiography showed secundum ASD (4mm). On MRI, bilateral cerebral atrophy and thin corpus callosum were observed. Karyotype and subtelomeric FISH were normal. This case is one of the few MMR cases having immunedeficiency.

The role of the vitamin D receptor signaling pathway in the development of axial myopia in children

A. N. Voitovich[1,2], *R. Bannour*[1,2], *T. S. Razorenova*[1,2], *V. I. Larionova*[1,2];
[1]*The Turner Scientific and Research Institute for Children's Orthopedics, Saint-Petersburg, Russian Federation,* [2]*Institute of Experimental Medicine, Saint-Petersburg, Russian Federation.*

The aim of this study was to investigate an association of the VDR (vitamin D receptor) A-3731G gene polymorphism with the occurrence of axial myopia in children. We examined 53 girls and 24 boys aged 4-17 yr from Russian population: 19(38 eyes) with high myopia, 44(88 eyes) with medium myopia, and 14(28 eyes) with emmetropia. The gene polymorphism was identified with PCR-RFLP. We have found a higher proportion of carriers of VDR A(-3731)allele in the medium myopia group compared to the emmetropia group (32% and 7%, respectively, OR=4,45, 95%CI 1,13-17,53, p=0,016). It is known that the variation of the A(-3731) allele frequency is significant between various populations, being the highest one in Africans (about 74%) and the lowest one in Caucasians (about 19%). The A(-3731) allele is an ancestral while the allele G(-3731) is mutant. Null hypothesis for explaining the mutant allele frequency raise in Caucasians is that this is a result of a random selection, for example, genetic drift during the period of human migration out of Africa. Alternative hypothesis is that the difference in the polymorphism variation is not random, being the result of natural selection. The latter may be true if the G(-3731) allele gives some benefits for survival outside Africa. We hypothesize that the vitamin D receptor is a key regulator of the eye growth, and G(-3731) allele gives more benefits in preventing against myopic eye growth. The increase in G(-3731) allele rates in non-African populations might be explained by changing of ultraviolet radiation intensity.

Ophthalmologic status of patients with Waardenburg syndrome

M. O. Mkheidze[1], **O. K. Yanvareva**[2];
[1]*Academy of Postgraduate Teacher Education, St.Petersburg, Russian Federation,* [2]*State University, St.Petersburg, Russian Federation.*

Waardenburg syndrome (WS) is a genetically heterogeneous syndrome characterized by pigmentary abnormalities and congenital sensorineural hearing loss. WS has been classified into 4 main phenotypes: WS1 (OMIM193500) with dystopia canthorum, WS2 (OMIM193510) without dystopia canthorum, WS3 (OMIM148820) with dystopia canthorum and upper limb abnormalities, WS4 (Waardenburg-Shah syndrome, OMIM277580), with the additional feature of Hirschsprung disease. WS1 and WS3 are both caused by mutation in the PAX3 gene. The overall incidence is 1/42,000 to 1/50,000 people. Here we report on 12 patients with WS (24 eyes, 4 boys and 8 girls aged from 4 mn to 15 yr). The period of follow-up supervision of the patients lasted from 6 mn to 15 yr. 7 patients had mothers with WS, the rest had parents without WS symptoms. Routine basic ophthalmic, pediatric and audiological observation was performed for all patients. All of them suffered from congenital sensorineural deafness. Ophthalmic status of all patients included dystopia canthorum, epicanthus, heterochromia irides. 5 patients (10 eyes) suffered from congenital ptosis, converging strabismus with surgical correction. 10 children (20 eyes) had refraction anomaly as hypermetropia and astigmatism corrected with spectacles. 2 patients (4 eyes) had refraction anomaly with nystagmus. All patients (24 eyes) had long lacrimal ducts that imitated symptoms of congenital dacryocystitis in early childhood and required to probe lacrimal ducts repeatedly. 10 patients had skin hypopigmentation. Early ophthalmic and audiological checkup and treatment were the necessary conditions for function optimization and social adaptation

A novel variation in 3'UTR of SLC26A4 gene in an Iranian family with Pendred Syndrome

R. Mozafari, *M. Babanejad, N. Nikzat, K. Kahrizi, H. Najmabadi;*
Genetics Research Center , University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran.

Background: Mutations in SLC26A4 gene that encodes pendrin is the second common cause of autosomal recessive deafness.Given that no genetic changes that lead to Pendred Syndrome (PS) in the 3'UTR region of SLC26A4 has been reported yet, here, we introduce the first data about a 3'UTR variation of SLC26A4 gene that has been segregated to PS.
Methods: Selecting pedigrees have been done with considering some clinical criteria and homozygosity mapping with flanking STR markers following conventional sequencing were performed the effect of the novel identified alteration on RNA folding was assessed using the mfold program.
Results: According to homozygosity mapping and confirmed clinical evidences such as goiter, vestibular aqueduct enlargement and positive perchlorate discharge test, we report a novel alteration in the 3'UTR of SLC26A4 gene led to PS. In addition, bioinformatics analysis showed that the introduced altered allele destabilized RNA structures; although, the Dot matrix analysis of wild-type and mutant form of selected sequence has not been showed any difference based on minimum free energy (ΔG= -21.5).
Conclusion: Our data suggest that identified variation might alter mRNA folding and it is conceivable that this new alteration can cause PS in the family under study.

J02.14

New polyurethane drug delivery system used for bevacizumab - an alternative to classic treatment of retinopathy of prematurity

R. Albulescu[1], *F. Borcan*[2], *N. Andreescu*[1], *F. Stoica*[1], *M. Puiu*[1];
[1]*"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania,* [2]*"Victor Babes" University of Medicine and Pharmacy, Faculty of Pharmacy, Timisoara, Romania.*

The retinopathy of prematurity (ROP), a multifactorial disease which is quite similar to familial exudative vitreoretinopathy, affects preterm infants with low birth weight and/or gestational age. The molecular identities of the genes which are involved in ROP remain uncertain, although the evidence for a genetic component of this disease is strong. Bevacizumab, known as Avastin, is an angiogenesis inhibitor who belongs to the class of monoclonal antibodies and it is considered as a possible treatment for patients diagnosed with cancers because it binds selectively to VEGF; some researchers have noticed impressive results in the field of severe ROP by testing it as an alternative remedy to the diode laser photocoagulation (the treatment of choice). The obtaining and characterization of eye drops based on polyurethane microparticles used as a drug delivery system for bevacizumab were the main aims of this research. The microparticles were synthesized using a polyaddition process coupled with a spontaneous emulsification. The microparticles' solutions were characterized by pH, size, and stability measurements; their irritation potential was evaluated on the mice skin by non-invasive techniques (tewametry, mexametry, and corneometry). A drug release study was performed by monitoring the degradation of these polyurethane microparticles for three weeks in two different media: simulated body fluid (SBF) and phosphate buffered saline (PBS); the influence of ultrasounds on the degradation of polyurethane microparticles was also evaluated. The results suggests the obtaining of a non-irritating material, with good stability, which presents a very slow degradation, beneficial for drugs which require low release rates.

J02.15

A report on a 4q25 deletion upstream of PITX2 in a child with unilateral Rieger syndrome

S. Scheidecker[1,2], *V. Pelletier*[1], *V. Kremer*[2], *C. Speeg-Schatz*[3], *N. Calmels*[4], *P. Calvas*[5], *H. Dollfus*[1];
[1]*CARGO (Centre de référence national pour les Affections Rares en Génétique Ophtalmologique), Hôpitaux Universitaires de Strasbourg, Strasbourg, France,* [2]*Service de cytogénétique, Hôpitaux Universitaires de Strasbourg, Strasbourg, France,* [3]*Service d'Ophtalmologie, Hôpitaux Universitaires de Strasbourg, Strasbourg, France,* [4]*Laboratoire de diagnostic génétique, Hôpitaux Universitaires de Strasbourg, Strasbourg, France,* [5]*Labratoire de génétique moléculaire, Hôpitaux de Toulouse, Toulouse, France.*

Rieger syndrome (RS) is a rare autosomal dominant disorder characterized by specific ocular, dental and umbilical anomalies. Mutations in *PITX2* and *FOXC1* genes explain about 50% of RS. Deletions of coding exons and chromosomal translocations and more recently a deletion of an upstream regulatory region of *PITX2* have been described. Our case is a girl aged 13 months who was referred in our Center for Rare Genetic Ophthalmologic Diseases (CARGO) because of unilateral eye anomalies and umbilical malformations, suggesting RS. The examination revealed posterior embryotoxon, irido-corneal adhesions and pupillary anomaly on the right eye. She had redundant periumbilical skin as well as anal anteposition. Sanger sequencing of *PITX2* and *FOXC1* was normal. CGHarray analysis revealed a de novo 4q25 deletion upstream of *PITX2*. The deletion involved the upstream non coding region of *PITX2*, similar to two previously reported RS patients (Volkmann et al. 2011, Reis et al. 2012). The conserved non coding elements upstream the gene were showed to be involved in regulation of pitx2/PITX2 expression in a zebrafish model (Volkmann et al. 2011). Disease-causing mutations outside the coding regions have been reported in other diseases, such as deletions of the downstream regulatory region of *PAX6* in aniridia (Lauderdale et al. 2000). The identification of this additional case highlights the importance of the loss of the upstream regulatory region in this disease and the importance of screening for this type of deletion in RS patients optimizing genetic counseling for this family.

J02.16

A novel mutation of the USH2C (GPR98) gene in an Iranian family with Usher syndrome Type II

N. Bazazzadegan, *K. Kahrizi, L. Jamali, N. Nikzat, A. Kashef, H. Najmabadi;*
Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran.

Objective: Usher syndrome (USH) is an autosomal recessive disorder illustrated with retinitis pigmentosa (RP) and sensorineural hearing loss with or without variable vestibular dysfunction. USH is genetically and clinically heterogeneous. At least fifteen loci and eleven genes identified in USH. Usher syndrome is divided into three subtype: type I (USH1); type II (USH2); and type III (USH3). USH2 is the most common form of Usher syndrome, responsible for moderate to severe hearing deficits, retinitis pigmentosa started around or after puberty associated with normal vestibular responses. Three loci associated with USH2 have been reported: USH2A (*USH2A*), USH2C (*GPR98*), and USH2D (*WHRN*). Defects in *GPR98* are the cause of Usher syndrome type 2C (USH2C). Here, we report on a consanguineous Iranian family with two affected individuals for whom we identified a novel mutation in *GPR98* (*VLGRI*) gene. **Methods:** After performing homozygosity mapping using microsatellite (STR) markers,we approached whole exome sequencing (WES) to detect the disease-causing mutation of homozygous regions. To confirm the identified homozygote variant in *GPR98*, sanger sequencing has performed in all family members. Consequently we sequenced 100 normal control to ensure detected variant would not be a polymorphism. **Results:** We identified a new mutation in *GPR98* segregating with USH2C in this family. The missense mutation c.10019T>G leading to p.Val3340Gly. **Conclusion:**This mutation is the second one, which has been reported for USH2C in Iranian population by our group. To the best of our knowledge, this is the first report of a genetically confirmed case of USH2C using WES in Iran.

The analysis of the GJA3 gene in patients with hereditary congenital cataract from Bashkortostan Republic (Russia)

I. I. Khidiyatova[1], *I. M. Khidiyatova*[1], *L. U. Dzhemileva*[1], *S. R. Avkhadeeva*[2], *M. T. Aznabaev*[2], *E. K. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ministry of Health and Social Development of the Russian Federation, Ufa, Russian Federation.*

Introduction: Cataracts are one of the leading causes of blindness in humans, and mutations in the connexin 46 (GJA3) and the connexin 50 (GJA8) genes cause congenital cataract. Different mutations in these genes lead to the development of distinct cataract phenotypes. The aim of the study was to analyze the GJA3 gene in patients from Bashkortostan Republic affected with congenital cataract.
Objective: DNA samples of 40 unrelated patients with isolated form of hereditary congenital cataract from Bashkortostan Republic were analyzed.
Methodology: The analysis was performed by direct sequencing of coding regions of the GJA3 gene.
Results: Three different nucleotide alterations were detected. In one patient of Tatar ethnic origin with zonular form of cataract the deletion c.del1126_1139 was detected; one patient of Tatar ethnic origin with zonular cataract and microcornea carried the missense mutation c. 398 G>A (p.Arg133Gln). Both alterations were found in the heterozygous state, hadn't been described in literature earlier, and presumably are functionally significant mutations. In one patient new nucleotide substitution c.231C>T (Phe77Phe) in the heterozygous state was found.
Conclusion: Thus, three previously undescribed structural changes in the gene GJA3 were detected in hereditary congenital cataract patients from Bashkortostan Republic. To determine their functional significance further investigation are required. The study was supported by RFBR grant (14-04-97007_r_povolgie_a).

J02.18

Mutation screening in autosomal dominant retinitis pigmentosa family using targeted next generation sequencing

K. Kamenarova[1,2], *K. Koev*[3,4], *C. Chakarova*[5], *R. Tzveova*[1,2], *D. Dacheva*[1,2], *V. Mitev*[1,2], *S. Bhattacharya*[5], *S. Cherninkova*[6], *R. Kaneva*[1,2];
[1]*Molecular Medicine Centre, Medical University - Sofia, Sofia, Bulgaria,* [2]*Department of Medical Chemistry and Biochemistry, Medical Faculty, Medical University -Sofia, Sofia, Bulgaria,* [3]*Clinical Centre of Emergency Medicine, Medical University-Sofia, Sofia, Bulgaria,* [4]*Department of Ophthalmology, University Alexandrovska Hospital, Sofia, Bulgaria,* [5]*Department of Genetics, Institute of Ophthalmology, UCL, London, United Kingdom,* [6]*Department of Neurology, University Alexandrovska Hospital, Sofia, Bulgaria.*

Background: Retinitis pigmentosa (RP) is a clinically and genetically heterogeneous disorder with an incidence of 1 in 3,500, or a total of 1.8 million people affected worldwide. So far at least 55 genes (RetNet) are known to be involved in the pathology among which 23 genes have been implicated in autosomal dominant RP (adRP). By using next generation sequencing (NGS) in combination with bioinformatic analysis, we aimed to identify the disease causing mutation in a large adRP-family of Gypsy origin.
Methods: Targeted NGS of 4,813 genes associated with known clinical phenotypes was performed on APEX-negative adRP-patient using the TruSightOne Sequencing Panel and MiSeq system of Illumina. Illumina VariantStudio software was used to filter single nucleotide variants (SNVs) and insertions/deletions (indels).
Results: We identified 9,330 SNVs and indels and after applying filtering criteria the numbers of remaining variants (in parentheses) were as follows: (i) exclude homozygous changes (5,857); (ii) exclude minor variant frequency <10% (5,846); (iii) keep nonsynonymous changes and splice variants (2,666); (iv) keep if same variant presents in <1% of the general population (608); (v) exclude dbSNP with minor allele frequency >1% (574); (vi) exclude if allele is present in at least one of 6,500 individuals of the Exome Variant Server database (527); (vii) disease phenotype consistent with autosomal dominant retinal degeneration (11). Additional exclusion criteria including lack of segregation of the mutant allele within the affected family members will be applied.
Conclusion: Our results suggest that new adRP-locus exists since no pathogenic changes were found in known adRP-genes.

J02.19

Deciphering the Genetic basis of Hearing Impairment in Iran; an Ethnic based Survey

M. R. Noori-Daloii[1], **F. Alizadeh**[1], *N. Jalilian*[1], *M. A. Tabatabaiefar*[2], *L. Kialashaki*[1], *A. Ahmadi-Shadmehri*[3];
[1]*Departmetn of Medical Genetics,School of Medicine,Tehran Univ. of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Cellular and Molecular Research Center, School of Medicine, Shahrekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran,* [3]*Center for genetic counseling, welfare and rehabilitation Organization, Birjand, Islamic Republic of Iran.*

Hearing loss is the most common sensory disorder worldwide which affects 1 of every 500 newborns. At least 50% of cases can be attributed to genetics, most often resulting in nonsyndromic deafness (70%), which is usually autosomal recessive (80%). Despite the heterogeinity, mutations in *GJB2* at DFNB1 locus are the major cause of autosomal recessive nonsyndromic hearing loss (ARNSHL) in many populations, including Iran (20%). The fact that many loci are involved together with the heterogeneity of the status, necessitate studying further loci in various Iranian ethnic groups. In this study, after mutation screening of *GJB2* and *GJB6*, we used homozygosity mapping to identify regions of autozygosity-by-descent in 23 large pedigrees all originating from a single province of Iran (South Khorasan), using STR markers for STR markers for 7 loci.
In our study, four out of the 23 families showed *GJB2* mutations. Interestingly heterogeinity within a family were observed, even in large consanguineous pedigrees. *GJB6* deletions were not detected. One family showed linkage to DFNB3 and one family showed to be linked to DFNB7/11. The remaining did not show linkage to the studied loci.
Our results once again emphasize the heterogeneity of HL among different Iranian ethnic groups .These results could provide further insight into the etiology of HL and may lead to better genetic diagnostics & counseling.

J02.20

Targeted next-generation sequencing for identification of ABCA4 gene mutations in Polish patients with retinal dystrophies

A. Ścieżyńska, *M. Ołdak, A. M. Ambroziak, M. Korwin, R. Płoski, J. P. Szaflik, J. Szaflik;*
Medical University of Warsaw, Warsaw, Poland.

The ABCA4 gene is one of the most important genes of the human retina. It encodes an ATP binding cassette (ABC) transporter that is expressed almost exclusively in the retina. Mutations in the ABCA4 gene cause a wide range of retinal degenerations. Due to the advent of therapeutic options, identification of a genetic cause of retinal diseases is becoming increasingly important. The aim of the project was to implement next-generation sequencing (NGS) for identification of ABCA4 gene mutations in a group of Polish patients with Stargardt disease, fundus flavimaculatus or cone-rod dystrophy. Genomic DNA isolated from peripheral blood of 58 patients served as a template. The introduced variant of NGS is based on the preparation of an amplicon library containing all coding sequences of the ABCA4 gene (50 exons). Next, the amplicons were sequenced using the genomic sequencer GS Junior System (Roche). Presence of allelic variants identified by NGS was confirmed by Sanger DNA Sequencing. To predict possible functional consequences of the identified missense variants, two different computational methods, i.e. SIFT and PolyPhen-2 were used. In the studied group of patients, 32 different known mutations and 20 different novel potentially pathogenic variants were found. Our study enabled identification of a genetic cause of retinal di-

sease in 88% of patients. Three patients (5%) did not carry any mutation in the ABCA4 gene and in four patients (7%) only one mutation was found. Patients with an unknown cause of the retinal disease will be examined using whole genome sequencing.

J03.01

Predictive value of alpha-1 antitrypsin level for Z mutation detection in chronic obstructive pulmonary disease

D. Serapinas[1,2], **R. Sakalauskas**[1];
[1]Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

Alpha1-antitrypsin (AAT) deficiency is an under-diagnosed condition in patients with chronic obstructive pulmonary disease (COPD). The aim of our study was to evaluate predictive value of quantitative methods of alpha1-antitrypsin for Z mutation detection in patients with chronic obstructive pulmonary disease. Ninety-one AAT deficiency genotypes (40 MZ, 39 MS, 1 SS, 3 SZ and 8 ZZ) were analysed. Calculated sensitivity of quantitative alpha-1 antitrypsin measurement by nephelometry for heterozygous PI*Z allele was 45% and for homozygous ZZ genotype - 88%. Specificity of quantitative alpha-1 antitrypsin analysis for heterozygous deficiency was 98% and for homozygous deficiency - 100%. Thus sensitivity of quantitative alpha-1 antitrypsin analysis is higher than specificity for both - heterozygous and homozygous deficiency.
The results of the present study support the general concept of targeted screening for AAT deficiency with adequate laboratory methods in European countries with PI*Z high frequency and large population of COPD patients with highest diagnostic value - AAT genotyping. A case detection programme of alpha-1 antitrypsin deficiency in patients with chronic obstructive pulmonary disease using quantitative methods could be used only in screening programs and exact diagnosis must be confirmed by determining AAT genotype.

J03.02

Identification of a novel missense COL4A5 mutation in Russian family with X- linked Alport syndrome by next Generation sequencing

D. Shentseva, *O. Groznova, A. Polyakova, V. Sukhorukov, N. Karahan, N. Konkova, V. Dlin, L. Shagam;*
The Russian National Research Medical University named after N. I. Pirogov, Moscow, Russian Federation.

Alport syndrome (AS) is a genetically determined glomerulopathy that is caused by mutations in type IV alpha collagen chain genes COL43, COL44 or COL45 and clinically characterized by hematuria, proteinuria and end-stage kidney disease (ESRD). The syndrome is often combined with sensorineural hearing loss and ocular pathology.
The coding exons and splice sites of the abovementioned genes were sequenced in four patients and two healthy controls from the family on Ion Torrent platform. Here we describe a novel dominant missense mutation c.G3098A, p.1033 G>D in the collagen type IV alpha-5 gene (COL4A5) that is present in all family members affected. The patients are characterized by early-onset hematuria, proteinuria (before 1 year of age), sensorineural hearing loss and the early age of ESRD onset. Neither of them demonstrates any ocular abnormalities.

J03.03

Mr. Lev Shagam

L. I. Shagam, *A. V. Polyakova, D. V. Shentseva, O. S. Groznova, V. V. Dlin, N. N. Konkova, V. S. Sukhorukov;*
Pediatric Clinical Research Institute of Pirogov Russian National Research Medical University, Moscow, Russian Federation.

Alport syndrome comprises ~3% of chronic kidney disease cases with estimated frequency of 0.02% in human population. It is a genetically determined glomerulopathy caused by mutations in genes encoding the alpha chains of type IV collagen. The protein protomers are most prevalent component of glomerular basement membrane (GBM). Among them, collagen α3α4α5 protomer is the most frequent in a mature GBM, its components being encoded by COL4A3, COL4A4 and COL4A5 genes. About 85% of all examined patients with Alport syndrome bear COL4A5 mutations (this type of nephritis is X-linked and dominant), whereas the remaining 15% demonstrate COL4A3 or COL4A4 mutations (autosomal form, usually recessive).
Genetic test is known to be the only direct diagnostic approach for Alport syndrome. Here we discuss the research and diagnostic prospects for the CDS sequencing of collagen type IV genes based on multiplex PCR followed by next generation sequencing on Ion Torrent platform. We designed a panel that covers 98% of the CDS with 5 bases of padding around targeted coding exons. This approach allowed us to identify both previously described and novel (including missense and frameshift) mutations that cause Alport syndrome in Russian population.
The problem of pathogenicity assessment and distinguishing between polymorphic variants vs malignant mutations is discussed. Different approaches exist including online prediction tools (e.g., PolyPhen, SIFT) and databases (pubmed, HGMD, LOVD, ClinVar etc.). We compare those tools for variant classification in Alport syndrome and other pathologies.

J03.04

Gene variant rs2305480 C>T in gasdermin B gene (GSDMB) and the risk of recurrent wheezing and asthma in Bulgarian infants

S. Mileva[1], *N. Yaneva[2], S. Andonova[2], M. Qnkova[1], I. Galeva[1], A. Savov[2];*
[1]Pediatric department, Alexandrovska hospital, Medical university- Sofia, Sofia, Bulgaria, [2]National Genetic Laboratory, Medical University-Sofia, Sofia, Bulgaria.

Objective: The gasdermin B (GSDMB) gene is located at 17q21.2 and recent reports suggest that GSDMB is associated with childhood asthma in several populations. We investigated the association of a SNP in GSDMB (rs2305480C>T) with recurrent wheezing, severity of bronchial obstruction and family history of asthma and allergy.
Materials and Methods: Family history of asthma and allergy, recurrent wheezing and atopy were assessed in 93 infants admitted to the hospital for bronchiolitis. All children were genotyped for rs2305480C>T by PCR RFLP analysis. The presence of AvaII restriction site was indicated by C-allele and the absence - by T-allele.
Results: Data were analyzed as a recessive genetic model. Genotype frequencies did not deviate significantly from expected under the Hardy-Weinberg Equilibrium - T/T genotype was 18%, C/T - 47% and C/C - 35%. Our data show that the genotype T/T is a possible risk factor for recurrent wheezing (OR 3,68, 95%, CI= 0,98-13,76). Children homozygous for T-allele are more likely to have a family history of allergy and asthma (OR 5,41, 95%, CI= 1,43-20,47) and early age of first wheezing - 6,88 mo compared to 10,4 mo for C/C, p= 0,02.
Conclusions: Our results support the role of GSDMB SNP (rs2305480C>T) for determining asthma phenotypes in preschool children. The study was financially supported by research grant (2013), Medical University - Sofia

J03.05

Novel deletion in AVPR2 gene causing complete nephrogenic DI

S. Cho[1], *C. Lam[2], S. Tong[2];*
[1]Kyung Hee University, Seoul, Korea, Republic of, [2]The University of Hong Kong, Hong Kong, Hong Kong.

Background: Nephrogenic diabetes insipidus (NDI) is characterized by the inability of urine concentration leading to a high risk of dehydration. In this study, we report a novel deletion in *AVPR2* gene causing complete NDI confirmed by microarray analysis. **Methods:** A male patient was admitted to due to polydipsia and polyuria. NDI was suspected and molecular studies were performed to investigate these clinical problems. **Results:** Sequencing result showed a total deletion (11535 bp) in *APVR2* gene (NG_009645.2:g.5303_16835del) on X chromosome accompanying 7-bp microhomology at the breakpoint. Following microarray analysis reconfirmed this complete deletion of *APVR2* preserving *LCAM1* and *ARHGAP4* gene. **Conclusions:** With sequencing and microarray analysis, we found the novel deletion in *AVPR2* causing complete NDI. As shown in this study, molecular diagnosis has several advantages compared with conventional in vivo test. First, patients unable to conserve water may become critically dehydrated in water deprivation test. There are several contraindications of this test, especially in other causes of polydipsia and polyuria such as DM, hypoadrenalism, or CRF. Second, molecular studies can give more detailed information that cannot be provided by conventional tests. In this patient, the sole deletion of *APVR2* preserving *LCAM1* and *ARHGAP4* meant NDI excluding central type. In addition, since *APVR2* is completely deleted, it can only be complete NDI, not partial type. Therefore, this study suggests that genetic testing is a safer and more useful laboratory tool than the physiologic test in diagnosing and subtyping NDI.

J03.06

Reversibility of bronchiectasis: case report of Kartagener's syndrome

D. Serapinas[1,2], **J. Jackutė**[3];
[1]Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania, [3]Department of Pulmonology and Imunology, Lithuanian university of health sciences, Kaunas, Lithuania.

Kartagener's syndrome is an autosomal recessive disorder primarily manifesting as ciliary movement disorder. Kartagener's syndrome is part of the larger group of disorders referred to as primary ciliary dyskinesias (PCD). Although the condition is usually inherited in an autosomal recessive pattern, and some specific gene defects have been recognized, it is clear that

the syndrome shows substantial genetic heterogeneity. The incidence of this genetic disorder is estimated to be between 1 and 2 per 30 000 births. Symptoms result from defective cilia motility in the airways. The recurrent pulmonary infections are caused by the grossly impaired mucociliary transport in the respiratory tract causing stasis of the mucus within the bronchi. Progressive and significant lung damage occurs up to the time of diagnosis. Although the management of patients with Kartagener's syndrome remains uncertain and evidence is limited, it is important to follow up these patients with an adequate and shared care system. This report presents a clinical case of Kartagener's syndrome in a 25-year-old woman. Computed tomography showed dextrocardia and bronchiectasis. After 7 years, good treatment results were achieved: radiological findings and lung function were improved. The present clinical case demonstrated reversibility of bronchiectasis even in congenital Kartagener's syndrome, thus indicating, that bronchiectasis progression is a complex interrelationship among genetic variation and a proper nonspecific management.

J03.07
The role of HLA typing for celiac disease diagnosis among children with autoimmune disorders

O. N. Belei[1], *O. Marginean*[1], *L. Olariu*[1], *M. Pop*[2], *M. Puiu*[3];
[1]*First Pediatric Clinic, University of Medicine and Pharmacy "Victor Babes" Timisoara, Romania, Timisoara, Romania,* [2]*Third Pediatric Clinic, University of Medicine and Pharmacy "Victor Babes" Timisoara, Romania, Timisoara, Romania,* [3]*Genetic Department, University of Medicine and Pharmacy "Victor Babes" Timisoara, Romania, Timisoara, Romania.*

Background:The association of celiac disease (CD) with several autoimmune conditions is well-known.Objectives:To determine the prevalence of CD among children with autoimmune thyroid disorders(AITD) and insulin-depended diabetes mellitus(IDDM) and to asses the diagnostic role of HLA typing among this patients.Methods:74 children with AITD(lot 1), 98 children with IDDM(lot 2) and 80 healthy children were screened for CD.In patients with at least one positive serologic test for CD, intestinal biopsy was performed.All children underwent HLA typing for DQ2/DQ8.Results:CD prevalence in lot 1 was 7%, in lot 2 was 6% and in control lot was 0%.All children diagnosed with CD presented DQ2/DQ8 haplotype.20% of the control subjects associated heterozygous DQ2 alleles.From 69 children with AITD/without CD,3 patients (4%) presented heterozygous DQ2 alleles.From 92 children with IDDM/without CD, 25 patients (27%) associated homo or heterozygous DQ2/DQ8alleles.There were significantly more cases with IDDM withoutCD but with predisposing haplotype for CD(27%) compared to the number of patients with AITD seronegative for CD and with DQ2/DQ8 alleles(4%) p<0,005.Conclusions: Recommending AITD and IDDM as selection parameters for CD screening in asymptomatic children is justified. HLA assessment cannot highlight a significant role of a certain allele in the pathogenesis of autoimmune comorbidity AITD/CD or IDDM/CD. DQ2 and DQ8 alleles are mandatory but insufficient for CD development.The intervention of environmental factors is very important.Performing as first line approaching HLA typing in asymptomatic at risk children is important.A negative result for DQ2/DQ8 alleles will render CD highly improbable and there will be no need for subsequent CD antibodies testing in such cases.

J03.08
NPHS2 and WT1 mutations in a romanian children Population with nephrotic syndrome

C. Duicu, *V. Moldovan, F. Tripon, A. Crauciuc, C. Banescu;*
University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.

Mutations in NPHS2 and WT1 genes are a frequent cause of steroid resistant nephritic syndrome (SRNS) and occur in 10-28% of children while mutations are absent from children with steroid-sensitive nephrotic syndrome (SSNS). The frequency and spectrum of mutations in these genes is unknown for the romanian population. **Material and methods** This study comprised 42 pediatric patients with NS. 50 healthy children were enrolled as a control group. NPHS2 R229Q polymorphisms were determined by the PCR and RFLP technique utilizing specific primers. Mutation analysis was performed in WT1 genes, in case of abnormality the corresponding sample was sequenced. **Results** In NS group 85.71% were SSNS and 14.29% were SRNS. Mutation of NPHS2 R229Q gene, was found just in two patients with congenital NS.Screening of WT1 gene showed one heterozygous mutation in the donor splice-site of intron 9:c.1228+5 G>A in one SRNS girl with normal karyotype. **Conclusion** The incidence of NPHS2 mutations in romanian children with NS is considerably lower than that among European childern (10-30%). WT1 mutation was present in girl with focal segmental glomerulosclerosis. Therefore screening of WT1 gene in all females with FSGS is necessary. Because NPHS2 R229Q gene mutation was found in all cases of CNS, a screening of this gene in children with CNS in the adjacent counties is required. Further studies with a larger number of patients are needed.

Acknowledgements This work was funded by Internal Research Grants of the University of Medicine and Pharmacy Tîrgu Mureş, Romania, contract no29/11.12.2013.

The Polymorphisms in the IREB2, CHRNA5, CHRNA3, FAM13A and HHIP Genes and Risk of Chronic Obstructive Pulmonary Disease in Russian Population

G. Korytina[1], *L. Akhmadishina*[1], *T. Victorova*[1], *J. Burdyk*[2], *S. Zagidullin*[2];
[1]*Institute biochemistry and genetics, Ufa, Russian Federation,* [2]*Bashkir Medical State University, Ufa, Russian Federation.*

Chronic obstructive pulmonary disease (COPD) is a multifactorial inflammatory disease primarily affecting distal respiratory pathways and lung parenchyma.
Genome-wide association studies have iden¬tified genetic variants influencing the risk of COPD. The aim of this study was to investigate whether IREB2, CHRNA5, CHRNA3, FAM13A and HHIP polymorphisms would be associated with COPD susceptibility in Russian populations.
Methods: six single nucleotide polymorphisms: rs13180 (IREB2), rs16969968 (CHRNA5), rs1051730, rs6495309 (CHRNA3), rs7671167 (FAM13A), rs13118928 (HHIP) were genotyped in a case-control study (511 COPD patients and 508 controls from Russia). To estimate the strength of association, odds ratios were calculated and potential confounding variables were tested by using logistic regression analysis.
Results: Statistical analysis revealed that SNP rs13180 (IREB2) was associated with COPD (P= 0.0004). Analysis showed an association of rs16969968 (CHRNA5) (P=0.0034) and rs1051730 (CHRNA3) (P=0.0015) in additive model and the A-A-G haplotype of rs16969968 (CHRNA5), rs1051730, rs6495309 (CHRNA3) genes polymorphisms (P= 0.0078) with COPD. The relationship between the rs13118928 (HHIP) (P=0.0017 for AG genotype) and COPD risk was found. Significant association with sever COPD were observed for rs13180 (P=0.0009), rs16969968 (P=0.0071), rs1051730 (P=0.0013), rs13118928 (P=0.003) polymorphisms. Early onset COPD (before 40 yrs) were associated with rs13180 (P=0.000001), rs16969968 (P=0.0001), rs1051730 (P=0.0004). The SNP rs13118928 near HHIP locus was significantly associated with pack-years of smoking in COPD patients (P= 0.029). We demonstrated that rs13180, rs13118928 and rs16969968 polymorphisms were associated with COPD only in smoking subjects.
We confirmed that SNPs the IREB2, CHRNA5, CHRNA3 and HHIP loci were associated COPD in Russian Population.

J03.10
MTHFR polymorphysms role in diabetic neuropathy

M. Balasar[1], *M. Çakır*[2], *M. S. Yıldırım*[1];
[1]*Necmettin Erbakan University Medical Faculty, Department of Medical Genetics, Konya, Turkey,* [2]*2Necmettin Erbakan University, Faculty of Medicine, Department of Endocrinology and Metabolism, Konya, Turkey.*

Diabetes Mellitus (DM), the most important public health problem of the 21th century, leads to significant mortality and morbidity due to underlying complications. C677T and A1298C polymorphysisms of MTHFR gene elevates plasma homocysteine levels, reduces plasma folic acid levels, and converts gene expression by altering methylation status in genome. These effects enable the MTHFR gene to be associated with multiple diseases such as cardiovascular diseases, cancers, and schizophrenia.
The present study looked for a possible association between C677T and A1298C polymorphysisms of the MTHFR gene in diabetic neuropathy development in diabetic patients and healthy volunteers. Thus a study group consisting of 103 diabetic peripheral neuropathy patients diagnosed via electrophysiological examination (ENMG) and a control group of 100 healthy was formed. C677T and A1298C polymorphysisms of MTHFR in the DNA samples were analyzed by pyrosequencing. MTHFR C677T genotype distribution was in study group CC: %43.7, CT: %42.7, TT: %13.6, and in the control group CC: %45.0, CT: 47.0, TT: %8.0 (p>0.05), MTHFR A1298C genotype distribution was in study group AA: %33.0, AC: %46.6, CC: %20.4 and in the control group AA: %43.0, AC: %44.0, CC: %13.0 (p>0.05). χ^2 test was used for statistical analysis and in the study group, the ratio of 2 or more mutant allele was found to be significantly higher compared to the control group (p=0.010). The data obtained from this study supports the view that the increase in the number of mutant alleles in MTHFR gene can increase diabetic neuropathy susceptibility in patients with diabetes.

J03.11
A novel (Q97R) MEFV gene mutation in a Turkish FMF patient

H. Kucuk Kurtulgan[1], *G. Bagci*[1], *M. E. Yildirim*[1], *O. Ozdemir*[2];
[1]*Cumhuriyet University, Faculty of Medicine, Department of Medical Genetics, Sivas, Turkey,* [2]*Çanakkale Onsekiz Mart University, Faculty of Medicine, Department of Medical Genetics, Çanakkale, Turkey.*

Familial Mediterranean fever (FMF) is an autosomal recessive autoinflammatory disease and characterised by episodic fever, serositis, arthritis, abdominal and pleuritic pain. FMF predominantly affects populations surrounding the Mediterranean basin including Armenians, Sephardic Jews, Arabs, Turks, Greeks and Italians. The MEFV gene mutations have been detected in the majority of FMF patients. MEFV gene is located on (16p13.3) comprises of 10 exons and encodes a protein of 781 amino acids called pyrin. Pyrin is expressed at high levels in granulocytes, monocytes and dendritic cells. Mutant pyrin cause dysfunction in the inflammasome complex and leads to excessive activation of IL-1β.

A total of 289 mutations and polymorphisms in the MEFV gene have been reported in Infevers database. Compared to other cities of Turkey, the highest prevalence of FMF is seen in Sivas city (Central Anatolia). Due to the most frequent mutations are M694V, E148Q, M680I (G/C) and V726A in Turkish FMF patients, we screened the mutations of these exons (2 and 10) of the MEFV gene using DNA sequencing method. During our MEFV gene mutation screening among FMF patients, we detected a novel nucleotide change Q97R (c.290A>G; p.Gln97Arg) at exon 2 of MEFV gene that cause of missense amino acid mutation in pyrin protein in a 22 years old female patient with typical FMF criteria.

Turkish FMF patients have a unique mutation spectrum together with our novel Q97R mutation. It is very important to detect novel missense mutations in order to explain their crucial roles in FMF pathogenesis.

Features of clorine ions concentration in suspected cystic fibrosis patients sweat test and its correlation with C reactive protein

D. Serapinas[1,2], M. Sauspreškis[1], **J. Žiuraitis**[1];

[1]Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

Backround: It is essential to confirm or exclude the diagnosis of cystic fibrosis in time and with accuracy in order to avoid inappropriate testing. The aims of this study was to determine features of Cl ions concentration in patients sweat test that were suspected having cystic fibrosis and to evaluate correlation between this concentration and C reactive protein levels in serum.

Methods: we investigated retrospectively case files of patients with performed sweat test in period of 2011-2012 in Hospital of Lithuanian University of Health Sciences Kauno Klinikos Paediatrics department. These patients were suspected having cystic fibrosis (n=48).

Results: 9 out of 48 patients (18,75 %) showed higher than normal Cl ions concentration values. 6 of them (12,5%) had a borderline concentration. Mean value of Cl ions concentration in males sweat was 25,37 mmol/l (p<0,05; PI=21,05-30,40) and there was no statistical significance compared to mean Cl ions concetration in females sweat which was 24,44 mmol/l (p<0,05; PI=19,96-28,91). In our study no mutations of CFTR gene were found. CRP test was performed in 17 cases (35,42%). No statisticly significant correlation between concentration of Cl ions in sweat and serum CRP was found (r= -0,16; p=0,531).

Conclusions: 18,75% of checked patients had a higher than normal Cl ions concetration in sweat test. No statisticly significant difference between Cl ions concentrations in sweat test according to gender was found in examined group.

J03.13

The prevalence of the cagA and vacA genotypes of H. pylori from patients with upper gastrointestinal diseases in Uzbekistan

A. Abdurakhimov[1], *D. Dalimova[1], S. Turdikulova[2], R. Mukhamedov[1];*

[1]Bioorganic Chemistry, Tashkent, Uzbekistan, [2]Educational-Experimental Centre for High Technologies in Tashkent, Tashkent, Uzbekistan.

Helicobacter pylori colonizes the gastric epithelium of more than one half of the world's human population. This pathogenic bacterium plays a causative role in the development of chronic gastritis, peptic ulcers, and gastric adenocarcinoma. There is increasing evidence that the genetic variability of H. pylori have a clinical importance. Several virulence factors of H. pylori have been described, such as cytotoxin associated gene (cagA) and vaculating cytotoxin (vacA). This study aimed to investigate the prevalence of the cagA and vacA genotypes of H. pylori from patients with upper gastrointestinal diseases and the relationship with clinical outcome in Uzbekistan. A total of 72 patients who underwent endoscopy were included in this study. DNA was isolated from gastroduodenal biopsy samples and the presence of cagA and vacA genotypes were determined by PCR. All patients were found to be H. pylori-positive. The main virulence strain observed in our cohort was the cagA+ strain identified in 56 patients (77,8%). From the 52 patients with gastritis, 30(57,7%) harbored cagA+ strains and 12(42,3%) were infected with strains that lacked cagA. CagA positivity was observed in 26(86,7%) of patients with peptic ulcer pathology, whereas CagA negativity was observed in 4(13,3%) of these patients. Four VacA genotypes were found: s1/m1(25,8%), s1/m2(46,8%), s2/m1(14, 5%), s2/m2(12,9%). Comparative analysis of resulting genotypes showed a high percentage of s1/m2 with a distribution of 72,7% in patients with peptic ulcer pathology (P < 0.05). The results of this study might be used for the identification of high-risk patients harboring H. pylori in Uzbekistan.

Methylation of miR-137 in gastric cancer and preneoplastic lesions

R. Steponaitiene[1,2], A. Link[2], J. Kupcinskas[1], C. Langner[2], L. Venclauskas[1], H. Pauzas[3], A. Tamelis[3], **L. Kucinskas**[1], *L. Kupcinskas[1], P. Malfertheiner[2];*

[1]Institute for Digestive Research, Lithuanian University of Health Sciences, Kaunas, Lithuania, [2]Department of Gastroenterology, Hepatology and Infectious Diseases, Otto-von-Guericke University, Magdeburg, Germany, [3]Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania, Kaunas, Lithuania.

INTRODUCTION: MicroRNA miR-137 is an important regulator of gene expression and functions as a tumor-suppressor gene. Expression of miR-137 is downregulated in glioblastoma and colorectal cancer (CRC) due to CpG island methylation, however, the role of miR-137 methylation in gastric carcinogenesis remains largely unexplored.

AIM &METHODS: The aim of our study was to characterize the epigenetic regulation of miR-137 in gastric carcinogenesis. We determined miR-137 CpG island methylation level in 81 pairs of primary gastric cancer tissues samples (T-GC) and corresponding adjacent normal mucosa (N-GC), 20 samples of normal gastric mucosa (N) and 23 gastric tissues from patients with chronic/atrophic gastritis ± intestinal metaplasia (CG) using bisulfite pyrosequencing and compared to 29 colorectal cancers (T-CRC) and corresponding adjacent normal colonic mucosa (N-CRC).

RESULTS: We confirmed the higher methylation level of miR-137 promoter in T-CRC tissues compared to adjacent normal colonic tissues (p=0.004). In similar fashion, but to a lesser extent, methylation of miR-137 promoter region was observed in T-GC tissues compared to adjacent non-cancerous tissues (N-GC) (p=0.045). When compared to the normal mucosa from controls and mucosa from patients with gastritis, we found gradual increase in miR-137 methylation (p<0.0001). In subgroup analyses of gastric cancer tissues, miR-137 methylation was more frequent in tumors localized in antrum compared to cardia and corpus (p=0.07).

CONCLUSION: MiR-137 methylation is a frequent event in gastric carcinogenesis. The gradual increase in miR-137 methylation, as demonstrated for normal mucosa, chronic gastritis and tumour tissues, may be an early event in gastric carcinogenesis.

Neonatal permanent diabetes caused by mutation *INS*/Y50C: integrated system CGMS and insulin pump

F. Ortolani[1], *V. Grasso[2], A. Tummolo[1], M. Masciopinto[1], S. Fedele[1], F. Papadia[1], R. Fischetto[1], M. Vendemiale[3], F. Barbetti[2], E. Piccinno[1];*

[1]UOC Malattie Metaboliche Genetica Clinica e Diabetologia Ospedale Pediatrico „Giovanni XXIII", Bari, Italy, [2]Laboratorio Diabete Mendeliano, Ospedale Pediatrico "Bambino Gesù", IRCSS, Roma, Italy, [3]Psicologia Clinica, Ospedale Pediatrico „Giovanni XXIII", Bari, Italy.

Case description: first born on term female, spontaneous delivery, SGA. No gestational diabetes, no familiarity for type 1 and 2 diabetes. Normal glycaemia at birth. Hospitalysed at 24 days for irritability and mild jaundice: blood glucose 509 mg/dl, normal venous hemogasanalysis. Transferred to our hospital in Bari, started rehydration and parenteral regular insulin (starting dose 0,02 IU/kg/h). **Diagnosis and therapy:** We positioned continuous glucose monitoring system (CGMS Medtronic Enlite 27 Gauge 6 mm), glycaemic range 80-200 mg/dl and insulin pump (Paradigm Veo, model 554C). Started therapy with Insulin Lispro (basal dose: 0,025 UI/h - 0,1 UI/h, pre-prandial bolus 0,025-0,1 UI with automatic suspension of basal insulin delivery for glycaemia <80 mg/dl). Exclusively breastfed, CHO calculation not easily performable. Negative IAA, GAD e IA2; C-peptide: 1,4 ng/ml - after few days 0,73 (0,46-3,5 ng/ml). Molecular analysis: *de novo* heterozygous mutation c.A149->G TAC (Tyrosin)>TGC (Cysteine), (p.Tyr50Cys; position 50 of proinsulin), described as INS/Y50C. Discharged, after 38 days, with CGMS and insulin pump (total basal insulin: 2,1 UI/day; 0,7 UI/kg/day), lower night basal dose, pre-prandial bolus (0,025 UI before every meal when glycaemia>150mg/dl). After 6 months of follow up, normal weight gain, good metabolic control (HbA1c: 6,4%). Cognitive development assessment: QI 141/100, age equivalent score 8 months and ¾ (Griffiths Mental Development Scale Revised 0-2). **Conclusions:** The integrated system (CGMS-insulin pump) is an elective therapy model in neonatal diabetes for personalizing insulin therapy, planning therapy modifications, studying glycaemic trend in real time, reducing glycaemic variability and avoiding psychological burden correlated to hypoglycaemia.

Prevalence and spectrum of CYP21A2 gene mutations in women with symptoms of hyperandrogenism in Uzbekistan

F. A. Khaidarova[1], *D. K. Davletchurin*[2,3], *D. A. Dalimova*[2], *B. S. Adilov*[2], *S. U. Turdikulova*[2];
[1]*Republican Specialized Scientific-Practical Medical Center for Endocrinology, Tashkent, Uzbekistan,* [2]*Institute of Bioorganic Chemistry, Academy of Sciences Republic of Uzbekistan, Tashkent, Uzbekistan,* [3]*National University of Uzbekistan, Tashkent, Uzbekistan.*

Worldwide prevalence of hyperandrogenism varied from 3% to 23%. This wide range of variation is assosiated with difficulties of differential diagnosis between polycystic ovary syndrome (PCOS) and nonclassic congenital adrenal hyperplasia (NCAH). Molecular-genetic analysis plays a significant role in this issue, because NCAH is a genetic disorder which developes due to mutations in the CYP21A2 gene.
Therefore, our study aimed to investigate the prevalence of CYP21A2 mutations in women with hyperandrogenism in Uzbekistan. Real-time PCR using allele specific primers and TaqMan probes were used to detect eight most frequent CYP21A2 gene mutations in 361 Uzbek women with hyperandrogenic symptoms. Our results showed that 11,7% of these women have mutations in the CYP21A2 gene. We found the following spectrum of mutations: C1994T-71,4%, T999A-9,5%, A/C655G-7,2%, deletion of 8 bp(707-714GAGACTAC)-4,75%, G1683T-4,75% and C89T-2,4%. In the investigated group of women we did not find T1380A and C2108T mutations. C1994T mutation was found to be the most common mutation in our cohort. Women who harbored this mutation had abnormal menstrual cycle and recurrent miscarriages. In conclusion, genetic screening for CYP21A2 gene mutations by means of real-time PCR is an effective method for differential diagnosis between polycystic ovary syndrome and nonclassic congenital adrenal hyperplasia at the patients with hyperandrogenic symptoms.

Introduction: Obesity is one of the fast spreading diseases. Insufficient physical activity is one of the main environmental factors in the etiology of the disease. Twin studies have revealed that genetic factors play an important role in physical activity levels. Although the underlying genetic factors are not clearly understood, studies have shown that the *LEPR* gene is among the candidate genes affecting physical activity level. In our study, we aimed to show the effect of *LEPR* gene mutations related with the physical activity in obese women. In addition, we evaluated the impact of *LEPR* gene on body composition parameters. **Material and Methods:** 66 overweight/obese women were included in our study. Patients were categorized into 3 groups due to physical activity index levels. After the extraction of genomic DNA from buccal cells, *LEPR* gene regions were amplified by PCR and PCR products were sequenced. Physical activity levels and body composition parameters were calculated by using actical accelerometer and impedance meter, respectively. **Results and Discussion:** Three reported polymorphisms**,** one in exon 6 and two others in intron 7 of the *LEPR* gene were detected. No relationship between physical activity levels and *LEPR* was observed. A correlation was found between resting metabolic rate and rs12405556 mutation. Furthermore, we determined a significant relation between different physical activity levels with fat mass, body mass index and total energy expenditure. Further studies are needed to make an interpretation about the relation between physical activity levels, body composition parameters and gene mutations.

Association and gene-gene interaction analyses of genetic variants in IL1B, IL1RN, IL8, IL10 and TNFA genes for peptic ulcer disease in Volga-Ural region of Russian Federation

A. Nurgalieva[1], *E. Shaymardanova*[1], *D. Nadyrshina*[1], *E. Blinnikova*[1], *L. Gabbasova*[2], *O. Kuramshina*[2], *A. Krukova*[2], *I. Khidiyatova*[1,3], *R. Khusainova*[1,3], *E. Khusnutdinova*[1,3];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Bashkir Medical State University, Ufa, Russian Federation,* [3]*Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Russia, Ufa, Russian Federation.*

A peptic ulcer disease (PUD) is an area of damage to the inner lining (the mucosa) of the stomach or the upper part of the intestine (duodenum). A bacterium, Helicobacter pylori, is the main cause of ulcers in this area. The genes that encode proinflammatory and anti-inflammatory cytokines are good candidate markers of host susceptibility to gastroduodenal disease.
The present study was performed to evaluate association and gene-gene interaction of polymorphisms of cytokines genes IL1B (rs1143634), IL1RN (rs71941886), IL8 (rs4073), IL10 (rs1800872) and TNFA (rs1800629) for PUD in Volga-Ural region of Russia.
This study enrolled 264 patients with gastric and duodenal ulcers (112 individual were H.pylori-infected), the control group included 277 unrelated individuals without gastro-duodenal pathology with different ethnic origins (Russians, Tatars, Bashkirs). Genotyping was performed by PCR-RFLP analysis. To investigate gene-gene interactions, we employed generalized multifactor dimensionality reduction (GMDR) method.
The analysis has revealed a strong association of C allele and CC genotype of the rs1143634 of the IL1B gene with PUD in Bashkirs ($\chi2$=7,61, p=0,006; OR=2,87 и $\chi2$=9,28, p=0,002; OR=4,49; 95%CI 1,78-11,35), confirmed by meta-analysis. We have also detected that H.pylori-positive PUD-individuals has significant lower frequency of AA genotype of rs4073 of the IL8 gene compared with healthy donors ($\chi2$=5,29, p=0,02; OR=0,46). The 3-locus GMDR-model of cytokine gene-gene interaction, including rs1143634 of IL1B, rs4073 of IL8 and rs1800872 of IL10 genes, was shown for male subgroup (p=0,0547).
Thus, we have determined that cytokine genes may contribute in genetic susceptibility for peptic ulcer disease.

J03.19

Rare germline MEN1 mutation increases susceptibility to pituitary adenoma

R. Peculis[1], *I. Balcere*[2], *V. Pirags*[2,3], *J. Klovins*[1];
[1]*Latvian Biomedical Research and Study Centre, Riga, Latvia,* [2]*Pauls Stradins Clinical University Hospital, Riga, Latvia,* [3]*University of Latvia, Riga, Latvia.*

Introduction. Pituitary adenomas are up to 15% of clinically active primary intracranial neoplasms. They are considered benign, non-metastatic tumors. Although pituitary adenomas have prevalence of 16.7% in general population, clinically significant tumors affect one individual out of approximately 1000 to 1300 people in general population. There is evidence that both genetic and epigenetic factors are important to development of human neoplasms.
Methods. Our study was carried out using 144 cases and 354 controls. Seven candidate genes (*AIP, MEN1, GNAS, SSTR2, SSTR5* and *DRD2* and *PRKar1a*) were selected based on literature research about pituitary adenoma genetics and 96 *tag* and non-synonymous SNPs genotyped using Illumina GoldenGate genotyping assay on Illumina BeadXpress system. Basic association test was used to test difference between cases and controls.
Results. Our data showed that non-synonymous (A→T) SNP rs2959656 in *MEN1* is strongly associated (OR=17.8 CI95%=2.2-145, P=0.0002) with development of pituitary tumor. Most patients were diagnosed while their adenoma were smaller than 10mm in diameter (microadenoma, stage I) as opposed to trend of pituitary adenomas being diagnosed in macroadenoma with extrasellar extension (stage II or III) (39 *vs.* 105 in our sample) suggesting increased secretory activity than typical adenomas of same stage. There was no association with particular hormone secreting profile. Another notable finding was SNP rs7131056 in *DRD2* gene which was associated with higher risk for adenoma extrasellar growth (OR=2.3 Ci95%=1.4-3.7, P=0.001) suggesting involvement of dopamine system in aggressiveness of pituitary adenomas.
Conclusion. Polymorphisms in *MEN1* and *DRD2* constitute to development and aggressiveness of pituitary adenomas.

The molecular genetic research of chemical hypersensibility among women in the case of autoimmune thyroiditis

K. Olga, *T. Viktorova;*
Institute of Biochemistry and Genetics Ufa scientific centre, Ufa, Russian Federation.

Autoimmune Thyroid Disease (AITD) is heterogenetic inflammatory disease of thyroid. Pathogenesis of AITD apparents by intensity of destruction thyroid follicles. According to the data from literature and own epidemiological surveys carried out in OAO «Gazpromneftechim Salavat» it was shown that AITD is occupational disease. The goal of research was molecular genetic analysis cytokine genes, cytokine receptors, signal transduction and ranscription factors IL6 (rs1800795), IL17A (rs4711998, rs1974226), JAK1 (rs310216), JAK3 (rs3212780), STAT1 (rs12693591), STAT3 (rs2293152), NFKB1 (rs28362491) in women with AITD working under the conditions of occupational hazards. DNA samples of 236 women living in the Republic of Bashkortostan. 116 women were present AITD. The number of healthy women was 120. Polymorphisms of analyzed genes were done by polyme-

rase chain reaction (PCR) and next digestion restriction endonucleases RsaI, MspI, TaqI, Hsp92II. NFkB insertion-deletion polymorphism was analyzed by PCR. Calculations were carried out on the programme SNPStats. The deviation from Hardy-Weinberg equilibrium were not found.
A genetic association between AITD and three of the eight genotyped SNPs was found in this study among women under the conditions of occupational hazards. It was determinated the association with AITD polymorphism rs28362491 NFkB gene in overdominant model OR=0.55 (CI 95% 0.33-0.92), p=0.00001. Association with AITD was identified in polymorphism rs12693591 STAT1 gene OR=1.76 (CI95% 1.03-2.99), 0.04 in dominant model (AC + AA vs. CC). Associations were found between rs310216 Jak1 gene OR=2.06 (CI95% 1.17-3.61), p=0.012 in the dominant genetic model (AG+AA vs. GG).
The work was done under supporting Russian Humanitarian Scientific Fund №13-06-00101.

Inherited alpha- 1 antitrypsin deficiency and spontaneous pneumothorax: possible causal relationship

D. Serapinas[1,2], **A. Narbekovas[2]**;
[1]Department of Pulmonology and Immunology, Lithuanian university of health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

Background. An increased incidence of serum alpha1-antitrypsin deficiency has been reported in patients with chronic obstructive pulmonary disease but has not been well proven in association with spontaneous pneumothorax. The aim of our study was to evaluate frequency of alpha-1 antitrypsin deficiency in subjects with spontaneous pneumothorax.
Methods. 39 patients with the diagnosis of spontaneous pneumothorax and 100 age- and sex-matched control subjects were included in the study. Alpha-1 antitrypsin concentrations were determined by nephelometry, Serum qualitative Z antitrypsin variant was analyzed using commercial ELISA kits and alpha-1 antitrypsin phenotyping was carried out by means of isoelectric focusing.
Results. AAT deficiency phenotypes were detected in 3 (7.7%) patients with spontaneous pneumothorax, and only in 1 (1%) case in the control group. However, the observed differences did not reach statistical significance due to the considerable size disproportion between groups. The mean serum alpha-1 antitrypsin level was significantly higher in patients with spontaneous pneumothorax (1.53±0.23 g/l) than controls (1.34±0.31 g/l) (p=0.03).
Conclusions. Preliminary data confirm the clinical importance of alpha-1 antitrypsin deficiency genotypes in patients with spontaneous pneumothorax and the need to screen them for alpha1-antitrypsin deficiency.

J03.22
WT1 mutations in Bulgarian steroid-resistant nephrotic syndrome patients

V. Penchev[1], *A. Boueva[2], R. Kaneva[1], V. Mitev[1], D. Rusinov[2], O. Beltcheva[1];*
[1]Molecular Medicine Center, Dept. of Medical Chemistry and Biochemistry, Medical University-Sofia, Sofia, Bulgaria, [2]University Pediatrics Hospital, Pediatric Nephrology and Hemodialysis Clinics, Sofia, Bulgaria.

Steroid-resistant nephrotic syndrome (SRNS) is a chronic, progressive disorder which affects approximately 10% of all children with nephrotic syndrome. Approximately 10% of all infantile ESRD cases are a consequence of SRNS, which makes the disease one of the major causes of child morbidity.
The genetic background of SRNS is diverse. The most common mutations are found in NPHS2 and WT1 genes. NPHS2 codes the protein podocin, which is an essential structural element of the podocytes slit diaphragm. WT1 encodes a transcription factor with key role for the urinary tract differentiation.
We present here the results from genetic testing of Bulgarian patients with SRNS. We used direct DNA sequencing to screen 22 children form 21 families for mutations in the coding regions of WT1 and NPHS2. We found several polymorphisms in both NPHS2 and WT1. In one patient we found a heterozygous R229Q substitution in the podocin gene, while two children carried novel missense variants in WT1. One of the novel WT1 mutations is located in exon 8, the other in exon 9. Both affect the zinc-finger structures of the DNA binding domain. Further tests were carried out for determining the origin of the two novel mutations and proving their role in disease.
We can conclude that in Bulgarian SRNS patients there is a prevalence of WT1 mutations above NPHS2 gene defects. Additional investigations need to be carried out in order to determine the genetic cause of the disease in the remaining patients.

J03.23
Tight Junction gene expression in intestinal epithelial cell monolayers

A. Jauregi-Miguel, *N. Fernandez-Jimenez, L. Plaza-Izurieta, J. R. Bilbao;*
BioCruces Reserch Institution/UPV-EHU, Leioa, Spain.

Introduction: Disrupted intestinal barrier function is observed during the development of autoimmune and inflammatory diseases like Crohn's and celiac disease, and several genetic associations have been detected (*PARD3* and *MAGI2*). Cell models are necessary for the investigation of the functional implications of associated candidate genes. The Caco-2 subclone, C2BBe1, are human derived brush border expressing cells that grow in homogenous monolayers that form tight junctions (TJ) and are potentially a good tool for this research. **Aim:** To determine the function of TJ-related genes during monolayer formation in C2BBe1 cells. Methods: C2BBe1 monolayers (300000 cells/cm^2) were grown in 0.4 µm pore size PET inserts in Dulbecco's Modified Eagle Medium (DMEM) with 4.5g/l glucose supplemented with 10% inactivated FBS and 1% non-essential amino acids, and transepithelial electrical resistance (TEER) was monitored every 24h for 6 days. RNA was extracted each day and the expression of the most relevant TJ genes for TJ formation (*TJP1, CLDN2* and *ACTB*) and associated *PARD3* and *MAGI2* was analyzed by RT-PCR. **Results:** All genes except *MAGI2* were expressed in C2BBe1 and mRNA levels increased during the formation of the monolayers. There was a significant positive being significantly correlation between TEER and *CLDN2* (r^2=0.76; p=0.005), *TJP1* (r^2=0.84; p=0.001) and *PARD3* (r^2=0.70; p=0.01) expression, but not in *ACTB*. **Conclusion:** Monolayer cultures are valid tools for functional analyses of TJ genes. However, studies to determine those genes that are expressed in each cell line must be performed.

J03.24
Detection of Turner Syndrome by PCR-based approach in patients from Uzbekistan

M. Mirkhaydarova[1], *S. Ismailov[2], R. Mukhamedov[1], N. Ibragimova[2];*
[1]Institute of Bioorganic Chemistry, Tashkent, Uzbekistan, [2]Scientific-Research Institute of Endocrinology, Uzbekistan Public Health Ministry, Tashkent, Uzbekistan.

Turner syndrome (TS) is one of the most common genetic disorder affecting females, occurring in approximately 1:2500 female births. TS occurs when an X-chromosome is completely or partially deleted or when X-chromosomal mosaicism is present. It is characterized by short stature, gonadal dysgenesis, primary hypogonadism, congenital heart disease, renal anomalies, and a variety of somatic features. Girls with TS benefit from early diagnosis and treatment with growth hormone. However, many girls with TS are not detected until after 10 yr of age, resulting in delayed diagnosis and treatment.
This study aimed to apply PCR-based approach for detection of Turner syndrome and elucidation the parental origin of the X chromosome in patients from Uzbekistan. We have amplified by polymerase chain reaction five polymorphic markers along the X chromosome (DXS1283E, DYS II, DMD49, AR and DXS52) and three markers along the Y chromosome (SRY, DYZ3 and DYZ1). In addition we analyzed patients DNA samples by SYBR Green and TaqMan probe based real-time PCR assay. The results of our study show that monosomy(45,XO) was present in 78% of cases, 45,X/46,XX mosaicism in 18,8%, and 45,X/46,XY in 3,2%. We also determined the parental origin of the X chromosome in the 2 patients. They had a paternal single X chromosome.
PCR-based approach can be recommended for the screening programs regarding detection of girls with TS in Uzbekistan.

J03.25
Average telomere length as a biomarker in children and adolescents with type 1 diabetes at the diagnosis

J. Kovač[1], *T. Hovnik[1], P. Kotnik[2], T. Tesovnik[1], K. Trebušak Podkrajšek[1,3], T. Battelino[2,3];*
[1]Center for Medical Genetics, University Children's Hospital, UMC Ljubljana, Ljubljana, Slovenia, [2]Department of Pediatric Endocrinology, Diabetes and Metabolic Diseases, University Children's Hospital, UMC Ljubljana, Ljubljana, Slovenia, [3]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia.

Introduction: Subjects with type 1 diabetes (T1D) an autoimmune chronic disease are prone to oxidative stress, increased levels of advanced glycation end-products and other factors leading increased risk for T1D complications. Shorter telomeres are associated with T1D complications and lower serum vitamin D levels.
Methods: Average telomere length (ATL), nutritional status (BMI-SDS) and vitamin D level at the onset of T1D were determined in 53 Slovenian T1D children/adolescents (median age 8.7 years, 1:1.3 male to female ratio) whole blood DNA samples. The ATL was determined with qPCR method, vitamin D levels were determined with HPLC method.
Results: There was a tendency between a shorter ATL and a higher BMI-SDS (rs=-0.241; p=0.08). In addition subjects with ATL in the higher ATL tertile tended to have a higher BMI-SDS when compared to those in the lower ATL tertile (0.259 ± 0.457 vs. -0.583 ± 0.282 SDS; p=0.06). Subjects in the upper BMI-SDS tertile had a lower serum vitamin D levels when compared to those in the lower BMI-SDS tertile (40.66 ± 3.07 vs. 52.86 ± 4.85 µmol/L; p=0.045). Vitamin D serum levels did not significantly differ between sub-

jects with ATL in the higher tertile and those in the lower tertile (47.71 ± 5.35 vs. 41.09 ± 3.10 µmol/L; p= 0.296).
Conclusion: T1D children/adolescents with a shorter ATL tend to have a higher BMI-SDS. Lower serum vitamin D levels were determined in T1D subjects with a higher BMI-SDS. An association between vitamin D serum levels and ATL was not determined.

J03.26

Association of *MMP3*, *ITGB5*, *ITGA4*, *ADAMDEC1*, *LIG1* genes with type 1 diabetes

N. V. Tarasenko[1], *I. A. Goncharova*[1], *M. V. Golubenko*[1], *E. I. Kondratieva*[2], *V. P. Puzyrev*[1,2];
[1]Research Institute of Medical Genetics SB RAMS, Tomsk, Russian Federation, [2]Siberian State Medical University, Tomsk, Russian Federation.

The search for new genetic variants involved in type 1 diabetes and its complications gives the opportunity for personalized medicine. In our study, 58 SNPs were studied in 48 genes which were associated in GWA studies with one or more of the following phenotypes: fibrogenesis, endothelial dysfunction, diseases of the cardiovascular continuum, type 1 diabetes (T1DM), and type 2 diabetes. Specimens were evaluated using the Sequenom MassARRAY (USA). Case-control study included 285 patients with T1DM and 300 population controls. All subjects were ethnically Russians living in Siberian region of Russia (Tomsk and Kemerovo cities). Association with the disease was obtained for the following genetic markers: *MMP3* rs679620 (AA, OR=2,03 (95% CI: 1,19-3,47), p=0,008), *ITGA4* rs1143674 (GG, OR=2,03 (1,27-3,26), p=0,003; allele G, OR=1,68 (1,24-2,27), p=0,001), *ITGB5* rs1007856 (TT, OR=1,67 (1,10-2,54), p=0,015; allele T, OR=1,31 (1,02-1,70), p=0,037), *ADAMDEC1* rs3765124 (AA, OR=1,76 (1,18-2,65), p=0,005; allele A, OR=1,31 (1,01-1,70), p=0,040), *LIG1* rs20579 (CC, OR=1,95 1,26-3,02), p=0,002; allele C, OR=1,91 (1,29-2,81), p=0,001). The *MMP3*, *ITGB5*, *ITGA4* and *ADAMDEC1* genes are involved in the formation of extracellular matrix and collagen metabolism. These associations can be explained by the participation of these genes in the formation of fibrotic changes in the renal tubules and interstitium, which leads to progression of diabetic nephropathy and deterioration of the patient condition. The *LIG1* gene is involved in DNA repair and recombination. Perhaps this gene is associated with type 1 diabetes through some basic metabolic pathway. Altogether, our results suggest that T1DM development is influenced by genes involved into fibrogenesis.

J03.27

Association study of promoter polymorphisms of *nucb2* gene in Iranian patients with type 2 diabetes

S. Mosammami[1], *V. R. Yassaee*[2,1], *Z. Soltani*[2], *K. Roohi Gilani*[3];
[1]Dept. of Medical Genetics, Faculty of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran, [2]Genomic Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran, [3]Labbafi Nejad Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.

Type 2 diabetes mellitus (T2DM) is characterized by both insulin resistance (poor tissue insulin sensitivity) and impaired insulin secretion from the pancreatic β-cell. Global prevalence of type 2 diabetes is increasing rapidly. Substantial evidence suggests that T2D is a multifactorial disease with a strong genetic component. Nesfatin-1, derived from the nucleobindin2 (NUCB2) precursor, was recently implicated as a mediator of anorexia in the central nervous system. Plasma nesfatin-1 concentrations were found to be elevated in subjects with both Impaired Glucose Tolerance (IGT) and newly diagnosed type 2 diabetes (nT2DM) and to be related with several clinical parameters known to be associated with insulin resistance. The aim of the present study is to investigate the association of polymorphisms of promoter of nucb2 gene in Iranian population.
We performed a case-control study consisted of 100 T2DM and 100 healthy individuals. Blood samples were obtained from subjects after informed consent was achieved. Isolated genomic DNA amplified for five SNPs at promoter of nucb2 by Sanger sequencing and results analyzed by Laser gene V7.1 and online software SNPanalyzer2.
Statistical analysis revealed a significant association for major allele of rs214088 (G) with type 2 diabetes in receive model (p=0.03; OR: 3.109, 95%CI: 1.064-9.082). In haplotype analysis, the CAG haplotype of nucb2 (rs214088, rs4757506 and rs214087) ascertained significant association with type 2 diabetes (p=0.03).
Our study suggests that there is a significant association between rs214088 at the promoter of nucb2 gene and T2DM. This SNP may applied as biomarkers for susceptibility of T2DM in Iranian population.

When speed matters: using rapid next-generation sequencing to confirm Wilson-disease in a patient with severe acute liver failure

K. Arvai[1], *D. Németh*[2], *F. Szalay*[2], *B. Balla*[1], *B. Tóbiás*[1], *P. Horváth*[2], *Z. Nagy*[2], *P. Lakatos*[2], *J. Kósa*[1];
[1]Semmelweis University PentaCoreLab, Budapest, Hungary, [2]Semmelweis University 1st Department of Internal Medicine, Budapest, Hungary.

Acute liver failure (ALF) is a rare form of Wilson disease (WD) developing mostly in young female patients. Use of chelating agents and supportive therapies including MARS (Molecular Adsorbent Recirculating System) in time may result in a remission in some cases making liver transplantation unnecessary. We are presenting here a 47 year old male patient with no alcohol consumption, negative hepatits- and autoantibody markers and with elevated transaminase and ferritin levels. The patient was admitted to our institution with severe ALF and with the potential diagnosis of haemochromatosis, but the patients coeruloplasmin level was low with very high level of ferritin. The D-penicillinamin test supported the diagnosis of WD, but the result of the genetic analysis of the most frequent disease causing mutation in Hungarian population (H1069Q) was negative (wild type). Targeted NGS-based analysis of the entire coding region of the ATP7B gene showed two different disease-causing alteration in this patient and made the diagnosis clear, showing the clinical potential of semiconductor based next generation sequencing with 36 hours of turn around time.

J03.29

Mutations in genes *HFE, SERPINA1, CFTR* in Wilson's disease patients in Latvia

A. Zarina[1], *L. Piekuse*[1], *M. Kreile*[1], *Z. Steinberga*[1], *I. Tolmane*[2,3], *J. Keiss*[2], *A. Chernusenko*[2], *V. Sondore*[2], *G. Cernevska*[4], *Z. Krumina*[4], *A. Krumina*[5];
[1]Riga Stradins university Scientific laboratory of molecular genetics, Riga, Latvia, [2]Riga East Clinical University Hospital, stationary "Infectology Center of Latvia", Riga, Latvia, [3]University of Latvia, Faculty of Medicine, Riga, Latvia, [4]Children Clinical university Hospital, Riga, Latvia, [5]Latvian Biomedical Research and Study Center, Riga, Latvia.

Introduction Liver inherited diseases are a group of genetically determined clinical entities that appear with an early chronic liver involvement. They include Wilson's disease (WD), hereditary haemochromatosis, and alpha-1 -antitrypsin deficiency. In addition, cystic fibrosis may cause a severe liver involvement in a significant percentage of cases. Mutations in the genes *HFE, SERPINA1, CFTR* could modify the pathogenesis and clinical appearance of Wilson's disease. **Aim** To detect frequency of the most common mutations causing inherited liver disorders mentioned above in patients with WD suggestive symptoms. *Material and methods* The study included 115 patients with WD suggestive symptoms and 295 unrelated healthy individuals. DNA analysis: both groups were tested for mutation C282Y and H63D in the gene *HFE*; F508del in the gene *CFTR*; PIZ and PIS in the gene *SERPINA1.* **Results** Frequency of different alleles: allele F508del in WD patients - 0.009, in control population - 0.01 (p=0.446); PIZ in WD patients - 0, in control group - 0.018 (p=0.058); PIS in WD patients - 0.019, in control group - 0 (p=0.045); C282Y in WD patients - 0.02, in control group - 0.035 (p=0.475); H63D in WD patients - 0.188, in control group - 0.121 (p=0.019; OR=1.687). **Conclusions** 1) Alleles PIS and H63D were more frequent in patients with WD suggestive symptoms that could indicate its significance in more severe and better detectable liver disorder in case of WD. 2) But still the role of iron overload and alpha-1-antitrypsin deficiency in the pathogenesis of Wilson disease is not finally elucidated.

Molecular characterization of *COL4A5* in young Thai males suspected for X-linked Alport Syndrome

N. Suvachittanont[1], *P. Sae-chew*[1], *P. Jittorntham*[1], *D. Pitidhammabhorn*[1], *S. Patputthipong*[2], *P. Chuengsaman*[3], *A. Nongnuch*[1], *O. Trachoo*[1];
[1]Ramathibodi Hospital, Bangkok, Thailand, [2]Uttaradit hospital, Uttaradit, Thailand, [3]Banphaeo Hospital-Prommitr Branch, Bangkok, Thailand.

Background: Presently, a number of young males affected by end-stage renal disease (ESRD) of unknown causes have been registered for renal replacement therapy. Either genetic or environmental causes cannot be excluded. However, search for monogenic causes is challenging since genetic screening can give the information regarding the approach to other patient's family members such as carrier screening. X-linked Alport syndrome (XLAS) is one of the suspected monogenic causes in young male patients. This particular syndrome is collagen IV-related nephropathy caused by the mutation of *COL4A5* on Xq22. Approximately 80% of XLAS leads to end-stage renal disease by the age of 40 with variable association with sensorineural hearing loss and ocular abnormalities. **Objective:** To characterize *COL4A5* mutation in Thai male patients affected by ESRD of unknown causes and to develop the rapid and efficient molecular testing strategies for identifying XLAS in clinical practice. **Methodology:** DNA extraction was performed from peripheral blood leukocytes of Thai male patients, age 10-40 years, affected by ESRD of unidentifiable causes. Three common mutations of COL4A5, C1564S, L1649R, R1677Q, were detected using qPCR and melting curve analysis. **Results:** Twenty patients were recruited in the study. Of them, *COL4A5* mutation was detected in four patients (20%). C1564S is the most prevalent

in this group. **Conclusion:** XLAS is the hidden cause of ESRD in young male patients affected by ESRD. Genetic screening is proposed to be necessary, not only for definite diagnosis, but also for genetic counseling and carrier testing in the family.

J03.31
A Retrospective Audit into the Screening for Complications in Patients with Hereditary Haemorrhagic Telangectasia (HHT) in the North West of England

A. Jackson[1], *T. Briggs*[2], *J. Clayton-Smith*[2];
[1]*University of Manchester, Manchester, United Kingdom,* [2]*Manchester Centre for Genomic Medicine, St Mary's Hospital, Manchester, Manchester, United Kingdom.*

Background: HHT affects approximately 1 in 5000 people and has been associated with mutations in ENG, ACVRL1 and SMAD4. Features of this disease are epistaxis, telengectasia, a family history and visceral arteriovenous malformations (AVMs). International guidelines on the screening of patients with HHT were published in 2011.
Method: Patients with HHT were identified using the Molecular Laboratory database at St Mary's Hospital, Manchester. Screening on mutation-positive patients was audited against the International guidelines.
Results: 54 patients were identified and 35 (65%) were found to have a mutation in either ENG or ACVRL1. Pulmonary and cerebral AVM screening was undertaken in 92% and 62% of patients respectively. Screening for anaemia in those over 35 years was undertaken in 21%. 2/19 (11%) eligible patients were tested for SMAD4 mutations (both negative). AVMs occurred in 29% ENG and 21% ACVRL1 patients. Lung AVMs were more common in the ENG group (24% vs 7%). One cerebral AVM was identified and this occurred in the ENG group. Liver AVMs only occurred in the ACVRL1 group (21% vs 0%). Overall, AVMs occurred more frequently in women than in men (38% vs 7%).
Conclusion: A consensus on screening for HHT patients is needed in the UK. It is globally accepted that screening for pulmonary AVMs and anaemia should be undertaken but cerebral screening is still controversial. SMAD4 mutations should be sought in those patients who are negative for ENG and ACVRL1. The breakdown of AVMs in this population adds further evidence to a genotype-phenotype correlation in HHT.

Primary hyperoxaluria type 1: Identification of a double mutation in AGXT gene in Tunisian families

H. Kanoun[1], *F. Jarraya*[2], *H. Mahfoudh*[2], *Y. Chaabouni*[2], *F. Makni*[3], *J. Hachicha*[2], *F. Fakhfakh*[1];
[1]*Human Molecular Genetic Laboratory, Faculty of medicine of Sfax, Sfax, Tunisia,* [2]*Research Unit 12ES14 and department of Nephrology, Hedi Chaker Hospital, Sfax, Tunisia,* [3]*Laboratory of Biochemistry, Hbib Bourguiba Hospital of Sfax, Sfax, Tunisia.*

Primary hyperoxaluria type 1 (PH1) is a severe autosomal recessive inherited disorder of glyoxylate metabolism caused by mutations in the AGXT gene on chromosome 2q37.3 that encodes the hepatic peroxisomal enzyme alanine:glyoxylate aminotransferase. These mutations are found throughout the entire gene and cause a wide spectrum of clinical severity. Rare in Europe, PH1 is responsible for 13% of the end stage renal failure in the Tunisian child. In the present work, we identified the double mutation c.32C>T (Pro11Leu) and c.731T>C (p.Ile244Thr) in AGXT gene in five unrelated Tunisian families with PH1 disease. Our results provide evidence regarding the potential involvement of c.32C>T, originally described as common polymorphism, on the resulting phenotype. We also reported an extreme intrafamilial heterogeneity in clinical presentation of PH1. Despite the same genetic background, the outcome of the affected members differs widely. The significant phenotypic heterogeneity observed within a same family, with a same genotype, suggests the existence of relevant modifier factors.

A five case molecular study of 3M syndrome

I. Ouertani[1], *H. Safraou*[2], *A. Zanati Jouini*[2], *F. Maazoul*[2], *R. Mrad*[2], *H. Chaabouni*[2];
[1]*department of congenital and hereditary disorders,, Tunis, Tunisia,* [2]*department of congenital and hereditary disorders,, tunis, Tunisia.*

3M syndrome is a rare autosomal recessive disease characterized by severe prenatal and postnatal growth retardation, facial dysmophism, unaffected intelligence and normal endocrine profile. Mutations are reported in three genes. CUL7 is the major gene responsible for the 3M syndrome accounting for 70% of cases. This work aims to establish the molecular diagnosis of 3M syndrome by detecting the presence of a founder mutation, previously reported among Maghrebian patients, in exon 24 of the gene CUL7 of five Tunisian patients with the typical features of the 3M syndrome. If the founder mutation is not detected, the molecular diagnosis of hotspots in exons 4 and 19 of CUL7 gene will be performed. Following the extraction of genomic DNA from peripheral blood sample, after parental consent, we performed a PCR amplification step followed by analysis by direct sequencing of the coding regions of exons 4, 18, 19, 24 and 25 of CUL7gene. Using these methods, we confirmed the presence of the founder mutation, del TG 4451-4452, in three of our patients . Furthermore, we did not detect either mutation or polymorphism in the five targeted exons of CUL7 gene in the index case of a second family that encloses two 3M patients. 3M syndrome is characterized by genetic heterogeneity that contrasts with the clinical homogeneity of the syndrome. We plan to complete the molecular diagnosis in the other exons of the major gene CUL7 before switching to the other two genes (OBSL1 and CCDC8) for cases of the family 02.

J04.02
Inherited alpha-1 antitrypsin deficiency and chondrosarcoma - causal relationship?

D. Serapinas[1,2], **D. Stakisaitis**[2];
[1]*Department of Pulmonology and Imunology, Lithuanian university of health sciences, Kaunas, Lithuania,* [2]*Mykolas Romeris university, Vilnius, Lithuania.*

Alpha 1-antitrypsin deficiency is a genetic risk factor for manifestation of COPD and chronic liver diseases. There is an ongoing worldwide discussion concerning the role of serpins (serine protease inhibitors) in tumor genesis. Protease inhibitors such as alpha 1-antitrypsin have generally been considered to counteract tumor progression and metastasis because of their ability to inhibit proteases. In this case report we analyze relationship between inherited alpha-1 antitrypsin deficiency and chondrosarcoma. A 47-year-old woman was admitted to the hospital with relapse signs of humerus chondrosarcoma. The patient also had a history of COPD. After chest X-ray and CT, alpha 1-antitrypsin deficiency was suspected. Severe alpha-1 antitrypsin deficiency (PiZZ homozygous genotype) was confirmed. Alpha 1-antitrypsin deficiency might have facilitated the development of chondrosarcoma. Because of a small incidence rate of such diseases, we presume that there is a slight chance for such rare disorders to manifest concurrently in the same patient.

J04.03
The importance of MEFV gene mutations in HLA-B*27 positive Ankylosing Spondylitis patients

H. Tozkır[1], *S. Tan*[1], *H. Gurkan*[1], *N. Tastekin*[2];
[1]*Trakya University, Medical Faculty, Department of Medical Genetics, Edirne, Turkey,* [2]*Trakya University, Medical Faculty, Department of Physical Therapy and Rehabilitation, Edirne, Turkey.*

Ankylosing spondylitis (AS) that is etiologically unknown, can cause back and lumbar pain, and environmental, immunological and genetic factors have a role in its pathogenesis, is a chronic inflammatory disease. HLA-B*27 gene, located on short arm of sixth chromosome, have significant role in susceptibility of AS disease. The predisposition of AS disease is higher in HLA-B*27 positive people than HLA-B*27 negative ones. Also, there are some patients who have both AS disease and MEFV gene mutation. In our study, association of MEFV gene mutations have been analysed in HLA-B*27 positive and negative patients who diagnosed as AS, and HLA-B*27 negative healthy controls. 80 patients including HLA-B*27 positive 36 male and 14 female AS patients, HLA-B*27 negative 11 female and 19 male AS patients have been studied in the research. 50 healthy controls including 17 female and 33 male HLA-B*27 negative healthy individuals have been studied. HLA-B*27 allele of both patient and control groups were determined by PCR-SSP method. Pyrosequencing method was used for detection of MEFV gene mutations. HLA-B*27 positive patient group and healthy control group were compared in terms of MEFV gene exon 2 and 10 mutations. Frequency MEFV gene exon 2 and 10 mutation is determined statistically higher in HLA-B*27 positive patient group than healthy control group (p= 0,012) We suggest that MEFV gene mutations may have a role in etiopathogenesis of HLA-B*27 positive AS disease. That hypothesis needs to be supported by further studies, involved in different populations including higher number of patient and control.

J04.04
Influence of sequence variations in MMP3 and GDF5 genes on risk of the anterior cruciate ligament rupture in the Russian population.

V. Pushkarev[1], *D. Dyatlov*[1], *A. Chmutov*[2], *Y. Pushkareva*[2], *K. Dedanov*[2];
[1]*Ural State University of Physical Culture, Chelyabinsk, Russian Federation,* [2]*South Ural State Medical University, Chelyabinsk, Russian Federation.*

Objectives: Anterior cruciate ligament (ACL) rupture is a severe multifactorial injury. A familial predisposition toward tearing ACL was demonstrated. Matrix metalloproteinases and growth differentiation factor 5 (GDF5) are important physiological mediators of extracellular matrix degradation, remodeling and chondrogenesis. The aim of this study was to determine impact of *MMP3* rs679620 and *GDF5* rs143383 variations on the risk of ACL

rupture in Russians.

Methods: 70 patients (18 women) with diagnosed ACL ruptures (ACL-group) and 247 asymptomatic controls were studied. Both groups consisted from similar on a sex, age, BMI, physically active unrelated Caucasians. gDNA was isolated from blood and buccal epithelium. Genotyping was performed by TaqMan® SNP Genotyping Assays (AppliedBiosystems, USA). The results were analyzed by using TaqMan® Genotyper Software (AppliedBiosystems). Hardy-Weinberg equilibrium (HWE) was checked by GDA software (http://hydrodictyon.eeb.uconn.edu/people/plewis/software.php). Goodness of fit test was conducted using the IBM-SPSS v. 21.

Results:

Groups	*GDF5* rs143383				
	A	G	AA	AG	GG
ACL	0.671	0.329	0.386	0.571	0.043
Control	0.596	0.404	0.369	0.453	0.178
	MMP3 rs679620				
	C	T	CC	CT	TT
ACL	0.543	0.457	0.357	0.371	0.271
Control	0.550	0.450	0.312	0.477	0.211

Significant deviation of genotypic frequencies from HWE was detected only for *GDF5* rs143383 in ACL-group (P=0.017). MAFs of tested SNPs in controls were similar to other Caucasians. Goodness of fit test reveals significant difference of *GDF5* rs143383 genotypic frequencies between groups. GG genotype carriers had a significantly decreased risk of ACL ruptures versus AG+AA genotypes ($\chi 2$ 5.995, P=0.014, OR 0.196, 95% CI 0.040 to 0.763). This study suggests a relationship between *GDF5* rs143383 variation and risk of ACL rupture in the Russian population.

Filaggrin mutations and atopic dermatitis in Volga-Ural region of Russia

G. F. Gimalova[1], *A. S. Karunas*[1,2], *Y. Y. Fedorova*[1], *E. R. Gumennaya*[3], *S. V. Levashova*[4], *E. F. Khantimerova*[4], *E. I. Etkina*[4], *S. Z. Zagidullin*[4], *E. K. Khusnutdinova*[1,2];
[1]*Institute of Biochemistry and Genetics, Ufa Scientific Centre, Russian Academy of Sciences, Ufa, Russian Federation,* [2]*Bashkir State University, Ufa, Russian Federation,* [3]*Dermatovenereologic Dispensary of the Republic of Bashkortostan, Ufa, Russian Federation,* [4]*Bashkir State Medical Unversity, Ufa, Russian Federation.*

Atopic dermatitis (AD) is a chronic inflammatory skin disorder and is often the first step in the atopic march. Mutations in the filaggrin gene (FLG), a key component of stratum corneum, have been identified as a strong predisposing factor for allergic diseases. In this study, we have screened three FLG loss-of-function mutations (c.2282del4, p.Arg501X and p.Arg2447X) in AD patients and controls. The AD group consisted of 448 AD patients (177 Russians, 126 Tatars, 145 individuals of mixed ethnic background). The control group included 408 non-atopic individuals (152 Russians, 109 Tatars and 147 individuals of mixed origin). Genomic DNA was isolated by phenol-chloroform extraction. The genotyping of SNPs was performed by PCR-RFLP. In our study the most prevalent FLG mutation was c.2282del4. The allelic frequency in AD patients was 6.61% in general group, 6.03% in Russians (p=2,3*10-4) and 9.35% in Tatars (p=1,6*10-5). In controls the frequency of c.2282del4 was significantly lower: 1.12% in total group, 0.97% in Russians and 0.46% in Tatars. Second mutation p.Arg501X in our groups was rarely found. In AD subjects and controls it was detected with following frequencies: 0.92% and 0.71% in general group, 0.90% and 1.36% in Russians, 0.85% and 0.47% in Tatars, respectively. The third FLG mutation p.Arg2447X was also found with low frequency: 0.82% in general group of patients and 0.31% in controls; in Tatars it was 1.75% and 1.33%, respectively. In Russians this mutation was absent. Our results show that FLG mutation c.2282del4 is strong predisposing factor for atopic dermatitis.

J04.06

Correlation between vitamin D receptor gene polymorphisms and atopic dermatitis in Canakkale population: a study based on, FokI and TaqI RFLP technique

S. Oguz[1], *F. Silan*[2], **Ç. AKURUT**[2], *N. Topaloglu*[3], *S. Isik*[1], *E. Sik*[2], *A. Uludag*[2], *Z. Ogretmen*[2], *O. Ozdemir*[2];
[1]*Canakkale Onsekiz Mart University Faculty of Medicine Department of Dermatology, Canakkale, Turkey,* [2]*Canakkale Onsekiz Mart University Faculty of Medicine Department of Medical Genetics, Canakkale, Turkey,* [3]*Canakkale Onsekiz Mart University Faculty of Medicine Department of Pediatrics, Canakkale, Turkey.*

Aim:The pathogenesis of atopic dermatitis (AD) includes genetic and environmental factors leading to immunological and nonimmunological dysfunctions. The VDR single nucleotide polymorphisms (SNPs), FokI and TaqI have previously been associated with atopic diseases such as allergic asthma. Methods:In a total of 88 AD patients and 96 healthy controls were included in the current study. The genomic DNA was isolated from peripheral blood-EDTA, and target VDR gene was genotyped by PCR-RFLP technique after VDR-FokI (rs2228570) and VDR-TaqI (rs731236) restriction enzymes digestion. Results were compared statisticaly. Results: We use Arlequin ver 3.5 integrated software for population genetics data analysis. Current results showed lack of association for VDR-TaqI polymorphism in AD but showed association for VDR-FokI in current cohort of AD (P=0.0364), (OR: 1.9526. Conclussion: The current preliminary results identified the association between VDR- FokI gene polymorphism and AD in Canakkale population. Results need to be confirme by large scale of patient groups.

J04.07

Vitamin D receptor gene polymorphisms in Iranian Azary patients with Behçet's Disease

H. Khodadadi[1], *E. Sakhinia*[2], *A. Khabbazi*[3], *M. Asghari Estiar*[4], *L. Emrahi*[5];
[1]*Babol University of Medical Sciences, Babol, Islamic Republic of Iran,* [2]*Department of Medical Genetics, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [3]*Connective Tissue Research Center, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [4]*Department of Medical Genetics, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [5]*Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran.*

The aim of our study was to investigate the association of four polymorphisms of the VDR gene (FokI, BsmI, TaqI and ApaI) with their susceptibility to Behçet's Disease (BD) and their clinical manifestations in respect to the Iranian Azari population. In this cross sectional study we considered the BsmI, FokI, ApaI and TaqI polymorphisms in 50 Iranian Azary patients with BD and 50 healthy controls, with the use of Polymerase Chain Reaction-restriction fragment length polymorphism. A significant difference was found for the FokI polymorphism between the case and control groups. The f allele frequency of 26% was present in BD patients, compared to only 13% in the control group. In addition, the f/f genotype was significantly associated with BD. We found no significant differences between the BD and control groups regarding the distribution of ApaI, BsmI, and TaqI genotype frequencies. We found no association between VDR polymorphisms and the clinical manifestations of BD. The VDR f allele and f/f genotype is associated with BD in the Iranian Azari population.

J04.08

Brooke-Spiegler syndrome: A rare association of thichoepithelioma, cylindroma and spiradenoma. Report of a familial mexican case

N. O. Dávalos, *Sanchez-Castellanos ME, Salazar-Davalos IM, Aceves-Aceves MA, Higareda-Gonzalez JO, Hernandez-Torres M, Ramirez-Garcia SA, Van-Dick M, Davalos IP, Garcia-Silva C;*
Instituto de Genética Humana, CUCS, Universidad de Guadalajara, Gudalajara, Mexico.

Introduction:

Brooke and Spiegler, independiently described an ephithelioma adenoides cysticum and skin endotelioma, as distinct entities. Brooke-Spiegler syndrome (BSS, OMIM#605041) characterized by benign adnexal neoplasia. Predominat tumors trichoepithelioma, cylindroma and spiradenoma appear childhood and early adolescence. BSS is autosomal dominant entity. The tumors located on head and neck, and increase throughout life. Trichoepithelioma showed flesh-colored papules on face; cylindromatosis presents erythematous nodules on the scalp; and blue-colored-painful lesions on trunk suggested spiradenomas. Pathogenesis is considered a defect in the diferentiation of folliculo-sebaceous-apocrine unit. Mutations have been identified in CYLD tummor suppressor gene, mapped to chormosome 16q12-q13.

Case Report:
