PLENARY LECTURES

PL1.1
RASopathies. The other face of RAS signalling dysregulation

M. Tartaglia;
Istituto Superiore di Sanità, Rome, Italy.

RAS proteins are small monomeric GTPases that function as molecular switches controlling a major intracellular signaling network that, depending on the cellular context, guides diverse biological functions, including proliferation, cell fate determination, survival, migration, differentiation, and senescence. RAS signaling is switched on upon stimulation by numerous cytokines, hormones, and growth factors, and mediates the appropriate cell response to external stimuli through the regulation of transcription, cytoskeletal rearrangement, and metabolism. Within this network, signal flow through the RAF-MEK-ERK pathway, the first identified mitogen-associated protein kinase (MAPK) cascade, mediates early and late developmental processes, including determination of morphology, organogenesis, synaptic plasticity, and growth.
Signaling through the RAS-MAPK cascade is tightly controlled, and its enhanced activation has been known for decades to represent a major event in oncogenesis. Activating somatic RAS gene mutations occur in approximately 30% of human cancers, and upregulation of this signaling pathway can also result from enhanced function of upstream signal transducers or RAS effectors, and inefficient function of feedback mechanisms.
Unexpectedly, discoveries derived from a massive disease gene hunting effort have recently established a novel scenario in which the upregulation of this signaling cascade underlies a group of clinically related developmental disorders, the RASopathies, characterized by facial dysmorphism, cardiac defects, reduced postnatal growth, variable cognitive deficits, ectodermal and musculoskeletal anomalies, and increased risk for certain malignancies. These disorders are caused by mutations in genes encoding RAS proteins, regulators of RAS function, modulators of RAS interaction with effectors or downstream signal transducers. Based on the relatively high prevalence of some of these disorders (i.e., Noonan syndrome and neurofibromatosis type 1), the dysregulation of this signaling pathway represents one of the most common events affecting developmental processes. These discoveries have also provided us with unpredicted molecular mechanisms converging toward the dysregulation of this signaling network.

PL1.2
Evolution of the HD gene

E. Cattaneo;
Department of Bioscience, University of Milan, Milan, Italy.

The *Hdh* gene arose with no CAGs in *Dictyostelium discoideum* (*Dd*), around 800 million-year ago before the protostome-deuterostome divergence (Zuccato, Physiol Rev 2010). The CAG then has appeared in and is unique to the deuterostome branch. Two CAGs are found in *Hdh* in sea urchin (*Strongylocentrotus purpuratus, Sp*), the first specie to carry a primitive nervous system, and two CAGs are present in amphioxus (*Branchiostoma floridae, Bf*), the first specie to exhibit a rudimental hollow nerve tube and cephalization. Four CAG are found in *Hdh* from the more evolved fishes, amphibians, and birds. The CAG further expands in mammals and reaches its maximum length in human. A study of 278 normal subjects revealed an increase in grey matter with increasing length of the CAG repeat (Muhlau, PlosOne 2012), indicating that CAG size could influence normal brain structure. Our hypothesis is that the progressive increase in CAG length in the *Hdh* gene observed during evolution may be implicated in the evolutionary changes that have occurred in the developing and adult nervous system throughout vertebrate phylogeny, with a possible role for the CAG in newly emerging cognitive functions in the mammalian brain. We have now collected the *Hdh* gene from new species both in the protostome and deuterostome branch. In addition to further analyze the CAG tract during mammalian evolution we have collected genomic DNA and amplified the CAG tract from non-anthropomorphic and anthropomorphic primates. Our reconstruction of htt phylogeny supports further that the CAG tract expands during deuterostome evolution and seems to correlate with the appearance and/or evolution of progressively more complex nervous systems.

PL2.1
Early-Onset Stroke and Vasculopathy Associated with Mutations in ADA2

I. Aksentijevich[1], *Q. Zhou*[1], *A. K. Ombrello*[1], *D. Yang*[2], *A. V. Zavialov*[3], *R. Sood*[1], *M. Boehm*[2], *D. L. Kastner*[1];
[1]*NHGRI/NIH, Bethesda, MD, United States,* [2]*NHLBI/NIH, Bethesda, MD, United States,* [3]*University of Turku, Turku, Finland.*

We initially observed 3 unrelated patients with fevers, livedo reticularis, vasculopathy, and early-onset recurrent ischemic strokes. We performed exome sequencing on affected patients and their unaffected parents that pointed to recessively inherited predicted-deleterious mutations in CECR1, encoding adenosine deaminase 2 (ADA2). All mutations are either novel or present at low frequency (<0.001) in several large databases, consistent with the recessive inheritance. Candidate gene screening was done in additional 6 patients. Nine patients shared 4/9 missense mutations in CECR1 along with conserved haplotypes. Computer modeling based on the crystal structure of the human ADA2 suggests that CECR1 mutations either disrupt protein stability or impair enzyme activity. All patients had at least a 10-fold reduction in serum and plasma concentrations of ADA2, and reduced ADA2-specific adenosine deaminase activity. ADA2 is expressed predominantly in myeloid cells and is a secreted protein. Animal models suggest that ADA2 is the prototype for a family of growth factors (ADGFs). Although there is no murine homolog of CECR1, there are 2 zebrafish homologs, Cecr1a and Cecr1b. Knockdown of a zebrafish ADA2 homolog caused intracranial hemorrhages and neutropenia, phenotypes that were rescued by wild type but not mutant human CECR1. Skin, liver, and brain biopsies from patients demonstrated vasculopathic changes characterized by compromised endothelial integrity, endothelial cellular activation, and inflammation although ADA2 is not expressed in the endothelial cells. Our data suggest that loss-of-function mutations in CECR1 are associated with a spectrum of vascular and inflammatory phenotypes ranging from early-onset recurrent stroke to systemic vasculopathy and/or vasculitis.

PL2.2
Disrupted auto-regulation of SNRPB causes cerebro-costo-mandibular syndrome

The discovery of highly conserved non-coding elements has unleashed a race to elucidate their functional significance. A class of intragenic highly conserved non-coding elements has previously been associated with regulating levels of core spliceosomal components, which affects the alternative splicing of downstream genes. These regulatory exons contain a premature termination codon, and trigger nonsense-mediated mRNA decay (NMD) when included in the associated transcript. In this study we identify mutations in one such exon in SNRPB as the cause of cerebro-costo-mandibular syndrome (CCMS). CCMS, one of the last unsolved classical Mendelian disorders, is a multiple malformation syndrome characterized by posterior rib gaps and micrognathia. The identified mutations fall within exonic splicing silencer sequences. We show by both qRT-PCR and a minigene reporter assay that these mutations cause increased inclusion of the alternative exon and decreased overall expression of SNRPB. This decrease is predicted to influence the splicing of a diverse but limited number of downstream target genes. Our data provide the first evidence for the functional importance of this class of conserved elements in the regulation of human development. We suggest that this exon, which is highly conserved across placental mammals but not other vertebrates, accords a subtle regulatory role to SNRPB which may have contributed to the complexity of mammalian development.

PL2.3
The First 100 patients diagnosed by whole-exome sequencing through FORGE Canada: Insights for Clinical Translation

S. L. Sawyer[1], *C. L. Beaulieu*[1], *T. Hartley*[1], *D. Bulman*[1], *J. Majewski*[2], *FORGE Canada Consortium, K. M. Boycott*[1];
[1]*Children's Hospital of Eastern Ontario Research Institute, Ottawa, ON, Canada,*

[2]Department of Human Genetics, McGill University, Montréal, QC, Canada.

An accurate genetic diagnosis is fundamental for pediatric patients with rare genetic disorders to improve disease management, access to resources, and recurrence risk counseling. A diagnosis also provides psychosocial benefits to families. The Finding of Rare Disease GEnes (FORGE) Canada project, which sought to identify novel rare disease genes by whole-exome sequencing (WES), shows that 36% of the solved disorders were secondary to mutations in known genes; 95 known disease genes were identified out of 264 total disorders studied. All patients had undergone standard of care genetic testing in Canada and no diagnosis was forthcoming. Thus, for 104 families, WES provided a clinical diagnosis; 24 of these were dominant (most de novo), 68 were autosomal recessive, four were X-linked mutations and one family had two disorders. Although many of the 104 families who received a clinical diagnosis were ascertained because of familial recurrence or consanguineous parents, 91 single affected patients without a family history were also included for WES. This latter subset of the above 264 disorders are representative of what geneticists often see in the clinic and had a diagnostic rate of 43%. Thus, WES would seem to be an efficient and cost-effective means of clinical diagnosis for many patients who are currently undiagnosed. Our findings suggest that patients with genetically heterogeneous disorders or sibling recurrence are the most likely to be diagnosed by WES. Canada is building on the success of these 104 diagnosed families to develop a national framework for clinical exome sequencing.

PL2.4
Transcriptomes of individual cells

C. Borel, *P. G. Ferreira, M. Garieri, F. A. Santoni, O. Delaneau, E. Falconnet, P. Ribaux, P. Makrythanasis, M. Guipponi, E. T. Dermitzakis, S. E. Antonarakis;*
University of Geneva Medical School, Geneva, Switzerland.

We sequenced hundreds of single-cell transcriptomes to decipher the cell-to-cell transcriptional variation. Starting from a homogeneous cell population of human female primary fibroblasts from one individual, we used the C1 Single-Cell-Auto-Prep-System to capture individual cells and to generate pre-amplified cDNA for next-generation sequencing. On average, 9322 genes per single-cell (RPKM >0.3) were detected, representing ~50% of the total genes detected by the bulk sample containing millions of cells. We noted a wide spectrum of transcriptional heterogeneity. Correlation analysis between single-cells showed an average coefficient of 62% (0.3-0.9). A large number of detected genes are cell-specific with gene mRNA levels variable between single-cells. Moreover, we identified cell-specific novel exons, multitude of alternative spliced isoforms and 3'UTR isoforms due to alternative polyadenylation. Hence, 1% of exons showed difference for exon inclusion between single-cells and 10% of 3'UTR contained alternative transcript termination sites.
To further assess the differential allelic expression at the single-cell level, WGS has been performed on this sample. Our data revealed that both alleles are actively transcribed for most of the detected genes. Interestingly, we observed a skewed monoallelic distribution in single-cells in a given snapshot of time. Indeed, for most of the genes, we detected one transcribed allele at the time in an individual cell. For a specific gene, rare are the individual cells expressing both alleles simultaneously. The results were validated in fibroblasts from a second individual. We will also provide a comprehensive survey of imprinted genes, X inactivation and escape.
S.E.A and E.T.D. laboratories contributed equally.

PL2.5
Chromosome X-wide association analysis discovers new loci for complex traits including a height locus not dosage compensated between men and women

T. Tukiainen[1,2,3], *M. Pirinen*[3], *A. Sarin*[3,4], *C. Ladenvall*[5], *J. Kettunen*[3,4], *T. Lehtimäki*[6], *M. Lokki*[7], *M. Perola*[3,4,8], *J. Sinisalo*[9], *E. Vlachopoulou*[7], *J. G. Eriksson*[4,10,9], *L. Groop*[11,3], *A. Jula*[12], *M. Järvelin*[13,14], *O. T. Raitakari*[15], *V. Salomaa*[4], *S. Ripatti*[3,16,17];
[1]*Massachusetts General Hospital, Boston, MA, United States,* [2]*Broad Institute of Harvard and MIT, Cambridge, MA, United States,* [3]*Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland,* [4]*National Institute for Health and Welfare, Helsinki, Finland,* [5]*Lund University and Lund University Diabetes Centre, CRC at Skåne University Hospital, Malmö, Sweden,* [6]*University of Tampere School of Medicine, Tampere, Finland,* [7]*Haartman Institute, University of Helsinki, Helsinki, Finland,* [8]*Estonian Genome Center, University of Tartu, Taru, Estonia,* [9]*Helsinki University Central Hospital, Helsinki, Finland,* [10]*Department of General Practice and Primary Healthcare, University of Helsinki, Finland,* [11]*Lund University and Lund University Diabetes Centre, CRC at Skåne University Hospital, Malmö, Finland,* [12]*National Institute for Health and Welfare, Turku, Finland,* [13]*School of Public Health, Imperial College London, London, United Kingdom,* [14]*Institute of Health Sciences and Biocenter Oulu, University of Oulu, Finland,* [15]*University of Turku and Turku University Hospital, Turku, Finland,* [16]*Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom,* [17]*Hjelt Institute, University of Helsinki, Helsinki, Finland.*

The X chromosome (chrX) has often been overlooked in genetic association studies, thus representing one potential source for the "missing heritability" for complex phenotypes. Additionally, as up to 15% chrX genes escape from X inactivation (XCI), chrX may be enriched in sexually dimorphic associations, further highlighting that chrX warrants attention.
We investigated the contribution of >400,000 chrX SNPs to the levels of twelve common quantitative phenotypes in almost 25,000 individuals from Finland and Sweden. ChrX-wide association analysis pinpointed three new loci: two for height (FGF16/ATRX/MAGT1, P-value=2.71×10-9; ITM2A, P-value=3.03×10-10) and one for fasting insulin (Xq23, P-value=5.18×10-9), the first X-chromosomal ones for these traits in Europeans. Interestingly, the genetic effects for height near ITM2A, a gene implicated in chondrogenesis and know to escape from XCI, showed sex-heterogeneity in a manner consistent with no dosage compensation between men and women, observation further supported by statistical model comparison and female-bias in ITM2A expression. Given the converging evidence, this height locus likely represents the first link between an XCI-escaping gene and phenotypic variation in a population sample, and we estimate it explains approximately 1.5% of the height difference between men and women.
Together our findings underline the value of including chrX in large-scale genetic studies of complex diseases and traits. Our estimate that chrX accounts on average 2.6% of complex trait heritability, suggests there are tens of associated chrX loci to be discovered, with the intriguing possibility that some of the loci can also contribute to sexual dimorphisms.
Ref. Tukiainen et al. PLoS Genet. 2014

PL2.6
Genome sequencing identifies major causes of severe intellectual disability

C. Gilissen[1], *J. Y. Hehir-Kwa*[1], *D. T. Thung*[1], *M. Van de Vorst*[1], *B. W. M. van Bon*[1], *M. H. Willemsen*[1], *M. Kwint*[1], *I. Janssen*[1], *A. Hoischen*[1], *R. Leach*[2], *R. Klein*[2], *R. Tearle*[2], *T. Bo*[3], *R. Pfundt*[1], *H. G. Yntema*[1], *B. B. A. De Vries*[1], *T. Kleefstra*[1], *H. G. Brunner*[1,4], *L. E. L. M. Vissers*[1], *J. A. Veltman*[1,4];
[1]*Radboud university medical center, Nijmegen, Netherlands,* [2]*Complete Genomics Inc, Mountain View, CA, United States,* [3]*State Key Laboratory of Medical Genetics, Central South University, Changsha, China,* [4]*Maastricht University Medical Centre, Maastricht, Netherlands.*

Severe intellectual disability (ID) occurs in 0.5% of newborns and is thought to be largely genetic in origin. The extensive genetic heterogeneity of the disorder requires a genome wide detection of all types of genetic variation. Microarray studies and more recently exome sequencing have demonstrated the importance of de novo copy number variations (CNVs) and single nucleotide variations (SNVs) in ID, but the majority of cases remains undiagnosed. Here we applied whole genome sequencing (WGS) to 50 patients with severe ID and their unaffected parents. All patients were negative after extensive genetic prescreening, including microarray-based CNV studies and exome sequencing. Notwithstanding this prescreening, de novo SNVs affecting the coding region provided a conclusive genetic cause in 13 patients and a possible cause for another 8 patients. In addition, we identified 7 clinically relevant de novo CNVs as well as one recessively inherited compound heterozygous CNV. These CNVs included single exon and intraexonic deletions of known ID genes as well as interchromosomal duplications. Local realignment of sequence reads allowed the mapping of most of these CNVs at single nucleotide resolution level and provided positional information for duplicated sequences. These results show that de novo mutations and CNVs affecting the coding region are the major cause of severe ID. Genome sequencing can be applied as a single genetic test to reliably identify and characterize the comprehensive spectrum of genetic variation, providing a genetic diagnosis in the majority of patients with severe ID.

PL3.1 - Summary
Incidental findings in clinical exome and genome sequencing

Diagnostic exome and genome sequencing data can be interrogated for clinically relevant variants other than those relevant for a diagnostic request. There are different opinions on the way to deal with these „incidental findings" in the clinic, on the potential benefits and risks to patients, on patient autonomy and on the obligation of laboratories to report these findings. These will be debated with representatives from both sides of the Atlantic.

PL3.1
Incidental findings in clinical exome and genome sequencing

R. Green;
Boston, MA, United States.

In 2013, the American College of Medical Genetics and Genomics (ACMG) issued Recommendations for incidental findings in clinical exome and genome sequencing. The Recommendations were written by a Working Group of 14 medical geneticists, laboratory geneticists, genetic counselors and ethicists who met regularly for 14 months to draft them. The draft Recommendations were presented for commentary in a public forum at the 2012 Annual Meeting of the ACMG, reviewed by 15 additional experts, and reviewed several times by the Board of the ACMG before being issued in March, 2013. The Recommendations

were recently amended in March, 2014.
The Recommendations were consensus-based, as empirical data on population penetrance and medical outcomes of identifying incidental variants are not available. The Recommendations called for molecular laboratories performing clinical sequencing for any indication on patients of any age to examine 56 genes associated with 24 actionable conditions for pathogenic variants. The Recommendations now suggest that patients be offered an option to decline these tests as a group at the time they are ordered.
Several clinical sequencing laboratories in the US have adopted the Recommendations and over 1000 reports of incidental findings have been issued. The incidence of the ACMG variants in unselected populations appears to be 2-4%. Additional data from our experimental laboratory of translational genomics on the issue of incidental findings will be presented.

PL3.3
Debate: Active search for clearly pathogenic variants that require direct clinical intervention; When related to late onset disorders, adults only.

M. Kriek;
Clinical Geneticist, Department of Clinical Genetics, Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands.

In 2013 the 'American College of Medical Genetics and Genomics' (ACMG) published a list of 56 genes that are proposed specific targets of a search for pathogenic variants in both children and adults (*Green et al.*). These genes are associated with diseases with an indication for immediate medical intervention of the patient or of a family member. The publication asserts that, in principle, the necessary patient data are available following a NGS procedure and therefore cannot be ignored. For purposes of clarity, the vast majority of these variants are removed during the various filtering stages of the normal trio analysis process and that identification of these variants will require additional actions.
During the American Society of Human Genetics meeting 2013, it was argued that consensus on a basic list of clearly pathogenic *variants* in the relevant genes is essential if this form of diagnosis is to be implemented in genetic diagnostics. A disadvantage of the approach as proposed by the ACMG (analysis of the entire gene, rather than focusing on known pathogenic gene variants) is that variants will be detected that have not been previously reported and/or are of undefined pathogenicity. This could result in considerable distress for the patient and family. To avoid this, only selected variants in the genes nominated by the ACMG will be analysed.
Another point of discussion is whether conditions that manifest later in life should be investigated in children. While the ACMG is in favour, *Ploem et al.* are of a different opinion: „When it comes to the unsolicited findings of NGS diagnostics in a young child, the interests of the child prevail over any wishes of the parents (not) to receive certain information." (NTVG 2014;158:A6757). This is consistent with ESHG recommendations (EJHG 2013;21:580-4)).
'In case of testing minors, guidelines need to be established as to what unsolicited information should be disclosed in order to balance the autonomy and interests of the child and the parental rights and needs (not) to receive information that may be in the interest of their (future) family'
A solution to these conflicting interests is as follows: where the index patient is a minor, a genetic predisposition for 'late onset' diseases for which immediate medical treatment is indicated will only be sought in parents. This is made possible by the setup of trio analysis in which variant lists are available for each parent.
Genetic variants that result in clinical manifestations that in require direct intervention during childhood will be analysed in the index patient, even when a minor.

PL3.4
Debate: Whole-genome sequencing in health care: proceed with caution and avoid incidental findings

M. C. Cornel;
VU University Medical Center, Amsterdam, Netherlands.

Whole-genome sequencing (WGS) of the human genome has a great potential to identify the genetic component of health problems, and probably, in the near future, at a lower cost than that of the current techniques. Proof of principle regarding the clinical utility of WGS followed by whole genome analysis (WGA) has been reported, especially for rare diseases. The Public and Professional Policy Committee of ESHG developed recommendations on whole genome sequencing for health care (EJHG 2013;21:580-4).
As a first element of the discussion, we have to consider all stakeholders involved: patients looking for a diagnosis, primary care physicians referring patients and following them for many years after the diagnosis, laboratory experts and clinical geneticists, legal and ethical experts. If a new technology is being implemented, a mutual learning process starts. Structures are needed for sharing experiences and establish testing guidelines at local, national and international levels.
When *in the clinical setting* either targeted sequencing or analysis of genome data is possible, it is preferable to use a targeted approach first in order to avoid unsolicited findings or findings that cannot be interpreted. The ACMG advocates (Genet Med 2013;15:565-74) that there is a potential for the recognition and reporting of incidental or secondary findings unrelated to the indication for ordering the sequencing but of medical value for patient care. The ESHG position is that whenever possible, such testing should be targeted to genome regions linked to the indication. Wider testing requires a justification in terms of necessity and proportionality. Adding screening targets to a diagnostic test violates the necessity criterion. Imposing this extra testing upon patients who need an answer to their clinical problem is at odds with respect for autonomy (Science 2013;341:958-9). Guidelines for the informed consent procedure in WGA must be developed (Hum Mutat. 2013;34:1322-8).
Also in a targeted analysis it is possible to detect an unsolicited genetic variant, indicative of serious health problems (either in the person tested or his or her close relatives) that allow for treatment or prevention. In principle, a healthcare professional should report such genetic variants (EJHG 2013;21:580-4).
To prepare the health care professionals for WGS in health care, a sustained effort at genetic education is required at various levels: in primary care to inform and refer people appropriately, and in specialized care to counsel or refer patients, and to discuss and interpret genetic test results adequately. Genetic experts should engage in discussing new developments in genetics, and explain the pros and cons of genetic testing and screening in clinical and commercial settings to inform the public and raise public awareness. Enhancing genetic literacy in patients and the lay public will help to involve wider society in this debate.

PL4.1
Gene Targeting into the 21st Century: Mouse Models of Human Diseases from Cancer to Neuropsychiatric Disorders

M. Capecchi;
Howard Hughes Medical Institute, University of Utah School of Medicine, Salt Lake City, UT, United States.

Gene targeting provides the means for modifying any gene in any desired manner in an intact, living animal, the mouse. This technology permits the evaluation of the function of genes in mammals. Because nearly all biological phenomena are mediated or influenced by the activity of genes, this methodology permits the analysis of the most complex biological processes such as development, learning, normal and aberrant behavior, cancer, immunology and a multitude of congenital human diseases. In the past, gene targeting has been used primarily to generate ‚knockout' mice, that is mice in which the chosen gene has been disrupted in the germline, such that every cell in the mouse carries the mutations. This methodology permits evaluation of the function of that gene in the intact mouse. However, many, if not most, genes have multiple functions. If one of those functions is critical to the survival of the mouse, then subsequent functions of that gene in the mouse cannot be evaluated by the above means. This problem can be circumvented by generating conditional mutations, that restrict the effects of the mutation temporally, spatially (to defined sets of cells or tissue), or both. In mice, conditional mutagenesis is achieved by combining gene targeting, which is achieved through homologous recombination, with a site-specific recombination system, such as Cre/loxP or Flp/FRT. Cre and Flp are recombinases that mediate recombination between specific, short DNA sequences, loxP and FRT, respectively. Gene targeting is used to flank your chosen gene with either loxP or FRT sites in the mouse germline. By restricting the production of the Cre or Flp recombinase to either a specific set of cells, a chosen temporal period, or both, within the developing or adult mouse, the gene is only excised from the genome of the mouse, in those selected cells, during that chosen temporal period, or both. I will describe a number of applications of gene targeting and conditional mutagenesis derived in our laboratory that address interesting biological questions from modeling human cancer to neuropsychiatric disorder in the mouse.

PL5.1
Signatures of Mutational Processes in Human Cancer

M. Stratton;
Wellcome Trust Sanger Institute, Hinxton, United Kingdom.

All cancers are caused by somatic mutations. However, the processes underlying the genesis of somatic mutations in human cancer are remarkably poorly understood. Recent large-scale cancer genome sequencing initiatives have provided us with new insights into these mutational processes through the mutational signatures they leave on the cancer genome. In this talk I will review the mutational signatures found across cancer and consider the underlying mutational processes that have been operative.

SYMPOSIA

S01.1
From rare disease to management of common disorders
M. Summar;

S02.1
Variation and genetic control of chromatin in humans
B. Deplancke;
Lausanne, Switzerland.

Understanding how a genome gives rise to complex phenotypes is one of the key unresolved questions in biology. In this talk, I will present results from our study aiming to examine the mechanistic relationship between genomic and molecular phenotypic variation. Specifically, we profiled three histone modifications (H3K4me1, H3K4me3, H3K27ac), two DNA binding factors (PU.1, RNA polymerase II), and gene expression in lymphoblastoid cell lines from 50 European individuals, reasoning that an integrated analysis of intermediate molecular phenotypes coupled with personal genome information might enable an in-depth characterization of non-coding variation. I will discuss how the resulting data allowed us to measure inter-individual variation in chromatin states, to predict sex-biased regulatory regions, and to map the regulatory architecture behind gene expression variation. As such, I will argue that we were able to provide a comprehensive view of chromatin state variation in a human population and to generate novel molecular insights into the propagation of genetic signals along the complex chain of molecular, regulatory events.

S02.3
Computational challenges in single-cell transcriptomics
J. Marioni;
EMBL-EBI, Hinxton, United Kingdom.

Recent technical developments have enabled the transcriptomes of hundreds of cells to be assayed in an unbiased manner. These approaches have enabled heterogeneity in gene expression levels across populations of cells to be characterized as well as facilitating the identification of new, and potentially physiologically relevant, sub-populations of cells.
However, to fully exploit such data and to answer these questions, it is necessary to develop robust computational methods that take account of both technical noise and underlying, potentially confounding, variables such as the cell cycle.
In this presentation I will begin by briefly describing how we used spike-ins to quantify technical noise in single-cell RNA-seq data, thus facilitating identification of genes with more variation in expression levels across cells than expected by chance. Subsequently, I will discuss a computational approach that uses latent variable models to account for potentially confounding factors such as the cell cycle before applying it to study the differentiation of Th2 cells. I will show that accounting for cell-to-cell correlations due to the cell cycle allows identification of otherwise obscured sub-populations of cells that correspond to different stages along the path to fully differentiated Th2 cells.
To conclude, I will briefly discuss further applications of single-cell RNA-seq in the context of studying neuronal cell types, including olfactory neurons.

S03.1
Pontocerebellar hypoplasia
K. Kutsche;
Institute of Human Genetics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Pontocerebellar hypoplasias (PCH) constitute a group of autosomal recessively inherited neurodegenerative disorders with prenatal onset. Classification based on clinical, neuroradiological and neuropathological characteristics divided PCH into eight subtypes; the underlying genetic cause has been identified in six PCH types (PCH1, PCH2, and PCH4-6 and 8). PCH2 represents the most frequent form of PCHs and typical clinical features are respiratory and feeding difficulties at birth, dyskinesia and chorea, severe impairment of cognitive and motor development, progressive microcephaly, and frequent death in late infancy or early childhood. MRI imaging in PCH2 shows brainstem and cerebellar hypoplasia, with the cerebellar hemispheres more affected than the vermis. In patients with PCH2, 4 and 5, biallelic mutations in genes encoding three subunits of the heterotetrameric transfer RNA (tRNA) splicing endonuclease complex, *TSEN54*, *TSEN2*, and *TSEN34* have been identified. PCH shows significant overlapping features with microcephaly with pontine and cerebellar hypoplasia (MICPCH), generally associated with loss-of-function *CASK* mutations. The classical MICPCH phenotype can be found in females who typically have moderate to severe intellectual disability and progressive microcephaly with pontine and cerebellar hypoplasia. Possible findings are ophthalmologic anomalies and sensorineural hearing loss. Males with a *CASK* mutation have also been identified. The phenotypic spectrum ranges from severe intellectual disability and MICPCH, or early-infantile epileptic encephalopathy to mild X-linked intellectual disability (XLID) with or without nystagmus. I will present an overview on clinical and genetic data of patients with PCH and MICPCH and how to discriminate the two conditions. My focus will be on the different *CASK* mutations in females and males and their associated phenotypes to help understanding genotype-phenotype relationships.

S03.3
Neuronal migration defects associated with mutations in tubulins and MT-related proteins
L. Broix, K. Poirier, Y. Saillour, N. Bahi-Buisson, **J. Chelly**;
Cochin Institute, INSERM Unit 1016, CNRS –UMR 8104, Paris-Descartes University, Paris, France.

Neuronal migration disorders such as malformations of cortical development are frequent causes of epilepsy and intellectual disability. Disrupted biological and cellular processes such as neuronal progenitors proliferation, neuronal migration, and cortical organization, are traditionally used as a basis for the classification of MCD. Etiologies of these disorders are heterogeneous and genetic studies in humans and mice have identified a spectrum of mutations in genes involved in an array of crucial processes that often disrupt the development of the cerebral cortex. Aside from genes such as ARX, GPR56 and WDR62, the importance of genes encoding cytoskeletal proteins has become evident. For example, mutations in DCX and LIS1, both of which encode proteins involved in MT homeostasis, are associated with a large spectrum of neuronal migration disorders. Moreover, MCD associated with mutations in α- or β-tubulin-encoding genes such as TUBA1A, TUBB2B, TUBB3 and TUBB5, have been also described. These tubulin-related cortical dysgenesis are thought to involve a combination of abnormal neuronal proliferation, migration and differentiation. More recently, we reported the association between mutations in TUBG1, DYNC1H1, KIF2A and KIF5C, and diverse forms of malformations of cortical development with or without microcephaly. We further showed that the mutations in these MTs-related proteins: KIF5C, KIF2A and DYNC1H1 affect ATP hydrolysis, productive protein folding and microtubule binding, respectively. In addition, we showed by in utero electroporation that in vivo downexpression by shRNA of mouse, Tubb3 and Tubg1, as well as expression of Kif2a mutants, interferes with proper neuronal polarization and migration, morphogenesis and intermediate progenitor proliferation.
Altogether, these findings together with literature data support the hypothesis that proliferation and migration are genetically and functionally interdependent. Finally, they reinforce the importance of centrosomal and

MT-related proteins in cortical development and strongly suggest that MT-dependent mitotic and post-mitotic processes are major contributors to the pathogenesis of MCD.

S04.1
Disease, networks and epistasis
C. Webber;
Neurological Disease Genomics, MRC Functional Genomics Unit, Department of Physiology, Anatomy & Genetics, Oxford University, Oxford, United Kingdom.

I will give an overview of our recent work in identifying the pathways and processes underlying complex disorders, illustrating how different functional genomics resources can each provide novel biological insights into the same phenotype-influencing gene network. The topologies of the identified networks can identify pathway loading (both additive and epistatic) along with the direction in which the pathway is perturbed, thereby inviting drug repurposing. I will also illustrate some of the novel integrative approaches that we've been applying in GWA/exome studies and used to determine the significance of a functionally-clustered genome.

S04.2
Understanding molecular mechanisms of human disease mutations and coding variants through 3D protein networks
H. Yu;
Ithaca, NY, United States.

To better understand the molecular mechanisms and genetic basis of human disease, we combined the massive scale of network systems biology with the supreme resolution of traditional structural biology to generate the first comprehensive atomic-resolution 3D interactome-network comprising 3,398 interactions between 2,890 proteins with structurally-defined interface residues for each interaction. We found that disease mutations are significantly enriched both among interface residues and other non-interface ones within the same domains, contradicting the previous assumption that only a few interface residues are mutation hot spots for disease. We further classified 94,476 disease-associated mutations according to their inheritance modes and found that the widely-accepted "guilt-by-association" principle does not apply to dominant mutations. Furthermore, recessive truncating mutations on the same interface are much more likely to cause the same disease, even if they are close to the N-terminus of the protein, indicating that a significant fraction of truncating mutations can generate functional protein products.

S04.3
From protein networks to disease mechanisms
R. Sharan;
Tel Aviv University, Department of Computer Science, Tel Aviv, Israel.

In recent years, there is a tremendous growth in large scale data on human proteins, their interactions, and their relations to diseases. These allow for the first time a systems-level analysis of the molecular basis of disease. In my talk I will describe several recent works in this direction, aiming to uncover novel disease proteins and their underlying pathways with implications to diagnosis and therapy.

S05.2
24 chromosome copy number analysis for preimplantation genetic screening
A. H. Handyside;
Illumina, Cambridge, United Kingdom.

Chromosome aneuploidy in human gametes and embryos is a major cause of IVF failure and miscarriage and can result in affected live births. To avoid these outcomes and improve implantation and live birth rates, preimplantation genetic screening (PGS) aims to identify any euploid embryos prior to transfer but has been restricted to analysis of a limited number of chromosomes. Over the last 15 years, various technologies have been developed which allow copy number analysis of all 23 pairs of chromosomes, 22 autosomes and the sex chromosomes, or '24 chromosome' copy number analysis in single or small numbers of cells. The pros and cons of these technologies will be reviewed and evaluated for their potential as screening or diagnostic tests when used in combination with oocyte or embryo biopsy at different stages.

S06.1
Risk is More Than a Number: About Risks and Probabilities and People's Perceptions of Genetic Risks
D. R. M. Timmermans[1,2];
[1]Department of Public and Occupational Health, EMGO Institute, VU University Medical Center, Amsterdam, Netherlands, [2]National Institute for Public Health and the Environment, Bilthoven, Netherlands.

Risk communication is an essential component of genetic counseling . Genetic testing and providing information about genetic predisposition may enable early disease detection, targeted surveillance, and may lead to effective prevention strategies and behavioral change. However, the impact of genetic information on people's perceptions may be limited. Most people are unfamiliar with probabilistic thinking and find it hard to understand risks. Moreover, risks are experienced differently depending on the characteristics of the risk. A risk is more than a number. It is not only the probability, the quantification of the uncertainty, but also the nature of the risk, the severity of the consequences and the degree of control what matters. People process and evaluate information about potential risks in two different ways: analytical-rational if possible, but always intuitive-affective. The characteristics of the risks as well as the way risk information is processed impact people's understanding and perception of risks. This perception may be in discordance with the way experts' perceive genetic risks. In order to enable people to make informed decisions, information about (genetic) risks should not only be adequate but should also be in line with people's perceptions or mental model. Discrepancies with people's mental model of genetic risks as well the abstractness of the risk information may hamper people's informed decision making. In this presentation I will discuss the factors affecting the perception of health risks and genetic risks in particular, the way people understand the risks communicated to them and what this means for risk communication

S06.2
Risk perception: what could be at stake in multiple genetic testing?
C. M. Julian-Reynier;
Institut Paoli-Calmettes, UMR912 Inserm, Marseille, France.

First the concept of risk perception will be introduced, highlighting its interest for clinical practice or various research fields. We will focus on associated factors and in particular on the potential role of emotions in risk perception. Then the evidence for the relevance of previous findings will be reviewed in the context of genetic risk assessment and genetic test result disclosure such as investigated in clinical genetics/genetic counseling. Different application fields such as cancer genetics will be selected as illustrations of different situational contexts. Finally the way these previous experiences and body of knowledge could help to anticipate the potential consequences of multiple risk information disclosure and to document specific recommendations in the context of the process of multiple genetic testing or next generation sequencing will be discussed.

S06.3
Risk Communication Methods for Helping Patients Understand the Risks and Benefits of Genetic Testing
A. Fagerlin;
University of Michigan, Ann Arbor VA Center for Clinical Management Research, Ann Arbor, MI, United States.

Making decisions about whether to undergo genetic testing or how to use information from genetic tests is exceedingly complex. The complexity is due, in part, to the numeracy demands required of patients to understand the information being presented. In this talk, I will discuss methods for improving patients understanding of risk and benefit information. Furthermore, I will discuss how different risk communication methods can influence risk perceptions. Finally, I will discuss the role of family history and how that affects patients' (hypothetical) perception of risk and how patients weigh information about their family history and their risks to make screening decisions.

S07.2
Epithelial stem cell in cell and gene therapy
M. De Luca;
Dipartimento di Scienze della Vita sede ex-Scienze Biomediche, Modena, Italy.

Adult stem cells are cells with a high capacity for self-renewal that can produce terminally differentiated progeny. Stem cells generate an intermediate population of committed progenitors, often referred to as transit amplifying (TA) cells, that terminally differentiate after a limited number of cell divisions. Human keratinocyte stem cells are clonogenic and are known as holoclones. Human corneal stem cells are segregated in the limbus while limbal-derived TA cells form the corneal epithelium. Self-renewal, proliferation and differentiation of limbal stem cells are regulated by the ΔNp63 (α, β and γ), C/EBPδ and Bmi1 transcription factors. Cultivated limbal stem cells generate sheets of corneal epithelium suitable for clinical application. We report long-term clinical results obtained in an homogeneous group of 154 patients presenting with corneal opacification and visual loss due to chemical and thermal burn-dependent limbal stem cell deficiency. The corneal epithelium and the visual acuity of these patients have been restored by grafts of autologous cultured limbal keratinocytes. In post hoc analyses, success was associated with the percentage of p63-bright holoclone-forming stem cells in culture. Graft failure was also associated with the type of initial ocular damage and postoperative complications. Mutations in genes encoding the basement membrane component laminin 5 (LAM5) cause junctional epidermolysis bullosa (JEB), a devastating and often fatal skin adhesion disorder. Epidermal stem cells transduced with a retroviral vector expressing the β3 cDNA can generate genetically corrected cultured epidermal grafts able to permanently restore the skin of patients affected by LAM5-β3-deficient JEB. The implication of these results for the gene therapy of different genetic skin diseases will be discussed.

S07.3
Therapeutic targeting of Phosphatidylinositol-3-kinase/AKT/mTOR signalling in segmental overgrowth disorders
R. Semple;
University of Cambridge, Metabolic Research Laboratories, Addenbrooke's Hospital, Cambridge, United Kingdom.

The type 1A phosphatidylinositol-3-kinase (PI3K) enzyme complex serves as a signal transducer for a diverse range of hormone and growth factor receptors, and harbours somatic activating mutations in a large number of cancers. We and others have recently established that mosaicism for many of the same mutations underlies a spectrum of disorders of segmental overgrowth, ranging from isolated macrodactyly to catastrophic overgrowth affecting large parts of the body and several tissues, and commonly associated with complex vascular anomalies. Identification of the underlying signalling defect in affected tissues has immediately suggested that pharmacological targeting of the PI3K/AKT/mTOR pathway may offer the first rational, effective therapeutic approach for these disorders. The effect of mTORC or PI3K inhibition in dermal fibroblasts from affected patients will be discussed, as well as the early experience of sirolimus treatment in a severely affected proband.

S08.2
Insights into European genetic history at fine geographic scales using haplotype-based approaches
S. Myers;
Dept of Statistics, Oxford University, United Kingdom

Wellcome Trust Centre for Human Genetics, Oxford University, United Kingdom

Modern genetic datasets are revealing features of our genetic history, and how this has shaped our genomes, in unprecedented detail. Across Europe, multiple invasions and migrations have taken place over the past several millennia, but the possible genetic effects of these and of subsequent regional isolation remain uncharacterised, partly due to the extremely subtle differences between the groups involved. We apply a set of approaches based on "painting" the genomes of people as haplotypic mosaics and describe insights into the existence and nature of extremely fine-scale differences among people from different regions of the UK, and Spain, as well as elsewhere in Europe. In the case of the UK, we show how these differences relate directly to specific historical migration events from other European countries, including invasions by Angles, Saxons and Jutes, and the Vikings. The groups involved in, genetic contributions, and dates, of these migrations are characterized based on genetic information alone.

S08.3
The role of population isolates in understanding genetic and complex diseases
P. Gasparini;
Trieste, Italy.

The use of isolated populations to reduce disease heterogeneity of complex disorders has already proven very useful in identifying DNA polymorphisms associated with complex diseases and quantitative traits. The study of complex traits in geographically and culturally isolated populations is particularly useful because the entire population can be analyzed, the relative weight of environmental variation can be controlled and genetic factors can be more easily identified. In these genetically and culturally homogeneous populations, a large proportion of individuals presenting a given trait is likely to share the same trait-predisposing gene inherited from a common ancestor. Furthermore, inbreeding, typical of small communities, reduces genetic heterogeneity and increases homozygosity, providing greater power for detection of susceptibility genes. We have created the Italian Network of Genetic Isolates (INGI) that collects the samples coming from several villages from 5 different Italian regions for a total of more than 6000 samples. Moreover, additional 1500 samples have been collected along the Silk Road. For all of them a great number of information regarding medical records, hematological parameters and lifestyle has been collected as well as DNA samples which have been genotyped with high density chip arrays. To evaluate the power to detect association in our cohorts we aimed at replicating several already published results and to verify if any new Italian specific loci were present. For example, GWAS were carried out on several hematological and serum lipids traits, blood glucose levels, blood pressure and anthropometric measures leading to the replication of 206 loci and to the discovery of some novel associations for BMI and weight. For 12 of these loci the top associated SNP was different from the one previously published highlighting the importance of having a population specific reference panel for personalized medicine. Moreover, specific genes/variants associated to phenotypes such as hearing, smell, taste and food preferences have been identified. More recently, new data have been obtained using whole genome sequencing data that allow refining the results previously obtained and will lead to the discovery of even more population specific genetic variants. Our results show that genetic isolates are a powerful resource for studying complex traits and thus to create genetic risk profiles which will be the bases for personalized medicine in Italy. Updated data will be presented and discussed.

S09.1
Twenty-five years of research in sarcomeric cardiomyopathies and therapeutic perspectives
H. Watkins;
University of Oxford, Oxford, United Kingdom.

Hypertrophic cardiomyopathy was one of the first monogenic cardiovascular disorders to be understood at the molecular level. Twenty years after the discovery of the first disease gene, HCM is still seen principally to be a disease of the sarcomere. At the biophysical level, the contractile protein mutations that cause HCM are seen to be activating in that they enhance Ca(2+) sensitivity, maximal force production, and ATPase activity. These defects then entrain secondary disturbances of energy deficiency and altered Ca(2+) handling that appear to be major common paths leading to the phenotype of hypertrophy and risk of sudden cardiac death. Importantly, these functional consequences of HCM mutations may lend themselves to specifically targeted approaches to disease modifying therapy for HCM, and phase I/II clinical trials have been completed or are underway.
In contrast, dilated cardiomyopathy is caused by mutations in genes encoding many different classes of proteins with very diverse roles in cardiomyocyte function, e.g. ranging from the nuclear envelope through to the contractile and force transduction apparatus. This indicates that the DCM phenotype is the end result of disparate pathways that lead to myocyte loss and fibrous replacement, suggesting that finding broadly applicable approaches to disease-modifying therapy may be difficult. In the subset of DCM caused by sarcomeric mutations the picture is clearer, and may lead to approaches to therapy, as DCM alleles result in functional changes that are the

opposite of the changes seen with HCM alleles: depressed motor function and reduced Ca(2+) sensitivity.

S09.2
Mendelian Randomization

M. V. Holmes;
University of Pennsylvania, Philadelphia, PA, United States.

Identifying causal biomarkers is important in the quest to prevent and treat cardiovascular disease. Mendelian randomization is a genetic epidemiological technique that can be used to make causal inference about biomarkers and environmental exposures.
I will talk about recent applications of Mendelian randomization with a focus on identifying potential therapeutic targets and understanding the role of physiological traits and environmental exposures in cardiovascular disease pathogenesis.

S09.3
Genetic testing in the clinical arena, current and future perspectives

P. Charron[1,2,3];
[1]Depart. of genetics, Pitié-Salpêtrière hospital, AP-HP, Paris, France, [2]INSERM UMR1166, Paris, France, [3]University UPMC Paris 6, Paris, France.

The recent development of molecular genetics in cardiovascular diseases has created a new understanding of their pathogenesis and natural history, and also new possibilities for the diagnosis of these genetic disorders through genetic testing. This has induced new expectations, and new demands, from both families and physicians regarding genetic counselling, DNA testing and application of this knowledge in clinical practice. The integrated use of genetic testing in routine practice developed rapidly in the context of monogenic cardiovascular disorders (such as cardiomyopathies, channelopathies, Marfan syndrome) with significant medical impacts on the management of patients or their families. This refers to diagnostic testing as well as predictive testing, prognostic evaluation and, rarely, prenatal or preimplantation diagnosis. Encouraging data were also identified in the context of pharmacogenetic interactions (such as Vitamin K antagonists, antiplatelet treatment) and multifactorial diseases (such as coronary artery diseases and heart failure).
The clinical utility of genetic testing was acknowledged through the production of international or national guidelines recommending routine genetic testing in monogenic disorders. However, its use in everyday clinical practice has been limited by the cost and complexity of conventional sequencing technologies. Advances in next generation sequencing technology (NGS) have the potential to solve this problem by analyzing substantially larger genomic regions at a lower cost than conventional capillary Sanger sequencing. But they may also pose new challenges. This was already obvious in preliminary studies that compared a number of variants found in cardiovascular diseases with exome or genome data from general population, and questioning the pathogenicity of variants previously considered as disease-causing. We will review the advantages, pitfalls, and clinical utility of NGS in the clinical setting of cardiovascular disorders, especially in the context of monogenic disorders.
Email : philippe.charron@psl.ap-hop-paris.fr

S10.1
Chromotrypsis

E. Cuppen[1], *W. Kloosterman*[2];
[1]Hubrecht Institute and Center for Molecular Medicine UMC Utrecht, Utrecht, Netherlands, [2]Center for Molecular Medicine UMC Utrecht, Utrecht, Netherlands.

De novo genomic rearrangements are a common cause of congenital abnormalities and mental retardation. However, in the majority of patients a molecular mechanism linking rearranged chromosomes to disease phenotype is lacking. This is particularly true for ultra-complex genomic rearrangements, such as those resulting from catastrophic chromosome shattering termed chromothripsis. We developed a family-based approach for dissecting the functional consequences of (complex) genomic rearrangements in patients with congenital disease. This approach combines gene-expression and chromatin profiling with functional studies in patient-derived cell lines and model organisms. We highlight two cases where family-based analysis and functional follow-up studies were instrumental to reveal the drivers of the disease phenotype. The described methodology is key for understanding disease in a large and broad category of patients with chromosomal aberrations of unclassified significance and thereby improves diagnosis and clinical decision-making.

S10.2
Kataegis: a mutation signature identified through whole-genome sequencing of human cancers

S. Nik-Zainal[1,2], *L. B. Alexandrov*[1], *B. J. Taylor*[3], *Y. Wu*[3], *D. Wedge*[1], *C. Rada*[3], *P. J. Campbell*[1], *M. Neuberger*[3], *M. R. Stratton*[1];
[1]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [2]East Anglian Medical Genetics Service, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, [3]Laboratory of Molecular Biology, Cambridge, United Kingdom.

Cancer is the ultimate disorder of the genome, characterised by not one or two substitutions, indels or copy number aberrations, but hundreds to thousands of acquired mutations that have been accrued through the development of a tumour. The set of mutations observed in a cancer genome is not simply a random accumulation of variants. It is the aggregate outcome of several biological mutational processes comprising an underlying mechanism of DNA damage mitigated by the DNA repair pathways that exist in human cells. Each mutational process will leave its distinctive mark or mutational signature on the cancer genome.
Recently, we set out to extract the mutational signatures characterizing the mutational processes that have been operative in 21 whole-genome sequenced breast cancers. Multiple distinct known and novel substitution, insertion/deletion and rearrangement signatures were unearthed by these analyses. Here, I will describe one particularly intriguing signature of localized regions of dense somatic hypermutation, called kataegis, in which substitutions at C:G base pairs occurring within a distinctive sequence context were found associated with clusters of genomic rearrangements. Using an algorithm developed to allow efficient detection of kataegis, we investigate other whole-genome sequenced cancers to show that this phenomenon is not restricted to breast cancer. These studies harness the full scale of whole-genome sequencing. Furthermore, detailed and considered analyses of genomic data can provide biological insights that would otherwise remain buried.
The mechanism of kataegis however, is unknown. On the basis of similarities in mutation class and sequence context in experimental systems, members of the AID/APOBEC family of cytidine deaminases were implicated. Using whole-genome sequencing approaches in model organisms, the mechanism underlying kataegis is slowly being unraveled.

S11.3
Copy number variants are a common cause of short stature

C. T. Thiel[1], *A. Reis*[1], *H. Dörr*[2], *A. Rauch*[3];
[1]Institute of Human Genetics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, [2]Department of Pediatrics and Adolescent Medicine, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, [3]Institute of Medical Genetics, University of Zurich, Zurich, Switzerland.

Shortness of stature is one of the most common pediatric concerns and has an incidence of 3 % in the general population. In the majority of patients with idiopathic growth deficit the etiology remains elusive in the absence of morphological details. This unknown etiology prevents a sufficient medical care in most cases.
As it has been proposed that the growth fundamentally regulated by genetic factors, GWAS found significant evidence for both single nucleotide and copy number polymorphisms associated with height variation in the general population. However, these associations explain only a small fraction of the overall variability of human height.
Based on the early identification of SHOX gene deletions as a common cause

of idiopathic and syndromic (Leri-Weil syndrome) short stature as well as copy number variation (CNV) as a common cause of intellectual disability, the hypothesis of a "rare variant - frequent disease" hypothesis seemed to be feasible for short stature. To address this hypothesis we thoroughly build a study group of more than 400 families with idiopathic short stature and conducted SNP array analysis to demonstrate the presence of CNVs as a common underlying cause of short stature. Molecular karyotyping was performed and CNVs of a minimum size of 50kb scored and compared to healthy controls. Based on this technique we found a significant odds ratio for aberrations above 100 kb only. Due to the number of potential disease causing CNVs a gene-centric analysis comparing known CNVs, gene functions, tissue expression and murine knock-out phenotypes was neccessary. We confirmed that 10 % of the patients had de novo and inherited CNVs in agreement to the segregation of the short stature phenotype in the families. These CNV regions include known microdeletion/duplication loci expanding the phenotypical spectrum of these entities. The pathogenicity of novel loci was substantiated by comparison to available information, especially the overlap with loci of genome wide association for short stature. Our data showed a clear connection between the prenatal onset of short stature as well as the severity of the growth deficit with the likelihood of the identification of causal CNVs. Thus, we confirmed CNVs as a main cause of idiopathic short stature. Further improvement of the array technology as well as the application of CNV identification based on next generation sequencing will lead to a more elaborate and detailed view on even smaller CNVs. Application of these methods can help to illuminate the complex heterogeneity of short stature.

S12.1
The Epigenetic Basis of Common Human Disease

A. P. Feinberg;
Johns Hopkins University, Baltimore, MD, United States.

Although epigenetic changes in the cancer genome have been known for 3 decades, the role of epigenetics in common human disease generally and its relationship to genetic variation has only recently begun to be explored. We have been developing whole-genome approaches to epigenetic analysis of human disease. Surprising results have been the discovery of CpG island shores and large hypomethylated blocks corresponding to nuclear lamina / heterochromatin lysine-modification regions (LOCKs), and accounting for the vast majority of epigenetic changes in cancer. We have also been contributing to a new field of epigenetic epidemiology that integrates genetic, epigenetic, and environmental factors, and we are applying these approaches to the study of autoimmune and neuropsychiatric disease. One of the most exciting developments in this recent work is the idea that epigenetic plasticity under genetic control may itself confer a survival advantage in evolution, and may also be important in normal tissue differentiation and response to the environment. In support of this idea, we have identified variably methylated regions (VMRs) in normal development. These same VMRs appear to be targets for disrupted methylation in cancer, pointing to a unifying model of cancer in which epigenetic dysregulation allows rapid selection for tumor cell survival at the expense of the host. We have also identified genetic variants that increase epigenetic plasticity in patients with autoimmune disease. Thus, will need to integrate genetic and epigenetic analysis in common disease risk assessment, prevention, and treatment, and also consider the role of epigenetic plasticity itself in disease pathogenesis.

S12.2
Intergenerational epigenetic programming in a mouse model of undernutrition

A. C. Ferguson-Smith;
University of Cambridge, Department of Genetics, Cambridge, United Kingdom.

Environmental factors during early life are critical for the later metabolic health of the individual and of future progeny. In a mouse model of maternal caloric restriction during pregnancy the metabolic physiology of offspring over two generations is affected, including via paternal transmission to the second generation. Here we explore whether the paternal experience of in utero undernutrition, with an impact on the health of his offspring, is an epigenetically inherited memory transmitted via his sperm methylome.

S12.3
Cancer Genetics and Epigenetics: Two Sides of the Same Coin?

P. A. Jones;
Chief Scientific Officer, Van Andel Research Institute, Grand Rapids, MI, United States.

Genetic and epigenetic alterations used to be considered as providing two separate pathways leading to cancer. However, recent whole exome sequencing of a large number of human cancers has led to the realization that many previously unknown mutations occur in genes which regulate the epigenome. These mutations could potentially alter DNA methylation patterns, histone modifications and the positioning of nucleosomes to profoundly alter gene expression in cancer. Mutations in these genes can therefore contribute to cancer just as epigenetic processes can cause mutations in tumor suppressor genes and disable DNA repair enzymes such as MLH1 and MGMT. The cross talk between the genome and the epigenome is therefore a fascinating new area of research which gives us unprecedented opportunities to understand carcinogenesis. Because many of the genes which are mutated are enzymes, these findings may also lead to new avenues for drug discovery. Epigenetic therapies are already a reality and we can expect great progress to be made over the next few years as new targets are identified and tested for their potential new cancer targets.

S13.1
State of the Art of Non-Invasive Prenatal Testing

L. S. Chitty;
London, United Kingdom.

Traditionally definitive prenatal diagnosis of genetic and chromosomal disorders has required analysis of fetal tissue obtained by invasive testing (usually chorionic villus sampling or amniocentesis) which carries a small but significant risk of miscarriage. The identification of cell free fetal DNA (cffDNA) in maternal plasma from four weeks gestation offered an alternative source of fetal genetic material for testing based on a simple maternal blood sample, thereby allowing earlier and safer prenatal diagnosis.
The majority of cell free DNA in maternal plasma emanates from the mother herself. This high background of maternal cfDNA meant that early applications were based on the detection of exclusion of alleles that were inherited from the father, e.g. SRY, or that arose de-novo, e.g. achondondroplasia. Fetal sex determination based on analysis of cfDNA is now widely available in Europe in pregnancies at risk of sex-linked disorders, where it is used to direct invasive testing. It is also available clinically in the UK for the definitive diagnosis of a number of conditions including some skeletal dypslasias and Apert syndrome, as well as for the exclusion of the paternal allele in families at risk of cystic fibrosis where parents carry different mutations. Elsewhere in Europe it has been used for the non-invasive diagnosis of other conditions such as Huntingdon Disease, but invasive testing has been required to confirm the fetal mutation status. The other major application is fetal Rhesus-D typing in RhD negative mothers where it is used both to inform pregnancy management in women with a history of haemolytic disease of the newborn, as well as to direct routine immunoprophylaxis with anti-D immunoglobulin to those RhD negative mothers carrying an RhD positive baby.
With the advent of next generation sequencing (NGS) it has become possible to estimate the proportion of sequence aligning to different chromosomes present in maternal blood and thereby detect fetal aneuploidy. This is now widely available in the private sector with detection rates for trisomies 13, 18 and 21 in excess of 99% with similarly high specificities. However discordant results are regularly reported and this test can only be considered a highly predictive screening test with invasive testing required to confirm positive results.
The potential for easy access to non-invasive prenatal diagnosis and testing has raised significant ethical concerns, largely with regard to maintaining informed parental choice, and the need for good health professional and public education. The huge commercial drive to implement NIPT for aneuploidy serves to heighten the need for early introduction of educational programmes and careful consideration of strategies required to facilitate appropriate implementation into public health services.

S13.2
Noninvasive prenatal testing creates an opportunity for antenatal treatment of Down syndrome

D. W. Bianchi[1], *T. Tarui*[1], *M. Ferres*[1], *J. Pennings*[2], *D. Slonim*[3], *F. Guedj*[1];
[1]*Tufts Medical Center, Boston, MA, United States,* [2]*National Institute for Public Health and Environment, Bilthoven, Netherlands,* [3]*Tufts University, Medford, MA, United States.*

Noninvasive prenatal testing (NIPT) for Down syndrome (DS) using massively parallel sequencing of maternal plasma DNA facilitates early detection of affected fetuses. If NIPT is performed at ~ 12 weeks of gestation it creates a potential 28-week window of opportunity in which to treat the fetus by orally administering small molecules to the mother. Our laboratory is using a 4 phase translational approach that involves human biomaterials (amniocytes and amniotic fluid), a mouse model of DS, and living human fetuses. In phase 1 we compared the transcriptome of fetuses with and without DS by analysis of cell-free RNA in amniotic fluid and showed that oxidative stress was a significant difference in the affected fetuses. In phase 2 we uploaded differentially-regulated genes into the Connectivity Map to identify candidate FDA-approved therapeutic molecules. In phase 3 drugs that had high efficacy in negating oxidative stress and showed low toxicity were selected for further studies in an animal model. We use the Ts1Cje mouse model of DS because affected males are fertile, yet

cognition is significantly impaired. We can therefore use wild type females for the treatment experiments, ensuring both a normal intrauterine environment and normal postnatal nurturing behavior. Treated and untreated affected pups and littermate controls are then evaluated using a variety of brain studies that include analyses of gene expression, histology, cellular proliferation and migration, and neurobehavior. In parallel, in phase 4 we are preparing for a human clinical trial by analyzing fetal brain growth using quantitative fetal magnetic resonance imaging (MRIs). To date, we have identified significant phenotypic differences in Ts1Cje embryos and neonates as endpoints to evaluate therapy. We have also shown encouraging, statistically-significant improvement in some neurobehavioral tests in adult mice. These results suggest that prenatal treatment in DS is an achievable goal.

S13.3
Clinical and social implications of NIPT

K. E. Ormond;
Stanford University School of Medicine, Stanford, CA, United States.

Noninvasive prenatal testing (NIPT) became clinically available in late 2011. Since that time, hundreds of thousands of pregnant women have undergone NIPT. This talk will discuss the social and ethical concerns that preceeded the clinical use of NIPT, as well as the data that exists on patient, provider and stakeholder attitudes towards NIPT now that it is in use.

S14.1
Developments in rapid DNA sequencing technology

J. O'Halloran[1], **J. Tyson**[2];
[1]Newcastle upon Tyne, United Kingdom, [2]QuantuMDx, Newcastle upon Tyne, United Kingdom.

S14.3
Impact of rapid DNA sequencing on diagnostic and public health microbiology

C. U. Köser;
University of Cambridge, Cambridge, United Kingdom.

Whole genome sequencing (WGS) promises to be transformative for the practice of clinical microbiology, and the rapidly falling cost and turnaround time mean that this will become a viable technology in diagnostic and reference laboratories in the near future. The objective of this talk is to provide an overview of a modern diagnostic microbiology laboratory in order to analyse at a very practical level where WGS might be cost-effective compared to current alternatives. I propose that molecular epidemiology performed for outbreak investigations and genotypic antimicrobial susceptibility testing for microbes that are difficult to grow represent the most immediate areas for application of WGS, and discuss the technical and infrastructure requirements for this to be implemented.

S15.1
Signaling networks in the auditory sensory cells unveiled by hereditary deafness

N. Michalski[1,2,3], **C. Petit**[1,2,3,4,5];
[1]Unité de Génétique et Physiologie de l'Audition, Institut Pasteur, Paris, France, [2]UMRS 1120, Institut National de la Santé et de la Recherche Médicale (INSERM), Paris, France, [3]Sorbonne Universités, UPMC Univ Paris 06, Paris, France, [4]Syndrome de Usher et autres Atteintes Rétino-Cochléaires, Institut de la vision, Paris, France, [5]Collège de France, Paris, France.

The biochemical study of the components and associated molecular networks of the auditory sensory cells, the hair cells, are strongly impeded by the small number of these cells. In contrast, human and mouse genetic approaches have proven to be powerful to identify such components.
The presentation will focus on the hair bundle of the hair cells that operates the mechano-electrical transduction (MET). This sensory antenna is comprised of several rows of rigid microvilli, known as stereocilia of a few femtoliters in volume, that are organised in a staircase pattern. The MET process relies not only on the MET machinery but also on the proper architectural and biophysical properties of the hair bundle. In addition, any defect that affects the mechanical elements involved in sound-induced oscillation of the hair bundle or its ionic environment necessary to drive hair cell depolarization, also perturbs MET. For each of these contributors to the MET, several key components have been identified by studying inherited deafness forms; they are used as entry points to decipher the involved molecular networks.
The presentation will illustrate how the genetic approach led to the discovery of molecules controlling the development, maturation and maintenance of the correct structure of the hair bundle and the MET process. It will illustrate how it enlightens our understanding of the way these proteins form molecular complexes *in vivo* and how these complexes work and cooperate together. A special emphasis will be put on the networks composed of proteins encoded by the genes responsible for the Usher syndrome, the most frequent cause of hereditary sensorineural deafness associated with retinitis pigmentosa. Usher genes are critically involved in hair bundle development and the MET machinery as well as the functioning of the photoreceptor cells. Recent results based on mouse and human genetics, which provide evidence for a molecular maturation of the auditory MET machinery, will be discussed.

S15.2
Genes and cellular pathway of Fanconi's anemia

J. Surrallés;
Group of Genome Instability and DNA Repair, Department of Genetics and Microbiology, Universitat Autònoma de Barcelona (UAB) and Center for Biomedical Network Research on Rare Diseases (CIBERER), Barcelona, Spain.

Fanconi anemia (FA) is a rare genetic disease characterized by bone marrow failure, malformations, chromosome fragility, hypersensitivity to DNA interstrand cross-linking (ICL) chemotherapy and a high predisposition to cancer, including leukemia and solid tumors such as head-and-neck and gynecological carcinomas. The only cure of the hematological disease, which is the major cause of early death, is bone marrow transplantation using an HLA compatible donor. Those families with unavailable donor rely on preimplantation genetic diagnosis with selection of an HLA related embryo and in the future implementation of advanced gene and cell therapies. All these novel therapeutic applications to human health are further complicated by the fact that at least 16 genes, from FANCA to FANCQ, are involved in this disease and their products interact in a complex genome stability and tumor suppression network. Notably, 4 out of 16 FA genes (FANCD1/BRCA2, FANCN/PALB2, FANCJ/BRIP1 and FANCO/Rad51C) are breast cancer susceptibility genes in otherwise unaffected mutation carriers. Therefore, the discovery of novel Fanconi anemia genes is important not only for the affected patients but also for the general population. In this context, I will present data on the discovery of a novel Fanconi anemia gene by whole exome sequencing. Interestingly, this gene (ERCC4 o FANCQ) is involved not only in FA but also in xeroderma pigmentosum, a melanoma susceptibility disorder with defective nucleotide excision repair (NER), and in XFE-type progeria. Our genetic and biochemical results indicate that depending on the balance between ICL repair and NER, mutations in the same gene lead to clinically three distinct disorders.

S15.3
Analysis of signalling pathways in Tbx1 mutants identifies a novel mechanism in coronary artery Morphogenesis

P. J. Scambler[1], *S. Ivins*[1], *J. Chappell*[1], *J. Suntharalingham*[1], *B. Vernay*[1], *T. Mohun*[2];
[1]UCL Institute of Child Health, London, United Kingdom, [2]MRC National Laboratory for Medical Research, London, United Kingdom.

Much of the phenotype of 22q11 deletion syndrome (22q11DS) is secondary to haploinsufficiency of the transcription factor TBX1. Several studies have demonstrated distinct temporal and tissue-specific requirements for Tbx1 during development. Identification of candidate targets has led to new insights into cardiovascular morphogenesis. One such potential target is the signalling protein CXCL12 and its receptor CXCR4. This pathway is involved in collective cell migration, initiating contact inhibition of locomotion (CIL-"chase and run") between NCC and ectodermal placode. We predicted that disruption of this pathway in Tbx1 null mice would lead altered NCC patterning, and therefore conditionally mutated the receptor in cardiac neural crest cells. However, no defects were observed suggesting major species differences in the role of CXCL12-CXCR4 signalling. Rather, we showed that CXCR4 positive endothelial cells were the main target cell population, and that disruption of signalling led to VSDs, great vessel defects, and semilunar valve defects. In addition, lack of CXCL12-CXCR4 signalling led to a major failure in the elaboration of mature coronary arteries from the coronary endothelial plexus. This deficiency could be traced to a failure of invasion of the aortic root by endothelial cells and subsequent anastomosis of plexus vessels with the aorta. Reduction of Cxcl12 expression in the outflow tract of Tbx1 null embryos may therefore underlie the minor coronary artery dysmorphogenesis seen in these animals. Others have implicated the CXCL12-

CXCR4 pathway in some of the neurological deficits observed in chromosomally engineered mouse models of 22q11DS, suggesting multiple, independent roles for this pathway in 22q11DS.

S16.1
SINEUPs: a new functional class of antisense non-coding RNAs that activate translation

S. Gustincich;
Trieste, Italy.

No abstract received at production date. Check the online database at www.eshg.org/astracts2014.0.html for possible updates.

S16.2
Molecular function of the repetitive (epi)genome in normal physiology and in disease

D. Gabellini;
Dulbecco Telethon Institute and San Raffaele Scientific Institute, Milan, Italy.

Only about 1% of the genome encodes for the ~20000 human proteins, which are similar in number and largely orthologous to those found in organisms of significant lower complexity. On the contrary, the proportion of non protein-coding DNA has increased with developmental complexity reaching 98.5% in humans. Interestingly, up to two thirds of the human genome is composed of non protein-coding repetitive sequences. Furthermore, a significant portion of the epigenetic modifications is present in these regions and DNA repeats are dynamically transcribed in different cells and developmental stages producing a vast pool of non protein-coding RNA (ncRNA) molecules. Thus, ncRNAs produced by DNA repeats may hold the key to understanding the regulatory complexity inherent in advanced biological networks.
Long ncRNAs (lncRNAs) represent the most numerous and functionally diverse class of RNA produced by mammalian cells. Despite the growing interest on lncRNAs, they still remain poorly explored in terms of biological relevance, cellular function, mechanism of action and involvement in disease. We have recently contributed to this field through the identification of the first activating lncRNA involved in a human genetic disease: facioscapulohumeral muscular dystrophy (FSHD).
FSHD is one of the most important genetic diseases affecting the skeletal muscle. It is an autosomal dominant disorder with a strong epigenetic component. Unlike the majority of genetic diseases, FSHD is not caused by mutation in a protein-coding gene. Instead, the disease is associated with a reduced copy number of the D4Z4 macrosatellite repeat mapping to 4q35. Despite years of intensive research, the molecular pathogenesis of FSHD remains largely unknown. We recently identified DBE-T, a chromatin-associated lncRNA produced preferentially in FSHD patients. DBE-T mediates a Polycomb to Trithorax epigenetic switch at the FSHD locus, driving chromatin remodeling and transcription of FSHD candidate genes.
Here, I will discuss our recent results regarding the regulation of DBE-T expression, the mechanism responsible for DBE-T tethering to chromatin and how this lncRNA regulates the epigenetic status of the FSHD locus.

S16.3
The SMN complex: RNA processing and motor neuron disease

L. Pellizoni[1,2];
[1]Department of Pathology and Cell Biology, Columbia University, New York, NY, United States, [2]Center for Motor Neuron Biology and Disease, Columbia University, New York, NY, United States.

At the post-transcriptional level, expression of protein-coding genes is controlled by a series of RNA regulatory events including nuclear processing of primary transcripts, transport of mature mRNAs to specific cellular compartments, translation and ultimately, turnover. These processes are orchestrated through the dynamic association of mRNAs with RNA binding proteins and ribonucleoprotein (RNP) complexes. Accurate formation of RNPs in vivo is fundamentally important to cellular development and function, and its impairment often leads to human disease. The survival motor neuron (SMN) protein is key to this biological paradigm: SMN is essential for the biogenesis of various RNPs that function in mRNA processing, and genetic mutations leading to ubiquitous SMN deficiency cause the neurodegenerative disease spinal muscular atrophy (SMA). I will discuss the expanding role of SMN in the regulation of gene expression through its multiple functions in RNP assembly and advances in our understanding of how disruption of SMN-dependent RNA processing pathways can cause motor neuron disease.

S17.2
Non-cell autonomous interactions promote sub-clonal heterogeneity

A. Marusyk[1,2], *D. Tabassum*[1,2], *V. Almendro*[1,2], *P. Altrock*[1,2], *F. Michor*[1,2], *K. Polyak*[1,2];
[1]Dana Farber Cancer Institute, Boston, MA, United States, [2]Harvard Medical School, Boston, MA, United States.

Cancers arise and progress due to the underlying Darwinian somatic evolution. It has been commonly accepted that biological and clinical behaviors of individual tumors reflect properties of the most abundant cells that have achieved clonal dominance by virtue of carrying the most "advanced" complement of oncogenic driver mutations. However, the recent influx of data from tumor genome sequencing has revealed a remarkable degree of genetic divergence within tumors, including sub-clonal differences in mutational status of key driver genes. This clonal heterogeneity begs obvious questions: i) what are the mechanisms that enable co-existence of genetically distinct populations, and ii) what are the biological consequences of this co-existence? Microenvironmentally constrained tumors represent a particularly interesting scenario: overcoming the bottleneck requires changes in the tumor environment induced by secreted factors, but it is not clear a priori whether the expression of a secreted factor capable of driving tumor outgrowth can provide an autonomous fitness advantage. To address this scenario, we have developed a mouse xenograft model of microenvironmentally-constrained tumors. Using this model, we have interrogated the impact of sub-clonal expression of secreted factors in contexts of either competition against the parental clone or that of polyclonal tumors. We found that tumor progression can be driven non-cell autonomously by a sub-population of cells that is unable to achieve clonal dominance. This non-cell autonomous driving of tumor growth is predicted to stabilize sub-clonal heterogeneity within tumors throughout clinically relevant time frames. This co-existence of biologically distinct sub-populations enables inter-clonal interactions that can affect clinically important phenotypes

S17.3
Circulating tumor cells: Detection, biology and clinical implications

K. Pantel;
Institute of Tumor Biology, University Cancer Center Hamburg, University Medical Center Hamburg Eppendorf, Hamburg, Germany.

Sensitive methods have been developed to capture circulating tumor cells (CTCs) in the peripheral blood at the single cell level (Pantel et al., Nat Rev Cancer 2008). CTCs are usually detected by immunostaining or RT-PCR assays, and more recently by the EPISPOT assay which measures the number of cells releasing/secreting tumor-associated marker proteins. Interestingly, detection of cell-free nucleic acids released by tumor cells into the blood might become an indirect way to detect micrometastatic disease (Schwarzenbach et al, Nat Rev Cancer 2011). At present, most CTC assays rely on epithelial markers and miss CTCs undergoing an epithelial-mesenchymal transition (EMT). New markers such as the actin bundling protein plastin-3 (Yokobori et al., Cancer Res. 2013) are not downregulated during EMT and not expressed in normal blood cells might overcome this important limitation and, therefore, increase the sensitivity of CTC assays. Recently, in vivo capture of CTCs with an antibody-coated wire placed into the peripheral arm vein has become feasible and allows now the "fishing" for CTCs from approx. 1.5 liters of blood within 30 minutes. CTC enumeration and characterization with certified systems provides reliable information on prognosis and may serve as liquid biopsy (Alix-Panabieres & Pantel, Clin. Chem. 2013; Pantel & Alix-Panabieres, Cancer Res., 2013). Interestingly, the subset of Ep-CAM^{low}, CD44^{high}, CD47^{+}, c-Met^{+} CTCs obtained from the peripheral blood of breast cancer patients might represent metastasis-initiator cells (Baccelli et al, Nature Biotech. 2013). Moreover, monitoring of CTCs before, during and after systemic therapy (e.g., chemotherapy, hormonal therapy, antibody therapy) might provide unique information for the future clinical management of the individual cancer patient. This information can be used as companion diagnostics to improve the stratification of therapies and to obtain insights into therapy-induced selection of cancer cells.

S18.1
Glyco-lipophobia: association with disorders of glycolipid and glycosylphosphatidylinositol anchor synthesis

H. H. Freeze;
Sanford-Burnham Medical Research Institute, La Jolla, CA, United States.

Thankfully, DNA and protein sequencing technologies revolutionized genetics and proteomics. Sadly, the two other macromolecules, carbohydrates and lipids, missed that technical revolution creating a malady called Glyco-lipophobia. Perhaps its development was predictable based on their molecular complexity, template-independent biosynthesis, and structural analysis without having defined functions. Fortunately, this condition is treatable, and given the discovery of over 100 genetic disorders in these pathways, treatment should not be delayed.
Glycosylation related genes comprise 1-2% of the human genome and those genes often fall into a series of distinct (sometimes overlapping) pathways. Each pathway generates sugar chains (glycans) for typical "clients". The best-known pathway is N-glycosylation found in secreted proteins, membrane-bound receptors, and signaling molecules. Some glycosylation disorders involve addition of glycans to lipids, not proteins. A few glycolipids are biosynthetic precursors of other pathways, but two define distinct pathways: glycosylphosphatidylinolsitol (GPI) anchors and glycosphingolipids (GSL). These molecules are often located in lipid rafts. Fifteen distinct disorders disrupt these pathways. All cells contain GPI and GSL, and affected patients display a range of mostly severe phenotypes that can include intellectual disability, seizures, ophthalmologic abnormalities, heart defects, and often plasma hyper- or hypo-phosphatasia. Simple biochemical indicators can help identify likely candidate genes from exome sequencing, and then also confirm those candidates. Cellular assays based on the established pathways can help design potential therapeutic screens.
Understanding the biosynthetic pathways not only suggests, and then confirms, candidate genes, but it creates avenues for therapy, based on the restoration of functional readouts. The powerful partnership of biochemistry and genetics can help eradicate or reduce Glyco-lipophobia. Patients and families have a vested interest in that victory: they need us to collaborate and cooperate, regardless of the target molecules and genes.

Update on lipidomic approaches in disorders affecting complex lipids metabolism: the example of cardiolipin

F. M. Vaz;
Academic Medical Center, Laboratory Genetic Metabolic Disease, Amsterdam, Netherlands.

Lipids are important components of cellular membranes but also function as signal molecules in many cellular processes including apoptosis, autophagy and inflammation. In the last decade many new inborn errors of metabolism have been identified, many by next generation sequencing, that are caused by a deficiency of genes involved in phospholipid metabolism. A complementary technique that is frequently applied to investigate the functional defect in these disorders is lipidomics, which strives to measure and quantitate as many lipids as possible by (tandem) mass spectrometry. This technique will be introduced followed by different examples that show that combining next generation sequencing and lipidomics is a synergetic combination that yields novel biomarkers for inborn errors of phospholipid metabolism.

S19.2
Using transcriptome sequencing to understand mechanisms of disease

T. Lappalainen;
New York Genome Center, New York, NY, United States.

Detailed characterization of cellular effects of genetic variants is essential for understanding biological processes that underlie genetic associations to disease. This is a particularly pressing question in the interpretation of personal genomes that necessitates accurate prediction and measurement of genome function. One approach to address this challenge is to combine genomic data to a cellular phenotype, such as the transcriptome measured by RNA-sequencing. The early population-scale RNA-seq studies such as GEUVADIS are now being complemented by Genotype-Tissue Expression project (GTEx), where we are creating a comprehensive public atlas of genetic effects on the transcriptome across multiple human tissues. These data have been used to characterize regulatory and loss-of-function genetic variants as well as imprinting both at the population and individual level. Common expression quantitative trait loci that associate to gene expression levels provide a powerful tool to understand genetic architecture of regulatory variation and its role in GWAS associations. Furthermore, allele-specific expression driven by regulatory variants and imprinting can impact on penetrance of coding variants. Finally, we systematically analyzed transcriptome effects of protein-coding loss-of-function variants. Measuring nonsense-mediated decay (NMD) triggered by SNPs and indels allowed us to understand and better predict NMD trigger and escape. Importantly, effects of loss-of-function variants appear highly context-dependent with frequent tissue-specific effects and dosage compensation. Altogether, our results demonstrate the power of integrating genome and transcriptome data not only to improve our general understanding of genetic variants, but also as a practical approach in future medical and clinical applications of personal genomics.

EDUCATIONAL SESSIONS

ES1.1
Genetics of familial forms of thrombocytopenia

A. Savoia[1,2];
[1]*Department of Medical Sciences, University of Trieste, Trieste, Italy,* [2]*IRCCS Burlo Garofolo, Trieste, Italy.*

Inherited thrombocytopenias (ITs) are a heterogeneous group of rare diseases characterized by bleeding risk sometimes associated with platelet dysfunction or other clinical features. More than twenty different forms have been characterized (Table 1). They account for almost 50% of the IT patients, suggesting that many forms are still unrecognizable.

The IT genes play a variety of roles in the complex process of megakaryopoisis and platelet production though their function is often unclear. In the rare forms of CAMT, CTRUS and TAR, thrombocytopenia is severe because of absence or reduction of megakaryocytes (MKs). Whereas in TAR, the platelet count tends to rise during life, in CAMT and CTRUS the disease progresses to bone marrow failure. Loss of function of MPL, the receptor of thrombopoietin, prevents production of Mks in the bone marrow of the CAMT patients. Less certain is instead the role of HOXA11 and RBM8A in CTRUS and TAR, respectively.

In another group of ITs there is a defect of MK maturation. In two of these forms, ANKRD26RD and PFD/AML, patients are also at risk of developing leukemias. Whereas the role of ANKRD26 remains obscure, RUNX1 is a master transcription factor regulating hematopoiesis. RUNX1 binds several other modulators, including FLI1, whose haploinsufficiency due to 11q23-ter deletions determines TCPT or JBS. In case of mutations of GATA1 or GFI1B, another two hematopoietic transcription factors, thrombocytopenia associates with red cells defects and reduction of alpha-granules. Absence of alpha-granules resulting typical gray appearance of platelets is a pathognomic feature of GPS. NBEAL2, the causative gene in this form, is likely to function in vesicle trafficking and generation of platelet granules.

The largest group of ITs could be related to defects of proplatelet formation, a process involving dynamic reorganization of the cytoskeleton, signaling pathways or apoptosis. Regarding the first aspect, mutations in genes encoding for components of the cytoskeleton (MYH9, ACTN1, TUBB1, WAS or FLNA) are likely to interfere with the correct proplatelet extension and platelet release. Of note, FLNA interacts with the C-terminus of GPIbalpha, one subunits of the von Willebrand factor receptor (GPIb/IX/V). Alterations of GPIb/IX/V cause BSS characterized by mild thrombocytopenia associated with reduction of platelet aggregation. Finally, defects of cytochrome c (CYCS) could be associated with increased apoptosis and premature release of platelets into bone marrow instead of blood stream.

This heterogeneity makes the molecular diagnostic testing a complex and time-consuming process. Next generation sequencing strategies will have a strong impact in the diagnosis of the known forms and cloning novel IT genes.

Table 1. Features of inherited thrombocytopenias classified according to possible defective processes of megakaryopoisis and platelet production.

ES1.2
Diagnosis and management of inherited thrombocytopenias

C. L. Balduini, *P. Noris, A. Pecci;*
IRCCS Policlinico San Matteo Foundation - University of Pavia, Pavia, Italy.

Until the end of the last century, a few forms of inherited thrombocytopenia (IT) were known and these disorders were considered exceedingly rare. Spontaneous bleeding was considered as a feature common to all patients and as the main clinical consequence of these disorders. Recently, many new forms of ITs have been identified and our view of these disorders has considerably changed. We realized that ITs are less rare than previously thought and that most patients have mild or no spontaneous bleedings. In many cases thrombocytopenia is discovered incidentally during adult life and its genetic origin is missed, exposing patients to the risk of misdiagnosis with immune thrombocytopenia. To avoid this mistake, it is therefore essential that ITs are considered in the differential diagnosis of any thrombocytopenia of unknown origin both in children and adults. Family history, to search for other affected family members, and physical examination, to identify the defects that typically associate with thrombocytopenia in syndromic forms, are useful tools in this respect, although negative results do not exclude the genetic origin of platelet deficiency. Microscope evaluation of blood films is another key element for differential diagnosis, as morphological anomalies of platelets (increased or reduced size, defects of granules or vacuolization), leukocytes (Döhle-like bodies in neutrophils) or red cells (anisocytosis) are observable in many ITs.

Once an IT is suspected, a diagnostic algorithm can guide further investigation toward the specific patient's disease. It is likely that next generation sequencing techniques will simplify this process in the near future.

A definite diagnosis is essential for proper patient management. In some forms of IT, the major risk for affected subjects does not derive from bleedings, but from the increased propensity to develop additional disorders, as hematological malignancies or kidney failure. In syndromic ITs, associated extra-hematological defects often have a much higher impact on patients' quality of life than the reduced platelet count. The identification of genotype-phenotype correlations for same disorders made feasible to identify and quantify the risks affecting each patient and to design personalized follow-up protocols.

A definite diagnosis is also required to personalize treatment, as platelet transfusions are no longer the only remedy for ITs (Table 1).

Hematopoietic stem cell transplantation can cure ITs and this treatment is the best option for a few disorders that invariably lead to death during childhood. The thrombopoietin mimetic eltrombopag is effective in increasing platelet count in the IT induced by MYH9 mutations, the most frequent form of IT, and this drug has been successfully used instead of platelet transfusions to prepare patients for elective surgery. Splenectomy has no role in ITs, except for patients with WAS mutations, whose platelet counts increase after spleen removal. Finally, effective treatments are available also for some extra hematological defects of syndromic ITs.

Table 1. Treatments for inherited thrombocytopenias

	Indications	Comments
Platelet transfusions	All ITs. To stop bleedings when local measures failed or are not possible	Use HLA-matched donors to reduce the risk of alloimmunization
Hemopoietic Stem Cell Transplantation	- Wiskott–Aldrich syndrome - Congenital amegakaryocytic thrombocytopenia	Successfully used also in a few patients with biallelic Bernard Soulier syndrome and life threatening hemorrhages
Eltrombopag	- MYH9-related disease	Used instead of platelet transfusions for preparing patients to surgery. Efficacy in other conditions to be tested
Splenectomy	- Wiskott–Aldrich syndrome - X-linked thrombocytopenia	It increases platelet count but also the risk of infections
Desmopressin	- All mild forms of IT. To stop bleedings and to prepare patients to surgery	Experimental. A test dose is recommended to identify patients who might benefit from this treatment for future bleedings-surgery
Antifibrinolytic agents	All mild form of IT. To stop or prevent bleedings, and to prepare patients to surgery	Experimental (anecdotal evidence of efficacy)
Recombinant factor VIIa	All inherited thrombocytopenias. To stop bleedings when all other treatments failed	Experimental (anecdotal evidence of efficacy). Risk of thrombosis

ES2.1
Using prediction scores in cardiovascular medicine

S. Ripatti[1,2,3];
[1]Hjelt Institute, University of Helsinki, Helsinki, Finland, [2]Institute for Molecular Medicine Finland (FIMM), Helsinki, Finland, [3]Wellcome Trust Sanger Institute, Hinxton, United Kingdom.

Genome-wide association (GWA) studies have provided hints and pointers towards causes of many common complex diseases and the current wave of large-scale sequencing efforts is likely to refine many of these signals. Using cardiovascular diseases (CVD) as an example, I will describe efforts to turn the association results into risk evaluations and efforts towards developing tools to help in preventive medicine.

Almost two thirds of the incident CVD cases are not identified as high-risk individuals using the currently widely used risk scores, such as the Framingham risk score. Almost 50 genetic loci have been indentified for coronary artery disease and even though the effect sizes of individual common variants identified by GWA studies are small, the large number of loci provide an opportunity to use the SNPs jointly in genetic risk scores (GRS). These scores have comparable risk profiles with quantitative risk factors like blood pressure or LDL cholesterol and have a potential to identify high risk individuals missed by the traditional risk factor screens.

Using results from prospective cohorts, I show how the genetic risk scores provide complementary information for prediction over the traditional risk factors and show how GRS help in identifying individuals with high risk. I discuss the potential benefits of targeted interventions using both traditional risk factor and genetic risk score information and show how already using the currently known risk loci provide an opportunity to prevent disease events. Finally, I discuss the need for developing tools to communicate the genetic risk to medical community and citizens, and the need to test the risk scores in clinical settings.

ES2.2
The benefits of using genetic information to design prevention trials

A. Hingorani;

Novel sequencing approaches in genetic disease research

A. Hoischen;
Department of Human Genetics, Radboud Institute for Molecular Life Sciences, Radboud university medical center, Nijmegen, Netherlands, Nijmegen, Netherlands.

Over the past decade the next generation sequencing has led to a revolution in human genetics and in disease gene identification in particular. This revolution was driven by new technologies that allowed new applications. But what's next?

In this educational session I will address the latest technological developments, for example: What to do with more and less expensive sequencing data? What do longer sequencing reads offer? Can we detect mosaicism reliably? I will also show new applications, for example the benefits of whole genome sequencing, new developments for exome sequencing and also new methods for highly multiplexed targeted re-sequencing.

ES3.2
Single cell genome and transcriptome sequencing

J. Lundeberg;
SciLifeLab, KTH- Royal Institute of Technology, Stockholm, Sweden.

Cells in a particular tissue are not identical. Instead, cells that are identical from a genomic point of view may have considerable variation in gene expression profile and protein levels, giving rise to a heterogeneous collection of cells with different behavior and appearance. Even the genomic DNA sequence may vary slightly between neighboring normal cells within a tissue albeit the differences are can be significant in adjacent tumor cells. In order to get information from single cells one need to isolate, study, and sometimes culture them, separately. This lecture will describe some of the advancements in genome and transcriptome analysis of single cells using massively parallel DNA sequencing and describe in more detail an approach to spatially identify gene expression in single cells in a tissue sections.

ES4.1
Protein replacement system: the case of polymerase-delta and MLH1 mutations in colon cancer.

J. Jiricny;
Institute of Molecular Cancer Research, Zurich, Switzerland.

Next generation sequencing has revolutionized the search for disease-causing genetic alterations. Unfortunately, the task of distinguishing the handful of causative mutations from the multitude of harmless polymorphisms remains daunting. We have developed a system that permits the study of all types of mutations in any gene of choice. The system is based on the generation of stable human cell lines that simultaneously and inducibly express a cDNA encoding the protein carrying the mutation of interest and shRNA against the endogenous mRNA. In this way, the endogenous wild type protein can be replaced with a variant expressing any mutation and, if desired, also a tag for affinity purification or visualization. In this presentation, I shall focus on polymerase-delta and MLH1, which have been found to be mutated in familiar and sporadic colon cancers.

ES4.2
Aging and cancer: The impact of DNA damage

J. H. J. Hoeijmakers;
Dept. of Genetics, Erasmus MC, Rotterdam, Netherlands.

Inherited defects in nucleotide excision repair (NER) removing helix-distorting DNA lesions are associated with cancer predisposition in xeroderma pigmentosum and neurodevelopmental deficits and segmental progeria in Cockayne syndrome and trichothiodystrophy (TTD). Mutations in single NER genes, such as XPD, are linked with all three disorders. Various single and double NER mouse mutants reveal that the severity of specific repair defects strictly correlates with the acceleration of selective premature aging features, whereas the type of DNA repair defect determines the kind of progeroid symptoms and/or cancer susceptibility. Microarray, functional and physiological studies revealed that persistent DNA damage, like caloric restriction, down-regulates the IGF1/GH-, lacto- and thyrotropic hormonal axes and upregulates anti-oxidant defenses, favoring maintenance at the expense of growth. This 'survival response' links accumulation of DNA damage and IGF1 control of life span. Micro- and mRNA expression profiling of normal, accelerated and delayed aging also revealed a clear parallel with the expression changes triggered by persistent transcription-blocking DNA lesions. These findings strongly support the DNA damage theory of aging. We will present phenotypes of conditional DNA repair models targeting aging to selected organs, parallels with Alzheimer's disease and the effect of nutritional interventions on the life span of progeroid repair mutants.

ES5.1
Genomic View of Mosaicism and Disease

N. B. Spinner, *L. K. Conlin;*
The Children's Hospital of Philadelphia and The Perelman School of Medicine, at The University of Pennsylvania, Philadelphia, PA, United States.

Mosaicism refers to the presence of two or more populations of cells with different genotypes within an organism, The timing of the events that lead to various mosaic genomic alterations can vary widely, leading to many different patterns of mosaicism. Mosaicism can result from abnormalities arising during meiosis, with correction during earliest development in some cells, or it may arise postzygotically, during early mitotic divisions. Mosaicism has been detected at surprisingly high frequency in the very early embryo, in miscarriages, in a wide variety of patients with clinical abnormalities and in normal individuals. In some cases, the clinical presentation might suggest mosaicism, as for example, in cases of ambiguous sex in an individual with XX/XY mosaicism, or in individuals with patchy pigmentation where lighter and darker skin may have different genotypes. However, in many cases mosaicism cannot be discerned at the clinical level. Mosaicism can be restricted to somatic tissues only, in which case it is unlikely to be inherited, or it can occur in both somatic and germline tissues, where transmission is possible, and in some cases it may be present in germ cells only, so that a normal individual is at risk for having multiple offspring with the mosaic finding. Mosaicism can be restricted to a single tissue, such as the brain or heart, causing tissue limited pathology, such as autism, schizophrenia or cardiac disease. In this session, we will trace the history of mosaicism from earliest examples of chromosomal mosaicism through recognition of mosaic DNA alterations and we will demonstrate how the utilization of SNP based chromosomal microarray analysis and next generation sequencing have vastly improved our ability to detect mosaicism, leading to markedly increased recognition of the role of mosaicism in human disease. We will discuss the clinical and molecular classes of mosaicism, their detection and the biological insights gained from these studies.

ES5.2
Revertant mosaicism in skin disease

M. F. Jonkman, *A. M. G. Pasmooij;*
University Medical Center Groningen, Groningen, Netherlands.

Revertant mosaicism (RM) refers to the co-existence of cells carrying disease-causing mutations with cells in which the inherited mutation is genetically corrected by a spontaneous post-zygotic event. RM in skin was first reported by us in 1997 in the genetic disorder epidermolysis bullosa (EB), which is characterized by lifelong fragile skin that easily forms blisters and erosions. In a patient with generalized atrophic benign EB, caused by compound heterozygosity at the COL17A1 locus, we found several patchy areas of healthy skin and provided molecular proof that the keratinocytes in the clinically unaffected skin were corrected by a gene conversion event, and consequently produced normal type XVII collagen. Mutations in as many as 18 genes can result in EB. Five of these genes have shown to revert: KRT14 encoding keratin 14 in EB simplex, LAMB3 encoding the β3 chain of laminin-332, and COL17A1 encoding type XVII collagen in junctional EB, COL7A1 encoding type VII collagen in dystrophic EB, and FERMT1 encoding kindlin-1 in Kindler syndrome. RM was also found in other heritable skin diseases: dyskeratosis congenita, and in ichthyosis in confetti (ichthyosis variegata) induced by increased homologous recombination of KRT10. Similar examples of "natural gene therapy" by RM have been described in Bloom syndrome, leukocyte adherence deficiency type 1, Wiskott-Aldrich syndrome, and RAG1-deficient severe combined immunodeficiency. This „natural gene therapy" phenomenon manifests as normal appearing skin areas surrounded by affected skin. Although initially thought to be rare, RM is now considered relatively common in genetic skin diseases. To address the issues relevant to RM, we will discuss the following questions: 1) What is the incidence of RM in heritable skin diseases? 2) What are the repair mechanisms in RM? 3) When do the revertant mutations occur? 4) How do you recognize revertant skin? 5) Do the areas of RM change in size? The answers to these questions allow us to acquire knowledge on these reverted cells, the mechanisms of RM, and utility of the reverted cells to the advantage of the patient. The revertant skin could potentially be used to treat the patient's own affected skin. Revertant skin cells can be used for transplantation by means of: 1) own skin biopsies, 2) cell suspension, 3) cultured epithelial cell sheet, 4) induced pluripotent stem cells reprogrammed as epithelial sheet for skin grafting or as haemopoietic stem cells for infusion. Transplantation of revertant skin biopsies has already succesfully been performed in a patient with EB.

ES6.1
Strategies for rare disease gene discovery in the era of next-generation sequencing

K. M. Boycott[1], *F. S. Alkuraya*[2];
[1]*Children's Hospital of Eastern Ontario Research Institute, University of Ottawa, Ottawa, ON, Canada,* [2]*King Faisal Specialist Hospital and Alfaisal University, Riyadh, Saudi Arabia.*

Assigning medically-relevant roles to human genes is at the core of medical genetics as a field. In the area of Mendelian genetics, such assignment should be relatively straightforward since the phenotypic effect of Mendelian genes is usually large and measurable. The recent ability to interrogate the entire genome (or its coding portion) has provided an unprecedented opportunity to rapidly discover disease-causing genes by circumventing historical roadblocks that characterized previous approaches. However, even this cutting-edge tool has its own set of challenges. In this session, the two presenters will share with the audience the lessons they learned from their ongoing effort to unravel the "Mendeliome", one gene at a time. They draw from their combined experience not only in the successful identification of >120 Mendelian genes, but also, and as importantly, from the many unexpected results they encountered in their research programs. The first presenter will provide an overview of the recent successes and pace of novel gene discovery and discuss the implementation of next-generation sequencing tools alone, or in combination with autozygosity positional mapping, to identify autosomal recessive Mendelian genes. The second presenter will continue the same theme by sharing experience with autosomal dominant disorders and their own set of associated challenges. Both presenters will discuss in detail the pitfalls of the various approaches and suggest some helpful strategies. The immediate and critical need to exchange information about rare variants in genes, which is likely to grow in even more importance as we start to identify genes that contribute a decreasing percentage to the overall Mendelian mutation burden, will be emphasized by both presenters. At the end of the session, it is hoped that interested investigators will have acquired basic knowledge on optimal designs of projects aimed to discover novel disease genes.

ES7.1
From Mutations in the Few to Drugs for the Many

M. R. Hayden;
Teva Pharmaceutical Industries, Petah-Tikva, Israel.

Black swans have existed in the imaginations of philosophers for thousands of years as a metaphor of extreme outliers and unexpected rare events of large magnitude and consequence. Philosopher's argued that even though black swans were extremely rare, collectively they had a vastly larger impact than common, regular occurrences. In genetics and drug discovery, the exceptional black swans of rare genetic illnesses can lead to high-impact discoveries beyond the realm of normal expectations. Following „extreme genetics" and "opposite phenotype" strategies, we have made inroads in studying many devastating rare genetic illnesses in order to decipher the basis for common diseases. Investigating the "Opposite Phenotype" of pain in rare patients who are unable to perceive or understand pain, we have developed new drugs that may be able to treat pain in a profound way for the general population. The importance of the rare patient and clinical genetics is crucial in the identification and validation of novel drug targets.

ES7.2
Genetic, cell biological and clinical interrogation of disease-causing CFTR mutations informs strategies for future drug discovery

C. E. Bear[1], *S. Molinski*[1], *T. Gonska*[1], *L. Huan*[1], *B. Baskin*[2], *I. Janahi*[3], *P. N. Ray*[1];
[1]*The Hospital for Sick Children, Toronto, ON, Canada,* [2]*Uppsala University, Uppsala, Sweden,* [3]*Hamad Medical Corporation, Doha, Qatar.*

Cystic Fibrosis (CF) is a common genetic disease caused by mutations in the *Cystic Fibrosis Transmembrane Conductance Regulator* (*CFTR*) gene that lead to reduction of CFTR anion channel function on the surface of fluid transporting epithelial tissues. The clinical phenotype is variable but severely affected individuals typically suffer from airway obstruction with recurrent episodes of inflammation and infection as well as pancreatic insufficiency. The need to overcome this gap in knowledge is urgent, particularly given the recent success in developing drugs that target the basic defects caused by CFTR mutation. VX-770 (or Ivacaftor) has been approved as a drug for patients bearing the relatively rare mutation: p.Gly551Asp mutation. The most common mutation, p.Phe508del, has been studied extensively and found to impair CFTR protein folding during synthesis. Knowledge regarding the molecular defects caused by p.Phe508del has driven development of targeted, interventional compounds, such as VX-809. The development of these drugs highlights the therapeutic relevance of understanding the basic defects caused by CFTR mutation. Approximately 2000 different variants in the CFTR gene have been reported in the CF Mutation Database, yet, the molecular consequences of less than 10% of these variants are understood. In this presentation, our interrogation of a rare variant, c.3700 A>G, will be discussed. This mutation leads to aberrant splicing and the in-frame deletion of six amino acids (p.Ile1234_Arg1239del) in a conserved region of the CFTR protein. The deletion of these residues, caused protein misfolding as in the case of p.Phe508del. These insights led us to test the efficacy of an investigational compound in trials for p.Phe508del and found that, in cell culture, VX-809 partially ameliorated the folding defect of p.Ile1234_Arg1239del-CFTR. Hence, these studies support the rationale for defining the molecular consequences of rare CFTR mutations in guiding decisions regarding future drug discovery efforts.

ES8.1
New Proposals for the Regulation of in vitro Diagnostic Devices (IVDs)

D. E. Barton[1,2], *S. Hogarth*[3];
[1]*National Centre for Medical Genetics, Dublin, Ireland,* [2]*School of Medicine & Medical Sciences, University College Dublin, Dublin, Ireland,* [3]*Department of Social Science, Health and Medicine, King's College, London, United Kingdom.*

The 1998 IVD Directive regulates the market for diagnostic tests within the EU, setting out standards for the design and manufacture of in-vitro diagnostic devices (IVDs) and providing mechanisms for the oversight of these standards. The current system is inflexible, unresponsive and does not do a good job of protecting patients from harm. In September 2012, the European Commission launched a proposal for a complete overhaul of the IVD regulations. While welcoming these proposals as a move towards a flexible, transparent and proportionate system which would bring the EU closer to international best practice, EuroGentest and ESHG have also expressed concerns about a number of provisions which do not provide effective regulation of the burgeoning commercial market for genomic diagnostics, including direct-to-consumer genetic testing. We have made detailed submissions to the Commission, to MEPs and to regulatory bodies to improve the proposed regulation in these areas. Tests manufactured and used within health institution labs are exempt from the current IVD Directive - the so-called "health institution exemption". EuroGentest has proposed that the health institution exemption should, in future, be restricted to accredited laboratories and should not apply to commercial laboratories. We believe that this provides an appropriate balance of test availability and patient safety. This proposal has been included in the new proposed Regulation. The ENVI Committee at the European Parliament has proposed that the new Regulation should include far-reaching provisions that would govern and restrict the interaction between clinical geneticists and their patients. The ESHG has taken a strong stance against these proposals and has commissioned a legal opinion that demonstrates that they breach the principle of subsidiarity and are beyond the legal competence of the European Union. We will report on progress in these efforts and on our plans for further action.

CONCURRENT SESSIONS

C01.1

Clinical implementation of non-invasive prenatal aneuploidy detection

N. Brison, *B. Bayindir, P. Brady, L. Dehaspe, S. Ardui, J. Van Houdt, H. Van Esch, E. Legius, T. De Ravel, K. Devriendt, J. R. Vermeesch;*
Center for Human Genetics, UZ Leuven, Leuven, Belgium.

The presence of cell-free fetal DNA in the maternal circulation has allowed for the development of methods for non-invasive detection of fetal chromosomal aneuploidies. Non-invasive prenatal testing (NIPT) thus avoids miscarriages due to invasive sampling of fetal material. We developed an innovative, fast, cost efficient workflow and high throughput analysis pipeline. For validation, cell-free DNA of 297 maternal blood samples were collected from women between 9-15 weeks of gestational age who were also undergoing invasive sampling for increased risk of fetal aneuploidy. Whole genome sequencing was performed on cell-free DNA sequencing libraries on a HiSeq2500 using the fast mode 50bp single-ends. In addition to the Z-scores, traditionally the main measure for non-invasive aneuploidy detection, we defined different new parameters which allow for a higher accuracy aneuploidy detection. Moreover, the use of Z-scores across sliding bins enables the distinction to be made between maternal and fetal CNVs. This approach resulted in 100% specificity and sensitivity for trisomy 21 and 18 detection (trisomy 21, n=17; trisomy 18, n=7). This analysis pipeline has been clinically implemented and accredited (ISO15189). An overview of our clinical experience, currently standing at 500 samples, will be provided. In addition to the traditional trisomies, we will present data on other aneuploidies and clinical management thereof.

C01.2

Clinical Validation of Noninvasive Prenatal risk assessment for fetal sex chromosome aneuploidies in maternal plasma using Direct ANalysis of Selected Regions (DANSR™) assays

K. H. Nicolaides[1,2], T. Musci[3], C. Struble[3], E. Wang[3], J. Hooks[3], A. Syngelaki[1], M. del Mar Gil[1], A. Oliphant[3], **A. Wolfberg**[3];
[1]Harris Birthright Research Centre of Fetal Medicine, Kings College Hospital, London, United Kingdom, [2]Department of Fetal Medicine, University College Hospital, London, United Kingdom, [3]Ariosa Diagnostics, San Jose, CA, United States.

Fetal cell-free DNA (cffDNA) in maternal plasma enables screening for fetal aneuploidy using next generation sequencing technologies. We have previously described using DANSR assays for biochemical analysis of chromosomes 13, 18, and 21, combined with the Fetal fraction Optimized Risk for Trisomy Evaluation (FORTE™) algorithm to compute the risk of trisomy with high sensitivity and specificity. We have developed additional DANSR assays for the X and Y chromosomes and have applied the FORTE algorithm on a two blinded sets of samples with and without sex chromosome aneuploidies (SCA). We report clinical validation results on HarmonyTM Prenatal Test's ability to detect fetal SCA.

609 samples comprised the two sets. All subjects provided informed consent. Matching fetal karyotype results from invasive testing were available for all subjects. Samples were processed as previously described with lab and analysis personnel blinded to fetal karyotype. FORTE models were built against monosomy X, XXX, XXY, XYY, and XXYY genotypes. Harmony results were compared against fetal karyotype.

All samples that passed standard Harmony QC metrics generated a sex chromosome result (100%; 95% CI: 99.4-100%). All were concordant with karyotyping for fetal sex (100%; 95% CI: 99.4-100%).

Directed analysis of cffDNA is accurate for risk assessment of non-mosaic fetal SCA. This is the largest fetal SCA validation study to-date. This demonstrates ability to expand Harmony to genetic conditions besides trisomies 13,18 and 21.

Harmony with XY Analysis performance

Karyotype	45, X	47,XXX	47, XXY	47, XYY
Sensitivity (95% CI)	93%(85.1-97.1%) 69 of 74	100%(60.1-100%) 6 of 6	100%(64.6-100%) 7 of 7	100%(43-100%) 3 of 3
Specificity (95% CI)	99.6%(98.6-99.9%)	99.4%(98.3-99.9%)	100%(99.3-100%)	100%(99.3-100%)

C01.3

mtDNA mutations variously impact mtDNA maintenance throughout the human embryofetal development

S. Monnot[1], *S. Rondeau[1], P. Vachin[1], E. Herzog[2], B. Bessieres[1], N. Gigarel[1], D. Samuels[3], L. Hesters[2], N. Frydman[2], G. Chalouhi[1], M. Rio[1], A. Rotig[1], A. Benachi[2], L. Salomon[1], A. Munnich[1], J. Bonnefont[1], J. Steffann[1];*
[1]Hopital Necker, Paris, France, [2]Hopital Beclere, Clamart, France, [3]Vanderbilt Medical Center, Nashville, TN, United States.

Mitochondrial DNA (mtDNA) mutations cause serious disorders maternally inherited with high transmission risk, resulting in requests for preimplantation or prenatal diagnoses. These procedures are hampered by our poor knowledge on the pathophysiology of mtDNA mutations during human development. Specifically, how mtDNA mutations impact the mtDNA content? We collected oocytes, embryos, placentas and fetal tissues at various stages of development, from controls and carriers of m.3243A>G (*MTTL1*, MELAS), m.8344A>G (*MTTK*, MERRF) and m.8993T>G (*MTATP6*, NARP). We devised a test assessing simultaneously mtDNA copy number (CN) and mutant load in single cells.

MtDNA CN increased from the germinal vesicle to the blastocyst stage in m.3243A>G cells, suggestive of a mutation-dependent induction of mtDNA replication, that may compensate for the respiratory chain dysfunction.

Analyses of placentas showed that mtDNA CN significantly increased in m.3243A>G at 11-GW, becoming identical to controls at delivery, probably owing to a placental energy demand maximal at the end of the 1st trimester.

Analyses of fetal tissues showed that mtDNA CN was similar in m.3243A>G vs control tissues apart from the lung; lower in m.8993T>G muscle, heart, and liver vs control. Mutant loads were identical in all tissues from a given fetus, indicating an absence of mutant load/mtDNA content correlation.

These data highlight the complex relationships between mtDNA mutations and mtDNA content, depending on mutation types, mutant loads, cell types and development stages. Transcriptome and mtDNA replication studies should help us in unravelling the molecular bases of these observations, of particular relevance for therapeutic approaches in mtDNA disorders.

C01.4

Whole-genome single-cell haplotyping, a generic method for preimplantation genetic diagnosis

M. Zamani Esteki[1], *E. Dimitriadou[1], L. Mateiu[1], C. Melotte[1], N. Van der Aa[1], P. Kumar[1], R. Das[1], J. Cheng[1], E. Legius[1], Y. Moreau[2], S. Debrock[3], T. D'Hooghe[3], P. Verdyck[4], M. De Rycke[4,5], K. Sermon[5], J. Vermeesch[1], T. Voet[1,6];*

Preimplantation genetic diagnosis (PGD) is the genetic testing of embryos prior to implantation to avoid the transmission of germline genetic disorders or of unbalanced chromosomal rearrangements when a parent is a balanced carrier. Current single-cell PCR or FISH PGD-assays require family-specific designs and labor-intensive workup. Array comparative genomic hybridization (aCGH)-based methods, which are mainly applied for preimplantation genetic screening (PGS) to discern diploid from aneuploid embryos, enable genome-wide aneuploidy detection but do not allow diagnosing single gene disorders. Here, we present a generic method that detects in single blastomeres not only the presence of Mendelian disorders genome wide, but also chromosomal rearrangements and aneuploidies, including their parental origin as well as the meiotic or mitotic nature of chromosomal trisomies. The method interrogates single nucleotide polymorphisms (SNPs) and uses a novel computational pipeline for single-cell genome-wide haplotyping and imputation of linked disease variants (siCHILD). Following stringent single-cell QC-metrics, a bimodal approach, based on discrete SNP-calls and continuous SNP B-allele fractions, respectively, reconstructs the parental haplotypes of the biopsied single cell. The approach proved accurate on 55 embryos from 12 couples carrying either autosomal dominant, recessive or X-linked Mendelian disorders, or simple or complex translocations. The method allowed diagnosing an embryo for multiple monogenic disorders at once, and, in contrast to current PGD for translocation cases, it enabled distinguishing embryos that inherited normal chromosomes from embryos that inherited a balanced configuration of the rearranged derivative chromosomes. The method facilitates genetic selection of embryos, and broadens the range of classic PGD.

C01.5

Scenarios for implementation of noninvasive prenatal testing (NIPT) for Down syndrome in a national health care system

E. Mersy[1], *C. E. E. M. de Die-Smulders[1], A. B. C. Coumans[2], L. J. M. Smits[3], G. M. W. R. de Wert[4], S. G. M. Frints[1], J. A. Veltman[1,5];*
[1]Department of Clinical Genetics, GROW School for Oncology and Developmental Biology, Maastricht University Medical Centre, Maastricht, Netherlands, [2]Department of Obstetrics & Gynaecology, Maastricht University Medical Centre, Maastricht, Netherlands, [3]Department of Epidemiology, Maastricht University Medical Centre, Maastricht, Netherlands, [4]Department of Health, Ethics and Society, CAPHRI School for Public Health and Primary Care and GROW School for Oncology and Developmental Biology, Maastricht University Medical Centre, Maastricht, Netherlands, [5]Department of Human Genetics, Donders Centre for Neuroscience, Radboud university medical center,

Nijmegen, Netherlands.

The implementation of non-invasive prenatal testing (NIPT) of Down syndrome (DS) in national health care systems requires decision-making about the possible restriction of NIPT to high-risk pregnancies, the timing of NIPT, and the combination with other tests. In this study, we combined ethical exploration with a decision-analytic model. We compared three implementation strategies: (1) restriction of NIPT to high-risk pregnancies on the basis of the combined test (CT) (risk for DS ≥ 1:200); (2) NIPT for all women at 13 weeks of gestation; (3) NIPT for all women at 10 weeks of gestation. Comparing strategy 1 to strategy 2, 95% fewer women underwent NIPT, and false positive 1st trimester screening results and invasive procedures were reduced by 95% and 37%, respectively. This was at the expense of a decrease in DS detection of 11% before 15 weeks of gestation and 4% throughout the entire pregnancy (3 DS cases/100,000 pregnancies). Comparing strategy 2 to strategy 3, NIPT was avoided in an additional 4% of pregnancies that would have resulted in miscarriage. Furthermore, delaying NIPT to 13 weeks allows for immediate confirmation by amniocentesis, and may be beneficial to women who may feel overloaded with information in 1st trimester. As NIPT currently does not detect all prenatal abnormalities, it should be offered subsequent to or alongside a nuchal translucency (NT) measurement. In all cases of fetal anomaly on ultrasound (including NT enlargement), broad genetic testing after invasive procedure should still be performed.

C01.6

Whole genome sequencing and analysis in prenatal screening: ethical reflection

G. de Wert, *W. Dondorp;*
Maastricht University, Maastricht, Netherlands.

Non-invasive prenatal testing (NIPT) for fetal abnormalities currently focuses on Down's syndrome. It is to be expected, however, that it will become possible to broaden the scope of screening with NIPT. As proof of principle, it has been demonstrated that the complete fetal genome can be sequenced using fetal DNA from maternal plasma, potentially allowing prenatal whole genome analysis.
This scenario makes a proactive ethical reflection of utmost importance. Normative issues to be addressed include the following: First, the prerequisite of proportionality. Do the possible benefits of whole genome sequencing and analysis in prenatal screening outweigh the possible harms and disadvantages? Secondly, would it be possible to fulfill the requirement of informed consent, given the wide range of possible outcomes of whole genome prenatal screening? Could so-called *generic* consent, based on pre-test information about general categories of test outcomes, be accepted as a sound variant of informed consent ? And thirdly: if whole genome prenatal screening would result in the birth of children whose genotype has been elucidated prenatally, the child's right *not* to know may be violated, i.e. the right of the future, competent, person to decide about predictive testing for later onset diseases. How to handle, then, possible conflicts between future parents' right to know and future children's right not to know?
This presentation offers a systematic exploration of these issues, aimed at contributing to adequate ethical guidance for whole genome prenatal screening.

C02.1

A novel variant in the SLC9A9 gene influences disease activity in interferon-beta treated multiple sclerosis patients

M. Sorosina[1], *F. Esposito*[1,2], *C. Guaschino*[1,2], *G. Liberatore*[1,2], *A. Osiceanu*[1], *V. Martinelli*[2], *D. Brassat*[3,4], *G. Comi*[2], *P. L. De Jager*[5,6], *F. Martinelli Boneschi*[1,2];
[1]*San Raffaele Scientific Institute, Laboratory of genetics of complex neurological disorders, Milan, Italy,* [2]*San Raffaele Hospital, Department of Neurology, Milan, Italy,* [3]*Hopital Purpan, Department of Neurology, Toulouse, France,* [4]*University of Toulouse, Toulouse, France,* [5]*Harvard Medical School, Boston, MA, United States,* [6]*Program in Medical and Population Genetics, Broad Institute, Cambridge, MA, United States.*

Aimed to identify genetic variants able to predict response to interferon beta (IFNβ), we performed a genome-wide association study in Italian relapsing-remitting multiple sclerosis (MS) patients treated with IFNβ. Rs9828519, achieved genome-wide significance (p=4.43x10^-8), and its effect was replicated in three independent cohorts of American, Italian and French patients (meta-analyzed p=7.78x10^-4). Rs9828519 is intronic of SLC9A9 gene, codifying for a sodium/hydrogen exchanger localised in the endosomes, not known to be involved in MS or in IFNβ pathways. With in vitro experiments, we observed an upregulation of SLC9A9 expression after IFNβ stimulation in PBMCs of 20 healthy controls (HC, p=4.01x10^-7) which was unrelated to the genotype status. Such upregulation was confirmed also in IFNβ-treated MS patients (GSE24427 and GSE26104 experiments: p=3.8x10^-3 and 0.030). No cis-effect of rs9828519 was observed in whole blood of MS patients, nor in PBMCs, CD14+ monocytes or CD4+ T lymphocytes collected from HC. For this reason we performed a trans eQTL analysis in 211 CD14+ monocytes isolated from HC followed by pathway analyses using three independent softwares. All of them enlighten an enrichment of IFNβ-related pathways of genes trans-regulated by rs9828519. We observed in the rs9828519GG samples an up-regulation of genes involved in IFNβ signalling, including STAT1, JAK1, STAT5B, but also an impairment of the final effects of IFNβ, with an upregulation of osteopontin and a downregulation of IL10. Here we report a new genetic marker that affects the response to IFNβ in MS patients supported by experimental evidences of the involvement in the IFNβ pathways.

C02.2

High throughput sequencing in sporadic forms of steroid-resistant nephrotic syndrome: heterogeneous genetic alterations can predict resistance to treatments

A. Provenzano[1], *B. Mazzinghi*[2], *F. Becherucci*[3], *L. Giunti*[2], *G. Sansavini*[3], *F. Ravaglia*[3], *R. Roperto*[3], *S. Farsetti*[3], *E. Benetti*[4], *M. Rotondi*[5], *L. Murer*[4], *L. Lasagni*[6], *M. Materassi*[3], *P. Romagnani*[6], *S. Giglio*[1];
[1]*Department of Clinical and Experimental Biomedical Sciences Medical Genetics Unit-Meyer Children's University Hospital, Firenze, Italy,* [2]*Medical Genetics Unit-Meyer Children's University Hospital, Firenze, Italy,* [3]*Pediatric Nefrology Unit-Meyer Children's University Hospital, Firenze, Italy,* [4]*Pediatric Nephrology, Dialysis and Transplantation Unit Department of Pediatrics, Universisty of Padua, Padua, Italy,* [5]*Unit of Internal Medicin and Enodcrinology University of Pavia, Pavia, Italy,* [6]*Excellence centre for research, transfer and high education for the development of de novo therapies, University of Florence, Firenze, Italy.*

Steroid-resistant nephrotic syndrome (SRNS) is a disorder that results in end-stage renal disease and can be potentially related to a genetic cause, especially when it occurs in children. However, because of genetic heterogeneity, the real burden of genetic alterations in sporadic cases is unknown. In this study, we explored the possibility that genetic alterations of podocyte's structure may explain lack of response to steroid treatment in children affected by sporadic childhood-onset nephrotic syndrome (NS), not only in a causative manner, but also as critical disease modifiers that influence response to steroid treatment and immunosuppressive agents.
We designed a custom sequencing array to target all exons and part of flanking sequences for known podocyte genes responsible for SRNS, that was applied through next generation sequencing to a selected cohort of 50 patients with sporadic NS and variable response to steroid treatment.
We identified a genetic cause in 40% of the 19 SRNS patients analysed. Modifier genes were observed in an additional 25% of patients exhibiting resistance to steroid, but nor disease causing neither disease modifier genes were observed in podocyte's genes of 30 additional children that were sensitive to steroids. Treatment with immunosuppressive agents was effective only among patients that were negative to the test, while none of the patients displaying genetic alterations responded to any immunosuppressive agent.
The results of this study suggest that in children affected by sporadic NS, resistance to steroid treatment may be related to genetic alterations in genes that control structure and function of the podocyte.

C02.3

Personalized thiopurine dosing based on TPMT genotyping reduces leucopenia occurrence and results in cost-savings in IBD patients; results from a randomized trial in the Netherlands

M. J. H. Coenen[1], *D. J. de Jong*[1], *C. J. van Marrewijk*[1], *L. J. J. Derijks*[2], *S. H. Vermeulen*[1], *D. R. Wong*[3], *O. H. Klungel*[4], *A. L. M. Verbeek*[1], *P. Hooymans*[3], *W. H. M. Peters*[1], *R. H. M. te Morsche*[1], *TOPIC recruitment team*, *W. G. Newman*[5], *H. Scheffer*[1], *H. Guchelaar*[6], *B. Franke*[1];
[1]*Radboud university medical center, Nijmegen, Netherlands,* [2]*Máxima Medical Centre, Veldhoven, Netherlands,* [3]*Orbis Medical Centre, Sittard-Geleen, Netherlands,* [4]*Utrecht University, Utrecht, Netherlands,* [5]*University of Manchester, Manchester, Netherlands,* [6]*University Medical Center, Leiden, Netherlands.*

More than 20% of inflammatory bowel disease (IBD) patients discontinue thiopurine therapy due to severe adverse drug reactions, among which leucopenia is one of the most serious. Thiopurine S-methyltransferase (*TPMT*) pharmacogenetic testing can be used to optimize thiopurine safety and efficacy. Nonetheless, in clinical practice it is only used on a limited scale. We performed a randomized controlled trial including 769 IBD patients starting on thiopurine treatment. Patients were randomly assigned to standard treatment (control) or pre-treatment screening (intervention) for three common *TPMT*-variants (*TPMT**2, *3A and *3C); patients heterozygous for a *TPMT*-variant received 50% of the standard thiopurine dose, and patients homozygous for the variants received 0-10%. Intervention and control groups were compared for leucopenia occurrence (leucocyte count $<3.0*10^9$/l) in the first 5 months after treatment initiation. Cost-effectiveness analysis included complete cases (patients with outcome (EQ-5D) and self-reported costs). Thirty-nine (9.8%) patients in the intervention and 35 pa-

tients (9.5%) in the control group carried a *TPMT*-variant. Among *TPMT*-variant carriers, leucopenia occurrence was significantly reduced in the intervention compared to the control group (2.6% versus 22.9%, relative risk 0.11, 95%CI=0.01-0.85).Overall, no difference in leucopenia occurrence was observed between the intervention and control group (7.3% versus 7.8%). Treatment efficacy (ΔEQ-5D) was similar for both study arms. Average costs (direct medical costs and indirect costs) were lower for patients in the intervention (n=238) compared to the controls (n=216): €4433 versus €6150, p=0.023. Prior-to-treatment TPMT screening reduces leucopenia risk in IBD patients treated with thiopurines without impeding treatment efficacy and results in substantial cost-savings.

C02.4

Genome-wide identification and phenotypic validation of loss of function mutations

L. G. Biesecker, *K. Lewis, D. Ng, J. Johnston, J. Mullikin;*
National Institutes of Health, Bethesda, MD, United States.

A typical human genome includes numerous apparent loss of function (LOF) variants, which may be attributed to sequencing or alignment errors, carrier states, hypomorphic alleles, gene redundancy, and true LOF alleles for haploinsufficiency-sensitive genes. It is critical for understanding gene function and for predictive medicine to assess the consequences of LOF variants. Prior efforts to understand the genotype-phenotype relationships were limited by ascertainment biases and the limitations of deidentified data. To approach this problem, we characterized the phenotypic consequences of LOF variation in an exome cohort of 950 individuals and iteratively validated the phenotypes. Exomes were generated by targeting and Illumina sequencing. Potential LOF variants were defined as nonsense, frameshift, and essential splice site variants. Analysis was restricted to HGMD genes. Variants with maf >0.005 in ClinSeq or dbSNP were excluded. We filtered for genes that cause disease in an autosomal dominant pattern by haploinsufficiency. Remaining variants were considered variants of interest, 87 were identified in 112 individuals. 85 of these individuals were evaluated for these disorders. We used stringent criteria for phenotyping and family history to identify variants that were causing disease. Of the evaluated patients, half (38/85) had evidence of disease. The negative cases illustrated issues with gene model errors, mechanisms of alternative translation starts, etc. The positive cases demonstrate the ability to perform predictive medicine and to use filtering methods to identify inapparent genetic disorders. These data also point to approaches that could unravel the functional consequences of genes not yet known to cause human phenotypes.

C02.5

The SickKids Genome Clinic: Developing and evaluating a pediatric model for individualized genomic medicine

M. S. Meyn[1,2], *S. Bowdin*[1,2], *N. Monfared*[1], *D. Merico*[1], *D. J. Stavropoulos*[1,2], *M. Girdea*[1,2], *R. Hayeems*[1], *M. Szego*[2,3], *G. Bader*[2], *R. D. Cohn*[1,2], *J. A. Anderson*[1], *R. Zlotnik-Shaul*[1,2], *M. Brudno*[1,2], *C. Shuman*[1,2], *C. R. Marshall*[1,2], *P. N. Ray*[1,2];
[1]*Hospital for Sick Children, Toronto, ON, Canada,* [2]*University of Toronto, Toronto, ON, Canada,* [3]*St. Joseph's Health Centre and St. Michael's Hospital, Toronto, ON, Canada.*

Genomic medicine is a clinical paradigm in which knowledge gained from analyzing an individual's genome is used to guide health care decisions throughout life, in order to anticipate, diagnose and manage disease. To pilot the implementation of genomic medicine in paediatrics we have developed the SickKids Genome Clinic, a multidisciplinary test bed that supports a wide range of research into the clinical uses of whole genome sequencing (WGS), from development of new bioinformatics pipelines and counselling models to health economics and bioethics studies. We are enrolling 150+ children/year who are undergoing diagnostic microarray analysis or multigene panel sequencing. Participants undergo WGS after their parents are counselled about WGS and have declared their preferences for learning their child's pharmacogenetic variants, adult-onset incidental/secondary medically-actionable variants (MAVs) and carrier status variants. Of the first 200 families approached, 117 agreed to participate, with ~75% of participants electing to learn about all available adult-onset secondary MAVs and carrier variants. Of the parents who decide to learn of their child's adult-onset secondary MAVs, approximately 60% also choose to learn if they carry the same variants. The most frequent concerns of parents are psychological burdens of identifying their child's secondary MAVs and fear of insurance discrimination. WGS data are analyzed using separate bioinformatics pipelines for primary disorder variants, structural variants and secondary variants. Initial WGS analyses have already yielded clinical diagnoses not revealed by conventional testing and support our hypothesis that WGS is superior to conventional multi-gene panels and clinical microarrays for identifying pathologic variants.

C02.6

Collaboration to integrate genomics into clinical care: a demonstration evaluation

C. Gaff[1], *N. Thorne*[1], *I. Macciocca*[1], *P. Waring*[2], *S. Forrest*[3], *P. Ekert*[4], *I. Winship*[5], *T. Lockett*[6], *M. South*[7], *A. Sinclair*[8], *Melbourne Genomics Health Alliance;*

Genomic technologies are proving transformative, but ensuring full clinical and research benefit from their application in clinical settings requires planning and collaboration. Working to a five year vision, seven research and healthcare organisations are conducting a demonstration project to test an ambitious, unified approach to meeting their diverse needs. Demonstration projects examine the application of structural innovations such as technology and non-structural innovations like health programs. They provide new insights into the process and value of implementing innovation, thereby informing decision-making about future implementation. Our highly novel, prospective project evaluates the feasibility of whole exome/genome sequencing as a single common assay for germline and somatic conditions, replacing current tests, for use in clinical and predictive care. Mimicking usual clinical practice, patients with one of five diverse germline or somatic conditions are being offered whole exome sequencing in parallel to routine investigations. Sequence data is generated by multiple diagnostic laboratories, analysis is then targeted to genes known to be related to the clinical condition using a common analytic pipeline. Data is available for reanalysis and research. Patient and clinician engagement in this clinically-led project is paramount. The demonstration project is being evaluated in terms of feasibility (can the model be built?), requirements (what does it take to build?), and impact (can it make a difference?) across all processes and with feedback from patients, clinicians and scientists supplementing data collection. We will describe the 'real world' strengths, weaknesses and barriers identified during collaborative implementation of the demonstration project across the seven organisations.

C03.1

Dominant β-catenin mutations cause a recognizable syndrome with intellectual disability, and are associated with learning deficits and structural and functional brain abnormalities in mice

M. H. Willemsen[1], *V. Tucci*[2], *T. Kleefstra*[1], *A. Hardy*[3], *I. Heise*[3], *S. Maggi*[4], *W. Wissink-Lindhout*[1], *A. Vulto-van Silfhout*[1], *B. de Vries*[1], *Z. Iqbal*[1], *H. Introduction: The recent identification of multiple dominant mutations in both humans and mice has enabled us to explore the molecular and cellular basis of beta-catenin function in cognitive impairment. Mutations in human beta-catenin have been identified as causative in a spectrum of neurodevelopmental disorders. Methods and Results: In identifying *de novo* beta-catenin mutations in patients with intellectual disability and careful characterization of their phenotype, we were able to define a recognizable intellectual disability syndrome. We have collected detailed clinical information of 7 patients with this novel syndrome. In parallel, the characterization of a chemically-mutagenized mouse line displaying features that are similar to these human mutations has enabled us to investigate the consequences of beta-catenin dysfunction through development and into adulthood. The mouse mutant, batface, carrying a Thr653Lys substitution in the C-terminal armadillo repeat in beta-catenin, displays a reduced affinity for membrane-associated cadherins. In association with this decreased cadherin interaction, we found that the mutation results in decreased intrahemispheric connections with deficits in dendritic branching, long-term potentiation and cognitive function. Conclusion: For the first time *in vivo* we showed how dominant mutations in beta-catenin underlie losses in its adhesion-related functions leading to severe consequences including intellectual disability, childhood hypotonia, progressive spasticity of lower limbs and abnormal craniofacial features in adults.

C03.2

De Novo loss of function mutations in *SETD5*, a novel methyltransferase gene within the 3p25 microdeletion syndrome critical region, cause intellectual disability

K. J. Carss[1], *D. Grozeva*[2], *O. Spasic-Boskovic*[2], *M. J. Parker*[3], *H. Archer*[4], *H. V. Firth*[5], *S. Park*[5], *N. Canham*[6], *S. E. Holder*[6], *M. Wilson*[7], *A. Hackett*[8], *M. Field*[9], *J. A. B. Floyd*[1,10], *UK10K Consortium, M. E. Hurles*[1], *F. L. Raymond*[2];

[1]*Wellcome Trust Sanger Institute, Hinxton, Cambridgeshire, United Kingdom,* [2]*Cambridge Institute for Medical Research, Cambridge, United Kingdom,* [3]*Sheffield Children's Hospital, Sheffield, United Kingdom,* [4]*University Hospital of Wales, Cardiff, United Kingdom,* [5]*Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom,* [6]*North West London Hospitals NHS Trust, Harrow, United Kingdom,* [7]*Children's Hospital at Westmead, Westmead, Australia,* [8]*Hunter Genetics, Waratah, Australia,* [9]*Royal North Shore Hospital, St. Leonards, Australia,* [10]*Queen Mary University of London, London, United Kingdom.*

To identify further Mendelian causes of intellectual disability (ID), we screened a cohort of 996 individuals with ID for variants in 565 known or candidate genes using a targeted next generation sequencing approach. Seven loss of function mutations (four nonsense variants- c.1195A>T, c.1333C>T, c.1866C>G, c.3001C>T and three frameshift variants- c.2175-76delCA, c.3770insG, c.3856delT) were identified in *SETD5*, a gene predicted to be a methyltransferase. All mutations were compatible with *de novo* dominant inheritance. The affected individuals had moderate to severe ID with additional variable features of brachycephaly; prominent high forehead with synophrys or striking eyebrows that are full and broad; a long, thin and tubular nose; long narrow upslanting palpebral fissures and large fleshy low set ears. Skeletal anomalies were a frequent finding including significant leg length discrepancy in two cases. Congenital heart defects, inguinal hernia or hypospadias were all reported. Behavioural problems were a prominent feature including an obsessive-compulsive disorder, hand flapping with ritualised behaviour and autism. *SETD5* lies within the critical interval for the 3p25 microdeletion syndrome. The *SETD5* mutation individuals have phenotypic similarity to those previously reported with a deletion in 3p25 and thus loss of *SETD5* may be sufficient to account for the clinical features observed in this condition. Our findings add to the growing evidence that mutations in methyltransferases that regulate histone modification are important causes of ID. This analysis provides sufficient evidence that loss of function of *SETD5* is a relatively frequent cause of ID (0.7%) and occurs as a rare *de novo* mutational event.

C03.3

Genetic heterogeneity in Hyperphosphatasia with Mental Retardation Syndrome due to mutations in PGAP3, a member of the GPI anchor synthesis pathway

D. Horn[1], *Y. Murakami*[2], *C. Daumer-Haas*[3], *B. Fischer*[1], *J. Hecht*[1], *U. Kölsch*[4], *S. Leiz*[5], *Y. Maeda*[2], *D. Mitchell*[6], *J. Phillips*[6], *S. Mundlos*[1,7], *P. N. Robinson*[1], *P. M. Krawitz*[1];

[1]*Institute of Medical Genetics and Human Genetics, Berlin, Germany,* [2]*Department of Immunoregulation, Research Institute for Microbial Diseases, Osaka University, Osaka, Japan,* [3]*Pränatal-Medizin München, München, Germany,* [4]*Institute of Medical Immunology, Charité Universitätsmedizin, Berlin, Germany,* [5]*Klinikum Dritter Orden, München, Germany,* [6]*Division of Medical Genetics and Genomic Medicine, Department of Pediatrics, Vanderbilt University School of Medicine, Tennessee, TN, United States,* [7]*Max Planck Institute for Molecular Genetics, Berlin, Germany.*

Different genes of the glycosylphosphatidylinositol anchor synthesis pathway, PIGV, PIGO, and PGAP2, have recently been implicated in hyperphosphatasia-mental retardation syndrome (HPMRS), also known as Mabry syndrome, a rare autosomal recessive form of intellectual disability with characteristic additional phenotypic features. We developed a diagnostic gene panel for targeting all known genes of the GPI-anchor synthesis pathway to screen patients matching these features, and detected compound heterozygous and homozygous mutations (c.439dupC, c.914A>G, c.314C>G) in PGAP3, a gene that is involved in the GPI-anchor maturation, in two unrelated patients with developmental delay, elevated serum alkaline phosphatase, seizures and particular facial anomalies. Our functional studies show that an impairment of the later GPI-anchor remodeling steps also causes HPMRS. In addition we analyzed the mutation spectrum of all four genes as well as the associated phenotypic spectrum in a large cohort of individuals diagnosed with HPMRS. Among this cohort biallelic PIGV mutations were identified in about 50 % of unrelated families whereas mutations of the other involved genes are less frequent. Our findings demonstrate that the severe end of the clinical spectrum presents as a multiple congenital malformation syndrome with a high frequency of Hirschsprung disease as well as vesicoureteral, renal, and anorectal malformations. At the other end of this spectrum HPMRS could present as apparently non-syndromic form of intellectual disability. Taken together with recent data, HPMRS displays a heterogeneous etiology caused by impairment of different steps of the GPI-anchor synthesis and is associated with a marked clinical variability regarding additional malformations and growth patterns.

C03.4

The significance of small copy number variants in neuro-developmental disorders

Despite abundant evidence for pathogenicity of large CNVs in neuro-developmental disorders (NDDs), the individual significance of genome-wide rare CNVs <500 kb has not been well elucidated in a clinical context. By high resolution chromosomal microarray analysis, we investigated non-polymorphic exonic CNVs sizing 1-500 kb in a cohort of 714 patients with NDDs, of which 8.8% had an obvious large disease causing CNV. Excluding recurrent false positive sites, we detected 96 small CNVs, of which 58 (60.4%) could be confirmed by secondary testing.

Six of the confirmed de novo or likely de novo CNVs were clearly pathogenic affecting the recurrent microdeletion region in 17q21.31 or OMIM morbid genes (*CASK, CREBBP, PAFAH1B1, SATB2*). Two further de novo CNVs affecting single genes (*MED13L*, *CTNND2*) were instrumental in delineating novel recurrent conditions. In addition, two unreported homozygous deletions were found likely pathogenic: An intragenic deletion of *ACOT7* which likely defines a novel autosomal recessive disorder, and a deletion of the genes *PREPL* and *C2orf34* representing a new variant of the hypotonia-cystinuria syndrome. Four of the inherited CNVs affecting previously reported sites (16p11.2, *AUTS2*, *NRXN3*, *GRM8*) were also considered likely pathogenic. In total 14 (24.1%) of the small CNVs were categorized as pathogenic or likely pathogenic (median size 130 kb), nine (15.5%) as likely benign and the rest remained unclear. These results verifies the diagnostic relevance of genome-wide rare CNVs <500 kb (overall ~2%; 1.1% de novo, 0.3% homozygous, 0.6% inherited) and their inherent potential for discovery of new conditions enabling better characterization of NDDs.

C03.5

Rare large CNVs are associated with intellectual disability, education level, and female fertility in general population

A. Reymond[1], *K. Männik*[1], *R. Mägi*[2], *A. Mace*[3], *A. Maillard*[3], *H. Alavere*[2], *A. Kolk*[2], *L. Leitsalu*[2], *A. Ferreira*[1], *M. Noukas*[2], *J. S. Beckmann*[3], *S. Jacquemont*[3], *Z. Kutalik*[3], *A. Metspalu*[2];

To investigate the burden of the rare large CNVs in the general population, we analyzed the Estonian Genome Centre cohort. It is a longitudinal, prospective, population biobank linked to comprehensive personal, educational, medical and daily life data of 5% of the Estonian adult population. Within a subset of 6819 individuals, we identified 60 carriers of known genomic disorder lesions, equivalent to a prevalence of 1% in the general adult population. Their phenotypes are reminiscent of those of carriers of identical rearrangements identified in disease cohorts. Importantly some of the associated traits appear to have been previously overlooked due to age-dependent penetrance.

We then generated the genome-wide map of rare autosomal CNVs and identified a total of 697 carriers of CNVs ≥ 250 kb with MAF ≤ 0.05%. While duplication carriers are equally distributed in both sexes, we observe a significant bias towards female carriers of deletion. This biased mutational burden supports the notion that females are somewhat "protected" from neurodevelopmental disorders. Cumulatively, these CNV carriers show a significant increase in the prevalence of intellectual disability and a decrease in the rate of higher-achieved education level, as well as a decrease of female carriers' fertility. In addition to CNV size, these effects are associated with the number and "quality" of encompassed genes and pronounced in carriers of deletions and duplications that encompass ≥3 and ≥10 genes, respectively. Our results suggest that large rare variants significantly impact life quality of carrier identified from non-clinical cohorts.

C03.6

Altered neuronal network in iPSC derived cortical neurons from patients with *MECP2* duplication syndrome

M. Ramocki[6], J. Lupski[5], P. Vanderhaeghen[3], A. Muotri[2], **H. Van Esch**[1];
[1]Center for Human Genetics, LEUVEN, Belgium, [2]University of California San Diego, School of Medicine, Department of Pediatrics/Rady Children's Hospital San Diego, Department of Cellular & Molecular Medicine, Stem Cell Program, La Jolla, CA, United States, [3]Institut de Recherches en Biologie Humaine et Moléculaire (IRIBHM), Université Libre de Bruxelles (U.L.B.), Brussels, Belgium, [4]Stem Cell Institute Leuven, Department of Development and Regeneration, Cluster Stem Cell Biology and Embryology, LEUVEN, Belgium, [5]Department of Molecular and Human Genetics, and Human Genome Sequencing Center Baylor College of Medicine, Houston, TX, United States, [6]Department of Pediatrics, Section of Pediatric Neurology and Developmental Neuroscience, Baylor College of Medicine, Houston, TX, United States.

We previously showed that increased dosage of methyl-CpG-binding protein-2 (MeCP2) leads to a severe neurodevelopmental disorder in males, designated as the *MECP2* duplication syndrome (MIM#300260). The increased dosage of MeCP2 is the result of a copy number gain at Xq28, including the *MECP2* gene and results in severe to profound neurodevelopmental delay with onset at birth, limited or absent speech, hypotonia, epilepsy, autistic behavior and motor dysfunction. We developed induced pluripotent stem cells from 3 patients with *MECP2* duplication syndrome carrying different duplication sizes, to study the impact of increased MePC2 dosage in human neurons. Differentiation of these iPSCs into neurons of cortical identity showed modulation in the expression of progenitor genes like *BLBP* and *FOXG1* and cortical genes like *RELN*, *CTIP2*, *TBR1* and *VGLUT*. Cortical neurons derived from Mecp2dup-iPSCs had more synapses, and altered network synchronization as well as dendritic complexity. Next, we tested a series of epigenetic drugs for the ability to rescue neuronal defects and validated two HDAC inhibitors as potential clinical candidates. Our model recapitulates early stages of the human *MECP2* duplication syndrome and represents a promising cellular tool to facilitate therapeutic drug screening for severe neurodevelopmental disorders.

C04.1

EIF2AK4 mutations cause pulmonary veno-occlusive disease, a recessive form of pulmonary hypertension

Pulmonary veno-occlusive disease (PVOD) is a rare and devastating cause of pulmonary hypertension that is characterized histologically by widespread fibrous intimal proliferation of septal veins and preseptal venules and is frequently associated with pulmonary capillary dilatation and proliferation. PVOD presents either sporadically or as familial cases.
In the French referral centre for severe pulmonary hypertension, we have identified 13 PVOD families: 5 with a confirmed diagnosis based on histological studies and 8 with a highly likely diagnosis, based on clinical, functional, and radiological criteria. All PVOD families were characterized by the presence of at least two affected siblings and unaffected parents, suggesting that the disease segregates as a recessive trait.
We used a whole-exome sequencing approach and detected recessive mutations (homozygous or compound heterozygous) in the *EIF2AK4* gene that co-segregated with PVOD in all 5 families initially studied. We subsequently identified mutations in the 8 additional PVOD families. We also found biallelic *EIF2AK4* mutations in 5 of 20 histologically confirmed sporadic PVOD cases. All identified mutations disrupted the function of the gene. In conclusion, we identified the first gene responsible for PVOD. Biallelic mutations in *EIF2AK4* gene were found in 100% of familial cases and in 25% of sporadic cases of PVOD, making this new gene a major player linked to PVOD development. This discovery significantly contributes towards understanding the complex genetic architecture of pulmonary hypertension. Further studies are needed to decipher the molecular mechanisms underlying the responsibility of the EIF2AK4 gene deficiency in the development of PVOD.

Congenital heart defects are the most common birth defect worldwide and a leading cause of neonatal mortality. Left ventricular outflow tract obstruction (LVOTO) is an important subtype, with lesions on the most severe end of this spectrum being significantly life limiting. Although mutations in several genes have been associated with LVOTO in the majority of cases the cause is still unknown. In an individual with LVOTO and a balanced chromosome translocation, the highly conserved *NR2F2* was found to be interrupted. Whole mount studies in mice showed Nr2f2 to be expressed in the atria and in human fetal samples, expression was also confirmed in the heart including in atrial tissue. A further study conducted exome sequencing in 13 parent-offspring trios and 112 unrelated patients with nonsyndromic atrioventricular septal defects, a further important subtype of CHD for which the genetic architecture is poorly understood. Five rare missense variants (two of which arose *de novo*) were found in *NR2F2*, a very significant enrichment (P=7.7×10^{-7}) compared to 5,194 controls. A further two CHD families were identified with other variants in *NR2F2*; a *de novo* substitution disrupting a splice donor site and a 3bp insertion that co-segregated in a multiplex family. *NR2F2* encodes a pleiotropic developmental transcription factor, and decreased dosage of *NR2F2* in mice has been shown to result in abnormal heart development. Furthermore, using luciferase assays, it was shown that all six coding sequence variants observed in patients significantly alter the activity of *NR2F2* target promoters.

Moyamoya is a cerebrovascular condition of unknown mechanism characterized by a progressive stenosis of the terminal part of the internal carotid arteries (ICA) and the development of abnormal "moyamoya" vessels leading to stroke. We describe a novel autosomal recessive disease leading to severe moyamoya and early onset achalasia in 3 unrelated families. Using genetic linkage and exome sequencing we identified in all 3 families homozygous mutations of GUCY1A3, the gene encoding the alpha1 subunit of soluble guanylate cyclase (sGC), the major receptor for Nitric Oxide (NO). Platelet analysis showed a complete loss of the mutated protein and an unexpected stimulatory role of sGC within platelets.The NO/sGC/cGMP pathway is a major pathway controlling vascular smooth muscle relaxation, vascular tone and vascular remodeling. Our data suggest that alterations of this pathway may lead to an abnormal vascular remodeling process in sensitive vascular areas with low blood flow and shear stress,such as ICA bifurcations. These data provide treatment options for these patients. They also suggest that investigation of members of this NO/sGC/cGMP pathway is warranted in both non syndromic moyamoya and isolated early onset achalasia. Data accepted in the Am J Hum Genet.

Venous anomalies are composed of ectatic veins with irregular smooth muscle coverage. They are commonly cutaneous. They usually occur as a single lesion without family history (sporadic Venous Malformation, VM). Some sporadic patients have multifocal lesions (Multifocal Sporadic Venous Malformation, MSVM). In the sporadic Blue Rubber Bleb Nevus syndrome (BRBN), patients also have multifocal lesions; pathognomonic are rubbery palmoplantar lesions and those located in the GI-track. In rare cases, venous malformations are multifocal because of autosomal dominant inheritance (Mucocutaneous Venous Malformation, VMCM). VMs progressively expand causing deformity, pain and local intravascular coagulopathy. Despite sclerotherapy or excision, lesions often progress or recur.

We have identified activating mutations in the endothelial tyrosine kinase receptor TIE2 in all four forms. VMs are mostly due to a single somatic amino acid change L914F. MSVMs and BRBNs are due to double mutations in cis. The BRBN mutations are somatic, whereas MSVM mutations seem mosaic. Moreover, a distinct cis-mutation is seen in MSVM. The inherited VMCM is due to a germline mutation combined with a somatic second-hit. These clinico-genetic entities are reflected by phenotypic differences in cells overexpressing mutant receptors. Activation of AKT is yet a common phenomenon. The capacity to form lesions clearly resides in mutant endothelial cells, which when injected to immunodeficient mice generate lesions mimicking human VM. Interestingly, an mTOR inhibitor is able to deter lesion development. Finally, in our therapeutic pilot study comprising five patients with VMs refractory to standard-of-care, an mTOR inhibitor diminished pain, intravascular coagulopathy and improved quality of life.

C04.5

A high yield of variants with a putative role as modifiers in patients with hypertrophic cardiomyopathy

S. Bardi[1], **F. Girolami**[1], *M. Benelli[1], B. Tomberli[2], E. Contini[1], G. Marseglia[1], C. Pescucci[1], G. Castelli[2], A. Fornaro[2], F. Cecchi[3], I. Olivotto[2], F. Torricelli[1];*

[1]Genetic Diagnostic Unit, Careggi University Hospital, Florence, Italy, [2]Referral Centre for Myocardial Diseases, Careggi University Hospital, Florence, Italy, [3]University of Florence, Department of Clinical and Experimental Medicine, Florence, Italy.

Next Generation Sequencing enables simultaneous screening of multiple genes for multiple patients in a single run. We designed a panel of 111 genes known to be associated to CMs to study 94 unrelated patients (80 with Hypertrophic Cardiomyopathy, HCM; 18 with Dilatative Cardiomyopathy, DCM and 6 with Arrhythmogenic Cardiomyopathy, AC). Targeted resequencing was performed on Illumina platform (98,13% of the regions with a depth of coverage of 20X or more, mean coverage on target of 530X). A mean of 1016 variants were found for each patient. Rare (frequency <0.05), non-synonymous, loss- of- function and splice-site variants were defined as candidates. Pathogenic or likely-pathogenic variants were all confirmed by Sanger and cosegregation was tested when possible. Excluding titin missense variants, we identified 48 variants (27 novel) in sarcomeric or associated genes in 48/70 HCM patients (68%), with 14% of complex genotype. MYH7, MYBPC3 and TNNI3 resulted the high-yield genes; 19 additional candidate variants (13 novel) in desmosomal and ion-channel genes in 14 patients (20%) were identified in this group. We identified 10 candidate variants (7 novel) in 7/18 DCM patients (39%) and 5 candidate variants in 3/6 AC patients (50%). A targeted protocol allowed the identification of likely pathogenic variants in a large proportion of patients with CMs, irrespective of phenotype. The unexpected finding of rare non synonymous variants in desmosomal and ion-channel genes among HCM patients raises important issues regarding their role as previously unappreciated modifiers of the disease, potentially relevant to risk prediction and counseling.

C04.6

Causal relationship of body mass index with cardiometabolic traits and events: a Mendelian randomization analysis

M. V. Holmes[1,2], *L. A. Lange[3], T. Palmer[4], M. B. Lanktree[5], IBC BMI Mendelian Randomization Group, E. E. Schadt[6], F. W. Asselbergs[7,8,2], A. P. Reiner[9,10], B. J. Keating[1];*

[1]University of Pennsylvania, Philadelphia, PA, United States, [2]University College London, London, United Kingdom, [3]University of North Carolina School of Medicine at Chapel Hill, Chapel Hill, NC, United States, [4]University of Warwick, Warwick, United Kingdom, [5]McMaster University, Hamilton, ON, Canada, [6]Mount Sinai School of Medicine, New York, NY, United States, [7]University Medical Center Utrecht, Utrecht, Netherlands, [8]Durrer Center for Cardiogenetic Research, Utrecht, Netherlands, [9]University of Virginia, Charlottesville, VA, United States, [10]Fred Hutchinson Cancer Research Center, Seattle, WA, United States.

Elevated body mass index (BMI) associates with cardiometabolic traits on observational analysis, yet the underlying causal relationships remain unclear. We conducted Mendelian randomization analyses using 14 SNPs associated with BMI from a recent discovery analysis to investigate the causal role of BMI with cardiometabolic traits. We used eight population-based cohorts, including 34,538 individuals of European ancestry with 4,407 type 2 diabetes (T2D), 6,073 coronary heart disease (CHD) and 3,813 stroke cases. A genetically-elevated one kg/m^2 increase in BMI resulted in higher levels of fasting glucose, insulin, interleukin-6 and systolic blood pressure but reduced levels of HDL-C and LDL-C (values reported in Table). Apart from LDL-C, all causal estimates were directionally concordant to observational estimates. A genetically-elevated one kg/m^2 increase in BMI increased odds of T2D but did not affect risk of CHD or stroke. A meta-analysis incorporating published studies with 27,465 CHD events in 219,423 individuals yielded a pooled odds ratio of 1.04 (95%CI: 0.97, 1.12) per 1 kg/m^2 increase in BMI. In conclusion, we identified causal effects of BMI on several cardiometabolic traits, however whether BMI causally impacts on CHD risk requires further evidence.

Table. Causal estimates for the relationship of BMI with cardiometabolic traits and events.

Traits (units)	Studies (Individuals)	Regression coefficient (95%CI)
Metabolic		
Fasting glucose (mmol/l)	6 (20,677)	0.18 (0.12, 0.24)
Fasting insulin (% difference)	3 (12,758)	8.47 (5.94, 11.06)
Inflammation		
C-reactive protein (% difference)	7 (24,319)	12.00 (7.95, 16.19)
Interleukin-6 (% difference)	5 (9,885)	7.00 (4.01, 10.08)
Fibrinogen (% difference)	6 (19,041)	0.92 (0.25, 1.59)
Blood pressure		
Systolic blood pressure (mmHg)	6 (30,136)	0.70 (0.24, 1.16)
Diastolic blood pressure (mmHg)	6 (30,137)	0.28 (0.03, 0.52)
Lipids		
HDL-C (mmol/l)	6 (24,943)	-0.02 (-0.03, -0.01)
LDL-C (mmol/l)	6 (23,364)	-0.04 (-0.07, -0.01)
Triglycerides (% difference)	6 (24,761)	0.82 (-0.61, 2.27)
Surrogate marker of CHD		
Carotid intima medial thickness (% difference)	3 (6,260)	1.12 (-0.42, 2.68)
Events	**Studies (Cases/ Individuals)**	**Odds ratio (95%CI)**
Type 2 diabetes	7 (4,407/31,844)	1.27 (1.18, 1.36)
Coronary heart disease	7 (6,073/ 26,193)	1.01 (0.94, 1.08)
Stroke	6 (3,813/ 23,782)	1.03 (0.95, 1.12)

[1]Institut für Humangenetik, Essen, Germany, [2]Manchester Centre for Genomic Medicine, Manchester, United Kingdom, [3]Institute of Human Genetics, München, Germany, [4]Institut für Klinische Chemie und Laboratoriumsdiagnostik, Jena, Germany, [5]Service de Génétique Clinique, Lille, France, [6]Department of Genetics, Groningen, Netherlands, [7]Department of Medical Genetics, Izmir, Turkey, [8]Seattle Children's Hospital, Seattle, WA, United States, [9]Abteilung Humangenetik, Bern, Switzerland, [10]Neurogenetics Unit, Sao Paulo, Brazil, [11]Department of Human Genetics, Regensburg, Germany, [12]Institute of Genetic Medicine, Newcastle University,, Newcastle upon Tyne, United Kingdom.

Burn-McKeown syndrome (BMKS) is characterized by cardiac defects, choanal atresia, sensorineural deafness and craniofacial dysmorphism and seems to be rare. X-linked or autosomal recessive inheritance was suggested.

We performed exome sequencing in five patients with BMKS and identified two heterozygous nonsense mutations in an autosomal gene (p.Glu117*; p.Glu13*) and one frameshift mutation (p.Val44Alafs*48). Screening for deletions in seven additional families revealed three large deletions (0.484, 1.164 and 4.7 MB), containing at least the entire candidate gene. Further three patients are currently being analysed. In two patients, no mutation was identified. All mutations and one deletion were inherited from a healthy parent, but in no case a second mutation was found in the coding region of the gene. Whole genome sequencing was performed in five patients, in all a 34 bp promoter deletion on the other allele of the same gene was identified. Segregation analyses for the promoter deletion revealed that all patients with a null mutation on one allele had the promoter deletion on the other allele. We screened 378 controls for the promoter deletion and found a minor

allele frequency of 1% for this population.
Preliminary results of primer extension analyses of RNA from peripheral blood suggest a negative effect of the 34 bp-deletion on the expression level of this allele. Further functional analyses are currently being performed.
In conclusion, our results indicate that BMKS is an autosomal recessive condition caused by an unusual mode of inheritance and highlight the importance of analyzing regulatory regions of causative genes.

C05.2

Genetic studies of mosaic birth defects affecting the skin by next-generation DNA sequencing

J. Rivière[1,2], *J. St-Onge*[1,2], *Y. Duffourd*[1], *J. Courcet*[1,3], *Fédération des Centres Labellisés « Anomalies du Développement » (FeCLAD), Filière des Maladies Rares en Dermatologie (FIMARAD), Société française de Foetopathologie (SOFFOET), L. [1]*Equipe d'Accueil 4271, Génétique des Anomalies du Développement, Université de Bourgogne, Dijon, France,* [2]*Laboratoire de Génétique Moléculaire, Centre Hospitalier Universitaire de Dijon, Dijon, France,* [3]*Centre de Génétique et Centre de Référence Anomalies du Développement et Syndromes Malformatifs de l'Interrégion Est, Centre Hospitalier Universitaire de Dijon, Dijon, France,* [4]*Centre d'activité de génétique clinique, Pôle pédiatrie, Hôpital Nord, CHU Amiens, Amiens, France,* [5]*Service de Dermatologie, Centre Hospitalier Universitaire de Dijon, Dijon, France.*

A large group of sporadic developmental disorders involving the skin are or may be caused by postzygotic mutational events. Although mosaic birth defects traditionally rank among the most complex forms of monogenic diseases for gene discovery studies due to the challenges of detecting mutations present in only a fraction of cells, exome sequencing recently emerged as a powerful tool in the context of postzygotic mosaicism. In recent years, we and others have identified mutations of PIK3CA and other PI3K/AKT/MTOR-pathway genes in several mosaic overgrowth syndromes including megalencephaly-capillary malformation, hemimegalencephaly, fibroadipose hyperplasia, Proteus, CLOVES, and Klippel-Trenaunay syndromes. Somatic HRAS and KRAS mutations were reported in isolated and syndromic sebaceous nevi, and GNAQ mutations were associated with Sturge-Weber syndrome and port-wine stains. To further study the genetic basis of mosaic birth defects involving the skin, we ascertained and collected blood and skin specimens from > 100 unrelated individuals with patterns of skin lesions suggestive of cutaneous mosaicism. Systematic targeted deep sequencing of known causative genes on a MiSeq instrument (Illumina) in subjects with a clinical presentation consistent with the aforementioned syndromes resulted in a diagnostic yield over 50% and led to identification of variants with allelic fractions as low as 1%. Exome sequencing studies based on paired samples or trios in subjects with a clinical presentation of unknown genetic cause led to identification of two new genes underlying two mosaic skin pigmentation syndromes. These findings highlight the value of next-generation sequencing, both for research and genetic diagnosis of mosaic skin disorders.

Stormorken syndrome is a rare autosomal dominant disorder characterized by miosis, thrombocytopenia/thrombocytopathy, mild hypocalcaemia, muscle fatigue, asplenia, dyslexia and ichthyosis. Presence of tubular aggregates has also been reported in muscle biopsies of adolescent and adult patients with the disease. We diagnosed Stormorken syndrome in four patients from two unrelated families. Using targeted sequencing and whole exome sequencing we identified the c.910C>T transition in a *STIM1* allele (p.R304W) only in patients and not in their unaffected family members. Stromal interaction molecule 1 protein (STIM1) is a finely tuned endoplasmic reticulum (ER) Ca2+ sensor. The effect of the mutation on the structure of STIM1 was investigated by molecular modeling, and its effect on function was explored by calcium homeostasis experiments. We show that STIM1 p.R304W variant may affect the conformation of the inhibitory helix and unlock the inhibitory state of STIM1 molecule. Results obtained from calcium imaging experiments using transfected cells together with the fibroblasts from one affected patient were in agreement with impairment of calcium homeostasis. The p.R304W mutation probably causes a constant Ca2+ release activated Ca2+ channels (CRAC) opening leading to a permanent entry of calcium in many cell types. Our results are in agreement with already published models for STIM1 structure and activation. We conclude that p.R304W mutation in STIM1 may be the cause of the Stormorken syndrome.

C05.4

TashT is a novel mouse model that phenocopies both the variable penetrance and male sex-bias of Hirschsprung's disease

N. Pilon[1], *K. F. Bergeron*[1], *T. Cardinal*[1], *A. M. Touré*[1], *D. W. Silversides*[2];
[1]*Université du Québec à Montréal, Montréal, QC, Canada,* [2]*Université de Montréal, St-Hyacinthe, QC, Canada.*

Neural crest cells (NCC) are progenitors of diverse cell types such as peripheral neurons and glia as well as melanocytes. Via an insertional mutation screen for loci affecting NCC, we identified several mouse lines that combine defects in pigmentation and formation of the enteric nervous system. One of these lines, named TashT, displays an aganglionic megacolon phenotype in a subset of homozygotes and, most interestingly, almost exclusively in males. This is highly reminiscent of human Hirschsprung's disease, a neurocristopathy with an incidence of 1/5000 newborns and a currently unexplained 4:1 male-to-female bias.
We localized the TashT transgene insertion site in a gene desert containing multiple highly conserved elements on chromosome 10. Migration assays as well as time-lapse imaging showed that megacolon is due to defective NCC migration within the gut mesenchyme, a defect generally more severe in males than females. At the molecular level, RNAseq analysis of TashT enteric NCC notably revealed upregulation of many genes encoding secreted proteins and downregulation of several X-linked genes. This analysis also identified the novel gene Fam162b as a strong candidate for being the TashT causative gene. Fam162b is located near the transgene insertion site and reporter gene as well as 3C assays suggest that this TashT overexpressed gene is normally repressed in NCC via long range interactions with some of the highly conserved elements near the transgene insertion site.
Altogether, our results demonstrate that the TashT line represents a unique mouse model that will help understand the male sex bias of Hirschsprung's disease.

C05.5

WNT pathway downregulation and Cornelia de Lange Syndrome

A. Pistocchi[1], *G. Fazio*[2], *L. R. Bettini*[2], *A. Cereda*[2], *L. Ferrari*[1], *F. Cotelli*[3], *A. Biondi*[2], *A. Selicorni*[2], *V. Massa*[4], **A. Marozzi**[5];

The cohesin complex is formed from a multi-subunit core and their associated regulatory proteins.
Genetic variants within components of the cohesin complex (NIPBL, SMC1A, SMC3, RAD21, PDS5, ESCO2, HDAC8) are believed to be responsible for a spectrum of human syndromes known as "cohesinopathies" that includes Cornelia de Lange Syndrome (CdLS), a multiple malformation syndrome affecting almost any organ and causing severe developmental delay. The cohesin complex has a canonical role in cell division and a non-canonical role in gene expression regulation. Cohesinopathies seem to be caused by dysregulation of specific developmental pathways downstream of mutations in cohesin components. However, it is still unclear how mutations in different components of the cohesin complex effect the output of gene regulation. In this study, zebrafish embryos and patient-derived fibroblasts were used to analyze abnormalities underlying CdLS, focusing on SMC1A, the second most commonly mutated gene responsible for the disease. We show that the knockdown of smc1a in zebrafish impairs neural development, increases apoptosis and specifically downregulates the canonical Wnt pathway that can be rescued by chemical activation suggesting a therapeutic potential for CdLS. The same downregulation of the WNT pathway is observed in SMC1A-mutated patient fibroblasts. Previously we have demonstrated that the haploinsufficiency of NIPBL, the cohesin gene mutated in Cornelia de Lange Syndrome, produces a similar phenotype in zebrafish and in CdLS patients. Finally, the double-knockdown of nipblb/smc1a in zebrafish shows a synergistic effect for the canonical role of cohesins in cell cycle and survival.

C05.6

Trio-based exome sequencing in ten unrelated cases of atypical CdLS

M. Ansari[1], *A. Meynert*[1], *H. Bengani*[1], *D. Braunholz*[2], *D. C. Soares*[1], *R. C. M. Hennekam*[3], *H. Kayserili*[4], *S. Avci*[4], *E. Wakeling*[5], *J. Tolmie*[6], *K. Tatton-Brown*[7], *M. Splitt*[8], *T. Homfray*[7], *A. F. Brady*[5], *S. G. Mehta*[9], *A. Ross*[10], *F. J. Kaiser*[2], *M. S. Taylor*[1], *D. R. FitzPatrick*[1];
[1]*Institute of Genetics and Molecular Medicine, Edinburgh, United Kingdom,* [2]*Universität zu Lübeck, Lübeck, Germany,* [3]*University of Amsterdam, Amsterdam, Netherlands,* [4]*İstanbul University, Istanbul, Turkey,* [5]*North West Thames Regional Genetics Service, Harrow, United Kingdom,* [6]*West of Scotland Genetic Services, Glasgow, United Kingdom,* [7]*St George's Healthcare NHS Trust, London, United Kingdom,* [8]*Northern Genetics Service, Newcastle upon Tyne, United Kingdom,* [9]*Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom,* [10]*North of Scotland Regional Genetics Service, Aberdeen, United Kingdom.*

Cornelia de Lange syndrome (CdLS) is a highly variable multisystem disorder with a broad phenotypic spectrum. Most typically-affected individuals carry de novo heterozygous loss-of-function mutations in NIPBL. Mutations in other components of the sister chromatid cohesion system, SMC1A, HDAC8, SMC3 and RAD21, result in phenotypes that overlap with CdLS but which can be highly atypical. We carried out trio-based exome sequencing in ten unrelated individuals with the diagnosis of atypical CdLS, who had previously been screened for intragenic mutations in the known CdLS genes and for genomic deletions or duplications. Using a likelihood-based approach, we identified nine de novo variants in eight cases, including de novo loss-of-function mutations in NIPBL (c.3150delA [p.Glu1050Aspfs*20]) and KMT2A (c.3649G>T [p.Glu1217*]), an essential splice-site mutation in PUF60 (c.604-2A>C) and a missense mutation in NAA10 (c.247C>T [p.Arg83Cys]). Furthermore, de novo, probably damaging missense mutations were identified in PIK3C3, PDCD6IP, UNC45A, NUP210 and CELF3. We then re-sequenced these genes in 85 of our mutation-negative CdLS and CdLS-like cases by AmpliSeq-Ion Torrent sequencing, which revealed three additional loss-of-function mutations in KMT2A. We also detected the aforementioned de novo mutation in NAA10 (c.247C>T [p.Arg83Cys]) in a similarly-affected, but unrelated individual. Molecular modelling suggests that the p.Arg83Cys conversion is likely to alter binding of NAA10 to acetyl CoA and would result in reduced acetylation activity of the protein. Our results highlight the genetic heterogeneity in atypical CdLS. They also demonstrate the phenotypic overlap between atypical CdLS and other dysmorphic conditions such as Wiedemann-Steiner syndrome as shown by molecular data.

C06.1

Resolving variants of unknown significance through reanalysis of 4,978 public RNA-seq samples

P. Deelen, *D. V. Zhernakova, M. van der Sijde, J. Karjalainen, J. K. van der Velde, M. de Haan, K. M. Abbott, C. Wijmenga, R. J. Sinke, M. A. Swertz, J. Fu, L. Franke;*
University Medical Center Groningen, Groningen, Netherlands.

In recent years, exome sequencing has emerged as a very effective strategy for genome diagnostics. However, the functional significance is unclear for many of the identified variants, hindering clinical interpretation. To improve upon this, we hypothesized that if a variant of unknown significance is affecting gene expression, it is more likely to be pathogenic (similar to what is known for common disease-associated SNPs, Westra et al, Nature Genetics 2013).

We therefore analysed publicly available RNA-seq data from 4,978 human samples from European Nucleotide Archive. We developed methodology to QC and harmonize the RNA-seq data and to account for differences in sequencing strategy, tissue differences and other (unknown) confounders. We subsequently called SNPs using GATK and imputed genotypes using BEAGLE. We assessed genotype quality using 462 samples for which both RNA-seq data and 1000G genotypes are available (Lappalainen et al, Nature 2013) and observed a 97% genotype concordance, indicating that RNA-seq is suitable for genotyping.

This enabled us not only to identify effects of common variants on the gene expression levels of 6,005 genes (cis-eQTLs), but also to identify the effects associations of rare variants and gene expression by assessing allele specific expression (ASE). We observed that many rare variants known to be pathogenic strongly associate with gene expression levels.

Since the amount of RNA-seq data that is available in public repositories is growing exponentially, we expect ASE analysis of rare variants will likely provide new tools to resolve many variants of unknown significance.

C06.2

The long non-coding RNA landscape of autoimmune diseases

C. Wijmenga, *I. Ricaño-Ponce, Y. Li, B. Hrdlickova, D. Zhernakova, J. Karjalainen, P. Deelen, S. Withoff, L. Franke, V. Kumar;*
Genetics Department, Groningen, Netherlands.

We have recently shown that the majority of predisposing autoimmune disease SNPs are intronic or intergenic and have the potential to be regulatory (Ricaño-Ponce & Wijmenga, 2013) by affecting expression of nearby genes (so-called eQTLs). It has become clear that non-coding RNAs are an important class of regulatory elements. Annotating autoimmune SNPs shows that close to 10% map to long non-coding RNA genes (lncRNA). Transcriptome analysis across 11 distinct immune cell types (granulocytes, monocytes, NK cells, B-cells, memory-T cells, naive CD4+ and CD8+ T-cells, and four CD4+ T-helper cell populations) revealed that these "autoimmune" lncRNAs are significantly enriched in immune cell types. We also correlated the autoimmune SNP genotypes with expression levels (eQTLs) of both coding genes and lncRNA genes and observed > 70% of the autoimmune SNPs to be eQTLs. Interestingly, ~16% of these eQTL SNPs also affect lncRNAs and as high as 6% of these eQTLs are specific to lncRNAs alone. To gain a first understanding on the biological processes in which these "autoimmune" lncRNAs are involved we performed pathway analysis based on co-expression profiles of lncRNAs and protein-coding genes using 5000 publicly available RNAseq samples. More than 90% of the autoimmune lncRNAs were significantly co-expressed with genes in cis (P = 0.009 to 4.64 x 10-92) that are at an average distance of 245 kb. Our results show that lncRNA-eQTLs represent a novel link between non-coding SNPs and the expression of genes, which can be exploited to understand the process of gene-regulation through lncRNAs in more detail.

C06.3

Population Scale Comprehensive Identification and Analysis of Complex Structural Variation Using Nanochannel Array

H. Dai[1], *A. Hastie*[1], *E. Lam*[1], *W. Andrews*[1], *T. Anantharaman*[1], *A. Pang*[1], *M. Saghibini*[1], *H. Sadoski*[1], *H. VanSteenhouse*[1], *M. Austin*[1], *X. Yang*[1], *T. Dickinson*[1], *Z. Dzakula*[1], *M. Xiao*[2], *P. Kwok*[3], **H. Cao**[1];
[1]*BioNano Genomics, San Diego, CA, United States,* [2]*Drexel University, Philadelphia, PA, United States,* [3]*Univ of California - San Francisco, San Francisco, CA, United States.*

Diseases are known to be associated with large (>1kb) genomic structural variation (SV). A variety of techniques such as karyotyping, FISH and array-CGH have been used for SV analysis. However, population scale comprehensive SV analysis remains impractical--too expensive or incomplete (exemplified by missing inversions and balanced translocations by aCGH methods). More recently, next generation sequencing (NGS) has been shown efficient for discovery of SNPs and small indels. However, complete and accurate SV discovery and analysis is complicated by the fact that variants often span tens to hundreds of kb or are rearranged throughout the genome, difficult to infer from short fragment sequencing. Thus, there is a blind spot in effectively detecting SVs within this range (1 kb ~ 1 Mb), referred to as the "dark matter" of the genome, overlooked in the past due to insufficient tools.

We demonstrate a new platform technology (Irys) to effectively linearize very long strands of gDNA (100 kb to Mbs) through nanochannels to directly visualize SVs and rearrangements preserved within intact and unamplified genomic DNA at single molecule level. De novo genome maps are assembled and hundreds to thousands of SV events are called. Data from individuals and trio families will demonstrate this highly comprehensive and cost effective approach, with results validated by multiple orthogonal methods.

For the first time, it is now feasible to do large population-based comprehensive structural variation studies using a single platform. This innovation will transform the diagnosis and treatment of diseases resulting from structural variants, particularly cancer.

C06.4

Chromatin loops and CNVs: the complex spatial organization of the 16p11.2 locus

M. Loviglio[1], *M. Leleu*[2], *N. Gheldof*[1], *E. Migliavacca*[1], *K. Mannik*[1], *J. Beckmann*[3], *S. Jacquemont*[4], *J. Rougemont*[2], *A. Reymond*[1];
[1]*Center for Integrative Genomics, Lausanne, Switzerland,* [2]*EPFL, Lausanne, Switzerland,* [3]*Swiss Institute of Bioinformatics, Lausanne, Switzerland,* [4]*Service de Génétique Médicale, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.*

16p11.2 600 kb BP4-BP5 deletion and reciprocal duplication have mirror impact on body mass index (BMI), head circumference (HC) and autism spectrum disorder/schizophrenia (ASD/SCZ). The nearby distal 16p11.2 220 kb BP2-BP3 rearrangements are similarly associated with mirror phenotypes such as obesity/underweight and macro-/microcephaly, as well as neuropsychiatric disorders. We demonstrated chromatin interplays between these regions, likely via long-range acting regulatory elements, using high-resolution 4C-seq technology using the promoters of the SH2B1, MVP,

KCTD13, ALDOA, TBX6 and MAPK3 genes as "viewpoints". Between 172 and 354 Blocks of Regulators in Chromosomal Kontext are found per viewpoint. These 3-dimensionnally adjacent genomic regions encompass genes that encode proteins that interact together (P=1.69e-9) and have been associated with autism (P=0.008). A dramatic reorganization of these chromatin interacting networks is displayed in cells of carriers of 600 kb BP4-BP5 deletion or duplication. In parallel, we profiled the transcriptome of lymphoblastoid cell lines of 50 deletion, 32 reciprocal duplication and 29 control individuals and identified 2209 differentially expressed (DE) genes using a numerical variable to reflect a dosage effect. 566 DE genes show a concomitant significant change in chromatin interaction (enrichment P=0.007).
Our results show that relevant chromatin conformation changes may arise from copy number variants. They strongly suggest a link between the observed chromatin perturbations and changes in gene expression, with a possible contribution of the chromosome conformation to the disease phenotype.

C06.5
Informing rare disease mechanisms: informatics for the International Mouse Phenotyping Consortium

T. F. Meehan, *on behalf of the MPI2 Consortium;*
European Molecular Biology Laboratory, European Bioinformatics Institute, Hinxton, Cambridge, United Kingdom.

The International Mouse Phenotyping Consortium (IMPC) is building the first truly comprehensive functional catalogue of a mammalian genome that will inform mechanisms of rare disease. The IMPC is coordinating efforts to generate a knockout mouse strain for every protein-coding gene. These mouse strains are characterized using a standardized, broad-based phenotyping pipeline and data is collected and archived centrally by the IMPC-Data Coordinating Centre. Dedicated 'data wranglers' are working with each phenotyping centre to ensure proper transfer and quality control of data. An automated statistical analysis pipeline identifies knockout strains with significant changes in phenotype parameters. Potential disease models are identified by orthologous gene and by orthologous phenotype features.
Over 3000 IMPC mouse strains have been produced, with emerging phenotype data available for hundreds of these strains. Users can freely access all data including new gene-phenotype via an intuitive web portal. Annotation with biomedical ontologies allows biologists and clinicians to easily find mouse strains with phenotypic traits relevant to their research. Users can register interest in genes so they may be informed as mouse models and new phenotype data become available. The community is invited to explore and provide feedback as we build this rich resource for rare disease research at:
www.mousephenotype.org

C06.6
Strategies for Exome Prioritization of Human Disease Genes

D. Smedley[1], *S. Kohler*[2], *A. Oellrich*[1], *J. Jacobsen*[1], *Sanger Mouse Genetics Group, K. Wang*[3], *C. Mungall*[4], *N. Washington*[4], *S. Bauer*[2], *D. Seelow*[2], *P. Krawitz*[2], *C. Gilissen*[5], *M. Haendel*[6], *S. E. Lewis*[4], *P. N. Robinson*[2];
[1]*Sanger Institute, Cambridge, United Kingdom,* [2]*Charite-Universitatsmedizin, Berlin, Germany,* [3]*University of Pennsylvania, Philadelphia, PA, United States,* [4]*Lawrence Berkeley National Laboratory, Berkeley, CA, United States,* [5]*Radboud University Nijmegen Medical Centre, Nikmegen, Netherlands,* [6]*Oregon Health & Sciences University, Portland, OR, United States.*

Whole-exome sequencing has revolutionized rare disease research, with over 100 disease-gene identifications since the first published success in 2010. However, many cases remain unsolved due to the fact that ~100-1000 loss of function, candidate variants remain after removing those deemed as common, low quality or non-pathogenic. In some cases it may be possible to use multiple affected individuals, linkage data, identity-by-descent inference, trio analysis, or prior knowledge of affected pathways to narrow down to the causative variant. Where this is not possible or successful, one approach is to use model organism phenotype data to evaluate whether a variant is likely to result in the patient's clinical manifestations. We have developed an algorithmic approach (PHenotypic Interpretation of Variants in Exomes; PHIVE) to semantically compare clinical and mouse phenotypes. The output is combined with measures of variant candidacy such as pathogenicity and allele frequency and synergistically improves performance: the causative variant is identified as the top hit in up to 83% of exomes, with a 54-fold improvement over variant-based prioritization alone. A web implementation (Exomiser) is freely available.
Another complementary approach we have developed ranks exome candidates based on their proximity in protein-protein networks to genes shown, or are suspected, to be associated with the disease. Again, combining this with variant-based measures of candidacy leads to large improvements in performance with up to 47% of exomes having the causative variant as the top candidate.
We are currently testing our approach in large-scale projects such as the Undiagnosed Disease Program and CareForRare.

C07.1
LysoPlex: an efficient strategy to study the role of lysosomal-autophagic-endocytic pathway

G. Di Fruscio[1,2], *A. Schulz*[3], *R. De Cegli*[1], *M. Mutarelli*[1], *M. Savarese*[1,2], *V. Singhmarwah*[1], *M. Filocamo*[4], *D. Di Bernardo*[1], *S. Banfi*[1,2], *T. Braulke*[3], *V. Nigro*[1,2], *A. Ballabio*[1,5,6];
[1]*Telethon Institute of Genetics and Medicine, Naples, Italy,* [2]*Dipartimento di Biochimica, Biofisica e Patologia Generale, Seconda Università degli Studi di Napoli, Naples, Italy,* [3]*Children's Hospital, Department of Biochemistry, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [4]*Centro di Diagnostica Genetica e Biochimica delle Malattie Metaboliche, Istituto G. Gaslini, Genova, Italy,* [5]*Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States,* [6]*Medical Genetics, Department of Pediatrics, Federico II University, Naples, Italy.*

Lysosome is a control centre for cellular clearance and energy metabolism: it is responsible for the degradation of the foreign molecules and the endogenous macromolecules. The essential role of lysosomes in phagocytosis and autophagy puts these organelles at the crossroads of several cellular processes. To understand the role of the lysosomal-autophagic-endocytic pathway in health and disease, we have developed LysoPlex, a Next Generation Sequencing-based workflow to sequence at high coverage 12,786 human exons of 891 genes involved in lysosomal function, endocytosis and autophagy pathway. We designed the enrichment probes using a Haloplex custom platform targeting 99.48% of exons. To validate the methodology, we created a training set of 15 DNA samples belonging to patients affected by 14 different LSDs, whose the molecular diagnosis was already known. Using LysoPlex, we were able to detect all the known mutations. Moreover, we used our strategy to identify disease-causing mutations in 50 patients clinically diagnosed as affected by neuronal ceroid lipofuscinoses (NCL). About 50% of samples have causative mutations and a subset of additional variations in other genes not directly correlated with the disease was also identified in each sample. In conclusion, LysoPlex is a cheap and fast NGS targeted platform for the molecular diagnosis of Mendelian LSDs and it is a precious tool to have a complete view of sequence variants in the genes involved in the lysosomal-autophagic pathway. Moreover, it can also be used to identify causative or predisposing mutations in a variety of debilitating human conditions such as common neurodegenerative diseases.

C07.2
Comparing Clinical Exome Sequencing versus Whole Exome Sequencing for monogenic diseases and undiagnosed patients

P. Joset, *M. Papik, K. Steindl, S. Papuc, M. Vincent, L. Gogoll, D. Niedrist, B. Oneda, A. Baumer, A. Rauch;*
Institute of Medical Genetics, University of Zurich, Schlieren-Zurich, Switzerland.

Since Whole Exome Sequencing (WES) demonstrated mutations in known disease genes in more than 30% of patients with severe non-specific ID (Rauch et al. 2012) and in 25% of mixed clinical patients (Yang et al. 2013) we investigated the diagnostic yield of NGS of large gene panels including all known disease genes (CES: "clinical exome sequencing") versus WES. So far we analyzed WES data of 99 unrelated patients with a variety of neurodevelopmental or congenital anomalies and CES data covering 2761 or 4813 known disease genes from 12 patients. WES revealed pathogenic mutations in known disease genes in a total of 23% of cases, which increased to almost 70% in cases with a precise clinical syndrome suspicion. Diagnostic yield of CES was 50% in total. Comparison of the average yield of ~135 private non-synonymous variants per case targeting the whole exome versus the ~65 for the 2761 and ~107 for the 4813 gene panel, indicates a more sensitive variant detection on the clinical disease panel. The increased sensitivity may be explained by the high average coverage of over 200x and a 10x coverage in almost 98% of the targeted region. Of 29 diagnosed cases, 41% represented autosomal dominant mutations, 52% were inherited in an autosomal recessive pattern and 7% had X-linked inheritance. In about 14% of WES cases in total, and in 31% of affected sib pairs we detected new possible disease causing candidate genes.
We conclude that CES is highly sensitive especially in cases with a syndromic clinical diagnosis.

C07.3
One generic automated workflow for both Sanger and ion semiconductor sequencing in routine DNA diagnostics

K. Neveling, *A. Diekstra, E. Bosgoed, A. Rikken, B. van Lier, E. J. Kamsteeg, M. Tychon, R. C. Derks, R. A. van Soest, A. R. Mensenkamp, H. Scheffer, M. R. Nelen;*
Radboud University Medical Center, Nijmegen, Netherlands.

Dideoxy-based chain termination sequencing developed by Frederick Sanger is the "gold standard" sequencing approach used by clinical genetic laboratories. Recently, new NGS technologies found their way into diagnostic

laboratories, enabling to sequence also large targeted gene panels or even complete exomes. These NGS approaches are normally used in parallel to conventional Sanger sequencing. The development of benchtop NGS machines now allows to analyze single genes or small gene panels using the new technologies, making these platforms increasingly competitive to Sanger sequencing.
Here we show that we have generated a generic automated ion semiconductor sequencing workflow which can be used in a clinical setting. Standard amplicon-based enrichment remains identical to the PCR for Sanger sequencing. A novel post-enrichment pooling strategy was developed, allowing to limit the number of library preparations and thereby reducing sequencing costs up to 60-70% compared to Sanger sequencing. A total of 1224 known pathogenic variants were used to perform a thorough validation, resulting in an analytical sensitivity of 99,92%,with a specificity of 99,99%. An additional study using a total of 100 patient-derived DNA samples was performed blinded and resulted in an analytical sensitivity of 99.60% and a specificity of 99.98%, comparable to Sanger sequencing. These data combined with the high scalability of our developed system makes it attractive to use ion semiconductor sequencing as our main mutation scanning technique, independent of the requested genes. We have therefore implemented this automated semiconductor sequencing workflow in our routine DNA diagnostics, and ISO15189 accreditation is in process.

C07.4
Setting sequencing thresholds for the use of next generation sequencing as a diagnostic tool

Y. Sun, M. J. V. Hoffer, C. A. L. Ruivenkamp, J. T. den Dunnen, **G. W. E. Santen**;
Leiden University Medical Center, Leiden, Netherlands.

Before replacing gene-by-gene Sanger sequencing with genome-wide NGS, it is essential that diagnostic laboratories investigate the relation between sequencing depth and test characteristics such as false-positive/negative rates, yield and coverage of relevant regions. In addition, capture bias needs to be evaluated when choosing between whole exome (WES) and whole genome sequencing (WGS).
To determine these factors we investigated 9 samples sequenced in diagnostic laboratories using both WES and WGS and 4 samples analysed by SNP-array and deep sequenced by WES. As intellectual disability (ID) is considered the primary indication for diagnostics using WES/WGS, we focused on a panel of ~400 ID genes. We observed no false-negatives in WES versus WGS for the ID gene panel region. In contrast, duplicated regions and regions with many variants in close proximity were problematic, suffering from increased false negative rates (> 1/100).
Subsequently we determined minimal sequencing criteria by applying GATK's experimental reference confidence score model on subsets of WES data (20-140*10^6 mapped reads). This revealed that (1) false positive rates are negligible, (2) false negative rates are below 1/1000, (3) the yield of identified variants is >95% with >30*10^6 mapped reads (~35X average depth), and (4) adequate depth can be reached for >95% of the bases of the ID gene panel with >60*10^6 mapped reads (~70X average depth) and >99% with > 140*10^6 mapped reads (~160X average depth).
We conclude that the applied methodology allows diagnostic laboratories to make informed decisions on sequencing criteria using few deeply sequenced WES datasets.

C07.5
EuroGentest guidelines for diagnostic next generation sequencing

G. Matthijs[1], *M. Alders*[2], *P. Bauer*[3], *A. Corveleyn*[1], *S. Eck*[4], *I. Feenstra*[5], *V. Race*[1], *H. Scheffer*[5], *E. Sistermans*[6], *E. Souche*[1], *M. Sturm*[3], *M. Weiss*[6], *H. Yntema*[5], *and the Participants to the EuroGentest workshop on Diagnostic NGS Guidelines;*
[1]Center for Human Genetics, Leuven, Belgium, [2]Department of Clinical Genetics, Academic Medical Centre (AMC), Amsterdam, Netherlands, [3]Institute of Medical Genetics and Applied Genomics, University Hospital, Tübingen, Germany, [4]Center for Human Genetics and Laboratory Diagnostics, Dr. Klein, Dr. Rost, Martinsried, Germany, [5]Department of Human Genetics, Radboud university medical center, Nijmegen, Netherlands, [6]VU University Medical Center, Amsterdam, Netherlands.

Next generation sequencing (NGS) is quickly being optimized for use in diagnostics. The technologies bring challenges at the technical level, in terms of data management and in the interpretation of results. Over the past 2 years, guidelines have been issued by the American, Australian, Dutch and British genetic professional societies. At EuroGentest, an expert group has been working on compiling, integrating and completing these guidelines. For instance, we believe that defining the 'diagnostic utility' of the NGS test is the laboratory's first duty when preparing to offer diagnostic NGS. Second, we introduce a scoring system for the different NGS assays depending on their quality and comprehensiveness. This is important for patients and clinicians to allow comparison of the diagnostic offer from the different laboratories. It could also be used by the health care system to evaluate and reimburse the tests. This scoring system is new, as it does not feature in any other guideline. As far as 'reportable range' is concerned, we propose the use of 3 specific percentages depending on the reference (technical target, coverage of transcript in a gene panel, coverage with reference to the genome) which will again allow to compare individual results within runs, between tests and between laboratories. The guidelines propose a template for reporting NGS results as well. Finally, the guidelines also deal with informed consent, unclassified variants and unsolicited findings, again from the laboratory standpoint. Similarly, they define the difference between research and diagnostics, with a practical solution to the 'duty to recontact'.

C07.6
Clinical exome sequence performance for reporting secondary genetic findings

E. Londin[1], *P. Clark*[2], *M. Sponziello*[3], *L. Kricka*[4], *P. Fortina*[1,3], *J. Y. Park*[5];
[1]Thomas Jefferson University, Philadelphia, PA, United States, [2]Children's Hospital of Philadelphia, Philadelphia, PA, United States, [3]Sapienza Universita' di Roma, Rome, Italy, [4]University of Pennsylvania Medical Center, Philadelphia, PA, United States, [5]University of Texas Southwestern Medical Center and Children's Medical Center, Dallas, TX, United States.

The American College of Medical Genetics and Genomics (ACMG) has recommended the reporting of clinically actionable incidental genetic findings in the course of clinical exome testing. Specifically, the pathogenic findings of 56 specific genes with known clinical importance should be reported. However, this assumes that exome sequencing returns data of sufficient quality using methods that were not validated for clinical use. To address this issue, we surveyed the potential false negative rate of mutations in the 56 ACMG genes. We retrospectively, analyzed forty-four exome datasets from four different exome capture kits and two-sequence platforms. The exome methods were examined for their ability to detect clinically relevant mutations in the 56 ACMG genes. A total of 17,774 pathogenic nucleotide variants are annotated in the Human Gene Mutation Database (HGMD) for the 56 genes, and data was examined for depth of coverage in the exome datasets. Overall, the four-exome methods had inadequate depth of coverage for accurate base calling ranging from 5.2% to 34.8% of the pathogenic variant positions. At least one gene in each exome method was missing >40% of the pathogenic variant positions. The worst performing method was predicted to miss >90% of clinically significant variant positions in the genes TMEM43, PCSK9, KCNQ1 and LMNA. The heterogeneous and occasional poor depth of coverage across this set of 56 genes illustrates the opportunity for further innovation in standardizing clinical NGS methods. Implementation of the ACMG incidental findings guideline requires recognition of the substantial possibility of reporting false negative results.

C08.1
Smc1a cohesin gene mutations in colorectal precancerous lesions

F. Cucco[1,2], *A. Servadio*[3], *V. Gatti*[4], *P. Bianchi*[5], *L. Mannini*[1], *A. Prodosmo*[4], *E. De Vitis*[1], *G. Basso*[5], *A. Friuli*[1], *L. Laghi*[6], *S. Soddu*[4], *G. Fontanini*[3], *A. Musio*[1,6];

Chromosome missegregation leading to chromosomal instability, is thought to play a pivotal role in cancer development. As major cohesin function is to assure correct chromosome segregation, increasing data suggests its involvement in tumorigenesis. Colorectal cancer (CRC) is a useful model for investigating the role of cohesin in carcinogenesis. CRC develops over the course of many years as a consequence of the accumulation of specific mutations in both oncogenes and tumor suppressor genes. These mutations arise in a characteristic sequence leading to early adenoma/dysplastic crypt, late adenoma and carcinoma. Two types of genomic instability have been identified in CRC: chromosomal instability (CIN), is present in around 85% of colorectal cancers, while the remaining 15% shows microsatellite instability (MSI). CIN was proposed as the major cause of cancer development more than 100 years ago, but its molecular mechanisms have not yet been completely defined. In this regard, the identification of gene(s) that gives rise to a CIN phenotype at an early stage of CRC development has been challenging. To this aim, we analyzed colorectal early adenomas and identified eleven mutations in SMC1A core cohesin subunit. Transfection of the SMC1A mutants identified in early adenomas and wild-type SMC1A gene silencing in normal human fibroblasts led to chromosomal instability. Since SMC1A is an X-linked gene, our finding suggests that a single allele mutation is enough to trigger chromosomal instability and tumorigenesis.
This work was supported by grants from Istituto Toscano Tumori and Associazione Italiana Ricerca sul Cancro to A.M.

Loss-of-function germ-line mutations in *BRCA1* (MIM #113705) confer markedly increased risk of breast and ovarian cancer. The full-length transcript codifies for a protein involved in DNA repair pathways and cell-cycle checkpoints. Several *BRCA1* splicing isoforms have been described in public domain databases, but the physiological role (if any) of *BRCA1* alternative splicing remains to be established. An accurate description of *naturally occurring* alternative splicing at this locus is a prerequisite to understand its biological significance. However, a systematic analysis of alternative splicing at the *BRCA1* locus is yet to be conducted.

Here, the Evidence-based Network for the Interpretation of Germ-line Mutant Alleles (ENIGMA) consortium combines RT-PCR, exon scanning, cloning, sequencing, and relative semi-quantification to describe naturally occurring *BRCA1* alternative splicing with unprecedented resolution. The study has been conducted in blood related RNA sources,commonly used for clinical splicing assays, as well as in one healthy breast tissue. We have characterized a total of 63 *BRCA1* alternative splicing events, including 35 novel findings. A minimum of 10 splicing events (Δ1Aq, Δ5, Δ5q, Δ8p, Δ9, Δ(9,10), Δ9_11, Δ11q, Δ13p, and Δ14p) represent a substantial fraction of the full-length expression level (ranging from 5% to 100%). Remarkably, our data indicates that *BRCA1* alternative splicing is similar in blood and breast, a finding supporting the clinical relevance of blood-based in vitro splicing assays.

Overall, our data suggests an alternative splicing model in which most non-mutually exclusive alternative splicing events are randomly combined into individual mRNA molecules to produce hundreds of different *BRCA1* isoforms.

Mutations in the E-cadherin gene, *CDH1*, account for 40% of hereditary diffuse gastric cancer (HDGC) cases. The genes responsible for the remaining cases of HDGC, as well as other familial gastric cancers (FGC) are currently unknown. We examined a large family with FGC and no *CDH1* mutations using a combination of genetic mapping with high-density SNP arrays and exome sequencing and identified that the cancer is associated with a germline coding variant (p.P946L) in mitogen-activated protein kinase kinase kinase 6 (*MAP3K6*). A somatic second-hit (p.H506Y) was present in DNA obtained directly from a tumor specimen of an affected individual. Screening of 115 unrelated individuals with non-*CDH1* FGC identified the p.P946L variant, as well as four additional coding variants in *MAP3K6* (p.F849Sfs*142, p.P958T, p.D200Y and p.V207G). These probands were negative for mutations in another 50 genes with links to gastrointestinal cancers also being screened in this cohort. These findings, together with what is known from mouse models about the role *MAP3K6* plays in oncogenesis, and previous studies showing the presence of somatic mutations in *MAP3K6* in non-hereditary gastric cancers, indicate that *MAP3K6* variants are a predisposing factor for FGC.

C08.4

Germline mutations in SUFU cause Gorlin syndrome and redefine the risk associated with childhood medulloblastoma.

W. G. Newman[1], *M. J. Smith*[1], *C. Beetz*[2], *S. Williams*[1], *Z. Bholah*[1], *B. Anderson*[1], *S. B. Daly*[1], *J. Urquhart*[1], *J. O'Sullivan*[1], *A. Kelsey*[1], *S. Bhaskar*[1], *D. G. Evans*[1];

[1]*University of Manchester, Manchester, United Kingdom,* [2]*University of Jena, Jena, Germany.*

Background Mutations in PTCH1 have been identified in approximately 70% of individuals with Gorlin syndrome. Methods Gorlin families were screened for PTCH1 mutations by DNA and RNA sequencing and MLPA. Selected cases without an identified mutation with more than one affected member underwent exome sequencing. Results PTCH1 mutations were identified in 42/70 (60%) of families fulfilling Gorlin syndrome criteria. Exome sequencing of four PTCH1 negative patients revealed a heterozygous germline SUFU mutation, c.550C>T (p.Gln184*), in one individual. Sanger sequencing of 23 further PTCH1 negative families identified a novel heterozygous SUFU missense mutation, c.544G>T (p.Asp182Tyr). MLPA screening of SUFU defined a deletion in one family, starting between exons 3 and 5 and removing the 3' end of the gene. All affected SUFU positive families contained a single case of medulloblastoma. Of 171 individuals meeting Gorlin syndrome criteria 115 (67%) have a PTCH1 mutation and 10 a SUFU mutation. Only two of 115 (1.8%) with a PTCH1 mutation have developed pathology proven medulloblastoma. Three of ten individuals from three families with SUFU-related Gorlin syndrome developed a medulloblastoma. Three cranial tumours occurred in follow up of two SUFU mutation cases, two meningiomas and a pilocytic astrocytoma. Conclusions The risk of medulloblastoma in Gorlin syndrome is reported as 5%. Our study redefines the risk of medulloblastoma in PTCH1 related Gorlin syndrome as ~2%, with a risk around 15 times higher in SUFU related Gorlin syndrome. We also show convincingly for the first time that SUFU mutations cause classical Gorlin syndrome.

C08.5

Evaluation of anti-cancer chemotherapy genotoxicity using a new p53 functional assay in human lymphocytes

J. M. Flaman, *E. Kasper, Y. Zerdoumi, F. Soubigou, G. Bougeard, T. Frebourg; Inserm U1079 and Rouen University Hospital, Rouen, France.*

Most of the conventional anti-cancer chemotherapies inhibit proliferation and survival of cancer cells by inducing DNA damages, are potentially mutagenic and therefore might promote development of secondary tumours, in particular in patients with inherited cancer risk. The p53 pathway is activated in response to any genotoxic stress. Our team has recently developed a new functional assay of p53 in human lymphocytes in order to classify the different germline *TP53* mutations detected in Li-Fraumeni syndrome. We adapted this assay to develop an universal genotoxicity test based on specific detection of p53 pathway induction. This simple test is based on the exposure of human wild-type *TP53* lymphocytes to chemical or physical agents, then on the measurement by RT-QMPSF of p53 target gene expression. The specificity of the p53 pathway induction is demonstrated by the same experiment carried out in lymphocytes harbouring a heterozygous *TP53* mutation, which compromises the response to genotoxic stress. Using this test, we evaluated the genotoxicity of the conventional anti-cancer drugs commonly used. This analysis revealed that all classes of anti-cancer drugs are genotoxic, with the exception of the mitotic spindle poisons, such as paclitaxel or derivatives of vinca alkaloids. These results suggest that the remarkable high rate of multiple primary tumours observed in patients with Li-Fraumeni syndrome may be due in part to the mutagenic effect of chemotherapies, and that the use of microtubules poisons may be of particular interest in these patients. This new functional assay should facilitate the identification of new non-genotoxic anti-cancer molecules.

C08.6

Functional analysis of mismatch repair gene variants of uncertain significance and their possible contribution to Lynch syndrome

M. Kasela[1], *R. Tricarico*[2], *J. Kantelinen*[1], *G. Gorelli*[2], *M. Genuardi*[2], *M. Nyström*[1];

[1]*University of Helsinki, Helsinki, Finland,* [2]*University of Florence, Florence, Italy.*

Objective: Germline pathogenic mutations in DNA mismatch repair (MMR) genes and especially in MSH2 and MLH1 predispose to Lynch syndrome (LS). However, many of the found variants are of uncertain significance (VUS), which complicates their risk assessment and calls for functional analyses before predictive gene testing and genetic counseling are offered to a family. **Methods:** 5 MLH1 and 4 MSH2 variants were identified in a set of Italian families with suspected LS. The probands from these families were investigated by sequencing of the coding regions of the genes and by microsatellite instability (MSI) and immunohistochemical (IHC) analyses of MMR proteins on tumor samples. Functional significance of the 9 putative LS predisposing VUS was analyzed in an in vitro MMR assay and expression/stability of the mutated variants evaluated by Western blot analysis (WB). **Results:** As a result, 2 MLH1 and 3 MSH2 variants showed no repair in the assay and were assessed as pathogenic, whereas 3 MLH1 and 1 MSH2 variant repaired as the wild type protein and were assessed as proficient. Lowered protein expression patterns in WB as well as in silico analysis together with MSI and IHC data further supported their pathogenicity. **Conclusions:** The functional analysis together with clinical, tumor pathological and in silico analysis helped to confirm pathogenicity in 5 out of 9 putative Lynch syndrome variants.

C09.1

Functional analysis of SHANK2 mutations identified in schizophrenia patients

S. Peykov[1], *S. Berkel*[1], *T. Böckers*[2], *K. Weiss*[3], *G. Schratt*[3], *S. Cichon*[4], *M. Rietschel*[5], *M. Noethen*[6], *G. Rappold*[1];
[1]*Institute of human genetics, Heidelberg, Germany,* [2]*Institute of Anatomy and Cell Biology, Ulm, Germany,* [3]*Institute of Physiological Chemistry, Marburg, Germany,* [4]*University of Basel, Basel, Switzerland,* [5]*Central Institute of Mental Health, Mannheim, Germany,* [6]*Institute of human genetics, Bonn, Germany.*

Genetic variants in the *SHANK2* gene have been previously reported in patients with intellectual disability and autism spectrum disorder. Our study focused on the analysis of *SHANK2* variants associated with schizophrenia. We analyzed all exons and exon-intron boundaries of the ProSAP1A_AB208026 isoform of *SHANK2* by Sanger sequencing in a cohort of 481 schizophrenia patients (177 trios and 304 singleton patients) and 374 unaffected individuals. We detected ten missense variants that affect protein structure which are only present in the patient group.
We used mutation prediction tools that are based on evolutionary protein conservation and chemical properties of amino acids to select the four most promising variants. *In silico* investigation is helpful to estimate a functional relevance of mutations, but cannot substitute the functional analysis itself. To analyze the functional impact of the four selected mutations, we conducted overexpression and knockdown-rescue experiments in primary hippocampal neurons from rat with a major focus on morphological changes of the neurons. Another major point of our study was to investigate the effect of different *SHANK2* isoforms and schizophrenia mutations on the actin structures. We used COS-7 cells as a model system and live cell TIRF (Total Internal Reflection Fluorescence) microscopy for imaging of actin structures. Additionally, we also performed actin polymerization assays to measure *in vivo* F-actin/G-actin ratio in our mutants compared to SHANK2 wild type. With these functional tests we were able to show for the first time a functional effect of SHANK2 variants which were identified in schizophrenia patients.

Parkinson's disease (PD) is a progressive neurodegenerative disease, and the second most prevalent neurologic disorder of the elderly. Although ~14% of patients have a family history of parkinsonism in only a small proportion of such pedigrees have pathogenic mutations been identified to underlie disease susceptibility. The majority of causal and disease-modifying variants remain unknown. We report longitudinal clinical, genealogic and comparative sequence (exome) analyses of affected multi-generational families. Genome alignment, variant annotation and comparative analyses were used to identify shared coding mutations. Initially we have examined concordant/discordant variant sharing within multi-incident pedigrees (n=10), using Mendelian models and maximum parsimony. We subsequently inspected variant segregation with disease and extended these findings to unrelated patients (n=1500) and control subjects (n=1500) of Scandinavian descent. In two families missense mutations in NOVA2 and RPE65 were found to segregate with parkinsonism and were not observed in control subjects of Scandinavian origin. Both variants were subsequently genotyped in a multi-ethnic case-control series submitted by the GEOPD Consortium (n=5000). Interestingly, two additional patients with familial parkinsonism were identified as RPE65 carriers and no controls. Moreover, sequencing of entire coding region of RPE65 and NOVA2, in multi-ethnic probands with familial parkinsonism (n=100), led us to identify more missense mutations. Our data provides evidence for two novel genes in the etiology of PD.

Bipolar disorder is a severe and highly heritable disorder of mood with a lifetime prevalence of about 1%. Molecular genetic studies have identified a number of susceptibility genes, with the relevant pathways, however, being still largely unknown.
microRNAs are a class of small non-coding RNAs. Accumulating evidence suggests that microRNAs contribute to basic mechanisms underlying brain development and plasticity thus suggesting their possible involvement in the pathogenesis of several psychiatric disorders, including bipolar disorder.
The aim of the present study was to systematically investigate whether common variants at all known microRNA loci (miRBase release 13.0) contribute to the development of bipolar disorder. We performed gene-based analyses for all microRNAs and +/- 20kb flanking sequences using VEGAS on the largest existing GWAS dataset of bipolar disorder comprising of 9,747 patients and 14,278 controls (Mühleisen et al., Nature Commun 2014). In this dataset we combined our data obtained from four European countries, Canada, and Australia with the GWAS results of the multinational Psychiatric Genomics Consortium.
Our analysis revealed that 98 of the 609 microRNAs showed nominally significant p values, indicating that bipolar disorder-associated microRNAs are enriched within the known microRNA loci (p=0.006). After correction for multiple testing, nine microRNAs (let-7g, miR-135a, miR-499, miR-581, miR-611, miR-640, miR-644, miR-708, miR-1908) showed a significant association with bipolar disorder. These included microRNAs known to be involved in neural development and synaptic plasticity.
Results from the investigation of the affected target genes and underlying regulatory networks supports these disease mechanisms and also suggests new mechanisms.

C09.4

Imbalance between excitation and inhibition in Neurons derived from *MECP2*, *CDKL5* and *FOXG1* iPSCs

I. Meloni[1], *T. Patriarchi*[1,2], *S. Amabile*[1], *A. Bartolini*[3], *D. Yasui*[4], *E. Calcagno*[5], *C. Lo Rizzo*[1], *F. Ariani*[1], *F. Mari*[1,3], *M. Mencarelli*[3,1], *J. W. Hell*[2], *A. Renieri*[1,3];
[1]*Medical Genetics, University of Siena, Siena, Italy,* [2]*Department of Pharmacology, School of Medicine, University of California Davis, Davis, CA, United States,* [3]*Genetica Medica, Azienda Ospedaliera Universitaria senese, Siena, Italy,* [4]*Department of Medical Microbiology and Immunology, University of California Davis, Davis, CA, United States,* [5]*Department of Neuroscience University of Torino, Torino, Italy.*

Rett syndrome is due to de novo mutations in *MECP2*, *CDKL5* or *FOXG1* genes. MeCP2 and FoxG1 are transcriptional regulators; *CDKL5* encodes for a

kinase protein involved in multiple cellular processes. In spite of their involvement in the same disease, a functional interaction between the three genes has not been proven and disease mechanism remain elusive. It has been suggested that an excitation/inhibition imbalance might play an important role in Rett pathogenesis. We have used a mouse model and a human model based on patients-specific iPSCs-derived neurons to test the hypothesis that in maturing neurons an initial excess of excitatory synapses might result in excitotoxicity finally leading to loss of excitatory synapses. We have established 3 iPSC lines for each gene. Quantitative RT-PCR on iPSCs-derived neurons demonstrated that *VGLUT1* is over-expressed while *GAD1* is down-regulated. Similarly, down-regulation of another inhibitory marker (*VGAT*) is observed in the mouse model. However, in this model a reduction of excitatory synapses (*VGLUT1*, *GluA1*, *GluA2*, *NR1*) is observed opposite to iPSCs-derived neurons.

Moreover, RNA and protein analysis shows an over-expression of *GRID1*, a member of the delta family of ionotropic glutamate receptors which induces preferentially inhibitory presynaptic differentiation of cortical neurons. Our data provide evidence in favour of excitotoxicity as an important contributing factor in Rett pathogenesis due to *MECP2* mutations and suggest a similar mechanism for *CDKL5*- and *FOXG1*-mutated patients. These results confirm the presence of an imbalance between excitation and inhibition thus providing novel insights into Rett pathophysiology.

C09.5

Left/right asymmetry genes are associated with handedness and appear relevant for neurodevelopmental disorders

S. Paracchini[1], *W. Brandler*[2], *A. Morris*[2], *D. Evans*[3], *S. Ring*[3], *J. Stein*[2], *A. Monaco*[2], *J. Talcott*[4], *S. Fisher*[5], *C. Webber*[2];

[1]*University of St Andrews, St Andrews, United Kingdom,* [2]*University of Oxford, Oxford, United Kingdom,* [3]*University of Bristol, Bristol, United Kingdom,* [4]*Aston University, Birmingham, United Kingdom,* [5]*Max Planck Institute, Nijmegen, United Kingdom.*

Humans display structural and functional asymmetries in brain organization, strikingly manifested through language and handedness. While we understand the biology of body asymmetries, the molecular basis of brain laterality is still unknown. We report a genome-wide association study (GWAS) for a quantitative measure of handedness and dexterity (pegboard) in individuals with dyslexia (n = 728). The most strongly associated variant, rs7182874 (P = 8.68×10^{-9}), is located in *PCSK6*, a gene known to activate NODAL, which is required to regulate left/right body axis determination. A novel approach for GWAS pathway analysis, based on gene-set enrichment strategies, showed that left/right asymmetry pathways are associated with handedness in both the dyslexia and a general population (n = 2666) cohorts. In particular, genes involved in corpus callosum development were enriched among the GWAS top hits. Furthermore, different markers at the PCSK6 locus were found to be associated with a measure of handiness in a completely independent study. The dyslexia-specific marker-trait association could be the result of an epistatic effect. Recent findings show that dyslexia candidate genes play a role in ciliogenesis, an important developmental process at the basis of left/right structural asymmetries determination. We propose that handedness is a polygenic trait controlled in part by the molecular mechanisms which establish left/right body asymmetry early in development, which in turn influence brain midline development and might be implicated in neurodevelopmental disorders. We are now investigating the molecular mechanisms underlying this association using neuronal stem cell and zebrafish models.

C09.6

Exome sequencing to disclose potential new pathogenetic variants in Rett patients without mutations in the known Rett genes

M. Marchi[1], *F. Cogliati*[1], *D. Gentilini*[1], *I. Cracco*[1], *D. Cittaro*[2], *M. Pintaudi*[3], *A. Vignoli*[4], *L. Giordano*[5], *E. Veneselli*[3], *B. Ben Zeev*[6], *L. Larizza*[1,7], **S. Russo**[1];

Mutations in the X-linked gene MECP2 are the main cause of classical Rett syndrome (RTT), while 28% of patients with early onset seizures and a small percentage of those with congenital variant forms carry mutations in CDKL5 and FoxG1 genes, respectively. About 5% of classical and 40-50% of atypical RTT patient remain without a molecular diagnosis. Aiming at disclosing novel candidate genes , a cohort of 31 Rett patients with both classic and atypical phenotype and unascertained genetic defect was processed .on a HiScan Illumina platform by True Seq Exome Enrichment. As most mutations in the known RTT causative genes discovered up to day have a de novo origin, we adopted this model and filtered heterozygous variants, prioritizing those predicted to introduce a frameshift or stop codon or splice or missense changes. Prioritization of the interesting genes took into account their expression in Central Nervous System and/or neuronal function, previous reported involvement in a known genetic disease and the interaction to genes/protein responsible for a resembling phenotype. By this approach we have validated by Sanger sequencing 57 variants corresponding to 38 genes. In 8 cases parents analysis has proved the de novo origin of the SNVs, which occur in GABA receptors, Sodium and Potassium neuronal channels, synaptic vesicular releasing factor and a transcriptional regulator. Our data confirm exome targeted NGS as a promising tool to disclose novel pathogenetic mechanisms leading to RTT.

C10.1

PLS3 mutations in X-linked osteoporosis and fractures: unraveling a new bone regulatory pathway

Osteoporosis with its consequences, i.e., fractures, is major health problem in ageing societies. As osteoporosis is a prevalent disorder, understanding its etiological factors is very important. We recently identified novel pathogenic variants in PLS3 (encoding Plastin 3 (PLS3), a filamentous-actin bundling protein) as a cause of X-linked osteoporosis and osteoporotic fractures in five Dutch families (van Dijk et al. NEJM 2013:369(16):1529-36). These loss-of-function variants cause decreased bone mineral density and increased risk of fracture in hemizygous young men whereas the clinical picture in heterozygous women ranged from asymptomatic to early-onset osteoporosis. It was highly unexpected that mutations in this gene would cause osteoporosis and fractures as it had never been described as a candidate gene for osteoporosis nor was it known to play a role in bone formation. However, results of in vivo analyses in zebrafish strongly supported a role for PLS3 as a bone regulatory protein. Furthermore, a rare variant (rs140121121) in PLS3 was found to be associated with a twofold increased fracture risk in elderly female carriers in the normal population indicating genetic variation in PLS3 as a novel etiological factor involved in common, multifactorial osteoporosis. However, the exact mechanism by which PLS3 mutations cause osteoporosis and fractures is unknown and currently subject of further investigations. Unravelling this new bone regulatory pathway is of great importance for understanding the aetiology of osteoporosis, increasing also the possibilities for prevention, diagnosis and treatment aimed at bone formation.

C10.2

Mutations in plastin 3 cause osteoporosis with fractures. Overexpression of PLS3 and other F-actin bundling proteins influence skeletal development in zebrafish and mice

J. Milbradt[1], *M. Dimitra*[2], *M. Riessland*[1], *N. Hamann*[3], *F. van Dijk*[2], *M. Peters*[1], *N. Mendoza Ferreira*[1], *M. S. Hosseini Barkooie*[1], *E. Janzen*[1], *M. C. Zillikens*[4], *M. Hammerschmidt*[5], *A. Niehoff*[3,6], *G. Pals*[2], **B. Wirth**[1];

Osteoporosis affects a large proportion of the human population, particularly women after menopause. Recently we reported that pathogenic loss-of-function variants in the plastin 3 (PLS3) gene, localized on Xq23 are causative of familial osteoporosis with fractures. Furthermore, a rare variant in PLS3 (rs140121121) associated with a 2-fold increased risk for fractures among elderly heterozygous women in two large cohorts from Rotterdam (Van Dijk et al, NEJM, Oct 2013). PLS3 is an ubiquitously expressed actin-

bundling protein that largely influences the dynamics of the actin cytoskeleton. We demonstrated that PLS3 mRNA co-injection dose dependently rescued malformations of the craniofacial muscular-skeletal system, body axis and tail phenotype induced upon pls3 morpholino injection in 3 and 5 dpf col1a1::eGFP transgenic zebrafish. Remarkably, affected patients with PLS3 loss of function mutations only presented a bone phenotype. The absence of systemic manifestations has led us to hypothesise that other F-actin bundling proteins may compensate for the loss of PLS3 in other tissues. Interestingly, α-Actinin (ACTN) was found to be overexpressed in patients' fibroblasts, possibly preventing more severe disease manifestations. Indeed co-injection of ACTN1 or ACTN4 mRNA, rescued the muscular-skeletal phenotype induced by pls3 knock-down in fish. Moreover, analysis of femora by micro computed tomography in 3-month-old transgenic mice overexpressing human PLS3 showed significant differences in cortical and trabecular bone structures when compared to control mice. These results strongly indicate that PLS3 is a novel etiologic factor for monogenic and mutifactorial osteoporosis and PLS3 and other F-actin bundling proteins are important regulators of bone development and maintenance.

C10.3

XYLT1 mutations in Desbuquois dysplasia type 2

C. Huber[1], *C. Bui*[2], *Y. Alanay*[3], *B. Tuysuz*[4], *C. Bole-Feysot*[5], *J. Leroy*[6], *G. Mortier*[7], *P. Nitschke*[8], *V. Cormier-Daire*[2];

Desbuquois dysplasia (DBQD) is a severe condition characterized by short stature, joint laxity and advanced carpal ossification. Based on the presence of additional hand anomalies, we have previously distinguished DBQD type 1 and identified CANT1 (calcium activated nucleotidase 1) mutations as responsible for DBQD type 1. We report here the identification of 5 distinct homozygous xylosyltransferase 1 (XYLT1) mutations in 7 DBQD type 2 cases from 6 consanguineous families. Among the 5 mutations, 4 were expected to result in loss of function and a drastic reduction of XYLT1 cDNA level was demonstrated in 2 cultured individual fibroblasts. No significant clinical or radiological differences could be found with the remaining 14 DBQD type 2 cases with unknown molecular bases. However, long term follow up of XYLT1 mutated individuals emphasizes the severity of the short stature (< -6 SD) contrasting with obesity, lower limb and foot deformities requiring often repeated surgeries and intellectual disability (5/7). Interestingly, respiratory distress was present at birth in 4/7 cases and spontaneously resolved in the first years of life but thorax narrowness persisted in the eldest children. Since xylosyltransferase 1 (XT-I) catalyzes the very first step in proteoglycan (PG) biosynthesis, we further demonstrated in the two individual fibroblasts a significant reduction of cellular PG content. Our findings of XYLT1 mutations in DBQD type 2 further support a common physiological basis involving PG synthesis in the multiple dislocation group of disorders. This observation sheds light on the key role of the XT-I during the ossification process.

C10.4

Mutations in endothelin 1 cause auriculocondylar syndrome and isolated question mark ears

C. T. Gordon[1], *F. Petit*[2], *P. Kroisel*[3], *L. Jakobsen*[4], *R. Zechi-Ceide*[5], *M. Oufadem*[1], *C. Bole-Feysot*[1], *P. Nitschke*[1], *A. Munnich*[1], *S. Lyonnet*[1], *M. Holder-Espinasse*[1], *J. Amiel*[1];
[1]*Université Paris Descartes, INSERM U-1163, Paris, France,* [2]*Hopital Jeanne de Flandre, Centre Hospitalier Regional Universitaire de Lille, Lille, France,* [3]*Institute of Human Genetics, Medical University of Graz, Graz, Austria,* [4]*Copenhagen University Hospital, Herlev, Denmark,* [5]*Hospital for Rehabilitation of Craniofacial Anomalies, University of Sao Paulo, Bauru, Brazil.*

Auriculocondylar syndrome (ACS) is a rare craniofacial disorder involving micrognathia, condyle hypoplasia and question mark ear (QME). QME, which involves a defect in the fusion of the lobe and helix, can occur as an isolated anomaly. Recently, mutations in PLCB4 and GNAI3 were identified in ACS. Both genes are predicted to function in the endothelin 1 (EDN1)-endothelin receptor type A (EDNRA) signalling pathway during the development of the pharyngeal arches. Following exclusion of PLCB4 and GNAI3 in a series of ACS and QME patients, we performed exome sequencing in three unsolved families, and identified a mutation in EDN1 in each case. A fourth EDN1 mutation was identified by direct sequencing. Two of the four cases involved patients affected with ACS, born to consanguineous, healthy parents; these patients harboured homozygous missense mutations in EDN1, each predicted to interfere with enzymatic cleavage of the EDN1 pro-protein. The other two cases involved patients with dominantly-inherited isolated QME; they harboured heterozygous EDN1 mutations - a premature stop in one case and a missense mutation affecting a highly conserved residue of the mature EDN1 peptide in the other. The nature of the mutations and the different modes of inheritance suggest that heterozygous loss of function mutations in EDN1 cause isolated QME and that homozygous hypomorphic mutations cause ACS. These are the first reported mutations of EDN1 in humans and suggest that ACS and QME are a phenotypic continuum resulting from impaired EDN1-EDNRA signaling.

C10.5

Defects in TAPT1, involved in Axial Skeletal Patterning, Cause a Complex Lethal Recessive Disorder of Skeletal Development

S. Symoens[1], *A. Barnes*[2], *F. Malfait*[1], *K. Vleminckx*[1], *W. Steyaert*[1], *D. Syx*[1], *E. Parthoens*[3], *M. Biervliet*[4], *G. Gillessen-Kaesbach*[5], *J. De Backer*[1], *H. Bächinger*[6,7], *A. De Paepe*[1], *J. C. Marini*[2], *P. J. Coucke*[1];
[1]*Center for Medical Genetics Ghent, Ghent University Hospital, Ghent, Belgium,* [2]*Bone and Extracellular Matrix Branch, NICHD, NIH, Bethesda, MD, United States,* [3]*Department of Biomedical Molecular Biology, Ghent University, Ghent, Belgium,* [4]*Center for Medical Genetics, Brussels University Hospital, Brussels, Belgium,* [5]*Institut für Humangenetik Lübeck, Universitätsklinikum Schleswig-Holstein, Lübeck, Germany,* [6]*Research Department, Shriners Hospitals for Children, Portland, OR, United States,* [7]*Department of Biochemistry and Molecular Biology, Oregon Health & Science University, Portland, OR, United States.*

TAPT1 encodes Transmembrane Anterior Posterior Transformation-1 protein. TAPT1 is evolutionarily conserved, with similar orthologs from yeast to vertebrae. ENU mutagenesis of TAPT1 resulted in embryonic lethality of murine homozygotes, with posterior to anterior transformations of thoracic and lumbar vertebrae. The mechanism by which this ubiquitously expressed protein causes a specific patterning defect is unknown. We combined homozygosity mapping with exome sequencing for a Moroccan family with three lethal fetuses affected with fractures of ribs and long bones, undermineralized skull and axial skeleton, hydramnios with ascites and dilated ventricles. We identified a homozygous c.1108-1G>C mutation in TAPT1, causing in-frame skipping of exon 10. A second TAPT1 mutation was identified by direct sequencing in a Syrian pedigree with three lethal fetuses with fractures and multiple congenital anomalies of brain, face, heart and lungs. These probands were homozygous for a missense mutation in TAPT1 exon 9 (c.1058A>T, p.Asp353Val). In both families, a diagnosis of recessive osteogenesis imperfecta (OI) was initially proposed. Both variants affect the second luminal loop of TAPT1. Proband fibroblast type I collagen has broadened electrophoretic mobility of alpha-chains in the cell layer, suggesting abnormal post-translational modification of collagen and a relationship with OI forms. Immunocytochemical staining of dermal fibroblasts revealed co-localization of TAPT1 with the centrosomal protein gamma-tubulin at the basal body of the cilium, suggesting TAPT1 might have a ciliary function. The novel autosomal recessive skeletal defects reported here underscore the importance of the cilium in embryonic bone formation. Functional studies with siRNA, zebrafish and expression studies are ongoing.

C10.6

ZIC1 mutations cause coronal craniosynostosis and learning disability

S. R. F. Twigg[1], *J. A. C. Goos*[2], *I. Westbury*[1], *S. J. McGowan*[1], *M. van Dooren*[2], *A. M. W. van den Ouweland*[3], *P. J. van der Spek*[4], *.. 500 Whole-Genome Sequences (WGS500) Consortium*[5], *S. A. Wall*[6], *I. M. J. Mathijssen*[2], *E. Pauws*[7], *A. O. M. Wilkie*[1,6];
[1]*Weatherall Institute of Molecular Medicine, Oxford, United Kingdom,* [2]*Department of Plastic and Reconstructive Surgery, Erasmus MC, Rotterdam, Netherlands,* [3]*Department of Clinical Genetics, Erasmus MC, Rotterdam, Netherlands,* [4]*Department of Bioinformatics, Erasmus MC, Rotterdam, Netherlands,* [5]*Wellcome Trust Centre for Human Genetics, Roosevelt Drive, Oxford, United Kingdom,* [6]*Craniofacial Unit, Oxford University Hospitals NHS Trust, Oxford, United Kingdom,* [7]*UCL Institute of Child Health, London, United Kingdom.*

Craniosynostosis, the premature fusion of the cranial sutures, is a serious disorder affecting approximately 1 in 2,500 children. Presentation and underlying cause is very heterogeneous and approximately 25% of cases have a single genetic basis. Using trio-based whole genome sequencing we identified a de novo nonsense mutation (p.S388*) of ZIC1 in a patient with bicoronal synostosis and severe learning disability. Two further de novo nonsense mutations were identified by resequencing in our craniosynostosis panel; both cases had similar phenotypes to the original patient. A fourth ZIC1 mutation encoding a missense substitution, was identified in a 3-generation family with bicoronal synostosis and normal to mildly impaired intellectual function.
ZIC1 encodes a transcription factor which, when heterozygously deleted with its contiguous neighbour ZIC4, is associated with Dandy-Walker malformation rather than craniosynostosis. This suggests that the ZIC1 mutations identified in our study might act through a gain-of-function mechanism

to cause suture fusion. Interestingly, the 4 identified ZIC1 variants all cluster within 42 nucleotides of the terminal exon; analysis of fibroblast RNA from the first case showed that the mutant transcript escapes nonsense-mediated decay. To gain further insight into the molecular mechanism we are characterising the in vitro activity of the mutant proteins. Furthermore we show that in mouse embryos Zic1 is expressed in the supraorbital region at E11.5-E12.5, consistent with a role for ZIC1 at a very early stage of cranial suture biogenesis. Overall these findings confirm ZIC1 as a new disease gene in coronal craniosynostosis, particularly when accompanied by unexplained learning disability.

C11.1

Polygenic risk for ADHD is associated with impaired educational achievement and lower IQ in the general population

E. Stergiakouli[1], *J. Martin*[2], *M. L. Hamshere*[2], *A. Thapar*[2], *D. M. Evans*[1], *N. J. Timpson*[1], *G. Davey Smith*[1];
[1]*MRC Integrative Epidemiology Unit at the University of Bristol, Bristol, United Kingdom,* [2]*MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff University School of Medicine, Cardiff, United Kingdom.*

Introduction
High levels of ADHD symptoms during childhood carry risk of worse academic performance and can impact on employment and earnings in adulthood. Polygenic score analysis was used to show that common risk alleles for clinical ADHD contribute to the risk of having higher ADHD symptoms in the general population (Martin et al. *in press*). We have used polygenic score analysis to investigate the contribution of common risk variants for clinical ADHD on educational performance and IQ in the general population.

Methods
Academic performance was assessed using results from Key Stage 3 national tests and externally marked GCSE examinations in 6,385 children from the Avon Longitudinal Study of Parents and Children (ALSPAC). Polygenic risk scores were calculated for ALSPAC children and their mothers based on the results of an ADHD GWAS (Stergiakouli et al. 2012).

Results
ADHD polygenic scores on the children were associated with worst educational outcomes as represented by both time points and also with lower IQ scores at age 15.5 (see Table). Moreover, ADHD polygenic scores on the mothers were associated with lower IQ in the mothers and worst educational outcomes in the children (see Table).

Discussion
Our results suggest that the same genetic variants that are relevant for an ADHD diagnosis are also implicated in impaired academic performance in the general population and lower IQ score in both children and adults.

Outcome	N	Beta coefficient (95% CIs)	p value
Score achieved at key stage 3	6385	-1.41(-2-(-0.81))	$4.2x10^{-6}$
Capped GCSE points	6298	-3.84(-5.96-(-1.72))	$4x10^{-4}$
IQ at age 15.5	3858	-0.77(-1.19-(-0.36))	$2.4x10^{-4}$
Mothers IQ	2313	-0.64(-1.2-(-0.08)	0.025

C11.2

Polygenic risk score analysis shows shared genetic aetiology between AN and five other psychiatric disorders

L. M. Huckins[1], *K. S. Mitchell*[2], *L. Thornton*[3], *WTCCC3 Consortium, GCAN Consortium, D. A. Collier*[4], *P. F. Sullivan*[5], *C. M. Bulik*[5], *E. Zeggini*[1];
[1]*Wellcome Trust Sanger Institute, Hinxton, United Kingdom,* [2]*Department of Psychiatry, Boston University, Boston, MA, United States,* [3]*Dept. of Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,* [4]*Institute of Psychiatry, King's College London, London, United Kingdom,* [5]*Department of Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States.*

Anorexia nervosa (AN) is marked by extremely low body weight and intense fear of gaining weight. We evaluated shared genetic determinants of AN and commonly comorbid psychiatric disorders (PsyD) by testing whether polygenic risk scores derived from genome-wide data of other PsyD can predict AN status. We obtained allele risk scores for major depressive disorder (MDD), bipolar disorder (BPD), autism (AUT), attention deficit hyperactivity disorder (ADHD) and schizophrenia (SCZ) from the Psychiatric Genomics Consortium (PGC). We divided each of these sets into 10 Pt significance level thresholds. The test set comprised AN cases and controls from a published Wellcome Trust Case Control Consortium 3 AN GWAS study. For every test set sample, we produced a polygenic risk score as a weighted sum of risk allele scores. Logistic regression was used to assess whether each PsyD polygenic score predicted AN case-control status. We computed pseudo R^2 values, and compared these to the values obtained when randomly permuting case-control status to measure the proportion of variance in AN explained by each PsyD risk score. Our pseudo R^2 values were ~0.5-1%, comparable to pseudo R^2 values in a recent PGC polygenic score analysis of five PsyD. We computed an empirical p-value for every significance threshold and found significant pseudo R^2 values at the lowest Pt threshold (Pt <0.001) for AN vs AUT (p=0.0009), MDD (p=0.009), and SCZ (0.0008), and at Pt <0.01 for BPD (p=0.0004). We demonstrated for the first time a shared genetic aetiology between AN and other PsyD using genome-wide data.

C11.3

Efficient estimation of pairwise genetic correlations between hundreds of quantitative traits from population samples of thousands of individuals

M. Pirinen[1], *C. Benner*[1], *T. Lehtimäki*[2], *J. G. Eriksson*[3,4,5], *O. T. Raitakari*[6,7], *M. Järvelin*[8,9,10], *V. Salomaa*[3], *S. Ripatti*[1,11,12];
[1]*Institute for Molecular Medicine Finland, Helsinki, Finland,* [2]*Department of Clinical Chemistry, Fimlab Laboratories, University of Tampere School of Medicine, Tampere, Finland,* [3]*Department of Chronic Disease Prevention, National Institute for Health and Welfare, Helsinki, Finland,* [4]*Department of General Practice and Primary Health Care, University of Helsinki, Helsinki, Finland,* [5]*Unit of General Practice, Helsinki University Central Hospital, Helsinki, Finland,* [6]*Department of Clinical Physiology and Nuclear Medicine, University of Turku and Turku University Hospital, Turku, Finland,* [7]*Research Centre of Applied and Preventive Cardiovascular Medicine, University of Turku and Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, Finland,* [8]*Department of Epidemiology and Biostatistics, MRC Health Protection Agency (HPA) Centre for Environment and Health, School of Public Health, Imperial College London, London, United Kingdom,* [9]*Institute of Health Sciences, University of Oulu, Oulu, Finland,* [10]*Biocenter Oulu, University of Oulu, Oulu, Finland,* [11]*Wellcome Trust Sanger Institute, Hinxton, Cambridge, United Kingdom,* [12]*Hjelt Institute, University of Helsinki, Helsinki, Finland.*

Several modern technologies, such as nuclear magnetic resonance and mass spectrometry platforms in metabolomics, produce high-dimensional phenotype data on individuals. A first step towards utilising high-dimensional phenotypes in genetic studies is to understand how their genetic components are related.
Recent algorithmic advances in multivariate linear mixed models have enabled variance component estimation for pairs of traits using population samples of individuals and genome-wide panels of SNPs. However, current methods have not been tailored for situations where hundreds of traits are available on the same set of individuals. For such settings, we introduce an algorithm that efficiently decomposes pairwise phenotypic correlations into genetic and environmental components.
We illustrate our approach with an application to 105 pairs of metabolic and anthropometric traits measured on up to 14,000 Finnish individuals. For example, we estimate that the observed phenotypic correlation (-0.41) between triglyserides (TG) and HDL cholesterol decomposes into an additive genetic correlation (-0.59, s.e. 0.06) and an environmental correlation (-0.36 s.e. 0.02).
We discuss the interpretation of genetic correlations as correlations between locus-wise genetic effects and characterise settings where prior information about genetic correlation increases statistical power to identify pleiotropic loci, i.e. loci that contribute to multiple traits.

C11.4

The influence of genotype and phenotype data quality control on SNP based heritability estimates within and across studies.

J. Hottenga[1], *I. Fedko*[1], *G. Willemsen*[1], *E. J. C. N. de Geus*[1], *B. Penninx*[2], *D. I. Boomsma*[1];
[1]*VU University Amsterdam, Amsterdam, Netherlands,* [2]*EMGO Institute for Health and Care Research, VU University Medical Center/GGZ inGeest, Amsterdam, Netherlands.*

Currently, many GWA studies are accompanied by additional analyses to get an estimate of the amount of heritability explained by the GWAS SNPs. Such analyses in unrelated individuals critically depend on the construction of a Genetic Relatedness Matrix (GRM) as implemented for example in the software package GCTA [1]. What sometimes seems a bit surprising is the large variation in the obtained point estimates between studies. Although heritability is a population specific characteristic, these GRM-based heritabilities seem more variable than e.g. heritabilities based on twin data. Using genotype data and a wide range of phenotypes from two large population based studies in the Netherlands (NESDA: Netherlands Study of Depression and Anxiety and NTR: Netherlands Twin Register), in addition to a set of simulated phenotypes, we examined the effects SNP selection based on GWAS QC, relational filters and phenotype transformations. For continuous traits, the results show that the GRM method is sensitive to SNP selection criteria, with - or without imputations, as well as deviation of phenotypes from the assumed normal distribution. For dichotomous traits, additional issues including non-random missingness of genotypes, play a role. Thus, a substantial part of the variation in GCTA heritability estimates may depend on data quality control and the selection of study individuals prior to the analysis.
1. GCTA: a tool for genome-wide complex trait analysis. Yang J, Lee SH, Goddard ME, Visscher PM. Am J Hum Genet. 2011 Jan 7;88(1):76-82. PMID: 21167468.

C11.5

Co-regulated transcripts associated to cooperating eSNPs define bi-fan motifs in human gene networks

A. Kreimer[1], *I. Pe'er*[2];
[1]*Department of Biomedical Informatics, Columbia University, New York, NY, United States,* [2]*Department of Computer Science, Columbia University, New York, NY, United States.*

Associations between the level of single transcripts and single corresponding genetic variants, eSNPs, have been extensively studied and reported. However, most expression traits are complex, involving the cooperative action of multiple SNPs at different loci affecting multiple genes. Finding these cooperating eSNPs by exhaustive search has proven to be statistically challenging. In this paper we utilized availability of sequencing data with transcriptional profiles in the same cohort to identify two kinds of usual suspects: eSNPs that alter coding sequence or eSNPs within the span of transcription factors (TFs). We devised a computational framework for examining pairs of such cooperating source eSNPs that are both associated with the same pair of target transcripts. We characterize such quartets through their genomic, topological and functional properties. We establish that this regulatory structure of cooperating quartets is frequent in real data, but is rarely observed in permutations. eSNP sources are mostly located on different chromosomes and away from their targets. In the majority of quartets, SNPs affect the expression of the two gene targets independently of one another, suggesting a mutually independent rather than a directionally dependent effect. Furthermore, the directions in which the minor allele count of the SNP affects gene expression within quartets are consistent. Same-effect eSNPs are observed more often than expected by chance. Cooperating quartets reported here in a human system might correspond to bi-fans, a known four nodes network motif previously described in model organisms. Overall, our analysis offers insights concerning the fine motif structure of human regulatory networks.

C11.6

Inferring the human embryonic selection via genomic data

K. Popadin, *P. Makrythanasis, S. E. Antonarakis;*
Department of Genetic Medicine and Development, Geneva, Switzerland.

Selection constantly filters out genomes with an excess of slightly deleterious variants (SDVs) maintaining the fitness of human population. In case of consanguineous marriages high level of homozygosity, observed in offspring, uncovers the damaging effect of many SDVs variants making the purifying selection more effective. We hypothesize that healthy offspring of consanguineous marriages carry a deficit of these variants as a result of the embryonic selection acting against the high genetic load. Using 50 genotyped pedigrees with consanguineous marriages we revealed a signature of purifying selection. First, by means of modified transmission disequilibrium test we observed a genome-wide deficit of rare derived alleles, transmitted from consanguineous parents to their healthy offspring. Because rare derived alleles are enriched in deleterious variants we assume, that the deficit of rare derived alleles could be a signature of embryonic purifying selection, which filters out low-fitted genomes with high load of mutations. Second, we expect that haplotypes, which are rarely seen in long Runs Of Homozygosity (ROH) harbor loci with high load of recessive mutations. Comparing the density of slightly deleterious variants inside and outside ROH we present an approach and the first results describing transmission of haplotypes identical by descent in consanguineous marriages. Further investigation of the genetic load of long ROH and the pattern of their inheritance can help to allocate mutations causing recessive autosomal diseases.

C12.1

Next generation sequencing as a reliable and efficient technique to identify mutations in patients with retinal dystrophies

Retinal dystrophies (RD) constitute a group of blinding diseases that show clinical variability and genetic heterogeneity. More than 20 different clinical diagnoses with over 200 genes have been associated with RD. This enormous heterogeneity is an obstacle to identify disease-associated mutations for any diagnostic- and research-based approach.
Next generation sequencing represents the most efficient technology to identify mutations in RD patients and families. In this study, we performed both, panel-based sequencing of 105 RD-associated genes for diagnostic purposes and exome sequencing for research cases.
We developed a diagnostic NGS pipeline to identify mutations in 170 genetically and clinically unselected RD patients. Underrepresented regions were examined by Sanger sequencing. We found mutations in 50 to 60% of retinitis pigmentosa and approximately 80% of syndromic (Bardet-Biedl or Usher syndrome) cases. Seventy-one novel mutations in 40 genes were identified, among which the genes USH2A, EYS, ABCA4, and RHO were more frequently affected by pathogenic sequence alterations. Occasionally, cases carried mutations in more than one RD-associated gene suggesting modifier effects of the additional variants. We further found possible dominant de-novo mutations in sporadic RD cases imposing difficulties for counseling of patients and families. Exome sequencing showed similar detection rates in 11 additional research-based RD cases confirming that both approaches are efficient to identify mutations in known disease genes. In contrast to panel sequencing, exome analysis provided the bases to search for gene candidates for RD.
In conclusion, NGS-based mutation analyses provide reliable and cost-efficient approaches to investigate genetically heterogeneous diseases like RD.

C12.2

New Hereditary hearing loss (HHL) genes/mutations identified by High throughput sequencing and genotyping in the Italian and Qatari populations.

G. Girotto[1], *D. Vozzi*[2], *E. Rubinato*[2], *A. Morgan*[1], *K. Abdulhadi*[3], *D. Vuckovic*[1], *M. Di stazio*[1], *A. d'Eustacchio*[2], *M. La Bianca*[1], *R. Badii*[4], *P. Gasparini*[5];
[1]*Dep. Medical Sciences, University of Trieste, Trieste, Italy,* [2]*Inst. Maternal and Child Health-IRCCS "Burlo Garofolo", Trieste, Trieste, Italy,* [3]*Audiology and Balance Unit, HMC, Doha, Qatar, Doha, Qatar,* [4]*Molecular Genetics Laboratory, HMC, Doha, Qatar, Doha, Qatar,* [5]*Dep. Medical Sciences, University of Trieste,Inst. Maternal and Child Health-IRCCS "Burlo Garofolo", Trieste, Trieste, Italy.*

To overcome the remarkable genetic heterogeneity of HHL an extremely powerful 3 steps "gene-identification strategy" was designed. STEP1 consists in a screening of 96 HHL genes by targeted re-sequencing (TS) on Ion Torrent PGM™ (3487 amplicons). Positive cases contribute to define an accurate molecular epidemiology picture while negative ones undergo a combination of STEP2 (linkage studies) and STEP3 (whole exome sequencing) or directly STEP3 (depending on pedigree size).
Illumina protocols were used for STEP2 and STEP3. Sequencing variants were annotated/filtered according to standard pipelines. This strategy was applied to a first series of 28 Italian and Qatari families. STEP1 characterized 43% of all families and led to the identification of several novel alleles in known HHL genes (Table1a). STEP2 identified four new HHL loci (Table1b), while STEP3 had already led to the discovery of 2 new genes (BDP1 and TBLY1) and it is in progress in the remaining 14 families. Briefly, p*2625Gluext*11 mutation resulting in an elongation of 11 residues of the BDP1 protein was identified in a recessive family. Bdp1 inner ear expression was confirmed by immunohistochemistry. In a pedigree showing a Y-linked pattern, the predicted pathogenic D69V mutation was identified in *TBLY1* gene. Functional studies are in progress to confirm its pathogenicity. This strategy proved to be very successful by explaining several unsolved cases. Updated data will be presented and discussed

C12.3

Disclosure of false disease genes - an underestimated potential of targeted and genomewide NGS: The example of MYO1A and deafness type DFNA48

T. Eisenberger[1], N. Di Donato[2], S. M. Baig[3], C. Neuhaus[1], A. Beyer[2], E. Decker[1], C. Bergmann[1,4], **H. J. Bolz**[1,5];
[1]Center for Human Genetics, Bioscientia, Ingelheim, Germany, [2]Institute for Clinical Genetics, Carl Gustav Carus TU Dresden, Dresden, Germany, [3]Human Molecular Genetics Laboratory, National Institute for Biotechnology and Genetic Engineering, Faisalabad, Pakistan, [4]Department of Medicine, University of Freiburg Medical Center, Freiburg, Germany, [5]Institute of Human Genetics, University Hospital of Cologne, Cologne, Germany.

MYO1A is considered the gene underlying autosomal dominant non-syndromic hearing loss type *DFNA48*, based on six missense variants, one small *in-frame* insertion and one nonsense alteration. By next-generation sequencing (NGS) targeting 66 deafness genes in 109 hearing-impaired patients, we identified three families (including a consanguineous one) that provide strong evidence against a causative role of *MYO1A* in inherited deafness: Two novel nonsense mutations (p.Tyr740* and p.Arg262*) and a previously described missense mutation were identified not only in the index patients in heterozygous state, but also in unaffected relatives. The hearing deficit in these families was clearly due to mutations in other deafness genes, *MYO7A*, *EYA1* and *CIB2*, respectively. All but two of the altogether ten *MYO1A* mutations have been annotated in dbSNP, and population frequencies (dbSNP, 1000 Genomes, Exome Sequencing Project) above 0,1% contradict pathogenicity assuming a dominant model. Moreover, one healthy individual from the consanguineous family was homozygous for the nonsense mutation p.Arg262*, compatible with a previously reported homozygous *Myo1a* knockout mice lacking any overt pathology. We conclude that *MYO1A* is dispensable for normal hearing and may even represent a non-essential gene, adding to the list of „erroneous disease genes" that is growing rapidly with increasing availability of data from large-scale sequencing projects. Data from individuals born to consanguineous parents are particularly valuable because they are enriched for homozygous loss-of-function variants, with the potential to unmask „false disease genes". Their identification is urgently needed to improve mutation databases and avoid pitfalls in diagnostics and genetic counseling.

C12.4

AON intravitreal injections to manipulate splicing in retinal cells

X. Gerard[1], *I. Perrault[1], A. Munnich[2], J. Kaplan[1], J. Rozet[1];*
[1]Imagine Institute, Laboratory of Ophthalmic Genetics, Paris, France, [2]Imagine Institute, Translational Genetics, Paris, France.

Purpose: Leber congenital amaurosis (LCA) is the leading cause of hereditary blindness in children. *CEP290* encodes a ciliary protein important to photoreceptor connecting cilium assembly and function. The *CEP290* intronic c.2991+1655A>G change is the most common LCA-causing mutation (10%). It introduces a cryptic exon in the mRNA encoding a premature termination codon. Recently, we made the proof-of-concept of antisense oligonucleotides (AON)-mediated exon skipping to correct the splicing in patient fibroblasts which recovered ability to ciliate. The purpose of this study was to make the proof-of-concept of exon-skipping *in vivo* using intravitreal injections of AONs. **Methods:** AONs were designed to skip mouse *Cep290* exon 36. Variable concentrations of 6-FAM-AONs were injected into the vitreous of C57BL/6J mice. Retinal sections and mRNA were prepared during 30 days post-injections (dpi) to follow *i)* the distribution of oligonucleotides across cellular layers and *ii)* exon skipping efficiency. **Results:** The most efficient AONs identified by *in vitro* analyses were injected in the vitreous of animals. Excellent correlation between the efficiency of exon skipping and AON injected dose has been demonstrated. Histological analyses revealed a wide distribution of AON in all retinal cell layers at least until 30 dpi. A linear amount decrease of mRNA lacking exon 36 was measured but still detectable at 30 dpi. **Conclusion:** Here we report that single intravitreal injection of AON allows efficient and persistent exon skipping in retinal cells. Hence, this strategy may be regarded as an attractive alternative to gene replacement therapy for 10 % of patients affected with LCA.

C12.5

Mutations in the tricarboxylic acid cycle enzyme, Aconitase 2,cause either isolated or syndromic optic neuropathy with encephalopathy and cerebellar atrophy

M. D. Metodiev[1], *S. Gerber[1], L. Hubert[1], D. Chretien[1], X. Gérard[1], P. Amati[2], N. Boddaert[3], A. Kaminska[3], I. Desguerre[3], J. Kaplan[1], A. Munnich[1,3], A. Rötig[1], J. Rozet[1], C. Besmond[1];*
[1]Institute Imagine, Paris, France, [2]CHU d'Angers, Angers, France, [3]Hôpital Necker-Enfants Malades, Paris, France.

Inherited optic neuropathy has been ascribed to mutations in mitochondrial fusion/fission dynamic genes, nuclear and mitochondrial DNA-encoded respiratory enzyme genes or nuclear genes of poorly known mitochondrial function. On the other hand, enzymopathies of the tricarboxylic acid cycle (TCA) have been reported to cause severe encephalopathies or isolated retinitis pigmentosa, but no TCA-cycle enzyme deficiency has been hitherto reported in isolated optic neuropathy. Studying a series of five patients with optic atrophy, we found homozygous or compound heterozygous missense and frameshift mutations in the gene encoding mitochondrial aconitase (ACO2), a TCA-cycle enzyme, catalyzing interconversion of citrate into isocitrate. Retrospective studies using patient-derived cultured skin fibroblasts revealed various degrees of deficiency in ACO2 activity but also in ACO1 cytosolic activity. Our study shows that autosomal recessive ACO2 mutations can cause either isolated or syndromic optic neuropathy. This observation supports the view that optic atrophy is a hallmark of defective mitochondrial energy supply and that extra-ocular involvement is not related to severity of the enzyme deficiency.

C12.6

Isolated foveal hypoplasia with secondary nystagmus and low vision is associated with a homozygous SLC38A8 mutation

Y. Perez[1], *L. Gradstein[2], H. Flusser[3], B. Markus[1], I. Cohen[1], Y. Langer[1,4], M. Marcus[2], T. Lifshitz[2], R. Kadir[1], O. S. Birk[1,4];*
[1]The Morris Kahn Laboratory of Human Genetics at the National Institute of Biotechnology in the Negev, Ben-Gurion University, Beer Sheva, Israel, [2]Department of Ophthalmology, Soroka Medical Center and Clalit Health Services, Faculty of Health Sciences, Ben-Gurion University, Beer Sheva, Israel, [3]Zussman Child Development Center, Soroka Medical Center, Faculty of Health Sciences, Ben-Gurion University, Beer Sheva, Israel, [4]Genetics Institute, Soroka Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel.

Foveal hypoplasia, always accompanied by nystagmus, is found as part of the clinical spectrum of various eye disorders such as aniridia, albinism and achromatopsia. However, the molecular basis of isolated autosomal recessive foveal hypoplasia is yet unknown. Individuals of apparently unrelated non consanguineous Israeli families of Jewish Indian (Mumbai) ancestry presented with isolated foveal hypoplasia associated with congenital nystagmus and reduced visual acuity. Genome-wide homozygosity mapping followed by fine mapping defined a 830 Kb disease-associated locus (LOD score 3.5). Whole-exome sequencing identified a single missense mutation in the homozygosity region: c.95T>G, p.(Ile32Ser), in a conserved amino acid within the first predicted transmembrane domain of SLC38A8. The mutation fully segregated with the disease-associated phenotype, demonstrating an ~10% carrier rate in Mumbai Jews. SLC38A8 encodes a putative sodium-dependent amino-acid/proton antiporter, which we showed to be expressed solely in the eye. Thus, a homozygous SLC38A8 mutation likely underlies isolated foveal hypoplasia. Intracellular localization of SLC38A8 using confocal microscopy indicated that SLC38A8 resides within the nuclear envelope and in the Golgi apparatus as well. The sub-localization of SLC38A8 is different than that of other SLC38 proteins, as all other members of this family are cytoplasmic transmembrane proteins. This may suggest that SLC38A8 has a different function altogether, and may not be an amino acid transporter as previously predicted. The precise role of SLC38A8 in normal eye development and function, and the molecular mechanisms through which its mutation causes foveal hypoplasia are yet to be elucidated.

C13.1

Stratified cancer screening in Europe using genomic information: conclusions and recommendations from the COGS project

T. H. S. Dent[1], *S. Chowdhury[1], A. Hall[1], N. Pashayan[2], P. D. P. Pharoah[3], H. Burton[1];*
[1]PHG Foundation, Cambridge, United Kingdom, [2]Centre of Applied Health Research, University College London, London, United Kingdom, [3]Department of Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom.

As part of the Collaborative Oncological Gene-environment Study (COGS), we investigated using genomic and other information to estimate individuals' risk of developing cancer and offering different screening and other preventive interventions according to the results. We concluded that genetic testing may soon be used in risk-stratified screening for breast and prostate cancer and that policy-makers should prepare for this.
Stratified screening could produce high rates of diagnosis and early treat-

ment, while sparing lower risk, disease-free people the risks and inconvenience of screening, and reducing costs. Achieving this with genomic information is attractive and increasingly feasible.
We will describe how this approach can be implemented, including how the screening offer would be made, how risk would be estimated, the age at which this could occur and the potential use of genetic data for other purposes. We will describe how management might differ depending on individuals' risk, communication of results and follow-up arrangements, and the different issues raised by modification of an existing screening programme (breast cancer) and the establishment of a new one (prostate cancer).
These issues will need careful handling to ensure outcomes are optimal and harms minimised.
Although we do not think the evidence is yet adequate to support risk-stratified screening for breast and prostate cancer, we believe that point will soon be reached. Further research is needed into impact, utility, cost-effectiveness, acceptability and ethical, legal and social implications. A critical factor may be whether targeting resources according to risk is seen as acceptable by the entire screening population.

C13.2

Expanding access to genetic counseling for hereditary breast and ovarian cancer with telephone delivery: A cluster randomized noninferiority trial

A. Y. Kinney[1,2,3], *K. M. Butler*[2], *M. D. Schwartz*[4,5], *J. S. Mandelblatt*[4,5], *K. M. Boucher*[3,6], *L. M. Pappas*[3], *A. Gammon*[3], *W. Kohlmann*[3], *S. L. Edwards*[3,6], *A. M. Stroup*[3,6,7], *K. G. Flores*[2], *R. A. Campo*[3];
[1]*University of New Mexico, Albuquerque, NM, United States,* [2]*University of New Mexico Cancer Center, Albuquerque, NM, United States,* [3]*Huntsman Cancer Institute, Salt Lake City, UT, United States,* [4]*Georgetown University Medical Center, Washington, DC, United States,* [5]*Georgetown-Lombardi Comprehensive Cancer Center, Washington, DC, United States,* [6]*University of Utah, Salt Lake City, UT, United States,* [7]*Rutgers Cancer Institute of New Jersey, New Brunswick, NJ, United States.*

Geographic barriers limit access to in-person cancer genetic services. We conducted a cluster randomized trial with high-risk women to test the equivalency and noninferiority of *BRCA1/2* telephone counseling to remote in-person counseling. 988 women, 25-74 years of age, with a personal or family history of breast and/or ovarian cancer enrolled. Participants were randomized by family unit to either telephone or in-person counseling. Assessments were done 1 week following pre-test and post-test counseling, and at 6 months. Cluster bootstrap methods were used to estimate the 95% confidence interval (CI) for the difference between test uptake proportions. Between-group intervention differences in psychosocial outcomes were estimated using linear models together with one-sided 97.5% CIs. Telephone *BRCA1/2* genetic counseling fulfilled the criteria for noninferiority to in-person remote counseling with regard to anxiety, cancer-specific psychological distress, and quality of life measures, as well as assessments of the informativeness, interpersonal sensitivity and partnership building of genetic counselors for both urban and rural dwellers. *BRCA1/2* testing uptake was lower following telephone (21.8%) than in-person pre-test counseling (31.8%) (CI=3.9%-16.3%). However, in-person counseling had higher average cost per participant counseled than telephone counseling ($654 vs. $278). The higher uptake of testing in the rural (35.1%) compared to the urban (25.2%) subgroups suggests that the genetic screening interests of rural populations may be underserved by existing health care systems. *BRCA1/2* telephone counseling appears to be safe and as effective as in-person counseling with regard to minimizing adverse psychological reactions and delivering patient-centered communication for both rural and urban dwellers.

C13.3

New approaches to bridge the gap between genetics research and primary health care in Ireland

S. Lynch[1,2,3], *R. O' Shea*[4], *R. O' Shea*[4], *J. Turner*[1], *A. Ward*[1], *M. Byrne*[5], *J. Casey*[6,2];
[1]*National Centre for Medical Genetics, Dublin 12, Ireland,* [2]*Academic Centre on Rare Diseases, University College Dublin, Dublin 4, Ireland,* [3]*Temple Street Children's University Hospital, Dublin 1, Ireland,* [4]*National Centre for Inherited Metabolic Disorders, Dublin 1, Ireland,* [5]*University College Dublin, Dublin 4, Ireland,* [6]*Temple Street Children's University Hospital, Dublin 12, Ireland.*

The translation of research findings on rare disorders from the laboratory into hospital practice can be challenging. Translation into primary healthcare is even more problematic due to lack of funding, infrastructure and communication with primary care staff. Through funding specific for dissemination, we have been able to engage with healthcare professionals (HCPs) using a multi-faceted approach. We developed a microsite (http://www.ucd.ie/medicine/rarediseases/), animation videos, guidelines handbook, Bioinformatics course and four nation-wide educational seminars.
The animation videos were designed for HCPs to help explain inheritance patterns and to educate about consanguinity. These graphical educational tools are being used by HCPs to overcome poor literacy in some families. We liaised with HCPs to develop a guidelines handbook to help with the management of common genetic disorders at a local level. We produced a series of common clinical scenarios that HCPs might encounter to help with advising on relative risk and genetic testing procedures. The two-day Clinical Bioinformatics course aimed to update our laboratory staff to enable translation of our research findings into our local diagnostic laboratory.
Our educational seminars covered topics such as carrier testing, intellectual disability, consanguinity, rare disease research and the role of advocacy. Discussions with seminar attendees suggest that there is a significant knowledge deficit when it comes to genetics in healthcare. However, encouragingly, HCPs voiced an overwhelming interest in gaining more knowledge about genetics and its application to their practice. We plan to continue our efforts and develop eLearning tools to support the integration of genetics into mainstream medicine.

C13.4

Unanticipated results in whole exome study: we've still a lot to learn

C. Skrzynia, *J. M. O'Daniel, D. Marchuk, K. Lee, J. S. Berg, J. P. Evans;*
University of North Carolina, Chapel Hill, NC, United States.

Mutations in SCN5A are associated with Brugada syndrome, LQTS, atrial fibrillation and other conditions with risk of sudden cardiac death. Evidence-based guidelines exist to significantly improve or avert the mortality and morbidity associated with these conditions. As such the ACMG included SCN5A on its list of incidental findings which it recommends should be returned as part of all whole-exome/genome sequencing tests. We outline three challenges faced in the return of unanticipated SCN5A variants: (1) Defining pathogenicity in the presence of reduced penetrance and a highly heterogeneous grouping of conditions; (2) Balancing potential psychosocial harm to patient/family with result disclosure vs. possible medicolegal ramifications of not reporting this type of results; and (3) Psychosocial impact of a risk for sudden cardiac death in the absence of a personal or family history context. Through the NCGENES whole exome sequencing study, these challenges are being explored in a cohort of ~500 patients. Incidental, medically actionable findings are reported and this is emphasized during the pre-test counseling. We present here our experience with incidental finding of SCN5A mutations detected in 8 of 145 (5.5%) participants. Each variant, previously reported as pathogenic, was independently reviewed and discussed with members of the molecular analysis team to reach consensus regarding interpretation of its pathogenicity. Upon review we determined there was convincing evidence for only one to be considered pathogenic and reported. The remaining were not reported, though future information may change the assessment of these interpretations.

C13.5

The stepping stone approach towards the Genetics Clinic of the Future

Routine application of genomics in the clinic faces many cross-cutting, controversial challenges. To map them, we have introduced the concept of the Genetics Clinic Of the Future (GCOF). Moreover we have developed a stepping stone approach to meet these challenges, comprising of field laboratories (the 'stepping stones') that address controversial, multi-dimensional

and interdependent challenges. Here we present three field laboratories, each of which are rooted in one of the main areas of the GCOF. Initially, we considered the effect of new phenomena like genome-first approaches and health data management on the organisation of the 'doctor's office'. In the second, we developed a broadly supported map of conditions and views on knowledge and data exchange, which is rooted in the 'server room'. Finally, we explored the possibilities for involvement of patients and non-patients in the 'living room' of the GCOF. Each field laboratory establishes focused, constructive interdisciplinary collaborations around 'radically interdisciplinary' topics. Based on the 'stepping stones' initiatives we set the route towards the GCOF: researchers from the natural and social sciences, medical professionals, healthcare managers, industry representatives, policy makers, patients and citizens collaboratively identify the design principles of genome data infrastructures as genomic technologies mature and become embedded in routine diagnostic procedures and health management systems.

C13.6

Teaching Genomic Medicine to Physicians - this is our responsibility as medical geneticists

I. Maya[1], *L. Basel-Vanagaite*[2,3,4], *E. Taub*[1], *A. Koifman*[5,6], *D. M. Behar*[7], *R. Tomashov-Matar*[1], *R. Sukenik-Halevi*[8], *D. Marom*[3,9], *A. Reches*[10], *M. Shaohat*[1,3];
[1]*Raphael Recanati Genetics Institute, Rabin Medical Center, Beilinson Campus, Petah Tikva, Israel,* [2]*The Raphael Recanati Genetic Institute and Felsenstein Medical Research Center, Rabin Medical Center, Petah Tikva, Israel,* [3]*The Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel,* [4]*Pediatric Genetics, Schneider Children s Medical Center of Israel, Petah Tikva, Israel,* [5]*Institute of Human Genetics, Soroka University Medical Center, Beersheba, Israel,* [6]*Ben-Gurion University of the Negev, Beersheba, Israel,* [7]*Rambam Medical Center, Haifa, Israel,* [8]*Meir Medical Center, Kfar Saba, Israel,* [9]*Pediatrics A, Schneider Children s Medical Center of Israel, Petah Tikva, Israel,* [10]*Souraski Medical Center, Tel Aviv, Israel.*

Background: Due to new discoveries in genomic medicine, and the transition of genetic knowledge from research laboratories into clinical practice, an increasing number of medical societies incorporate recommendations regarding genomic tests and therapeutics into routine clinical guidelines. Primary care practitioners have inadequate knowledge and skills in medical genetics and many are unaware of the technical, ethical, legal and psychosocial implications of genetic testing. **Methods**: We initiated a „genomic education" program for the purpose of providing physicians from different medical fields advanced knowledge in genomic medicine . We emphasized the main take-home messages for physicians, defined as: risk calculation for various genetic diseases, recognition of the mode of inheritance from the pedigree, guidelines for decision-making on which molecular tests to use, interpretation of test results and their clinical implications. **Results:** To date, 82 physicians have participated in 6 courses of our „genomic education" program, which included lectures, workshops and guided tours in genetic laboratories. In the „pre-course" examination the average score was 56% (range 20%-80%), whereas in the „post-course" examination it was 79% (range 40%-100%). The average improvement in score as a result of the course was 21% (range 0%-80%). The physicians who participated in our program reported a very high level of satisfaction from the theoretical and practical knowledge they aqired as well as the concept of a „one-week update course". **Conclusion:** A one-week „genomic education" program is an effective strategy to update primary care physicians regarding the advances in Genomic Medicine in order to improve their care of patients.

C14.1

Insights into the genetic architecture of anthropometric traits using whole genome sequence data

E. Zeggini, *UK10K consortium;*
Wellcome Trust Sanger Institute, Hinxton, United Kingdom.

Body weight and fat distribution measures are associated with increased risk of cardiometabolic disease. As part of the UK10K study, we have investigated the genetic architecture of anthropometric traits in 3,538 individuals with 6.5x whole genome sequence (WGS) data from the ALSPAC and TwinsUK cohorts. Variants discovered through WGS, along with those from the 1000 Genomes Project (1KGP), were imputed into additional individuals from the ALSPAC and TwinsUK cohorts with GWAS data (total sample size 9,979). We investigated association between anthropometric traits and 8.6 million low frequency and common variants (MAF>0.01). We are in the process of obtaining *in silico* replication of prioritised signals. In interim replication analysis across ~15,000 samples, 43 out of 66 novel signals for BMI have the same direction of effect in the replication cohorts (p-value=0.0093). We examined the concordance of the direction of effect at established loci for each trait. Out of the 31 established independent loci for BMI that were present in our data, 28 have the same direction of effect (p-value=2.3e-06). For weight, 10 out of 11 known loci (p-value=0.006), and for height 151 out of 172 loci (p-value<2.2e-16) have the same direction of effect, respectively. We estimated the improvement in genome-wide signal captured relative to those present in HapMap 2, HapMap 3 or 1KGP. We find no appreciable increase in variance explained as density increases, suggesting that the contribution of variants with MAF>0.01 are likely to be well-captured by existing GWAS implementation. Larger sample sizes will be required to refine these estimates.

C14.2

Genome of the Netherlands imputation identifies seven new loci for quantitative ECG traits in meta-analysis of 30,000 samples

Genome-wide association studies (GWAS) of quantitative electrocardiographic (ECG) traits in large consortia identified over 50 loci associated with QRS, RR, QT and PR intervals, with even more loci discovered in ongoing HapMap-based meta-analyses in larger sample sizes. We hypothesized that imputation from sequencing-based reference panels may help in identifying new loci as the contribution of lower-frequency variation has not yet been extensively characterized. In the current study, we meta-analyzed GWAS results from 30,000 samples on the QRS, RR, QT and PR intervals after imputing 19 million SNPs from the Genome of the Netherlands (GoNL) reference panel (998 unique haplotypes). This approach proved successful; in addition to many known loci, we identified seven novel locus-trait associations. Of the seven novel loci, three were for PR, three were for QT and one was for QRS. Two were novel trait/locus combinations for loci previously observed for other ECG traits. Several others are involved in ion handling crucial to cardiac electrophysiology. The dense coverage of the genome (~seven times more SNPs than HapMap-based studies) also enabled us to study known loci in much finer detail. In conclusion, we show that larger reference panels with more accurate haplotype estimates and denser SNP data enable us to find new loci and fine-map previously known ones.

C14.3

Genome-wide association analysis identifies a new gene involved in salt perception and liking

A. Robino[1,2], *N. Pirastu*[1,2], *C. Mansfield*[3], *D. Hwang*[3], *D. R. Reed*[3], *P. Gasparini*[1,2];
[1]*Institute for Maternal and Child Health - IRCCS "Burlo Garofolo", Trieste, Italy,* [2]*University of Trieste, Trieste, Italy,* [3]*Monell Chemical Senses Center, Philadelphia, PA, United States.*

Salt perception and genetic variation in taste receptors may be important determinants of individual differences in salt intake, which in turn represents a risk factor for the development of hypertension and cardiovascular diseases. Genetic variations in taste perception are well known for bitter, sweet and umami taste, while little is known on the genetic bases of human salt perception. To investigate this area, salt taste responses were collected on ~ 900 healthy adults coming from 6 different small villages from North-Eastern Italy. NaCl taste intensity was assessed with the labelled magnitude scale (LMS) using a concentration of 1M and the log10 of the intensity ratings were used for the analysis. Genotyping data were imputed to the 1000G SNP set and used to perform a GWAS of salt perception including sex and age as covariates. A significant association with rs547916 SNP (p-value=5.6x10-08), closely located to the KCNA5 gene, was detected. A replication analysis was carried out on an American cohort confirming the association with salt liking phenotype (p-value=0.002). KCNA5 encodes a member of potassium channel voltage-gated, shaker-related subfamily and belongs to the delayed rectifier K+ (DRK) channels that in the mammalian taste system play a central role in specific taste transduction pathways. A study has also shown that KCNA5 is the major functional DRK channel expressed in the in rat taste buds. Further experiments are needed to better clarify KCNA5 role in salt perception and liking and possible implications for cardiovascular diseases.

C14.4

ImmunoSeq: Discovery of novel rare variants implicated in autoimmune and inflammatory diseases by targeting regulatory regions in immune cells

A. Morin[1,2], *T. Kwan*[1,2], *L. Letourneau*[2], *K. Tandre*[3], *M. Eloranta*[3], *V. Arseneault*[2], *M. Caron*[1,2], *A. Madore*[4], *G. Bourque*[1,2], *A. Montpetit*[2], *A. Syvanen*[5], *L. Ronnblom*[3], *M. G. Lathrop*[1,2], *C. Laprise*[4], *T. Pastinen*[1,2];

University and Genome Quebec Innovation centre, Montréal, QC, Canada, [3]Department of Medical Sciences, Section of Rheumatology, Uppsala University, Uppsala, Sweden, [4]Département des sciences fondamentales, Université du Québec à Chicoutimi, Saguenay, QC, Canada, [5]Department of Medical Sciences, Molecular Medicine and Science for Life Laboratory, Uppsala University, Uppsala, Sweden.

Comprehensive DNase I hypersensitive site (DHS) mapping by the ENCODE project identified all classes of cis-regulatory elements. Recent studies showed enrichment of complex trait GWAS noncoding hits in DHS. However, GWAS hits only partially explain complex trait heritability. The discovery of rare variants located in regulatory regions specific to immune cells should explain part of this heritability. Our approach combines selective DNA capture of relevant regulatory regions coupled to next-generation sequencing. Genome-wide DHS mapping data from the ENCODE and NIH Roadmap Epigenomics Projects were used to select regulatory regions of immune cells. We designed a custom DNA capture panel (Roche SeqCap EZ developer) to target these selected regions, as well as exonic and HLA regions. Captured DNA (163Mb) is indexed (5-fold per lane) for sequencing on Illumina HiSeq2000 system, yielding average coverage of ~28x. We first applied the "Immunoseq." assay to 30 healthy individuals from Sweden (Uppsala BioResource), where we have existing transcriptome, methylome and ChIP-seq data from three primary immune cells (monocytes, B-cells and T-cells). The capture panel was also applied to 150 trios from the Saguenay–Lac-Saint-Jean asthma familial collection (complex trait with immune and inflammatory components). We observe an enrichment of variants in the vicinity of allelicly differentially expressed genes (p<1e-10) as well as potential impact of rare conserved variants on allelic differential expression of genes (p<0.05). This highlights the 1) potential impact of rare variations on functional mechanism in immune cells and 2) power of our targeted capture approach to identify novel rare variants in regulatory regions.

C14.5

Exome array analysis in >30,000 Europeans establishes a functional role for G6PC2 and identifies novel coding variants influencing glycaemic traits

A. Mahajan[1], *X. Sim[2], H. J. Ng[3], A. K. Manning[4], M. A. Rivas[1], H. M. Highland[5], A. E. Locke[2], N. Grarup[6], H. K. Im[7], A. P. Morris[1], J. B. Meigs[8], C. M. Lindgren[1], A. L. Gloyn[3], on behalf of T2D-GENES and GoT2D consortia;*

[1]Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom, [2]Center for Statistical Genetics, University of Michigan, Ann Arbor, MI, United States, [3]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, United Kingdom, [4]The Broad Institute, Cambridge, MA, United States, [5]Human Genetics Center, Univ of TX Health Sci Cent at Houston, Houston, TX, United States, [6]Novo Nordisk Foundation Center for Basic Metabolic Research, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, [7]Department of Health Studies, University of Chicago, Chicago, IL, United States, [8]Massachusetts General Hospital, Boston, MA, United States.

To identify coding variants associated with fasting glucose (FG) and fasting insulin (FI) levels, we analysed exome array data in up to 33,407 non-diabetic individuals of European ancestry. We identified multiple glucose-lowering coding variants in *G6PC2*, which resides in an established FG genome-wide association study (GWAS) locus. Conditional single-variant association analysis established the presence of two coding variants at exome-wide significance (P<5x10^{-7}) in this gene, one common (P_{COND}=7.1x10^{-10}, 48.1% MAF, p.V219L) and one rare (P_{COND}=1.3x10^{-11}, 0.8% MAF, p.H177Y), both were independent of the GWAS SNP at this locus and of each other ($P_{V219L\ COND\ on\ H177Y}$=4.0x10^{-7} and $P_{H177Y\ COND\ on\ V219L}$=3.7x10^{-10}). Gene-based analysis (P_{SKAT}=8x10^{-10}) highlighted another coding variant p.Y207S (MAF=0.5%) with evidence of association with FG. *In vitro* studies of these *G6PC2* variants showed a reduction in protein expression by 98% (p.H177Y, p<0.001), 100% (p.Y207S, p<0.001) and 43% (p.V219L, p<0.01) compared to wild-type in HEK293 cells, with similar results in INS1E cells. Protein expression was rescued with a proteasome inhibitor implying degradation of unstable G6PC2 proteins via the ubiquitin-proteasome pathway. Expressed variant proteins localized as expected to the endoplasmic reticulum. We also identified two genes not mapping to previously reported GWAS loci in which coding variants were associated with FG (*GLP1R*: P=4.4x10^{-7}, 1.6% MAF, p.A316T) or FI (*URB2*: P=3.8x10^{-7}, 0.1% MAF, p.E594V). These data establish a functional role for *G6PC2* in FG homeostasis and identify novel glycaemic trait loci. They do not support a role for low-frequency or rare coding variants in explaining previously reported association signals at GWAS loci.

C14.6

Transethnic association study of IBD identifies novel risk loci and shows pervasive sharing of genetic risk factors across populations

J. Z. Liu[1], *S. van Sommeren[2], R. K. Weersma[2], C. A. Anderson[1], The International IBD Genetics Consortium;*

[1]Wellcome Trust Sanger Institute, Hinxton, United Kingdom, [2]University of Groningen, Groningen, Netherlands.

There are now over 163 loci associated with inflammatory bowel disease (IBD) susceptibility in European populations, though little is known about their contribution to disease risk in non-European populations. Using the custom Immunochip array, we genotyped 9,846 individuals of East Asian (Japan, South Korea, Hong Kong, China and UK individuals of East Asian descent), Indian and Indo-European (Iranian) descent. Combining these with the existing cohort of 81,248 individuals of European descent (Jostins et al. Nature 2012), we identified 14 novel IBD susceptibility loci at genome-wide significance (P<5×10-8). The majority of IBD risk loci were shared between both Europeans and non-Europeans, and differences in the amount of variance explained in disease liability at each locus were driven by a combination of differences in allele frequencies and effect sizes. For instance, the variance in Crohn's disease (CD) liability explained by four independent risk variants at TNFSF15 was 19 times greater in East Asians than Europeans, a reflection of the risk-increasing alleles being more common and having larger odds ratios in East Asians. Aggregation of all SNPs assayed on the Immunochip revealed significant genetic correlation (0.4-0.85) for IBD between European and non-European populations. Together, this study increases the total number of IBD susceptibility loci to 177 and demonstrates the pervasive sharing of genetic risk factors across populations, though there exists heterogeneity in the variance explained per locus.

C15.1

BCAP31 mutations cause a new X-linked syndrome with deafness, dystonia, central hypomyelination and disorganization of the Golgi apparatus

P. Cacciagli[1,2,3], J. Sutera-Sardo[1,2], A. Borges-Correia[1,2], J. Roux[1,2], I. Dorboz[4], J. Desvignes[1,2], C. Badens[1,2,3], M. Delepine[5], M. Lathrop[5,6], P. Cau[1,2,7], N. Lévy[1,2,3], N. Girard[2,8], P. Sarda[9], O. Boespflug-Tanguy[4,10], **L. Villard**[1,2];

BAP31 is one of the most abundant proteins of the membrane of the endoplasmic reticulum (ER). It is a chaperone protein involved in several pathways, including ER-associated protein degradation, export of proteins from the ER to the Golgi, and programmed cell death. BAP31 is encoded by the BCAP31 gene located in Xq28. It is highly expressed in neurons. We identified loss of function mutations in BCAP31 in seven individuals from three different families and one missense mutation in another fourth family. These people suffer from intellectual and motor disability, dystonia and sensorineural hearing loss with abnormal white matter. The association of these clinical signs define a new X-linked syndrome. In primary fibroblasts from patients, we found that the absence of BCAP31 changed the morphology of the ER and disorganized the Golgi apparatus in a significant proportion of cells. We demonstrated that the constitutive deficiency of BCAP31 did not activate the response to unfolded proteins (UPR) nor triggered cell death. Rather, our data suggest that the absence of BAP31 affects ER and Golgi apparatus metabolism and that BAP31 plays an important role in ER-Golgi exchanges. These results provide a molecular basis for a new Mendelian syndrome and connect intracellular protein trafficking with a severe congenital neurological disorder.

C15.2

Mutations in KPTN Cause Macrocephaly, Neurodevelopmental Delay, and Seizures

E. L. Baple[1], *R. Maroofian[1], B. Chioza[1], M. Izadi[2], H. E. Cross[3], S. Al-Turki[4], K. Barwick[1], A. Skrzypiec[1], R. Pawlak[1], K. Wagner[5], R. Coblentz[5], T. Zainy[1], M. A. Patton[1], S. Mansour[6], P. Rich[6], B. Qualmann[2], M. E. Hurles[4], M. M. Kessels[2], A. H. Crosby[1];*

The proper development of neuronal circuits during neuromorphogenesis and neuronal-network formation is critically dependent on a coordinated and intricate series of molecular and cellular cues and responses. Although the cortical actin cytoskeleton is known to play a key role in neuromorphogenesis, relatively little is known about the specific molecules important for this process. We identified nine affected individuals from four Ohio Amish families affected by an autosomal recessive, variable form of neurodevelopmental delay. The most consistent features were global developmental delay, macrocephaly, anxiety, and some features suggestive of a pervasive developmental disorder. In addition, a primary seizure disorder was described in three cases. Using a combination of autozygosity mapping, linkage

analysis and whole-exome sequencing, we demonstrated that two founder mutations in KPTN, encoding kaptin, can result in this phenotype. Our immunofluorescence analyses in primary neuronal cell cultures showed that endogenous and GFP-tagged kaptin associates with dynamic actin cytoskeletal structures and that this association is lost upon introduction of the identified mutations. Taken together, our studies have identified kaptin alterations responsible for this disorder and have defined kaptin as a molecule crucial for normal human neuromorphogenesis. Finally, our identification of two KPTN mutations within this Anabaptist population parallels the situation seen for a number of other genes with multiple mutations that also commonly cause inherited diseases globally (e.g., GJB2 mutations in inherited hearing loss, and ATM mutations in ataxia telangiectasia), indicating that kaptin neurodevelopmental delay might be similarly widespread.

C15.3

REPS1 is a novel gene of Neurodegeneration with Brain Iron Accumulation

A. B. Drecourt[1], *N. Boddaert*[2], *I. Desguerre*[3], *D. Chretien*[1], *A. Munnich*[3], *A. Rötig*[1];
[1]*INSERM U1163 Institut Imagine, Paris, France,* [2]*Department of Radiology, Hôpital Necker-Enfants Malades, Paris, France,* [3]*Department of Pediatrics, Hôpital Necker-Enfants Malades, Paris, France.*

Neurodegeneration with brain iron accumulation (NBIA) encompasses a group of rare neurogenerative disorders with different clinical, brain MRI and molecular features, underlined by progressive extrapyramidal dysfunction and iron accumulation in the brain. To date, mutations in PANK2, PLA2G6, FA2H, ATP13A2, C2orf37, CP, FTL and WDR45 have been associated with NBIA. Nevertheless a large number of individuals have "idiopathic NBIA", with unknown etiology. Exome sequencing of two sisters with NBIA identified two heterozygous mutations in the REPS1 gene. REPS1 is involved in endocytosis and the two mutations (p.Ala113Glu and p.Val78Leu) affect its EH1 domain that interacts with RAB11FIP2. Western Blot analysis detected a low level of REPS1 in patient's fibroblasts. The function of REPS1 in iron metabolism is unknown, but it was shown that RABB11-FIP2 functions in transferrin recycling. We investigated the iron metabolism and oxidative stress in patient's fibroblasts. Patient fibroblasts exhibited a dramatic iron overload, measured by a colorimetric ferrozine-based assay. Consistently steady-state levels of ferritin, iron responsive protein (IRP1) and SOD2 were increased whereas aconitase activity was decreased. This indicates that REPS1 mutations induce deregulation of iron metabolism. Over-expression of the wild-type REPS1 cDNA in patient's cells reduces the iron overload of these cells that display almost normal iron content. Our experiments demonstrate that REPS1 is a new gene of NBIA. Improvement in our understanding of the biochemistry and pathophysiology of this form of NBIA will help develop novel therapeutics for this neurological condition.

C15.4

Interferon type 1 response regulator *USP18* is mutated in severe pseudo-TORCH syndrome

M. Meuwissen[1,2], *R. Schot*[1], *G. Oudesluijs*[1], *S. Tinchert*[3], *L. van Unen*[1], *D. Heijsman*[4], *M. Lequin*[5], *M. Kros*[6], *R. Willemsen*[1], *R. Brouwer*[7], *W. van IJcken*[7], *R. de Coo*[8], *J. Dudink*[9], *A. Bertoli Avella*[1], *F. Verheijen*[1], *G. Mancini*[1];
[1]*Dept. of Clinical Genetics, Erasmus University Medical Center, Rotterdam, Netherlands,* [2]*Universitair Ziekenhuis Brussel, Vrije Universiteit Brussel, Brussel, Belgium,* [3]*Dept. of Clinical Genetics, Medizinische Universität Innsbruck, Innsbruck, Austria,* [4]*Dept. of Bioinformatics, Erasmus University Medical Center, Rotterdam, Netherlands,* [5]*Dept. of Radiology, Erasmus University Medical Center, Rotterdam, Netherlands,* [6]*Dept. of Pathology, Erasmus University Medical Center, Rotterdam, Netherlands,* [7]*Center for Biomics, Erasmus University Medical Center, Rotterdam, Netherlands,* [8]*Dept. of Child Neurology, Erasmus University Medical Center, Rotterdam, Netherlands,* [9]*Dept. of Neonatology, Erasmus University Medical Center, Rotterdam, Netherlands.*

Pseudo-TORCH syndrome indicates a group of disorders putatively linked to autoimmunity and is characterized at birth by cerebral calcification, microcephaly, enlarged ventricles, cerebellar atrophy and the development of hyperbilirubinemia, thrombocytopenia and hepatomegaly resembling congenital infections. There is overlap with Aicardi-Goutières syndrome (AGS), caused by mutations in genes involved in RNA catabolism, indirectly leading to increased Interferon type I signalling. We report on patients from two families with pseudo-TORCH, cerebral haemorrhage and early demise.
The first consanguineous family included 3 affected sibs. Using linkage analysis, whole exome sequencing and sanger sequencing of the non-covered exons in the linkage area, we identified a homozygous truncating mutation in USP18, causing total absence of USP18 transcript in cultured fibroblasts, compared to normal expression in controls. In the second family, including two sibs, the same truncating mutation in heterozygous form was found. No transcript was amplified from cells of the two patients, suggesting that a second mutation is present in areas not covered by Sanger sequencing.
USP18 is an interferon-stimulated gene and itself a key regulator of interferon response both in native antibacterial and antiviral immunity and in autoimmune response. Usp18 knockout mice have cerebral hemorrhage and hydrocephalus with ependymal necrosis. Microscopy of patient brain tissues shows severe ependymal abnormalities, similar to the mouse.
In conclusion, USP18 mutations are a novel genetic cause of pseudo-TORCH syndrome and severe cerebral hemorrhage which provide for the first time a direct link between the IFN type I signalling pathway and the disease phenotype.

C15.5

Loss of CTNND2 is associated with borderline intellectual dysfunction in humans and neuronal migration defects in zebrafish

W. Hofmeister[1], *D. Nilsson*[1,2], *A. Topa*[3], *B. Anderlid*[1], *F. Vezzi*[2], *V. Wirta*[2], *M. Nordenskjöld*[1], *E. Syk Lundberg*[1], **A. Lindstrand**[1];
[1]*Karolinska Institutet, Stockholm, Sweden,* [2]*Science for Life Laboratory, Stockholm, Sweden,* [3]*Sahlgrenska University Hospital, Gothenburg, Sweden.*

Cytogenetically visible chromosomal translocations are a unique resource as they can pinpoint strong effect genes. Here we report a mother and daughter with borderline intelligence and learning problems within the dyslexia spectrum and two apparently balanced reciprocal translocations; t(1;8)(p22;q24),t(5;18)(p15;q11). By low coverage mate-pair whole genome sequencing we were able to pinpoint the genomic breaks to within a 2kb window and the DNA breakpoints were then verified by PCR and Sanger sequencing. The 5p breakpoint was located between exon 7 and 8 of CTNND2. By genome wide array comparative genomic hybridization we identified an additional individual with similar phenotypic presentation and a maternally inherited 163kb microdeletion exclusively involving CTNND2. The microdeletion at 5p11.2 is present as mosaicism in the mother and absent in the patient's healthy siblings.
Inappropriate migration of cortical neurons has been postulated as a potential mechanism for various neurological disorders including dyslexia, given the potential role of CTNND2 in neuron motility, we were particularly interested in assessing defects in neuronal migration in vivo. Knockdown of one of two zebrafish CTNND2 orthologues using antisense morpholino oligonucleotides showed mostly normal development of the neuronal clusters. However, analysis of a subpopulation of forebrain neurons expressing GFP under the islet promoter (isl:GFP) in knockdown embryos showed the presence of misplaced isl:GFP cells between the telencephalon and diencephalon indicative of a defects in migration. This suggests that defective migration of subpopulations of neuronal cells due to loss of CTNND2 could be part of the underlying mechanism behind the cognitive dysfunction in the patients.

C15.6

Novel (ovario)leukodystrophy related to *AARS2* mutations

Purpose: This study was focused on patients with a leukoencephalopathy of unknown cause with the aim to define a novel, homogeneous phenotype suggestive of a common genetic defect, based on clinical and MRI findings, and to identify the causal genetic defect, shared by patients with this phenotype.
Methods: Independent exome sequencing studies were performed in two unrelated patients with a novel leukoencephalopathy. MRI findings in these patients were compared to MRIs in a database of unclassified leukoencephalopathies. Eleven additional patients with similar MRI abnormalities were selected. Clinical and MRI findings were investigated.

Results: Exome sequencing revealed compound heterozygous mutations in *AARS2* encoding mitochondrial alanine-tRNA synthetase in both patients. Functional studies in yeast confirmed the pathogenicity of the mutations in one patient. Sanger sequencing was performed in the eleven additional patients and revealed *AARS2* mutations in four patients. The in total six patients with *AARS2* mutations had childhood to adulthood onset signs of neurological deterioration consisting of ataxia, spasticity and cognitive decline with features of frontal lobe dysfunction. MRIs showed a leukoencephalopathy with involvement of left-right connections and ascending and descending tracts, and cerebellar atrophy. All female patients had ovarian failure. Signs of cardiomyopathy were not observed.
Conclusions: Mutations in *AARS2* have been found in a severe form of infantile cardiomyopathy in two families. We present six patients with a novel phenotype caused by *AARS2* mutations, characterized by a distinctive leukoencephalopathy and, in female patients, ovarian failure, indicating that the phenotypic spectrum associated with *AARS2* variants is wider than previously reported.

Human phosphoglucomutase 3 (PGM3) catalyzes the conversion of GlNAc-6-P into GlcNAc-1-P, during the synthesis of UDP-GlcNAc, a sugar nucleotide critical to multiple glycosylation pathways. PGM3-defects have earlier been associated with hematopoietic deficiency in a mouse model. We identified three unrelated patients with recurrent infections, congenital leukopenia including neutropenia, B and T cell lymphopenia, and progression to bone marrow failure. Whole exome sequencing revealed novel, deleterious mutations in the PGM3 gene in all three subjects, delineating a new type of congenital disorder of glycosylation (CDG). Functional studies of the human immunodeficiency-associated PGM3 gene variants in E.coli cells demonstrated reduced PGM3 enzyme activity with decreased phosphate group transfer from position GlcNAc-6-P to GlcNAc-1-P. Two of the 3 patients had skeletal anomalies with short stature, brachydactyly, and intellectual disability, however these additional features were absent in the third patient, showing the clinical variability of the disease. Two patients were transplanted using a cord blood hematopoietic stem cell and a matched-related donor bone marrow; both had successful engraftment and correction of neutropenia and lymphopenia. We define PGM3-CDG as a novel cause of treatable genetic immunodeficiency, document the power of whole exome sequencing in gene discoveries for rare disorders, and illustrate the utility of genomic analyses in studying combined and variable phenotypes.

Lenz-Majewski syndrome (LMS) constitutes a unique rare disease characterised by the association of generalised sclerosing bone dysplasia, intellectual disability, cutis laxa and distinct craniofacial, dental, and distal limb anomalies. By using whole-exome sequencing in four patients and selecting variants according to the predicted dominant de novo etiology model, we identified causative heterozygous missense mutations in PTDSS1 gene, which encodes phosphatidylserine synthase 1 (PSS1). Subsequently, three additional patients were screened by Sanger sequencing and similar mutations were found. In total, five different missense mutations affecting four specific PSS1 amino acids were identified in the seven patients studied to date. PSS1 is one of two enzymes involved in production of phosphatidylserine. Phosphatidylserine synthesis was increased in patients' intact fibroblasts and end-product inhibition of PSS1 by phosphatidylserine was significantly reduced. Therefore, these mutations cause a gain-of-function effect associated with regulatory dysfunction of PSS1. In support of this model, craniofacial defects similar to those found in LMS, were observed following expression of mutant but not wild-type PTDSS1 in zebrafish. Interestingly, total phospholipid cellular content was similar between patient and control fibroblasts. Ongoing lipidomic studies suggest that the identified mutations cause abnormal fatty acid composition of individual subclasses of membrane phospholipids. In conclusion, we have identified LMS as the first human disease caused by disrupted phosphatidylserine metabolism and one of the few examples of gain-of-function mutations affecting an enzyme. Our results bring important insight to the understanding of phosphatidylserine metabolism and point to an unexplored link with bone development and homeostasis.

C16.3

Homozygous *FIBP* truncating mutation in a new multiple congenital anomalies syndrome with overgrowth, macrocephaly, Iris coloboma, and learning disabilities

Fibroblast growth factors (FGFs) pathways determine crucial cellular roles for proliferation, migration, fate and survival, by various extracellular and intracellular modes of action. Acidic FGF extracellular action usually consists of binding multiple forms of cell surface receptors, leading to the activation of cytoplasmic tyrosine-kinase pathways but it also enters into the nucleus to stimulate DNA synthesis. The acidic fibroblast growth factor intracellular binding protein (FIBP) is a FGF1 binding protein widely expressed in human tissues, but its function remains unknown in FGF signaling. We performed exome sequencing in a 22-year-old man, born from healthy consanguineous parents, and presenting with an undefined phenotype associating overgrowth, marfanoid habitus, macrocephaly, facial dysmorphism, large thumbs, bilateral iris coloboma, ventricular septal defect, mitral valve prolapse, venous insufficiency, moderate scoliosis, and learning disabilities. A homozygous nonsense mutation (p.Gln218*) was identified and was absent in unaffected siblings. FIBP is known to be expressed in brain, eye, heart and kidneys, consistent with the patient's clinical features. Additional functional results argue for the pathogenicity of the mutation in the phenotype: 1) FIBP cDNA was undetectable in patient's fibroblasts; 2) the intracellular FGF pathway was deregulated with increased FGF-1 protein level; 3) The XTT test and Ki67 labelling exhibited a higher proliferation capacity in patient's

fibroblasts than controls. In
conclusion, we present the first implication of the *FIBP* gene in a novel autosomal recessive multiple congenital abnormalities syndrome and the results of pathophysiological studies.

C16.4

Hidden mutations in Cornelia de Lange Syndrome (CdLS) - Limitations of Sanger sequencing in molecular diagnostics

F. J. Kaiser[1], *D. Braunholz[1], J. Eckhold[1], J. Pozojevic[1], K. Wendt[2], E. Watrin[3], H. Rieder[4], G. Gillessen-Kaesbach[5];*
[1]Sektion für Funktionelle Genetik am Institut für Humangenetik, Lübeck, Germany, [2]Department of Cell biology, Erasmus Medical Center, Rotterdam, Netherlands, [3]Institut de Génétique et Développement, UMR6290-CNRSfaculté de Médecine Rennes, Rennes, France, [4]Institut für Humangenetik Düsseldorf, Universitätsklinikum Düsseldorf, Düsseldorf, Germany, [5]Institut für Humangenetik, Lübeck, Germany.

CdLS is a clinically and genetically heterogeneous developmental disorder. Patients are characterized by distinct facial features, growth retardation and cognitive delay. Whereas half of the patients show mutations in the *NIPBL* gene, mutations in *SMC1A, SMC3, RAD21* or *HDAC8* account for additional 10%. Interestingly, recent data using DNA from buccal mucosa (BM) tissue could identify a high proportion of mosaic mutations in *NIPBL* which were not detected in DNA from blood samples. Here we report on two unrelated patients with characteristic CdLS phenotype, who were mutation negative by Sanger sequencing analyzing DNA from blood and BM samples.
Subsequent Ion Torrent panel sequencing on DNA of BM using a custom made Ion AmpliSeq enrichment that includes the five known CdLS genes beside eleven functionally-associated candidate genes, could detect a mosaic nonsense (17%) and a mosaic missense mutation (13%) in *NIPBL*. Interestingly SNaPshot fragment analyses were able to confirm both mutations in DNA from BM, fibroblasts and urine samples but did not detect these mutations in DNA from blood. Additional Sanger sequencing approaches using DNA from all four tissues could only detect both mutations in fibroblast DNA.
In summary, our data strongly support a high frequency of mosaic *NIPBL* mutations in CdLS-patients. More importantly, it also shows the limitations of current sequencing approaches in diagnostics, even when using DNA of BM as recently suggested. Thus we recommend the use of high coverage sequencing techniques on DNA of BM, especially when analyzing patients with characteristic CdLS-phenotypes and negative Sanger sequencing results.

C16.5

RNA Polymerase II activity is affected at the promoter regions in SMC1A-mutated Cornelia de Lange Syndrome cells

L. Mannini[1], *S. Bilodeau[2], C. Amato[1], V. Quarantotti[1], F. Cucco[1,3], I. D. Krantz[4], A. Musio[1];*
[1]Istituto di Ricerca Genetica e Biomedica, Consiglio Nazionale delle Ricerche, Pisa, Italy, [2]Centre de recherche en cancérologie de l'Université Laval and Centre de recherche du CHU de Québec (Hôtel-Dieu de Québec), Département de biologie moléculaire, biochimie médicale et pathologie, Faculté de Médecine, Université Laval, Québec, QC, Canada, [3]Dipartimento di Biologia, Università di Pisa, Pisa, Italy, [4]Division of Human Genetics, The Children's Hospital of Philadelphia and the Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, United States.

Mutations in genes encoding cohesin subunits or regulators, namely NIPBL, SMC1A, SMC3, HDAC8 and RAD21, have been linked to Cornelia de Lange syndrome (CdLS). It has been hypothesized that the dysregulation of gene expression by chromatin remodeling likely represents the underlying pathogenesis of CdLS, however the exact mechanism by which this is effected is unknown. To gain a better understanding of this process we investigated whether the gene transcription machinery was somehow affected by SMC1A mutations. We used chromatin immunoprecipitation coupled with massively parallel DNA sequencing (ChIP-seq) to identify genomic regions co-occupied by cohesin, NIPBL and RNA pol II in normal human lymphoblastoid cells. Genes co-localizing cohesin, NIPBL and RNA pol II have been compared to gene expression data from CdLS cell lines. Finally, we investigated the recruitment of RNA pol II onto genes differentially expressed in CdLS mutated cells. Our results indicate that SMC1A mutations reduce the recruitment of Pol II at promoter regions and also affect the activity of the Pol II elongating form. These findings highlight the pivotal role of cohesin in transcriptional regulation and the effect on Pol II occupancy may explain the typical gene dysregulation observed in CdLS cell lines.

C16.6

In silico and functional characterization of KMT2D/MLL2 missense mutations as causative in Kabuki syndrome

P. De Nittis[1], *L. Micale[1], B. Augello[1], C. Fusco[1], A. Romano[2], B. Piccinni[3], M. Pellico[1], B. Mandriani[1], C. Rinaldi[1], A. Di Lauro[1], T. Verri[3], L. Zelante[1], G. Merla[1,4];*
[1]Medical Genetics Unit, IRCSS Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy, [2]Institute of Experimental Neurology, Division of Neuroscience, San Raffaele Scientific Institute, Milan, Italy, [3]Department of Biological and Environmental Sciences and Technologies, University of Salento, Lecce, Italy, [4]PhD Program, Scienze della Riproduzione e dello Sviluppo, University of Trieste, Trieste, Italy.

Kabuki syndrome (KS) is a multiple congenital malformation syndrome characterized by facial features, skeletal anomalies, dermatoglyphic abnormalities, mental retardation, and postnatal growth deficiency. Heterozygous mutations in the KMT2D gene are detected in 60% of Kabuki patients. KMT2D gene encodes a H3K4 histone methyltransferase that plays important role in the epigenetic control of active chromatin states modulating the expression of genes essential for embryogenesis and development. A subset of KS individuals was recently identified with mutations in the chromatin modifier KDM6A. We performed a mutational screening on 303 Kabuki patients by direct sequencing, MLPA, and qPCR, detecting 133 patients with KMT2D and four with KDM6A mutations. Among the KMT2D mutations we identified 46 missense variants across the entire length of the KMT2D gene, 16 were inherited from an apparently asymptomatic parent.
Aim of this study is to ascertain the pathogenicity of KMT2D missense mutations through an integrative analysis of bioinformatics tools and biochemical and cellular assays. We used an innovative in silico approach that combines comparative analysis and motif/domain search tools with threading/homology modeling protocols to predict functional/structural effect of KMT2D missense variants and identify and confirm potential pathogenic mutations. Due to the huge size of KMT2D gene, we devised a strategy where minigenes carrying KMT2D missense variants were generated. We evaluated their potential pathogenicity effects by measuring KMT2D enzymatic activity and expression level of KMT2D known target genes. Our strategy should offer a valuable support to estimate the real deleterious effect of KMT2D missense variants, an issue in diagnostic counseling.

C17.1

A dominant mutation in CHCHD10 causes neurodegenerative disorder with mitochondrial DNA instability

V. Paquis-Flucklinger[1,2], *S. Bannwarth[1], S. Saadi[1], A. Chaussenot[2], E. Genin[1], K. Fragaki[1], L. Berg-Alonso[1], S. Lacas-Gervais[3], V. Serre[4], A. Verschueren[5], C. Rouzier[1], G. Augé[1], C. Cochaud[2], F. Lespinasse[1], J. Pouget[5];*
[1]IRCAN, UMR CNRS 7284/INSERM U1081/UNS, Nice, France, [2]Department of Medical Genetics, CHU Nice, Nice, France, [3]Joint Center for Applied Electron Microscopy, Nice, France, [4]UMR7592 CNRS, Paris, France, [5]Department of Neurology, Timone hospital, Marseille, France.

Mutations in OPA1 and MFN2, two genes encoding membrane proteins involved in mitochondrial dynamics, are responsible for mitochondrial DNA (mtDNA) instability disorder with "Autosomal Dominant Optic Atrophy (ADOA) plus" phenotype. We report a large family with a late-onset complex phenotype including motor neuron disease, cerebellar ataxia, cognitive decline and myopathy. Muscle biopsy showed ragged-red and COX negative fibres with combined respiratory chain deficiency and abnormal assembly of complex V. The multiple mitochondrial DNA (mtDNA) deletions found in skeletal muscle revealed a mtDNA instability disorder. By whole-exome sequencing (WES), we identified a missense mutation (c.176C>T; p.Ser59Leu) in the CHCHD10 gene that encodes a coiled-coil helix coiled-coil helix protein, whose function was unknown. We show that CHCHD10 is a mitochondrial protein located in the intermembrane space and enriched at cristae junctions. Patient fibroblasts carrying the CHCHD10 mutation present with a respiratory chain deficiency and a fragmentation of the mitochondrial network. Furthermore, we show that overexpression of CHCHD10S59L triggers mitochondrial fragmentation in HeLa cells, thus confirming the deleterious effect of this mutant on mitochondrial morphology and network. DRP1-K38A, which is resistant to fission, did not modify the mitochondrial fragmentation observed in cells expressing CHCHD10S59L, suggesting that the CHCHD10 mutant leads to impaired fusion activity. This work, suggesting that CHCHD10 plays a role in mitochondrial fusion and/or in maintenance of cristae morphology, highlights the critical role of mitochondrial dynamics in terms of human disease and mitochondrial genome stability.

C17.2

Decoding Mitochondrial Disorders using Exome Sequencing

L. Kremer[1], *T. Haack[1], R. Kopajtich[1], B. Haberberger[1], C. Biagosch[1], T. Wieland[1], E. Graf[1], T. Schwarzmayr[1], T. Strom[1], P. Freisinger[2], T. Klopstock[3], T. Meitinger[1], W. Sperl[4], J. Mayr[4], H. Prokisch[1];*
[1]Helmholtz Zentrum München, Neuherberg, Germany, [2]Klinikum Reutlingen, Reutlingen, Germany, [3]Friedrich-Baur-Institut, LMU München, München, Germany, [4]Paracelsus Medical University, Salzburg, Austria.

Mitochondrial disorders are a heterogeneous group of diseases characterized by faulty oxidative phosphorylation. Despite good progress in the field, most disease causing mutations still have to be identified. We applied whole exome sequencing in 300 unrelated individuals with juvenile-onset mitochondrial disorder. In a quarter of patients, we detected mutations in known disease genes. In another quarter of patients, we identified mutations in ge-

nes previously not associated with mitochondrial disorders. Mutations in the majority of genes are rare and could be identified due to loss-of-function alleles in evolutionary conserved genes such as MGME1, the first exonuclease involved in mitochondrial replication (Kornblum et al., Nat. Genet. 2013). Mutations in other genes are more frequent, with ACAD9 being the most common finding with more than 15 cases, providing statistical evidence for the association with isolated respiratory chain complex deficiency. More difficult to identify are missense mutation in genes coding orphan proteins such as FBXL4, a protein with unknown function associated with reduced mitochondrial protein content. Additional diagnostic challenges are patients with recessive mutations in more than one gene resulting in a compound clinical phenotype.

Evolving topics are tRNA modifying enzymes (ELAC2, MTO1 and GTPBP3) and tRNA synthetases, both involved in the translation of mitochondrial proteins as well as cofactor metabolism defects. The later offers rational therapeutic options as for example riboflavin supplementation in the case of mutations in the riboflavin transporter SLC52A2.

In summary, the genetically heterogeneous group of mitochondrial disorders is an example par excellence for the application of genome wide sequencing.

C17.3

Lentivial vector based hematopoietic stem cell gene therapy mediates sustained expression of functional thymidine phosphorylase in mitochondrial neurogastrointestinal encephalopathy mouse model

R. Yadak[1], *J. Torres-Torronteras*[2], *Y. Cámara*[2], *E. Bogaerts*[1], *G. de Ruijter*[1], *R. Martí*[2], *N. van Til*[1], *G. Wagemaker*[1], *I. de Coo*[1];

[1]*Eramus Medical Center, Rotterdam, Netherlands,* [2]*Laboratory of Neuromuscular and Mitochondrial Disorders, Barcelona, Spain.*

MNGIE is an autosomal recessive disease caused by deficiency of the enzyme thymidine phosphorylase (TP), resulting in systemic accumulation of nucleosides thymidine (Thd) and deoxyuridine (dUrd), and mtDNA deletions, depletion and dysfunction. We aimed to use *ex vivo* lentiviral vector (LV) hematopoietic stem cell (HSC) gene therapy to deliver human TP enzyme in $Tp^{-/-}Upp^{-/-}$ double knockout mice, a model for MNGIE disease. To that end, LV transduced *Tp-/-Upp-/-* HSCs containing the native cDNA sequence (TP) or codon optimized (TPco) driven by the phosphoglycerate kinase (PGK) or the spleen focus forming virus (SFFV) promoter were transplanted in sublethally irradiated *Tp-/-Upp-/-* mice. Wild type mice had detectable but very low levels of enzyme activity in blood cell fractions (0.07 ± 0.03nmoles/h/mg, N=4), 1 month post transplantation, enzyme activities increased at least 90-fold in LV recipient mice (LV-TP and LV-TPco = 150±4 and 96±4 nmoles/h/mg respectively, N=4), with a 400-fold increase observed in recipients of LV-SFFV-TPco (450±5, N=4), resulting in reduction of Thd and dUrd in plasma and urine. TP activity was detectable in brain of gene therapy-treated mice 14 months after treatment (average of 1.2-fold in LV-TP and LV-TPco compared to wild type and 36-fold for LV-SFFV-TPco), which significantly reduced the nucleoside levels.High molecular chimerism (76.5±8.2 % donor chimerism, N=12) with low LV vector copy numbers (1.01±1.1VCN/donor derived cell, N=12)were achieved.Overall, HSC gene therapy resulted in stable TP expression and long-term biochemical correction without geno-phenotoxicity in MNGIE mice to be further optimized to develop a clinical protocol to treat MNGIE patients.

C17.4

Deletion of a distant-acting enhancer near *C16ORF91* underlies recessive congenital diarrhea

D. Oz-Levi[1], *I. bar Joseph*[2], *T. Olender*[1], *D. Marek-Yagel*[3], *A. Alkelai*[1], *E. K. Ruzzo*[4], *P. Tatarsky*[1], *H. Reznik-Wolf*[5], *C. Hartman*[6], *R. Shamir*[6], *R. Kleta*[7], *D. B. Goldstein*[4], *E. Pras*[5], *L. A. Pennacchio*[8], *D. Lancet*[1], *Y. Anikster*[5];

[1]*The Weizmann Institute of Science, Rehovot, Israel,* [2]*Sheba medical center, Ramat Gan, Israel,* [3]*Sheba Medical center, Ramat Gan, Israel,* [4]*Center for Human Genome Variation, Duke University School of Medicine, Durham, NC, United States,* [5]*Sheba Medical Center, Ramat Gan, Israel,* [6]*Schneider Medical Center, Petach-Tikva, Israel,* [7]*Centre for Nephrology, University College London, London, United Kingdom,* [8]*Lawrence Berkeley National Laboratory, Berkeley, CA, United States.*

We studied eight patients from seven families of Jewish Iraqi origin, suffering from congenital diarrhea, historically defined as intractable diarrhea of infancy syndrome (IDIS). Next-generation sequencing and SNP arrays identified two structural genomic deletion alleles near *C16ORF91*, leading to a homozygous deletion of a 1500bp intergenic critical region (ΔV) shared by all patients. The ΔV region contained a segment with vertebrate evolutionary conservation and transcription factor binding clustering. ΔV was shown by mouse embryo transgenic assay to harbor a robust enhancer, active in specific sub-regions of stomach, duodenum and pancreas at early developmental stages (E11.5-14.5). In a mouse ΔV deletion strain, homozygous offspring had on average 36% smaller post-natal weight as compared to heterozygotes, significantly modified intestinal content reminiscent of diarrhea with a continued lethality of knockout from days 3 to 21 post-partum. RNA sequencing of gut and stomach biopsy in an adult patient showed major downregulation (X10 to X200) of several gastrointestinal peptide hormones transcripts compared to controls, suggesting enteroendocrine cell dysfunction. No gene in a ±1Mb interval around the enhancer showed mRNA disregulation, to be expected if enhancer action extends to adults. Intriguingly, we observed a 30 fold mRNA downregulation of *ARX*, a transcription factor previously implicated in syndromic diarrhea. Circularized chromosome conformation capture (4C) is currently employed at different mouse developmental stages, seeking further information on potential enhancer targets. Our results suggest that congenital diarrhea in our patients involves a rare case of enhancer-mediated phenotype, perhaps involving failure of enteroendocrine development or function.

C17.5

Genetic testing leads clinical care in neonatal diabetes: a new paradigm

E. De Franco[1], *S. E. Flanagan*[1], *J. A. L. Houghton*[1], *H. Lango Allen*[1], *R. Caswell*[1], *D. J. G. Mackay*[2,3], *K. I. Temple*[3], *S. Ellard*[1], *A. T. Hattersley*[1];

[1]*Institute of Biomedical and Clinical Science, University of Exeter Medical School, Exeter, United Kingdom,* [2]*Wessex Regional Genetics Laboratory, Salisbury Health Care Trust,, Salisbury, United Kingdom,* [3]*Human Genetics and Genomic Medicine, Faculty of Medicine, University of Southampton, Southampton, United Kingdom.*

Before next-generation sequencing, genetic testing was based on selection of a gene (or small number of genes) in which mutations had been identified in patients with recognisable, discrete phenotypes. For neonatal diabetes this included a transient subtype and syndromes such as Wolcott-Rallison. In this study we investigated the impact of testing all known genetic causes of neonatal diabetes.

We studied 1020 patients from 79 countries with diabetes diagnosed <6 months of age. Mutations were identified by targeted next-generation sequencing of 21 genes, Sanger sequencing or 6q24 methylation analysis.

A pathogenic mutation was identified in 840 patients (82%). The most common cause was a potassium channel mutation (n=390); most of these patients achieve improved glycaemic control after transfer from insulin to sulfonylureas. The median age at referral decreased from 271 weeks in 2004 to 18 weeks in 2013. Patients with a genetic diagnosis of Wolcott-Rallison syndrome referred <12 months of age were therefore more likely to have isolated diabetes at referral (85% vs 33% >12 months) and develop additional features (e.g. liver failure) after testing. A genetic diagnosis also predicts diabetes remission: 88/94 patients (94%) referred <3 months received a genetic diagnosis of transient neonatal diabetes before remission.

Comprehensive genetic analysis identified causal mutations in >80% of cases. More patients are now referred at presentation with isolated diabetes and the genetic result predicts clinical course and development of related features. This represents a new paradigm for clinical care with genetic diagnosis preceding the development of clinical features and guiding clinical management.

C17.6

Safety and efficacy of pravastatin and zoledronate association in Hutchinson-Gilford Progeria: two-years treatment results of a phase II, open label, single arm clinical trial (ClinicalTrials.gov #NCT00731016)

A. De Sandre-Giovannoli[1,2,3], *S. Sigaudy*[1,2,3], *P. Bourgeois*[1,2,3], *S. Miloudi*[4], *P. Roll*[1,2,3], *G. Gorincour*[5], *J. Gentet*[6], *F. Sabatier*[7,8], *L. Arnaud*[8], *N. André*[6], *P. Cau*[1,2,3], *R. Truillet*[4], *E. Jouve*[4], *J. Micallef*[8], *N. Lévy*[1,2,3];

Hutchinson-Gilford progeria syndrome (HGPS) is an extremely rare developmental disorder affecting children with segmental features of aging, including thin skin, loss of subcutaneous fat, alopecia, osteopenia and accelerated cardiovascular arteriosclerotic disease, leading to death at the mean age of 13 years. The syndrome is due to a mutation in the gene encoding lamins A/C, leading to the production of an aberrant lamin A precursor called progerin. Intranuclear progerin accumulation exerts multiple toxic effects which ultimately lead to organismal premature aging. Preclinical data provided proof-of-principle that the combined use of zoledronate and pravastatin (ZoPra) could ameliorate several disease parameters, including

growth, bone density and survival. On these bases, we conducted in Marseille La Timone Hospital a phase II, open label, single arm trial including 12 European HGPS patients, aiming to test the safety and efficacy of two years of ZoPra treatment (10 to 20 mg/day oral pravastatin and 0.05 mg/kg intravenous zoledronate every 12 weeks). The adverse events observed in this study were consistent with those expected in the HGPS population and none warranted treatment discontinuation. ZoPra induced clinical beneficial effects, including an amelioration of rates of weight gain and lipid profiles, bone mass increases, reduced mesenteric fat together with increased leptin levels, reduced thrombocytosis and concurrent reductions of circulating endothelial microparticles and endothelial progenitor cells, suggesting reduced vascular injury. Our results are discussed in light of previous results of a phase II lonafarnib trial in HGPS.

C18.1

Molecular Inversion Probe based Resequencing Identifies Recurrently Mutated Genes in Intellectual Disability

A. Hoischen[1], *L. E. L. M. Vissers*[1], *B. P. Coe*[2], *C. Gilissen*[1], *A. Vulto-Silfhout*[1], *J. Schuurs-Hoeijmakers*[1], *M. van de Vorst*[1], *M. Steehouwer*[1], *P. de Vries*[1], *C. Baker*[2], *K. Witherspoon*[2], *B. J. O'Roak*[2], *J. Shendure*[2], *H. G. Brunner*[1], *C. Romano*[3], *B. B. A. de Vries*[1], *J. A. Veltman*[1], *E. E. Eichler*[4];

[1]*Department of Human Genetics, Radboud university medical center, Nijmegen, Netherlands,* [2]*Department of Genome Sciences; University of Washington, Seattle, WA, United States,* [3]*Unit of Pediatrics and Medical Genetics, IRCCS Associazione Oasi Maria Santissima, Troina, Italy,* [4]*Department of Genome Sciences & Howard Hughes Medical Institute; University of Washington, Seattle, WA, United States.*

Exome sequencing studies of individuals with intellectual disability (ID) and related neurodevelopmental disorders have identified many de novo mutations but few recurrently mutated genes1,2. We therefore applied a molecular inversion probe (MIP) based resequencing method to screen 42 ID candidate genes - mainly from a previous study2 - in ~2,500 patients with the clinical diagnosis of ID and 1,000 healthy controls. This approach allowed targeted multiplex enrichment of 768 DNAs per week per fte, and barcoding allowed simultaneous sequencing of up to 3,072 samples for the 42 gene panel per HiSeq2000 sequencing run. This resulted in an average coverage of >300x coverage per sample, allowing highly accurate variants calling.
We discovered predicted loss-of-function (LoF) events for more than half of the candidate genes, including multiple recurrent de novo nonsense and frameshift mutations in several genes including CHD2, GATD2B and MYT1L. This together with ongoing 'reverse-phenotyping' of the affected individuals further supports the pathophysiological role of these genes in intellectual disability. We were also able to analyze copy number status for these candidate genes, and discovered de novo CNVs, deletions and duplications, that implicate new dosage sensitive genes. Despite the challenging task to prove causality, latest technological improvements allowed entering a golden age of 'neurodevelopmental-gene' discovery which promises to improve not only our understanding of disease but provide fundamental insight into the biology of human brain development.

Intellectual disability is a major public health problem, characterized by an extreme genetic heterogeneity, with several hundred genes implicated in monogenic forms with or without autism, complicating molecular diagnosis. In patients without evocative syndromic forms the offer is limited to Fragile-X testing and array-CGH, leaving most cases undiagnosed. Trio-Exome sequencing was recently proposed as a diagnostic approach, but remains costly for general implementation. We thus tested targeted exon sequencing of 217 genes previously implicated in X-linked ID, or in autosomal dominant or recessive forms in which ID is the major clinical concern. We analyzed 106 patients (mostly males and sporadic cases) with molecularly undiagnosed ID. One third of them harbored autistic features.
We identified causative mutations in 26 patients: sixteen in X-linked genes (*ATRX*, *CUL4B, DMD*, *FMR1*, *HCFC1, IL1RAPL1*, *IQSEC2*, *KDM5C*, *MAOA*, *MECP2*, *SLC9A6*, *SLC16A2, PHF8),* 10 *de novo* in autosomal genes (*DYRK1A*, *GRIN1*, *MED13L*, *TCF4*, *RAI1*, *SHANK3, SLC2A1*, *SYNGAP1*). We detected likely-causative mutations requiring additional validation in 5 patients (in *NLGN3* for instance). Our findings confirm MED13L as an ID gene, but raise doubts on *SHROOM4* or *SRPX2*. We identified causative mutations in syndromic genes in patients deviating from the classic phenotype. Some genes were hit more than once suggesting they correspond to more frequent conditions. The identification of mutations in 25-29% of patients proves the diagnostic efficiency of this strategy, higher than CGH and comparable to trio-exome sequencing at lesser cost. We have now updated our captured gene list to 270 genes, and will report on its use.

C18.3

Comprehensive NGS based diagnostics in over 1000 patients with epileptic disorders

[1]*CeGaT GmbH, Tübingen, Germany,* [2]*Division of Human Genetics, University Children's Hospital, Inselspital, Bern, Switzerland,* [3]*Department of Neurology and Epileptology, University of Tübingen, Tübingen, Germany.*

Purpose: Epileptic disorders have a highly heterogeneous background and a strong genetic contribution. Knowing the underlying molecular defect can be very valuable for diagnosis, guiding treatment and estimating recurrence risks. For this purpose we have developed a comprehensive diagnostic panel. **Method:** 461 relevant genes were selected from the literature, and subdivided into subpanels according to their phenotypes. Following customized target enrichment, NGS was performed, followed by bioinformatic analysis. Variants with a global minor allele frequency <5% were selected for evaluation and identified mutations were validated using Sanger sequencing. **Results:** In our study, over 1000 patients with epileptic disorders were analyzed. 20% of patients had pathogenic mutation(s) and 29% were inconclusive, partly being predicted pathogenic but unknown variants, partly due to non-segregation of identified variants. 51% of the cases remained unsolved. We observed rare variants in 203 different genes, with *SCN1A*, *SCN2A, CACNA1A*, *MECP2* and *KCNT1* being mutated most frequently. Across the cohort, 78 genes were identified as causative only once, emphasizing the advantage of diagnostic panels for very rare conditions.
Conclusion: We have developed a highly reliable and cost-efficient diagnostic NGS panel to analyze the genetic basis of epilepsies. We detected mutations in patients with clear and unspecific epilepsies, as well as in patients suffering from very rare conditions. This enables better understanding of genotype-phenotype correlations, and gives new insights into complex modes of inheritance such as combinatorial effects of variants.

C18.4

Planar cell polarity gene mutations contribute to the etiology of human Neural Tube Defects

P. De Marco[1], *E. Merello*[1], *G. Piatelli*[1], *A. Cama*[1], *Z. Kibar*[2], *V. Capra*[1];

[1]*Istituto Giannina Gaslini, Genova, Italy,* [2]*CHU Sainte Justine Research Center, Montreal, QC, Canada.*

Neural tube defects (NTDs) are congenital malformations affecting 1 infants per 1000 births. The most common forms of NTDs are anencephaly and myelomeningocele, which result from the failure of fusion in the cranial and spinal regions of the neural tube, respectively. Population and family studies indicate a complex etiology to NTDs involving environmental and genetic factors that remain undetermined. Animal models have strongly implicated the Wnt non canonical planar cell polarity (PCP) pathway in the pathogenesis of NTDs. PCP is the process of by which cells become polarized in the plane of an epithelium. PCP core members include the transmembrane protein Frizzled (Fz), the intracellular proteins Dishevelled (Dsh), Strabismus (Stbm), Flamingo (Fmn), Prickle (Pk) and Diego. Downstream effectors include the small GTPases of the RhoA family and JNK that upon activation lead to a variety of cellular responses including cytoskeletal rearrangements. Our research group has demonstrated a link between some of the PCP genes and human NTDs. We identified 52 rare mutations in a cohort of 629 NTDs patients in seven PCP genes (*VANGL1*, *VANGL2*, *PRICKLE1*, *CELSR1*, *FZD6*, *DVL2*, *FUZ*) that were absent in ethnically-matched controls. The 94% of the mutations were missense changes and a pathologic role was demonstrated for 46 of them by using bioinformatic prediction tools and *in vivo* and/or *in vitro* bioassays. Overall, the identified mutations realize of about 10% of NTD cases. We hypothesize that rare variants of PCP pathway must interact with other genes to modulate the incidence and severity of the disease.

C18.5

Clinical exome sequencing for cerebellar ataxia and spastic paraplegia reveals novel gene-disease associations and uncovers unanticipated rare disorders

E. Kamsteeg, *B. P. van de Warrenburg, S. T. de Bot, M. A. A. P. Willemsen, S. Vermeer, M. I. Schouten, R. Meijer, M. Pennings, C. Gilissen, H. Scheffer;*
Radboud University Medical Centre, Nijmegen, Netherlands.

Clinical exome sequencing is an unbiased test that is used for straight-forward causative mutation detection, or for the discovery of novel (allelic) gene - disease associations. Often, it leads to broader disease spectra, or reverse phenotyping. Here, we describe the use of clinical exome sequencing for a group of 76 probands with ataxia or spastic paraplegia. Since these patients have had extensive testing (4.5 genes on average) before inclusion, mutations were not anticipated in the 'common' genes. In a two-tier analysis, variants in known disease genes were analysed first, followed by analysis of the 'full' exome data set if no causative mutations were identified. Subsequently, segregation analyses, enzyme tests or reverse phenotyping tests have confirmed or excluded the pathogenicity of most variants. In those 76 patients, we have thus detected causative mutations in 16, and likely-causative in another 9, all in the known disease genes. Some of the identified diseases are very rare or even the second case described. Furthermore, another 8 putatively-causative mutations were detected in genes outside the known disease genesl, and await confirmation (functional tests or other families with mutations in those gene). Some of the latter diseases may be allelic disorders, while others may be novel. In conclusion, exome sequencing for these neurological disorders has resulted in a molecular diagnosis in one-third of the patients, and has provided a candidate gene identification in approximately 1/10. More importantly, it has also provided some patients with a molecular diagnosis that was both unanticipated and otherwise not revealed.

C18.6

WES detects disease causing SNVs and CNVs in Primary immunodeficiencies

Primary immunodeficiencies (PIDDs) constitute a heterogeneous group of genetic diseases affecting the immune system. Depending on the genetic etiology, symptoms range from mild to severe and life threatening. Knowledge of the molecular genetic cause and disease mechanism is important and can direct targeted and curative therapy. However, subtype classification is difficult as patients often have overlapping phenotypes. In addition, >250 PIDD genes have been reported, and few are offered for diagnostic genetic testing. We examined the utility of whole-exome sequencing (WES) to detect single nucleotide variants (SNVs) and copy number variations (CNVs) in the diagnosis of PIDDs. As of Feb 2014, 225 patients with extensive immunological and genetic testing from 200 families have been recruited from Texas Children Hospital (Houston, USA) and Oslo University Hospital (Norway). Strategies for genetic analysis were tailored based on clinical data, immunophenotyping and family history, but for most families only the proband was subjected to WES. Initially, WES data were systematically screened for variants in reported and potential PIDD genes. In addition, a computational CNV prediction pipeline was applied to enable identification of potential disease-causing CNVs from the WES data. Analysis of the first 110 families identified PIDD relevant variants in 60% of cases; half of these attaining a definitive molecular PIDD diagnosis. The other half had previously reported PIDD-causing variants, but with an unexpected or extended clinical phenotype, or heterozygote, potential deleterious variants in recessively inherited PIDD genes. Other interesting findings include PIDD-causing CNVs, somatic reversion causing mosaicism, and 13 potential novel disease genes.

Endogenous hypercortisolism, referred to as Cushing's syndrome, is associated with excess morbidity and mortality. Corticotropin-independent Cushing's syndrome is caused by tumors or hyperplasia of the adrenal cortex.

We performed exome sequencing of ten cortisol-producing adenomas and matched control tissue to identify somatic mutations and evaluated recurrent mutations in candidate genes in adenomas of additional 171 patients. We further performed genome-wide copy number analysis in 35 patients with cortisol-secreting bilateral hyperplasias. We studied the effects of these genetic defects both clinically and in vitro.

Exome sequencing revealed somatic mutations in the PRKACA gene, which encodes the catalytic subunit of cyclic AMP-dependent protein kinase (PKA), in 8 of 10 adenomas. Overall, PRKACA somatic mutations were identified in a total of 22 of 59 adenomas (37%) from patients with overt Cushing's syndrome; these mutations were not detectable in patients with subclinical hypercortisolism (n=40) or in other adrenal tumors (n=82). Among 35 patients with bilateral cortisol-producing hyperplasias, 5 carried a germline copy number gain of the chromosome 19 region, including the PRKACA gene. In vitro studies demonstrated impaired inhibition of both PKA catalytic subunit mutants by the PKA regulatory subunit, while cells from patients with germline chromosomal gains showed increased protein levels of the PKA catalytic subunit; in both instances, basal PKA activity was increased.

This study links genetic alterations of the catalytic subunit of PKA to human disease. Germline duplications of this gene result in bilateral adrenal hyperplasias, whereas somatic PRKACA gain-of-function mutations lead to unilateral cortisol-producing adrenal adenomas.

C19.2

A mutation in SEC61A1 causes autosomal dominant interstitial kidney disorder associated with anemia and growth retardation

Autosomal dominant tubulo-interstitial kidney disease refers to a group of disorders characterized by progressive loss of kidney function and the eventual need for dialysis and kidney transplantation. While mutations in the UMOD, MUC1, and REN genes have been identified as the primary causes of this disorder, there remain a number of families in whom the genetic cause has not been identified. Here we report a three-generation family with autosomal dominant progressive chronic kidney disease associated with congenital anemia and intrauterine growth retardation. Ultrasound examinations revealed small dysplastic kidneys without cysts, and a kidney biopsy revealed tubular atrophy with secondary glomerular sclerosis. We performed genome-wide linkage analysis and identified a candidate region with a maximum LOD-score of 2.7 on chromosome 3q. Combining whole exome sequencing data with our critical interval, we identified a c.553A>G variant causing a p.Thr185Ala change in SEC61A1. SEC61A1 encodes the alpha-subunit of the SEC61 complex, responsible for the translocation of proteins across the endoplasmic reticulum membrane. Suppression of se-

c61a1 in zebrafish embryos led to an absence of convolution of the pronephric tubules, whereas the pronephric ducts were unaffected, a phenotype similar to the tubular atrophy seen in our patients. This phenotype could be rescued by wild type SEC61A1 mRNA, but not with mRNA encoded from the p.Thr185Ala allele, suggesting that the variant is a loss of function. Taken together, our genetic findings and the functional studies support SEC61A1 as a causal gene for a novel, dominant syndromic form of progressive chronic kidney disease with tubular atrophy.

Progressive familial intrahepatic cholestasis (PFIC) is an autosomal recessive disorder manifesting as early-onset cholestatic liver disease. In 1998 mutations in three genes encoding membrane transporters were identified. However, 30% of patients remain without genetic diagnosis. Combined targeted resequencing (TRS) and whole-exome sequencing were used to analyse a cohort of 33 children, from 29 families, with chronic cholestatic liver disease and no mutations in known PFIC genes. Most were from consanguineous families. Homozygous mutations in *TJP2* were identified in 12 individuals of 8 families; all were predicted to abolish translation. *TJP2* encodes a cytosolic component of cell-cell junctional structures, linking integral membrane proteins such as claudins with actin filaments. Immunohistochemistry and western blotting of liver tissue from these patients showed a complete absence of TJP2 protein. Claudin-1 was not localised, but showed no alteration in protein level. Tight junctions were abnormal on transmission electron microscopy. A further 53 cholestatic patients were then examined by TRS. Mutations in *TJP2* were identified in 8 families. All mutations were protein-truncating mutations, except for three families with missense mutations. One missense mutation, p.His788Leu, was found in 2 unrelated families with severe early-onset cholestasis, which subsequently remitted. Previously a single, incompletely penetrant, missense mutation was identified in *TJP2* in Amish patients with isolated hypercholanaemia. In conclusion, a complete absence of TJP2 causes severe cholestatic liver disease, with destabilization of tight junction structures, whilst missense mutations in *TJP2* can lead to less severe phenotypes. These findings highlight the importance of TJP2 in the maintenance of liver integrity.

C19.4

Identification and functional characterization of ESR2, a new disease gene for 46,XY disorders of sex development (DSD)

D. Baetens[1], *T. Guran*[2], *L. De Cauwer*[3], *L. Looijenga*[4], *K. De Bosscher*[3], *M. Cools*[5], *E. De Baere*[1];

[1]*Center for Medical Genetics, Ghent University Hospital and Ghent University, Ghent, Belgium,* [2]*Zeynep Kamil Maternity and Childrens' Diseases Training and Research Hospital, Division of Pediatric Endocrinology and Diabetes, Istanbul, Turkey,* [3]*Cytokine Receptor Lab, Department of Medical Protein Research, VIB, Ghent, Belgium,* [4]*4Department of Pathology, Erasmus MC-University Medical Center Rotterdam, Rotterdam, Netherlands,* [5]*Department of Pediatrics, Division of Pediatric Endocrinology, Ghent University Hospital and Ghent University, Ghent, Belgium.*

Disorders of sex development (DSDs) are congenital conditions with atypical development of chromosomal, gonadal or anatomical sex. The prevalence of these conditions is 1 in 4500, milder genital abnormalities are seen in 1 in 300 births. Today, the molecular cause is known in only 50% of cases.
Here, homozygosity mapping in a patient with syndromic 46,XY DSD revealed a potential functional candidate gene for DSD, namely *ESR2*, encoding the Estrogen Receptor beta. Sanger sequencing revealed a homozygous in-frame deletion in *ESR2* in this patient, c.541_543del (p.Asn181del). The deleted amino acid is located in the DNA-binding domain and is highly conserved. This deletion was absent in an ethnically matched control population. *ESR2* mutation screening in a 46,XY DSD cohort revealed an additional heterozygous mutation c.251G>T (p.Gly84Val). Prediction programs suggest an effect on protein function (SIFT, Polyhen, Mutation Taster). In addition the affected amino acid is conserved until fruitfly.
Immunohistochemistry in an 8-weeks old human male embryo showed ER-beta expression in the hindgut and the eyes, which might recapitulate the systemic manifestations of the index case.
Dose-response assays with DPN, ERE-luc and TK-3xEREluc constructs, and ER-beta wild type and mutant constructs in HEK293T cells showed a differential transcriptional activation of the ER-beta mutants.
In conclusion, our study sustains a role of *ESR2* as novel disease gene for syndromic 46,XY DSD. It is expected that further functional studies of these ER-beta mutants will provide insights into their molecular consequences and into the role of *ESR2* in the pathogenesis of 46,XY DSD.

C19.5

LRP5 variants associated with development of polycystic kidney and liver disease

W. R. Cnossen[1], *R. H. M. te Morsche*[1], *A. Hoischen*[2], *C. Gilissen*[2], *H. Venselaar*[3], *S. Mehdi*[4], *C. Bergmann*[5,6], *M. Losekoot*[7], *M. H. Breuning*[7], *D. J. M. Peters*[7], *J. A. Veltman*[2], *J. P. H. Drenth*[1];

[1]*Department of Gastroenterology and Hepatology, Radboudumc, Nijmegen, Netherlands,* [2]*Department of Human Genetics, Radboudumc, Nijmegen, Netherlands,* [3]*Center for Molecular and Biomolecular Informatics, Radboudumc, Nijmegen, Netherlands,* [4]*Department of Surgery, Faculty of Medicine, University Mohammed First, d'Oujda, Morocco,* [5]*Center for Human Genetics, Bioscientia, Ingelheim, Germany,* [6]*Center for Clinical Research, University Hospital Freiburg, Freiburg, Germany,* [7]*LDGA-Department of Clinical Genetics, Leiden University Medical Centre, Leiden, Netherlands.*

Autosomal dominant polycystic kidney disease (ADPKD) is a Mendelian disorder characterized by multiple renal cysts that progressively leads to renal disease. Polycystic livers are the most common extra-renal manifestation (83%). About 90% of ADPKD families harbor a *PKD1* or *PKD2* mutation, but others remain indistinct. Previous studies hypothesized involvement of a third locus. Recently, we identified mutations in a novel gene (*LRP5*) associated with isolated polycystic liver disease (PCLD).
We analyzed all exons of *LRP5* in a cohort of 29 patients with and 50 patients without prescreening of *PKD1/2* and *PKHD1*. We identified 2 novel and 2 rare variants in 4 unlinked ADPKD patients. One family demonstrated obvious segregation of the novel *LRP5* variant with the disease.
In silico analyses predicted both novel and 1 rare *LRP5* variant to be pathogenic, and the remaining variant as possibly damaging. All 4 variants were not found in exome data from 1,300 individuals of predominantly European ancestry sequenced in-house. The 2 novel *LRP5* variants were absent in several (inter)national databases and also excluded in a control set of 1,000 Dutch and 525 Moroccan DNAs of healthy, unrelated individuals.
For 3 mutations homology modeling predicted that ionic interactions disappear which diminishes the protein domain function. Luciferase activity assays were performed in eukaryotic cells transfected with wild-type and mutant *LRP5*. Wnt signal activation was significantly reduced in 2 novel and 1 rare *LRP5* variant.
In conclusion, these findings contribute to the pathofysiology of renal and hepatic cystogenesis with involvement of the canonical Wnt signaling pathway.

C19.6

Digenic model in Alport syndrome

M. Mencarelli[1,2], *M. van Geel*[3], *H. Storey*[4], *C. Fallerini*[1], *L. Dosa*[1,2], *M. Antonucci*[1,2], *F. Cetta*[5], *A. van den Wijngaard*[3], *S. Yau*[4], *F. Mari*[1,2], *M. Bruttini*[1,2], *F. Ariani*[1], *K. Dahan*[6], *B. Smeets*[3], *F. Flinter*[7], *A. Renieri*[1,2];

[1]*Medical Genetics, University of Siena, Siena, Italy,* [2]*Genetica Medica, Azienda Ospedaliera Universitaria Senese, Siena, Italy,* [3]*Clinical Genetics, Maastricht University Medical Centre, Maastricht, Netherlands,* [4]*DNA Laboratory, GSTS Pathology, Guy's Hospital, London SE1 9RT, London, United Kingdom,* [5]*IRCCS MultiMedica, Milan, Italy,* [6]*Université Catholique de Louvain, Louvain-La-Neuve, Belgium,* [7]*Department of Clinical Genetics, Guy's & St Thomas' NHS Foundation Trust, Guy's Hospital, London SE1 9RT, London, United Kingdom.*

Alport syndrome (ATS) is a clinically and genetically hereditary nephropathy, that is often associated with deafness and ocular lesions. Monogenic inheritance models are well known, with semidominant X-linked inheritance, linked to *COL4A5* gene, or autosomal dominant or recessive inheritance, linked to *COL4A3* or *COL4A4* gene. The increased availability of high throughput sequencing permits identification of kindreds with pathogenic mutations in more than one disease-gene, also exploring digenic inheritance models. We have found 6 kindreds, in which the proband had 2 pathogenic mutations in different Alport associated genes. In 4 out of 6 cases it was shown that each

mutation was inherited from one of the parents. In most cases heterozygotes had less severe disease than the double heterozygotes. In two cases mutations involved the *COL4A5* and *COL4A4* genes, whereas in the remaining 4, mutations involved the *COL4A3* and *COL4A4* genes. Mutation pathogenicity was ascertained on the basis of the following criteria: non polymorphic missense mutations in key aminoacids, as Glycine in the collagen Gly-X-Y triple helical domain, or truncating mutations. In conclusion, results from new technologies showed that some cases of ATS may segregate according to a digenic inheritance model. This model has previously been shown in other diseases, such as retinopathies, cardiomyopathies or intellectual disability. Our results are of interest both from a scientific point of view and for genetic counselling. Clinical geneticists should be familiar with more complex models of inheritance, which could alter the recurrence risk.

C20.1

Single cell allele-specific expression (ASE) in Down syndrome and common aneuploidies

G. Stamoulis[1], *P. G. Ferreira[1], P. Makrythanasis[1], F. Santoni[1], M. Guipponi[2], M. Garieri[1], E. Falconnet[1], P. Ribaux[1], E. T. Dermitzakis[1,3], C. Borel[1], S. E. Antonarakis[1,2,3];*

Trisomy 21 is a model disorder of altered gene expression. Several studies have addressed the transcriptome differences between normal and affected individuals; however all of these studies suffer from the presence of 'noise' due to gene expression variation among different individuals. We have previously used a pair of monozygotic twins discordant for trisomy 21 in order to study the global dysregulation of gene expression (*Nature* in press 2014). The majority of previous studies focused on aneuploidies were conducted on cultured cell populations or tissues, but studies focusing on gene and allelic expression behavior at the single cell level are lacking. In this study we explore the allele specific expression in Trisomy 21 using transcriptome studies in single cells. We have used 40 normal cells and 48 trisomic cells from the fibroblasts of the monozygotic twins discordant for trisomy 21 and compared the ASE (allele specific expression), and their transcriptional metrics in these two cell groups. We observed a pattern of biased or monoallelic expression for the majority of the genes across single cells. These results will be presented and discussed. In addition a series of samples from mosaic trisomy 21, trisomy 13 and trisomy 18 are in different stages of investigation. These studies in single cells will provide a fundamental understanding of the gene expression dysregulation and allele specific expression in aneuploidies.

C20.2

Distinct properties of de novo mutations from whole genome sequencing of 50 patient-parent trios

M. Pinelli[1,2], *B. Tan[1,3], J. M. van de Vorst[1], R. Leach[4], R. Klein[4], L. E. L. M. Vissers[1], H. G. Brunner[1,5], J. A. Veltman[1,5], A. Hoischen[1], C. Gilissen[1];*

De novo germline mutations create the genetic variability that is the driving force of species evolution. However, they also can cause sporadic genetic diseases if they affect critical genomic regions. Whole Genome Sequencing (WGS) of parent-offspring trios allows us for the first time to study the result of mutational processes in a single generation in full detail. Here we report on the rate and pattern of de novo mutations based on WGS of 50 trios at high (80x median) coverage.
We identified an average of 58 de novo mutations (DNM) per trio (range 32-84), 2,883 DNMs in total. By using the segregation of informative SNPs we determined the parental origin for 678 DNMs, and found a paternal/maternal ratio of 4 to 1 (79%/21%), consistent with previous data. Using the parental origin of these DNMs we found a significant correlation between the paternal age and the number of paternal DNMs (Spearman's p=0.006) as well as a suggestive results for the correlation between maternal age and the number of maternal DNMs (p=0.08).
We find that DNMs do not occur completely random in the genome, but are spatially clustered within individuals (observed=28 (0.9%), expected=1.3 (0.004%), p-value<10-16) and have a sequence context that is enriched for CpGs (observed=482 (20.6%), expected=58 (2.6%), p-value<10-16). In conclusion, our study provides insight into the parental origin and distribution of de novo mutations throughout the human genome.

C20.3

Study of the regulatory landscape of *SHOX* in 503 LWD and ISS cases uncover a key role of the upstream *cis*-regulatory element CNE-3

H. Verdin[1], A. Fernández Miñán[2], K. De Leeneer[1], L. Borms[1], S. Janssens[1], B. Callewaert[1], F. Malfait[1], A. Kariminejad[3], K. De Waele[4], J. De Schepper[4], I. François[5], A. Dheedene[1], B. Menten[1], J. L. Gómez-Skarmeta[2], **E. De Baere**[1];
[1]Center for Medical Genetics, Ghent University, Ghent, Belgium, [2]Centro Andaluz de Biología del Desarrollo, Consejo Superior de Investigaciones Científicas and Universidad Pablo de Olavide, Sevilla, Spain, [3]Kariminejad-Najmabadi Pathology & Genetics Center, Shahrak Gharb, Tehran, Islamic Republic of Iran, [4]Department of Pediatric Endocrinology, Ghent University Hospital, Ghent, Belgium, [5]Department of Pediatrics Endocrinology, University Hospital Leuven, Leuven, Belgium.

Leri-Weill Dyschondrosteosis (LWD) and idiopathic short stature (ISS) are caused by a variety of molecular defects of *SHOX* and the downstream PAR1 region. Interestingly, the first deletion and duplication of the upstream regulatory PAR1 region have recently been described in ISS, suggesting a new pathogenic mechanism for ISS. Here, we aimed to evaluate the contribution of copy number variations (CNVs) of upstream enhancers to the molecular pathogenesis of LWD and ISS, and to characterize the chromosomal architecture of the regulatory landscape of *SHOX*.
We performed CNV analysis of three previously characterized upstream enhancers (CNE-5, CNE-3 and CNE-2) using quantitative polymerase chain reaction (qPCR) analysis in 503 prescreened LWD and ISS patients with unknown molecular diagnosis. Three deletions and three enhancer duplications were found in five unrelated ISS patients respectively. Interestingly, their shortest region of overlap only contains CNE-3, pointing to a crucial role for this upstream enhancer. Using chromosome conformation capture assays (3C and 4C-seq), we demonstrated reproducible interactions of CNE-3 with the *SHOX* promoter. Finally, the 4C-seq study allowed us to map the complete regulatory landscape of *SHOX*, extending more than 1 Mb both upstream and downstream of the *SHOX* promoter.
In conclusion, our study substantiates a role of upstream CNVs in ISS patients. In addition, we provided evidence for a key role of CNE-3 as upstream enhancer. Finally, our study indicates an important role for the extended regulatory region of *SHOX* to be included in molecular diagnostics of *SHOX*-associated phenotypes.

C20.4

Pseudoautosomal region 1 length polymorphism in the human population

M. A. Mensah[1,2], *M. S. Hestand[1], M. H. D. Larmuseau[3,4,5], M. Isrie[1], N. Vanderheyden[3], M. Declercq[1], E. L. Souche[1], J. Van Houdt[1], R. Stoeva[1], H. Van Esch[1], K. Devriendt[1], T. Voet[1], R. Decorte[3,4], P. N. Robinson[2], J. R. Vermeesch[1];*
[1]KU Leuven, Department of Human Genetics, Leuven, Belgium, [2]Institut für Medizinische Genetik und Humangenetik, Charité - Universitätsmedizin - Berlin, Berlin, Germany, [3]UZ Leuven, Laboratory of Forensic Genetics and Molecular Archaeology, Leuven, Belgium, [4]KU Leuven, Department of Imaging & Pathology, Biomedical Forensic Sciences, Leuven, Belgium, [5]KU Leuven, Department of Biology, Laboratory of Biodiversity and Evolutionary Genomics, Leuven, Belgium.

The human sex chromosomes differ in sequence, except for the pseudoautosomal regions (PAR) at both the short and the long arm, denoted as PAR1 and PAR2. The boundary between PAR1 and the unique X and Y sequences was established during the divergence of the great apes. During a copy number variation screen, we noted a paternally inherited chromosome X duplication in 15 independent families. Subsequent genomic analysis demonstrated that an insertional translocation of X chromosomal sequence into the Y chromosome generates an extended PAR. The insertion is generated by non-allelic homologous recombination between a 548 bp LTR6B repeat with two paralogues located within PAR1 as well as at a distance of 105 kb from the PAR boundary on the X chromosome. The identification of the reciprocal deletion on the X chromosome in one family and the occurrence of the variant in different chromosome Y haplogroups, demonstrate this is a recurrent genomic rearrangement. In contrast to its perceived evolutionary stability, we demonstrate that a PAR1 length polymorphism exists in the human population. This finding represents a novel mechanism shaping sex chromosomal evolution.

C20.5

Comparative proteomic analysis of different fragile X syndrome cell lines

S. Lanni[1], F. Palumbo[1], M. Goracci[1], G. Mancano[1], A. Vitali[2], V. Marzano[3], F. Iavarone[3], F. Vincenzoni[3], M. Castagnola[3], P. Chiurazzi[1], **E. Tabolacci**[1], *G. Neri[1];*
[1]Institute of Medical Genetics-Catholic University, Rome, Italy, [2]Institute ofChemistry of Molecular Recognition-CNR--Catholic University, Rome, Italy, [3]Institute of Biochemistry and Clinical Biochemmistry-Catholic University, Rome, Italy.

Fragile X syndrome (FXS), the leading cause of inherited intellectual disability, is caused by absence of the FMRP protein due to expansion over 200 repeats of the CGG tract at the 5' UTR of the FMR1 gene and subsequent

DNA methylation. We have already characterized rare individuals of normal intelligence with CGG expansion over 200 repeats without DNA methylation (unmethylated full mutation, UFM), which have relatively normal transcription and translation, and represent the status of FXS cell lines prior to gene silencing. We have compared the three types of cell lines (normal control WT, FXS and UFM fibroblasts) with a proteomic approach in order to demonstrate possible differences that might clarify the mechanisms through which the rare UFM cells remain unmethylated and transcriptionally active. Protein extracts were compared by LC-ESI LTQ Orbitrap MS/MS analysis after mono-dimensional SDS-PAGE and trypsin digestion. Interrogation of the dataset for differential protein expression shows that some metabolic pathways are deregulated in UFM cells when compared to FXS cells. Among these pathways, mitochondrial metabolism (oxidative stress) is of particular interest considering its role in neurodegenerative diseases (like FXTAS) and particularly in epigenetic regulation. The deregulated proteins, specifically mitochondrial SOD (SOD2), were validated by Western blot. The interaction of target mRNAs with FMRP was assessed by RNA immunoprecipitation. Preliminary data suggest that mitochondrial metabolism is likely to have a role in DNA hypomethylation of UFM cell lines.

Supported by Telethon Onlus, FRAXA Foundation and Italian Association for fragile X syndrome.

C20.6

RNA-DNA Differences in Endoplasmic Reticulum Stress Response

A. L. Richards[1], *S. Liu*[2], *Z. Zhu*[3], *V. G. Cheung*[2,1];

[1]*University of Michigan, Ann Arbor, MI, United States,* [2]*Howard Hughes Medical Institute, Chevy Chase, MD, United States,* [3]*Life Sciences Institute, Ann Arbor, MI, United States.*

The endoplasmic reticulum (ER) is an organelle where proteins are synthesized and modified. ER stress occurs when there is an excess of misfolded proteins, and if the stress persists, then apoptosis is induced. Here we study RNA editing as a part of the ER stress response and how RNA editing modulates the cellular response to promote cell survival. We sequenced the RNA and DNA of B-cells from 10 individuals before and following 2 and 8 hours of tunicamycin treatment to induce ER stress. By comparing the RNA and DNA sequences, we identified 15,823 A-to-G editing sites in 1,523 genes as targets of RNA editing by ADAR (Adenosine Deaminase Acting on RNA). Among these sites, 314 showed significant changes in editing level following ER stress (p-value<0.01; ANOVA). These sites are found in genes known to be involved in ER stress response: RNA processing, protein transport and apoptosis. For example, sites found in *XIAP* (*X-linked Inhibitor of Apoptosis*) show a 3-fold increase in editing level. Furthermore, ADAR knock-down increases apoptosis following ER stress, suggesting that RNA editing is induced to promote cell survival. The effect of ER stress on editing level is not limited to canonical ADAR editing, as we also detected other types of differences between the RNA and DNA sequences whose levels change following tunicamycin treatment. In this presentation, we will describe RNA sequence modification as a critical step in ER stress response and cell survival.

Dowling-Degos disease (DDD) is an autosomal dominant genodermatosis which is characterized by progressive reticulate hyperpigmentation affecting the flexures, large skin folds, trunk, face and extremities. We previously identified loss-of-function mutations in KRT5 in fewer than half of the individuals of our DDD cohort.

We undertook an exome sequencing approach to identify additional genetic causes of DDD by focusing on five unrelated affected individuals without KRT5 mutations. Data analysis revealed three heterozygous mutations (c.11G>A (p.Trp4*), c.652C>T (p.Arg218*), c.798-2A>C) in these five individuals, all of which are in POGLUT1, encoding protein O-glucosyltransferase 1. By further screening of POGLUT1 in our unexplained cases of DDD, we identified six additional mutations. Immunohistochemistry of skin biopsies of affected individuals with POGLUT1 mutations showed significantly weaker POGLUT1 staining in the upper parts of the epidermis compared to healthy controls. Immunoblot analysis revealed that translation of the wild type POGLUT1 and a mutated form with an amino acid substitution led to the expected size of about 50 kDa, while a nonsense mutation led to a truncated protein of about 30 kDa. Immunofluorescence analysis identified a co-localization of the wild type protein with the endoplasmic reticulum and a notable aggregating pattern for the truncated protein. Protein modeling and transcript analysis supported the pathogenicity of the identified mutations. Recently, mutations in POFUT1, encoding protein O-fucosyltransferase 1, were also reported to be responsible for DDD. Both POGLUT1 and POFUT1 are essential regulators of Notch activity. Our results emphasize the important role of the Notch pathway in pigmentation and keratinocyte morphology.

C21.2

The phenotypic spectrum of SHOC2 c.4A>G (p.Ser2Gly)

Noonan-like syndrome with loose anagen hair (Mazzanti syndrome) (MIM 607721) is caused by an invariant mutation in the *SHOC2* gene (c.4A>G, p.S2G). The disorder is characterized by facial features resembling Noonan syndrome, short stature, GH deficit, developmental delay, congenital cardiac defects, and a distinctive hair phenotype characterized by easily pluckable, slow growing hair in anagen phase.

We report on a large cohort of patients with molecularly confirmed diagnosis from an international research collaboration. In all patients, the c.4A>G change was invariably identified. Clinical data from a total of 89 patients (25 previously published) was available. The ages ranged from 0.08 - 39 years (median at 9.0 years). Short stature and an intellectual disability were present in most of the patients, and were more common than in patients with *PTPN11*, *SOS1* or *RAF1* mutations. Proven growth hormone deficiency was diagnosed in 42% of patients with known test results. *SHOC2* mutation-positive individuals also have a recognizable facial phenotype. Heart defects were common, but differently distributed compared to patients with mutations in other RASopathy genes. Multiple defects were documented in 51% of cases. Overall, Mazzanti syndrome represents a recognizable condition within the spectrum of RASopathies, with a single recurrent mutation, p.S2G, accounting for the vast majority of cases.

C21.3

Heterozygous germline mutations in *A2ML1* are associated with a disorder clinically related to Noonan syndrome

Noonan syndrome (NS) is a developmental disorder characterized by short stature, facial dysmorphisms and congenital heart defects. To date, all mutations known to cause NS are dominant, activating mutations in signal transducers of the RAS/MAPK pathway. In 25% of cases, however, the genetic cause of NS remains elusive, suggesting that factors other than those involved in the canonical RAS/MAPK pathway may also play a role. Here, we used family-based whole exome sequencing of a case-parent trio and identified

a *de novo* mutation, p.(Arg802His), in *A2ML1* which encodes the secreted protease inhibitor Alpha-2-Macroglobulin-Like-1. Subsequent resequencing of *A2ML1* in 155 cases with a clinical diagnosis of NS led to the identification of additional mutations in two families, p.(Arg802Leu) and p.(Arg592Leu). Functional characterization of these human *A2ML1* mutations in zebrafish showed NS-like developmental defects, including a broad head, blunted face and cardiac malformations. Using the crystal structure of A2M, which is highly homologous to A2ML1, we identified the intramolecular interaction partner of Arg802. Mutation of this residue, Glu906, induced similar developmental defects in zebrafish, strengthening our conclusion that mutations in *A2ML1* cause a disorder clinically related to NS. This is the first report of the involvement of an extracellular factor in NS, and RASopathies in general, providing new leads for better understanding of the molecular basis of this family of developmental diseases.

C21.4

A mutation in PAK3 with a dual molecular effect deregulates the RAS/MAPK pathway and drives an X-linked syndromic phenotype

Loss of function mutations in *PAK3* contribute to non-syndromic X-linked intellectual disability (NS-XLID) by affecting dendritic spine density and morphology. Linkage analysis in a three-generation family with affected males showing intellectual disability, agenesis of corpus callosum, cerebellar hypoplasia, microcephaly and ichthyosis, revealed a candidate disease locus in Xq21.33q24 encompassing over 280 genes. By sequencing all coding exons of the X chromosome, we identified a single novel variant within the linkage region, affecting a conserved codon of *PAK3*. Biochemical studies showed that, similar to NS-XLID-associated lesions, the predicted amino acid substitution (Lys389Asn) abolished the kinase activity of PAK3. In addition, it conferred a dominant negative function to the protein that drives the syndromic phenotype. The *in silico* tridimensional model of the mutated proteins and *in vitro* inhibition of protein neosynthesis by cycloheximide treatment revealed that NS-XLID mutations make the inactive kinase unstable and prone to degradation, while Lys389Asn confers stability to PAK3 protein, which escapes its physiologic degradation. Finally, *in vivo* studies in zebrafish embryos showed that PAK3^{N389} leads to a perturbation of the MAPK signaling and to alterations of cerebral and craniofacial structures, through an uncontrolled kinase-independent function. Our data expand the spectrum of phenotypes associated with PAK3 mutations, characterize a novel mechanism resulting in a dual molecular effect of the same mutation with a complex PAK3 functional deregulation, and provide evidence for a direct functional impact of aberrant PAK3 function on MAPK signaling, with the generation of a phenotype that could be included within the clinical spectrum of Rasopathies.

C21.5

Activating mutations in RRAS underlie a phenotype within the RASopathy spectrum and contribute to leukaemogenesis

RASopathies, a family of disorders characterised by cardiac defects, defective growth, facial dysmorphism, variable cognitive deficits and predisposition to certain malignancies, are caused by constitutional dysregulation of RAS signalling predominantly through the RAF-MEK-ERK cascade. We report on two germline mutations in *RRAS*, a small monomeric GTPase controlling cell adhesion, spreading and migration, underlying a variable phenotype with features partially overlapping Noonan syndrome, the most common RASopathy. We also document that somatic *RRAS* mutations rarely occur in juvenile myelomonocytic leukaemia, a childhood myeloproliferative/myelodysplastic disease caused by upregulated RAS signalling, defining an atypical form of this haematological disorder rapidly progressing to acute myeloid leukaemia. Two of the three identified mutations affected known oncogenic hotspots of *RAS* genes, and conferred variably enhanced RRAS function and stimulus-dependent MAPK activation. Expression of a RRAS mutant homolog in *Caenorhabditis elegans* enhanced RAS signalling, and engendered protruding vulva, a phenotype previously linked to a RASopathy-causing SHOC2 mutant. These findings establish a functional link between RRAS and RAS signalling, and reveal an unpredicted role of enhanced RRAS function in human disease.

C21.6

A New Mouse Model for Costello Syndrome

T. Sorg[1], *B. Arveiler[2], M. Birling[1], G. Bou About[1], M. Champy[1], F. Dupuy[2], I. Goncalves[1], M. Jagla[1], H. Jacobs[1], H. Meziane[1], G. Pavlovic[1], N. Philip[2], F. Radvanyi[2], R. Rossignol[2], M. Roux[1], S. Sigaudy[2], Y. Herault[1], D. Lacombe[2];*
[1]ICS, Illkirch, France, [2]CHU, Bordeaux, France.

Costello Syndrome (CS) is a distinctive rare multisystem disorder comprising characteristic prenatally increased growth retardation, coarse facial features, redundant skin with deep palmar, plantar creases and papillomata of later onset. CS patients present also laxity of small joints, tight Achilles tendons, cardiac malformations, and developmental delay. The primary cause of CS was associated to the germ line activation of *H-Ras* oncogene, with a common missense mutation G12S in 80% of the patients. Here we describe the generation and the consequent phenotypic characterization of a genetically engineered mouse model of CS, by introducing the oncogenic G12S mutation by homologous recombination into the mouse Ras gene. The effect of the *H-Ras* G12S mutation was evaluated on behavioral, visual, metabolic, cardiac and histological traits in young adult animals. The behavioral analysis revealed that *H-Ras* G12S mutant males displayed reduced locomotor activity, accompanied by decreased muscle strength and altered motor coordination performance. In addition, the cardiac exploration revealed that *H-Ras* G12S mutants exhibit a hypertensive phenotype combined with tachycardia. In conclusion, the *H-Ras* G12S mutant mice showed a polysyndromic phenotype reproducing some of the CS features observed in patients. The future study of the here-described CS mouse model should have a significant impact of our understanding of CS disease. The use of *H-Ras* G12S mutant mice as a CS mouse model opens up new fields of investigation to better understand the pathophysiology of the disease and to evaluate drugs dedicated to the reduction of the disease associated symptoms.

C22.1

The impact of reporting exome and whole genome sequencing: Predicted frequencies of primary, secondary and incidental findings based on modelling

L. Burnett[1,2,3], *L. C. Ding[1], R. M. Lew[4], D. Chesher[1,2], A. L. Proos[1];*
[1]Pathology North, Royal North Shore Hospital, Sydney, Australia, [2]Sydney Medical School, University of Sydney, Sydney, Australia, [3]School of Information Technology, University of Sydney, Sydney, Australia, [4]Department of Obstetrics and Gynaecology, QEII Research Institute for Mothers and Infants, University of Sydney, Sydney, Australia.

The American College of Medical Genetics and Genomics (ACMG) has released practice guidelines recommending reporting of incidental findings (IFs) from exome and whole genome sequencing by Massively Parallel (Next Generation) Sequencing for multiple conditions. Policy statements from additional agencies are still being developed, with many attempting to take into consideration the predicted increase in workload of reporting IFs and secondary findings. We describe the effects on rates of various diagnostic findings of changing the sensitivity, the specificity, the implications of varying diagnostic criteria and a priori prevalence, and of increasing the number of included conditions.
Methods: We developed a simple mathematical model based on binomial

probability for predicting rates of diagnostic findings. We primed and validated the model using published variant frequencies and population carrier frequencies. Monte Carlo simulation was used to predict population carrier frequencies as a function of numbers of potentially deleterious genomic variants in sampled individuals.
Results: The model correctly calculates observed rates of IFs and genetic carriers. Changing the model's parameters shows that even minor changes in diagnostic criteria or sequencing accuracy causes large variation in rates of diagnostic findings.
Conclusion: Our model correctly explains observed rates of diagnostic findings. Key drivers of rates include diagnostic criteria, variant frequency, disease penetrance, and sequencing and bioinformatics accuracy. Rates of IFs are relatively insensitive to even large increases in the number of conditions included, but rates of genetic carriers are very sensitive to the number of conditions tested. These findings have great relevance to recommended practice and policy.

C22.2

Defending the child's right to an open future concerning genetic information

A. L. Bredenoord[1], *M. C. de Vries*[2], *J. J. van Delden*[1];
[1]*University Medical Center Utrecht, Julius Center, dept Medical Humanities, Utrecht, Netherlands,* [2]*Leiden University Medical Center, dept Pediatrics, Leiden, Netherlands.*

There has been a discussion regarding the ethical acceptability of genetic testing of children for years, resulting in the majority view that minors should only be tested for early onset disorders where treatment or preventive options exist. Two principles underlie this consensus: first, the beneficence-based best interest standard that urges physicians to test for clinically relevant and actionable results. Second, the child's right to an open future principle that urges physicians not to test for adult onset disorders and carrier status, in order to preserve the child's future autonomy right to make its own decisions, also concerning the possible obtainment of genetic information.
The emergence of next generation sequencing (NGS) technology seems to challenge the previous consensus. There now is a growing list of commentators and examples from practice showing disagreement on whether conditions that do not have immediate consequences for the health of the child should be disclosed to parents. The American College of Medical Genetics and Genomics for example recently proposed to relinquish the current distinction between pediatric and adult genetic testing policy, thereby abandoning the child's right to an open future, while the American Academy of Pediatrics maintains the previous consensus.
In this paper we explain the normative rationale that underlies the current debate on a child- versus family centred genetic testing policy and argue that the right to an open future should remain a leading ethical principle in pediatric genomics.

C22.3

Implementation of a duty-to-recontact system in molecular and clinical genetics: perspectives from professionals and patients

M. Plantinga[1], *W. Lamers*[1], *A. V. Ranchor*[2], *M. A. Verkerk*[3], *E. Birnie*[1], *I. M. van Langen*[1];
[1]*UMCG, Clinical Genetics, Groningen, Netherlands,* [2]*UMCG, Health Psychology, Groningen, Netherlands,* [3]*UMCG, Medical Ethics, Groningen, Netherlands.*

Advances in DNA-diagnostic techniques and NGS are leading to more diagnoses, but also to interpretation problems. Many findings cannot be interpreted yet, but may prove medically relevant in the future. Currently, there is no moral or legal obligation to recontact former patients. Many geneticists nevertheless consider it desirable to recontact patients when important new information arises. The UMCG (Groningen, NL) is investigating whether to develop a recontacting system in clinical genetics and how one could be implemented. We explored how professionals and patients from our university hospital feel on these two issues. We organised a focus group discussion with 12 professionals (clinicians, clinical geneticists and laboratory staff) and two group discussions with 3 and 5 patients, respectively, in which we discussed the desirability and requirements for successfully implementing recontacting. Both professionals and patients agreed that recontacting is desirable and implementation could be successful if the following requirements are met: (1) provide a guideline describing the responsibilities of molecular geneticists, genetic counsellors, and patients. This would also specify what information requires recontacting, which information should be given priority, and how recontacting should take place; (2) availability of a lab-based databank containing up-to-date genetic information and the possibility to automatically match new genetic information, e.g. on former variants of unspecified significance, with patients/groups for which the information is important; (3) patient's preferences regarding recontacting (e.g. what type of information and which recontacting medium to use); (4) development of e-health devices facilitating automatic recontacting.

C22.4

International views on sharing incidental findings from whole genome research

A. Middleton[1], *M. Parker*[2], *C. Wright*[1], *H. Firth*[1], *E. Bragin*[1], *M. Hurles*[1], *O. DDD Project*[1];
[1]*Wellcome Trust Sanger Institute, Cambridge, United Kingdom,* [2]*Ethox Centre, University of Oxford, Oxford, United Kingdom.*

Whilst genome-wide sequencing in a research setting may be used to explore the genetic basis of a phenotype it also offers the chance to opportunistically screen for additional results unrelated to the research project but relevant to the participants' future medical health (termed 'incidental findings', IFs).There is a wealth of medical and ethics literature supporting the feedback of IFs, yet there are limited empirical work offering a voice from both professional and public stakeholders directly affected by this.
A cross-sectional, web-based survey investigated the attitudes of 6944 individuals from across 91 countries towards searching for and sharing IFs. Participants included 4961 members of the public, 533 genetic health professionals, 843 non-genetic health professionals and 607 genomic researchers.
Eighty percent of participants believed that IFs from sequencing studies should be made available to research participants if they want them. Treatability and perceived usefulness of the data were important with 98% personally interested in learning about life-threatening conditions that were preventable. However, only 31% of participants thought genomic researchers should actively search for IFs that were not relevant to their research study. Genetic health professionals were the most likely to take this view (OR = 3.09, CI 2.23-4.28, $P < 0.0001$). This may be due to their appreciation of the complexities involved in translating genomic data in the clinic. Participants felt that genomic researchers should be able to focus on their research question without being forced to actively search for IFs, potentially at the expense of their study.

C22.5

Newborn screenings and whole genome sequencing: the real need of a genuine public involvement

M. Tomasi[1], *A. Santosuosso*[2];
[1]*University of Trento, Trento, Italy,* [2]*University of Pavia, Pavia, Italy.*

In the last decade newborn-screening programs and whole genome sequencing are making their way in clinical practice.
The question we focus on is whether the intrinsic persistence in time of genetic characters (monitored in newborn-screening programs), once combined both with the rules governing bio-banks which store those information and the natural lifelong evolution of personal individuality (from infancy to old age), creates an apparently inextricable set of problems.
In this paper we have the ambition simply to draw a list of them in order to open up a space for a public interdisciplinary discussion about new arising challenges that need to be framed and faced by public policies.
Some examples are:
- The complex and not yet unraveled relationship between the gradual evolution of the interested person and epigenetic developments.
- Regulations of parents' opting in/out screening programs and the chances of modifying their choices during time.
- The involvement of relatives and future siblings.
- The (im)possibility of a real opt out during the phase of reconsent.
- Difficulties arising from the organizational rules of biobanking in relation to the described long lasting process of consent.
- Privacy issues deriving both from the stable relationship between person and collected data (impossible anonymousness) and the possibility of control over informational flows.
We maintain it is necessary to foster a real engagement of community in genuine discussion on a) benefits of a universal system of genetic monitoring and b) ethical and legal implications for personal rights.

C22.6

Current Developments in the Regulation of Direct-to-Consumer Genetic Testing in Europe

L. M. Kalokairinou[1], *H. C. Howard*[2], *P. Borry*[1];
[1]*KU Leuven, Leuven, Belgium,* [2]*Radboud University Nijmegen, Nijmegen, Netherlands.*

In recent years direct-to-consumer (DTC) genetic testing has provoked a lot of debates and lead to various statements and opinions of professional societies, medical associations and governmental bodies. In October 2013 the European Parliament voted a Regulation on In Vitro Diagnostic Medical Devices. This document is waiting for approval by the Council of the European Union which might still provide amendments to the text. When approved, this new Regulation is expected to introduce important regulatory changes in the field of medical devices, and especially in the field of genetic testing. In this presentation, we aim to present and evaluate the major impact of

this Regulation on the field of DTC genetic testing. First, adopting the current proposal will mean that genetic tests, including both health-related and lifestyle tests, will be subjected to a pre-market assessment by independent notified bodies. Second, according to the risk class they fall into, IVD devices will have to comply with revised requirements for clinical evidence. Third, the proposal requires appropriate genetic counseling for all genetic tests and classifies them as "prescription only". Finally, DTC advertising of devices classed as prescription only will be banned. Full implementation of these provisions would greatly impact DTC genetic testing companies as the present offer and advertising would no longer be tolerated. This work aims to clarify the proposed amendments and contribute to the ongoing discussion regarding the desirable degree of genetic testing regulation and the appropriate balance between promoting innovation and securing consumers' safety by using legal tools.

P01.002-M
Chromosome methylation and hydroxymethylation patterns are dynamically reprogrammed during human preimplantation development

A. V. Tikhonov[1,2], *O. A. Efimova[1,2], A. A. Pendina[1,2], M. I. Krapivin[1], I. D. Fedorova[2], T. V. Kuznetzova[1,2], V. S. Baranov[1,2];*
[1]Saint-Petersburg State University, St.Petersburg, Russian Federation, [2]D.O.Ott Research Institute of Obstetrics and Gynecology, St.Petersburg, Russian Federation.

We analyzed the distribution of 5-hydroxymethylcytosine (5hmC) and 5-methylcytosine (5mC) in metaphase chromosomes from IVF-produced human triploid zygotes and morphologically abnormal cleavage stage embryos. To obtain metaphase chromosomes, zygotes and embryos were treated with 0.1% colchicines, 0.9% sodium citrate and fixed with freshly prepared 3:1 methanol:acetic acid. Then, QFH/AcD-banding technique was applied and cytosine modifications were detected by indirect immunofluorescence.
In zygotes, parental sets of chromosomes had reversed patterns of methylation and hydroxymethylation. Paternal sets, detected by the presence of chromosome Y, contained little 5mC, but were enriched in 5hmC, while maternal chromosomes were heavily methylated and contained little 5hmC. Thus, active demethylation in zygotes involves both parental genomes, but is more intensive in paternal genome. Metaphase chromosomes from zygotes had band-specific distribution of 5hmC: R-bands, but not G-bands and pericentromeric heterochromatin, were enriched with 5hmC. In contrast, 5mC did not demonstrate band-specific distribution. In 3-cell embryos, chromosomes with sister chromatids differed both in the levels of 5hmC and 5mC were identified. Number of these asymmetric chromosomes in blastomeres decreased with each cleavage division up to the blastocyst stage. At the blastocyst stage asymmetric chromosomes were rarely encountered. This advocates for the replication-dependant loss of 5hmC and 5mC.
Thus, maternal and paternal chromosomes demonstrate reverse patterns of 5hmC and 5mC at the zygote stage. The number of both methylated and hydroxymethylated chromosomes decrease during cleavage divisions, suggesting replication-dependant loss of modified cytosine.

P01.003-S
Single-tube multiplex-PCR panels of highly polymorphic STR markers for application to prenatal and pre-implantation genetic diagnosis of alpha- and beta-thalassemia and fragile X syndrome

M. Chen[1], *A. S. C. Tan[1], H. Law[2,3], S. S. Chong[1,4];*
[1]National University of Singapore, Singapore, Singapore, [2]KK Women's and Children's Hospital, Singapore, Singapore, [3]Duke-NUS Graduate Medical School, Singapore, Singapore, [4]National University Hospital, Singapore, Singapore.

Alpha- and beta-thalassemia and fragile X syndrome (FXS) rank among the most common monogenic disorders globally. Prenatal diagnosis (PND) and pre-implantation genetic diagnosis (PGD) of these disorders are usually performed by direct mutation detection. Flanking polymorphic markers provide alternative indirect mutation detection through linkage analysis, or serve to corroborate direct mutation testing results. Currently, limited numbers of linked markers have been optimized and validated for PND/PGD of these diseases. We performed *in silico* mining to identify 24, 99 and 122 short tandem repeats (STRs) within 1 Mb on either end of the *HBA*, *HBB* and *FMR1* loci, respectively. Markers with low heterozygosity (HET) and/or polymorphism information content (PIC) after preliminary analysis on 16 anonymous DNAs were dropped, prior to large scale testing on 288 or 480 anonymous DNAs. The 9-plex *HBA* STR set (0.68≤PIC≤0.92; 0.71≤HET≤0.93; 10≤alleles≤34) can be further multiplexed with the Y1 box or other *HBA2* exonic fragments for simultaneous deletion/point mutation detection with linkage analysis, for either HbBart's or HbH disease. The 15-plex *HBB* STR set (0.70≤PIC≤0.89; 0.74≤HET≤0.90; 10≤alleles≤23) is further multiplexed with additional *HBB* exonic fragments to allow simultaneous thalassemia major mutation detection with linkage analysis. The 13-plex *FMR1* STR set (0.40≤PIC≤0.86; 0.49≤HET≤0.87; 6≤alleles≤17) can be analyzed in parallel with *FMR1* CGG repeat expansion mutation detection for FXS, using aliquots of whole genome amplified (WGA) product. All three single-tube multiplex-PCR STR assays have been optimized for use on genomic DNA, single cells, as well as WGA products of single cells.

P01.004-M
Two unusual unbalanced X chromosome rearrangements: a case report

M. Exlerova[1], *V. Wernerova[1], V. Horinova[1], I. Slamova[1,2], H. Filková[2], V. Vallova[2], P. Kuglik[2], J. Sobotka[3], P. Texl[1];*
[1]Sanatorium Helios ltd., Laboratory of Medical Genetics, Brno, Czech Republic, [2]Department of Medical Genetics, University Hospital, Brno, Czech Republic, [3]SpadiaLab a.s., Laboratory of Medical Genetics, Novy Jicin, Czech Republic.

The human X chromosome is characterized by genomic instability and rearrangements, associated with various X-linked disorders such as moderate intellectual disability, muscular dystrophies or reduced fertility. In the Laboratory of Medical Genetics that operates as a department of IVF clinic, we are preferentially focusing on fertility connected scope. Here we show two women presenting amenorrhea associated with de-novo X chromosome aberration. First, we report on the case of a 23-year-old woman presenting phenotype close to isochromosome i(Xq) with short size and primary oligo-amenorrhea. Classical cytogenetic observation revealed a deletion of the chromosomal region Xp11-Xpter. With using FISH, CGH and mBAND methods, de novo duplication in the chromosomal region Xq25q28 was also discovered. As the second case, we describe 30-year-old woman who was referred to our IVF clinic because of infertility and amenorrhoea. At the age of 18 years, she was placed on oral contraceptive pills for cycle activation. Now she has been experiencing amenorrhea again and she has been unsuccessful to become pregnant. The cytogenetic analysis revealed de novo deletion in the Xq21.2-qter region. Further analysis by FISH, CGH and mBAND methods led to the revelation of Xp22.31-pter duplication. If we had contented ourselves only with the classical cytogenetic analysis, both cases could be underestimated as simple X chromosome deletions. However, our detailed observations led us to suspect that a complex aberration may be present. These two cases show that conscientious cytogenetic analysis at 550 ISCN bands level in combination with other molecular methods is essential for accurate diagnosis.

P01.005-S
Anti Müllerian Hormone (AMH) association analysis on about 1,000 caucasian women highlights 2 suggestive loci

C. Barbieri[1], *M. Traglia[1], V. Vanni[1], T. Nutile[2], S. Ulivi[3], L. Portas[4], C. Sala[1], C. Masciullo[1], M. Cocca[1,3], L. Pagliardini[1], M. Ciullo[2], P. Gasparini[3], M. Pirastu[4], P. Panina[1], E. Papaleo[1], A. La Marca[5], D. Toniolo[1];*
[1]Division of Genetics and Cell Biology, San Raffaele Research Institute, Milan, Italy, [2]Institute of Genetics and Biophysics, National Research Council (CNR), Napoli, Italy, [3]Institute for Maternal and Child Health–IRCCS Burlo Garofolo, Trieste, Italy, [4]Institute of population genetics, National Research Council (CNR), Sassari, Italy, [5]Institute of Obstetrics and Gynaecology, University of Modena and Reggio Emilia, Modena, Italy.

AMH is a dimeric glycoprotein member of the TGF-β superfamily expressed in the growing follicles of the ovary. AMH concentration in serum essentially reflects the ovarian follicular pool. AMH levels decreases during reproductive life, becoming undetectable after the menopause. Serum levels vary broadly by the age of decrease of female fertility (~ 41 years): the discovery of genetic variants responsible for the high variability could be useful to predict fertility and age of menopause.
AMH levels were measured in serum of 946 genotyped fertile women <=40 years old, 709 from the Italian Network of Genetic Isolates (INGI) and of 237 from the Obstetrics and Gynecology Unit of San Raffaele Hospital.
A meta-analysis for AMH adjusted for age was performed on genotypes imputed to the low variants enriched 1000G panel. Two suggestive loci were identified: a locus on chromosome 6 (MAF=0.017; p=8.05E-08) and a second locus on chromosome 3 (MAF=0.22; p=2.21E-07).
Meta-analysis will have to be enlarged by additional samples to increase the statistical power of the association analysis. Several hundred samples will be provided by different italian sources and 4,000 young women from Estonia will be available to replicate the results.

P01.006-M
Clinical and cytogenetic features of de novo Wolf-Hirschhorn (4p-) syndrome and partial trisomy 7p confirmed by array comparative genomic hybridization

Y. Suk, *Y. Kim, S. Seo, H. Chi, Y. Cho;*
Samkwang Medical Laboratories, Seoul, Korea, Republic of.

Wolf-Hirschhorn syndrome (WHS) is a well known genetic condition caused by a partial deletion of the short arm of chromosome 4. Although the critical region for determining the phenotype is at 4p16.3, the great variability in the extent of the 4p deletion and the possible contribution of additional genetic rearrangements lead to a wide spectrum of clinical manifestations. Here, we report perinatal diagnosis and molecular cytogenetic characterization of a newborn infant with WHS and partial trisomy of 7p. The patient was a female neonate with facial dysmorphia including ocular hypertelorism, micrognathia, both preauricular pit, low set ears, and short and stubby fingers. Fetal agenesis of the corpus callosum was suspected by cranial ultrasonography. Laboratory analysis showed that she had acute renal failure. Chromosomes analysis by G-banding revealed 46,XX,add(4)(p16.3) karyotype. To delineate the origin of additional genomic gain in chromosome 4, array comparative genomic hybridization (CGH) was performed. Array CGH sho-

wed a 1.34 Mb sized loss on chromosome 4p (4pter-->16.3) and a 32.48 Mb sized gain on chromosome 7p (7pter-->14.3). Therefore, the final karyotype of the patient was defined as 46,XX,der(4)t(4;7)(p16.3;p14.3). The parental karyotypes were normal. In this case, we describe for the first time, as far as we know, the clinical and cytogenetic analysis of a patient with concomitant occurrence of partial of Hirschhorn (4p-) syndrome and partial trisomy 7p. This report suggests that the array CGH would be a valuable diagnostic tool for identifying the origin of small additional genetic materials.

P01.007-S
Preimplantation genetic screening of copy number variations (CNVs) using oligonucleotide-based array comparative genomic hybridization

P. Kuglik[1,2], *D. Paralova[3], J. Smetana[1,2], V. Vallova[1,2], A. Mikulasova[1,2], R. Gaillyova[2], V. Hubinka[3], L. Slivkova[3], S. Machac[3], M. Koudelka[3];*
[1]Department of Genetics and Molecular Biology, Institute of Experimental Biology, Faculty of Science, Brno, Czech Republic, [2]Department of Medical Genetics, University Hospital, Brno, Czech Republic, [3]Reprofit International Ltd., Brno, Czech Republic.

Chromosome aneuploidy is the most prevalent genetic abnormality in human embryos and represents the leading genetic cause of miscarriages. In view of this fact, diagnosis of embryos for chromosome abnormalities using array-CGH, i.e. preimplantation genetic screening (PGS), is suitable way to improve clinical outcomes in patients undergoing in vitro fertilization (IVF). In our work we analyzed of the whole genome profiles from trophoectoderm cells in 23 patients and 9 healthy donors (DEM). Overall, we evaluated 118 embryos using oligonucleotide-based CytoSure Single Cell Aneuploidy Array 8x15K. The copy number abnormalities (CNAs) were found in 23.7% of all embryos. While incidence of CNAs in DEM embryos was 11.8% of samples, CNAs in patient´s embryos occurred in 28.6% of samples. Aneuploidies of chromosomes were observed in 26.7%, segmental imbalances were proved in 6.8% of embryos. In patient´s cohort, we found overall 35 different CNAs. The most common aneuploidies were trisomy 21 and 13 (both 8.3%), whereas the most frequent losses of genetic material were monosomy 8 (12.5%) and 18 (8.3%). Two patients had embryos with complex aneuploidy. Segmental CNAs were found in 5q, 8p, 8q, 14q and 16p. In DEM embryos, we observed two 2 structural CNAs (gain 13q; loss 7p) and 2 cases with aneuploidies (trisomy 19, monosomy 18). This study shows that oligonucleotide array is novel progressive tool for sensitive genome-wide analysis of chromosome instability and opens the route towards high-resolution preimplantation screening which improves selection of embryos and implantation rates. Supported by OP VK CZ.1.07/2.4.00/31.0155 and CZ.1.07/2.3.00/20.0183

P01.008-M
Copy Number Variation (CNV) in azoospermic males

K. L. Eiklid[1], *I. Holm[2], K. Waagner Birkeland[2,3];*
[1]Deparment of medical genetics,Oslo University Hospital, Oslo, Norway, [2]Deparment of medical genetics, Oslo University Hospital, Oslo, Norway, [3]Oslo and Akershus University College of Applied Sciences, Oslo, Norway.

We tested 95 males from the biobank at Department of Medical Genetics, Oslo University Hospital for Copy Number Variations (CNV). All males were azoospermic and referred for infertility testing, but no futher information was known. They had normal karyotype, and no deletion in AzF region on chromosome Y nor mutations in the CFTR gene. As controls we used 94 males from our biobank, who had fathered a child and did not have the abberation found in their child on aCGH.
The samples were run on Agilent technology array comparative genome hybridization with 180K and 400K resolution according to the manufactures procedure. 23 patients were run on 180K aCGH against a single sample control, 35 against a multisample control, and 37 patients on a 400K array with multisample control. We found totally 1863 CNVs in the patient group (19.6/patient) and 973 (10.3/patient) in the control group. For patients and controls run with same resolution (180K) we found 9.2 and 10.3 CNVs per patients.
The CNVs in the control group were subtracted from the patient group. We also eliminated CNV's in regions with no known genes. The remaining 154 chromosome regions were checked for CNV's known for expression or function in testis in the Database of Genomic Variants (DGV). There were no major large chromosome regions common for all patients and no regions earlier described as candidate genes. This left us with 12 new interesting small CNV regions not described before, that might affect male infertility.

P01.010-M
Non invasive prenatal diagnosis of beta-Thalassemia: application of Ion Torrent sequencing and long-range PCR haplotyping in 18 cfDNA samples

L. Saba, *A. Picciau, M. Masala, V. Capponi, M. Rosatelli;*
Dipartimento di Sanità Pubblica, Medicina Clinica e Molecolare, Università degli studi di Cagliari, Cagliari, Italy.

The discovery of fetal DNA in maternal plasma has provided a new source of fetal genetic material that can be safely obtained from maternal blood and successfully processed for non invasive genetic diagnosis (NIPD). We describe a protocol for non-invasive prenatal diagnosis of β thalassemia with a next generation sequencing approach and Ion Torrent technology. Eighteen experiments of NIPD of β-thalassemia have been carried in cfDNAs of women who underwent PD for β-thal. In total, we have amplified and sequenced 47 amplicons mapping in the beta-globinic gene cluster and further 3 amplicons (ZFX/ZFY, SRY and TSPY1) useful to detect fetal sex and fractional fetal DNA. In the validation phase we have included the parental DNAs and trophoblast DNA to infer parental haplotypes inherited from the fetus. In the meanwhile we have developed a protocol to infer parental haplotypes without fetal information. The method is based on haplotype selection by allele-specific long-range PCR (LR-PCR) with allele-specific primers with the 3' base complementary to the mutated or to the normal allele for the most common β-thalassemia mutations. These reactions were performed with an high fidelity polymerase able to amplify genomic targets extending both downstream and upstream the causative mutations. By this approach, the 69.4% of fetal haplotypes, mainly of paternal origin, has been correctly identified in the cfDNAs processed. Following these encouraging results, we are working in order to improve the performance of our platform by extending the analysis to a higher number of SNPs and by developing specific algorithms of analysis.

Conradi-Hunermann-Happle (CDPX2) syndrome is a rare X-linked dominant skeletal dysplasia. It is usually lethal in males, while affected females show wide clinical heterogeneity. Mutations have been reported in EBP, which is involved in cholesterol biosynthesis. To date, severe prenatal occurrence has been reported in only 6 females.
In order to characterize this severe phenotype, we analyzed the 8 prenatally-diagnosed female cases of severe EBP mutations listed in France. The mean age at prenatal diagnosis was 22 weeks of gestation. The ultrasound features included mainly bone abnormalities: shortening (7/8) and bowing of the long bones (4/8), stippled epiphyseal cartilage (5/8) and irregular aspect of the rachis (5/8). The pregnancy was terminated in 6/8 cases. Fetal examination revealed ichthyosis in all cases and skeletal X-rays showed constant epiphyseal stippling, with frequent asymmetrically shortened long bones and bowing. All cases appeared de novo except for two fetuses with moderately affected mothers, who presented ichthyosis and short stature, and one case of germinal mosaicism. In order to explain the high intrafamilial clinical heterogeneity, the X-inactivation pattern was studied in one familial case. Skewed X-inactivation was found in the mother's lymphocytes (cDNA study showed that the wild allele was mainly expressed) and random X-inactivation was found in the different fetal tissues affected.
In conclusion, we report additional cases of severe prenatal CDPX2 presentations in female fetuses. Even though the majority of these were de novo cases, our familial cases argue for careful genetic counselling in this condition.

P01.012-M

Fetal Fraction estimate in twin pregnancies using directed cell-free DNA analysis

C. Struble[1], A. Syngelaki[2], A. Oliphant[1], K. Song[1], K. H. Nicolaides[2,3], **D. Hollemon**[1];
[1]Ariosa Diagnostics, San Jose, CA, United States, [2]Harris Birthright Research Centre of Fetal Medicine, Kings College Hospital, London, United Kingdom, [3]Department of Fetal Medicine, University College Hospital, London, United Kingdom.

Objective: To estimate fetal fraction (FF) in monozygotic and dizygotic twin pregnancies.
Methods: Maternal plasma samples were obtained from 35 monochorionic twin pregnancies with male fetuses (monozygotic) and 35 dichorionic pregnancies discordant for fetal sex (dizygotic) at 11-13 weeks' gestation. Cell-free DNA was extracted and chromosome-selective sequencing with digital analysis of selected regions (DANSR TM) was carried out. The fetal-fraction optimized risk of trisomy evaluation (FORTE TM) algorithm was used to estimate FF using polymorphic alleles. In dizygotic twins the FORTE algorithm was modified to estimate the smallest FF contribution of the 2 fetuses. In both types of twins, FF was also determined by analysis of Y-chromosome sequences. Results: In monozygotic twins, the median total FF was 14.0% (range 8.2-27.0%) and in dizygotic twins the median smallest FF was 7.9% (4.9-14.0%). There were significant associations in FF between the methods using polymorphic alleles and Y-chromosome sequences for both monozygotic ($r = 0.951$, $p < 0.0001$) and dizygotic ($r = 0.743$, $p < 0.0001$) twins.
Conclusions: The study demonstrates the feasibility of an approach for cfDNA testing in twin pregnancies. This involves estimation of total FF in monozygotic twins and estimation of the lower FF of the 2 fetuses in dizygotic twins.

P01.013-S

Prenatal Diagnosis of Aneuploidy by Cell Free Fetal DNA in Maternal Plasma

M. Saberi[1], *M. Akbari*[2];
[1]Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran, [2]Tarbiat Modares University, Tehran, Islamic Republic of Iran.

This study examined the methylation difference in AIRE and RASSF1A between maternal and fetal DNA, and the implication of this difference in the identification of free fetal DNA in maternal plasma and in prenatal diagnosis of trisomy 21. Maternal plasma and amniotic fluid samples were collected from 30 singleton pregnancies. Methylation-sensitive restriction enzymes in digestion of differential maternal-fetal methylation followed by fluorescent quantitative PCR (MSRE + PCR) were employed to detect trisomy 21. Diagnosis of trisomy 21 was established according to the ratio of fetal-specific AIRE to RASSF1A that are hypermethylated in maternal plasma and are not digested with methylation sensitive restriction enzymes. All of the results were approved with karyotype results. Based on the data from 22 euploidy pregnancies, the 95% reference interval of the fetal AIRE/RASSF1A ratio in maternal plasma was 0.33-1.77, which was taken as the reference value for determining the numbers of fetal chromosome 21 in 30 pregnancies. Firstly, 18 from 22 euploidy pregnancies were detected euploid correctly and 4 cases incorrectly so the early sensitivity rate was 81.81% (18/22). But by repeating the test with better digestion, the four cases made correct results so the final sensitivity rate was 100% (22/22). All of the eight trisomy 21 pregnancies were diagnosed with this method correctly so the specificity of this method was 100%. Also with performing STR-Typing and checking paternal alleles in maternal plasma and comparison with maternal alleles in 16 loci, the protocol of cell free fetal DNA extraction from plasma were confirmed.

P01.014-M

Non-invasive EXamination of Trisomy (NEXT) Study: Directedcell-free DNA analysis versus 1st trimester combined screening for Trisomy 21 risk assessment in a large Routine pregnancy population

T. Musci[1], M. Norton[2], H. Brar[3], B. Jacobsson[4], G. Swamy[5], A. Ranzini[6], M. Tomlinson[7], L. Laurent[8], L. Pereira[9], H. Cuckle[10], J. Spitz[11], **D. Hollemon**[1], *R. Wapner[12];*
[1]Ariosa Diagnostics, San Jose, CA, United States, [2]University of California San Francisco, San Francisco, CA, United States, [3]Perinatal Diagnostic Center, Riverside, CA, United States, [4]Sahlgrenska University, Goteborg, Sweden, [5]Duke University School of Medicine, Durham, NC, United States, [6]St. Peter's University Hospital, New Brunswick, NJ, United States, [7]Northwest Perinatal Center, Portland, OR, United States, [8]University of California, San Diego, La Jolla, CA, United States, [9]Oregon Health and Sciences University, Portland, OR, United States, [10]Columbia University Medical Center, New York, NY, United States, [11]Perinatal Quality Foundation, Oklahoma City, OK, United States, [12]Columbia University, New York, NY, United States.

Non-invasive prenatal testing (NIPT) with cell-free DNA (cfDNA) is highly accurate for fetal trisomy evaluation in high-risk pregnancies. Routine pregnancy population NIPT performance has not been evaluated in a large prospective study. Our objective was to compare NIPT with directed cfDNA analysis to first trimester combined screening (FTS) for trisomy 21 risk assessment in a general pregnancy population.
This prospective multi-center blinded cohort study compared HarmonyTM Prenatal Test, a directed cfDNA test, with FTS using first trimester PAPP-A, hCG and nuchal translucency measurement. Women with a singleton fetus presenting in the first trimester for routine prenatal screening for fetal aneuploidy were eligible. Participants had both FTS and Harmony. FTS results were provided as part of routine care. Participants and care providers were blinded to Harmony results, calculated as probability scores. Pregnancies were followed for newborn outcomes. Invasive test results or neonatal phenotype,with karyotype confirmation in cases of suspected aneuploidy, were used for trisomy 21 identification. Harmony, FTS results and outcomes were reported to an independent data coordinating center. Primary outcome was comparison of the area under the ROC curve for trisomy 21 test performance of the Harmony and FTS.
18,955 women were enrolled across 38 centers in USA, Canada and Europe from March 2012 to April 2013. The mean maternal age was 30.6 (18-52) years. The mean gestational age was 12.4 (10-14.3) weeks. Follow-up is complete.
Study results will be presented. Implications for use of NIPT for trisomy 21 risk assessment in the general pregnancy population will be discussed.

A case report of a high level 46,XX/46XY true chimerism without clinical effect in a healthy female who gave birth to healthy twins after IVF

K. Adamová[1], *M. Godava[1], R. Vrtěl[1], J. Dostál[2], J. Ehrmann[3], Z. Slobodová[3], M. Kvapilová[1], H. Filipová[1], P. Čapková[1], R. Vodička[1];*
[1]Department of Medical Genetics and Foetal Medicine, University Hospital and Palacky University, Olomouc, Czech Republic, [2]Center of Assisted Reproduction – Department of Obstetrics and Gynecology, University Hospital and Palacky University, Olomouc, Czech Republic, [3]Department of Clinical and Molecular Pathgology, University Hospital and Palacky University, Olomouc, Czech Republic.

Chimerismis a rare event in humans when two or more genetically distinct cell lines occur in an individual. It is mostly connected with ovotesticular disorder of sexual developpent. We now present a case of high level 46,XX/46,XY
chimerism in a healthy woman who was karyoptyped prior to IVF. The fenotype of the proband was that of a normal woman with an unambiguously female external and internal genitalia.The XX/XY cell lines were detected in peripheral lymphocytes, buccal mucosa, urine sediment and also in all other subsequently biopted tissues: skin, both ovaries,
peritoneum and endometrium.The male cell line was detected by FISH technique(CEP X/Y SateliteIII DNA probes) in all samples at a propotion of 20-50%. The presence of SRY was confirmed using PCR. The chimerism was confirmed by STR multipexes
on chromosomes X, 13, 18, 21 and by STR markers kit (AmpFlSTR Identifiler PCR Amplification Kit). The
result of the analysis proved tetragametic origin of the chimerism.Our proband underwent three cycles of IVF with own oocytes and ICSI. The third cycle was successful. ET of 2 embryos was performed and after normal preganacy healthy female twins were born.

P01.016-M

Cell culture conditions of chorionic villous samples do not modify the genomic imprinting pattern at locus 11p15.5

L. Paganini[1], *S. Giangiobbe[1], R. Silipigni[2], R. Falcone[1], E. Bonaparte[1], M. Calvello[1], M. F. Bedeschi[3], S. Guerneri[2], S. M. Sirchia[4], M. Miozzo[5,6], S. Tabano[1,6];*
[1]Division of pathology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [2]Medical Genetics Laboratory, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [3]Clinical Genetics Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [4]Department of Health Sciences, Università degli Studi di Milano, Milano, Italy, [5]Division of patologi, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [6]Department of Pathophysiology and Transplantation; Università degli Studi di Milano, Milano, Italy.

Methylation of the CpG islands is a common epigenetic marker of gene repression. Monoallelic and parental-specific DNA methylation pattern at the Imprinting Control Region 1 (ICR1) and 2 (ICR2) regulates the expression of IGF2/H19 and KCNQ1/CDKN1C domains at the imprinted locus 11p15.5. Alterations of ICR1 and ICR2 methylation state are common in Beckwith-Wiedemann (BWS) and Silver-Russell (SRS) syndromes and a robust molecular investigation is crucial to support phenotypic evidences, particularly in prenatal diagnosis for BWS. Since it is known that cell culture conditions could per se modify the epigenetic signature of the cells, we aimed to compare ICR1 and ICR2 methylation profile in fresh chorionic villus samples (CVS) with the corresponding cell cultures (CVC) to verify whether methylation at ICRs is stable after cell culture. By pyrosequencing we analyzed 9 CVS and their relative CVC from healthy pregnancies that underwent prenatal

diagnosis for maternal age. The range of methylation levels of ICR1 and ICR2 in control CVS was previously reported by our group (ICR1: 38-48%; ICR2: 37-47%). Herein, we found that the mean methylation percentage of ICR1 and ICR2 remains stable after cell cultures: CVS= ICR1: 44% ± 1,7%; ICR2: 42% ± 1,8%, CVC= ICR1: 44% ± 2,3%; ICR2: 42% ± 3,1%. The high stability of such genomic imprinted regions makes them useful to be investigated in prenatal diagnosis.

P01.019-S
Prenatal diagnosis: chromosomal microarray in fetuses with increased nuchal translucency

E. M. Vestergaard[1], *D. Lildballe*[1], *R. Christensen*[1], *O. B. Petersen*[2], *I. Vogel*[1];
[1]*Department of Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark,* [2]*Department of Gynecology and Obstetrics, Aarhus University Hospital, Aarhus, Denmark.*

Chromosomal microarray has significant advantages over standard metaphase karyotyping for detecting large chromosomal imbalances and alterations smaller than 10 MB in size. The method has besome an important diagnostic instrument in the prenatal setting for pregnancies with abnormal ultrasound findings. In our clinical setting (The Central Region, Denmark), more than 90 % of pregnant women receive combined 1st trimester screening and 2nd trimester anomaly scan via the public health care system. Since January 2013 we have used a two-tiered approach for invasive diagnostics of all foetuses with nuchal translucency > 3.5 mm (99 percentile) in 1st trimester pregnancies. This consists of a fast prenatal analysis for common aneuplodies by QF-PCR followed by chromosomal microarray on samples with normal QF-PCR test results. The analysis methods used are the Elucigene QST*R kit (GenProbe) and comparative genomic hybridization-based microarrays (SurePrint G3 Human CGH microarray 180K, Agilent). DNA was extracted directly from chorionic villus samples using the Maxwell® system.
We demonstrate the usefulness of microarray testing in this clinical setting based on our laboratory experiences.

P01.020-M
Clubfoot as an indication to perform array-cgh on prenatal diagnosis even when isolated?

E. Andreucci[1], *R. Biagiotti*[2], *E. A. Maiandi*[2], *S. Covezzi*[2], *G. Marseglia*[3], *A. Guarino*[2], *E. Cariati*[2], *S. R. Giglio*[1,4];
[1]*Medical Genetics Unit, Meyer Children's University Hospital, Florence, Italy,* [2]*Medical Surgical Feto-neonatal Department, Meyer Children's University Hospital, Florence, Italy,* [3]*Genetic Diagnostics Unit, Careggi University Hospital, Florence, Italy,* [4]*Medical Genetics Unit, Department of Clinical and Experimental Biomedical Sciences, University of Florence, Florence, Italy.*

We report on the first pregnancy of a 31 year old healthy female. At 13+2 weeks of gestation, a combined test was carried out, which showed a calculated risk for trisomy 21 of 1:38 (NT 1,8mm, free β-hCG 1,52MoM and PAPP-A 0,22MoM). The patient decided to undergo chorionic villus sampling which showed a normal foetal karyotype (46,XY). At 17+6 weeks of gestation an ultrasound showed isolated bilateral clubfoot, no further genetic testing was offered. At 19+6 weeks of gestation the ultrasound confirmed the isolated bilateral talipes equinovarus and at 23+5 weeks of gestation hypospadia and dilated hyperechogenic bowel was also noted: array-CGH testing on foetal DNA was offered and the patient accepted. The array-CGH analysis showed a de novo 3,4Mb deletion on 5q31.1 (131825068-135229731) encompassing, among many others, the PITX1 gene, whose heterozygous mutations have been associated with congenital clubfoot and other skeletal anomalies. Patients with partially overlapping deletions have been described in the literature and most share common features like developmental delay, short stature and dysmorphic features. The pregnancy was interrupted at 30 weeks of gestation. This case might suggest that clubfoot, which is generally considered a mainly isolated congenital defect and for which no further genetic testing is offered in prenatal diagnosis, might be the first sign of a more complex picture which could also include other congenital defects and, possibly, developmental delay. Should we consider clubfoot, even when isolated, an indication to perform array-CGH on foetal DNA?

P01.021-S
CNV and Aneuploidy Detection by Ion Semiconductor Sequencing

A. Rico[1], *K. Rhodes*[2], *F. Hyland*[2], *K. Konvicka*[2], *R. Gottimukkala*[2], *G. Altun*[2], *C. Roth*[2], *C. Dowds*[2];
[1]*Thermo Fisher Scientific, Saint Aubin, France,* [2]*Thermo Fisher Scientific, Carlsbad, CA, United States.*

Ion Torrent™ semiconductor sequencing, combined with Ion AmpliSeq™ technology, provides simultaneous identification of copy number variants (CNVs), single nucleotide variants (SNVs), and small insertions and deletions (indels) from a research sample by means of a single integrated workflow. 100% of assayed CNV regions (n=34) were detected using a reference set of 31 samples with known chromosomal aberrations. Low-pass whole-genome sequencing data, with approximately 0.01x read coverage, allowed the rapid ≤10 hour analysis of aneuploidies from research samples with extremely low initial input DNA amounts—even from a single cell. Using a control set of 10 samples with known chromosomal aberrations, 100% of the copy number changes were found, ranging from gains or losses of whole chromosomes to subchromosomal alterations tens of megabases (Mb) in size. The Ion PGM™ System minimizes the high cost and complexity of next-generation sequencing and, with Ion Reporter™ Software, facilitates user-defined CNV and aneuploidy detection, with three sensitivity options so that copy number analysis workflows can be tuned to achieve desired levels of sensitivity and specificity.

P01.022-M
Fetal intracerebral hemorrhage and cataract: think COL4A1

E. Colin[1], *A. Denommé-Pichon*[1], *A. Guichet*[1], *M. Gorce*[1], *S. Chevalier*[2], *E. Tournier-Lasserve*[3], *L. Sentilhes*[4], *D. Bonneau*[1];
[1]*Department of Biochemistry and Genetics, CHU Angers, Angers, France,* [2]*Department of Ophthalmology, CHU Tours, Tours, France,* [3]*Reference Center for Rare Vascular Diseases of the Eye and the Brain, Lariboisière Hospital, Paris, France,* [4]*Department of Obstetrics and Gynecology, CHU Angers, Angers, France.*

The COL4A1 gene encodes the alpha1 chain of type IV collagen, a crucial component of nearly all basement membranes. Mutations in COL4A1 were first associated with cerebral microangiopathy and familial porencephaly and have later been implicated in a clinicopathologic broad-spectrum affecting the brain, eyes, kidneys and muscles. Recently, COL4A1 mutations have also been identified prenatally in fetuses with intracranial hemorrhage (ICH). We report two additional prenatal cases of COL4A1 mutations in fetuses with ICH and cataract.
Case 1: Fetal ultrasound examination (US) at 23 weeks' gestation (WG) showed left cataract, left ventriculomegaly and hyperechogenic lesion of basal ganglia. Fetal magnetic resonance imaging (MRI) at 32 WG confirmed the subependymal hemorrhage affecting the left hemisphere.
Case 2: Fetal US examination at 31 WG showed hyperechogenic lesion in left hemisphere with thalamic echogenicity and bilateral cataract. Fetal MRI at 32 WG showed a left-sided periventricular parenchymal hemorrhage and mild ventriculomegaly.
In both these cases, the involvement of COL4A1 was evoked because congenital cataracts had been previously reported in association with ICH in pediatric cases.
The sequencing of COL4A1, performed on fetal DNA after termination of pregnancy, evidenced two heterozygous novel missense mutations c.2317G>A (p.Gly773Arg) and c.3005G>A (p.Gly1002Asp) in fetuses 1 and 2 respectively.
The two cases reported here show that the COL4A1 mutation should be envisaged in fetuses with prenatal ICH especially in the presence of lens abnormalities at US examination. Molecular confirmation of a COL4A1 mutation may have important implications for the outcome of the pregnancy and for genetic counseling.

P01.023-S
Validation And Clinical Application Of A Next-Generation Sequencing (Ngs)-Based Protocol For 24-Chromosome Aneuploidy Screening Of Embryos

F. Fiorentino[1], *A. Biricik*[1], *S. Bono*[1], *L. Spizzichino*[1], *E. Cotroneo*[1], *G. Cottone*[1], *F. Spinella*[1], *F. Kokocinski*[2], *C. Michel*[2], *M. Minasi*[3], *E. Greco*[3];
[1]*"GENOMA" - Molecular Genetics Laboratory, ROME, Italy,* [2]*BlueGnome Ltd, Cambridge, United Kingdom,* [3]*European Hospital, Reproductive Medicine, ROME, Italy.*

The rapid development of next-generation sequencing (NGS) technologies has generated an increasing interest in determining whether NGS could be reliably used for preimplantation genetic screening (PGS), i.e. for comprehensive aneuploidy screening of human embryos produced from patients undergoing in-vitro fertilization treatments, with the purpose of identifying and selecting for transfer euploid embryos.
We performed a large validation study to determine the accuracy of a NGS-based 24-chromosomes aneuploidy screening protocol. NGS ability to accurately identify aneuploidy was assessed in three steps: 1) a blind evaluation of karyotypically-defined chromosomally abnormal single cells; 2) a retrospective blinded assessment of 244 embryos previously analyzed by array-comparative genomic hybridization (aCGH); 3) a prospective trial involving a parallel evaluation of 192 blastocysts, from 55 clinical PGS cycles, with both NGS and aCGH techniques.
The NGS method was robust, with 454/454(100%) samples yielding results. Aneuploidy diagnoses were fully concordant with those obtained using aCGH technique. NGS was also able to detect chromosomal mosaicism in 54/54(100%) of mosaic embryos assessed. Clinical application of the NGS

protocol revealed 76(39.6%) euploid blastocysts. Following transfer of 50 embryos, 30 women had a sustained pregnancy (63.8% clinical pregnancy rate/ET; 64.0% implantation rate).
This is the first study reporting extensive validation and clinical application of NGS for PGS purpose, allowing identification and transfer of euploid embryos resulting in healthy pregnancies. Evidence of accuracy demonstrates that NGS represents a reliable high-throughput methodology for comprehensive aneuploidy screening, capable of detecting whole chromosome aneuploidies and segmental changes in embryos, with the potential to revolutionize preimplantation diagnosis.

P01.025-S
A new case of Apert's syndrome detected prenatally in Romania

M. Militaru[1], *A. Trifa*[2,3], *R. Popp*[2], *C. Andrei*[3], *M. Stefanut*[3], *T. Kovacs*[4], *M. S. Militaru*[2,3];
[1]*University of Medicine and Pharmacie"Iuliu Hatieganu", Department of Pediatrics 2, Cluj-Napoca, Romania,* [2]*University of Medicine and Pharmacie"Iuliu Hatieganu", Department of Medical Genetics,, Cluj-Napoca, Romania,* [3]*Genetic Center, Cluj-Napoca, Romania,* [4]*University of Medicine and Pharmacie"Iuliu Hatieganu" Department of Obstetric and Gynecology I, Cluj-Napoca, Romania.*

Apert's syndrome (Acrocephalo-syndactyly) is a rare congenital condition characterized by primary craniosynostosis, mid face malformations and symmetrical syndactyly of the hand and feet. The incidence of Apert's syndrome is about 15/1.000.000 live birts and is inherited in an autosomal dominant fashion, but sporadic cases are also frequent. Case report: A 32-year-old, gravida 4, para 0 woman was referred for fetal evaluation at 22 weeks of gestation because of digital abnormalities in the fetus. A prenatal ultrasound at 22 weeks of gestation revealed frontal bossing, low set ears, depressed nasal bridge, digital fusion, and bilateral syndactyly of the hands and feet. Amniocentesis was performed and the cytogenetics and the molecular test was done. A DNA testing for the FGFR2 gene was immediately performed using uncultured amniocytes, which revealed a heterozygous (P253R) mutation in the FGFR2 gene. The karyotype was normal, 46,XY. The woman decided to discontinue the pregnancy, and a male baby was delivered with frontal bossing, midface hypoplasia and bilateral syndactyly of the hands (mittenhands) and feet. Conclusions: A molecular analysis of FGFR2 using uncultured amniocytes is useful for rapid confirmation of Apert syndrome at prenatal diagnosis. The baby was the first case with Apert's syndrome confirmed by genetic testing in Romania.

P01.026-M
Could a combination of QF-PCR and SNP-array methods replace standard karyotyping in CVS?

J. Hodacova, *V. Becvarova, N. Jencikova, H. Pekova, J. Horacek, J. Sehnalova, M. Louckova, R. Mansfeldova, E. Svobodova, V. Nedomova, L. Hnykova, H. Hroncova, M. Putzova, I. Soldatova, L. Krautova, D. Stejskal, M. Trkova;*
Gennet, Prague, Czech Republic.

In the 2010 - 2014 period 689 chorionic villus sampling **(**CVS) were successfully performed. QF-PCR and a complete chromosomal examination (karyotyping) was a standard examination schema for all samples. Abnormal results were found in 184 samples (26.9 %). Totally 165 (89.7 %) cases out of these 184 pathological results has been announced by QF-PCR (most frequently an autosomal aneuploidy) prior to karyotyping. This is in contrast to 19 abnormal findings detected only due to classic chromosomal examination (9 balanced aberrations, 9 mosaics of both autosomes and gonosomes, 1 unbalanced aberration). In the same period of time 102 CVS (with normal karyotype and QF-PCR results) were evaluated by SNP-array (Illumina). Well-defined pathogenic microdeletions or microduplications were detected in 7 CVS (6.8 %) indicated from following reasons: increased nuchal translucency (5 cases), heart defect (1 case) and anal and esophageal atresia (1 case).
In our study, an examination of CVS based on QF-PCR method only would let 19 abnormal findings (2.5%) undetected out of which only 10 (1.45 %) are defined as pathological (9 mosaics of both autosomes and gonosomes, 1 unbalanced aberration). In all 10 cases we suppose that these aberrations would be detected by SNP-array evaluation. In addition to it, re-examination of CVSs with normal karyotypes and QF-PCR results by SNP-array allowed us to detect another 7 submicroscopic pathological abnormities. Based on these data we consider the classic karyotype examination to be still an invaluable part of the CVS testing procedure.

P01.027-S
Invasive prenatal diagnosis in bizkaia: a 20-year experience

I. Huerta[1,2], *M. Télez*[1,2], **M. Arrieta**[2], *M. Barasoain*[2], *L. Iglesias*[3], *I. Riveiro*[1], *J. Muga*[3], *M. Longa*[3];
[1]*GENETIC Laboratory, Bilbao, Spain,* [2]*Department of Genetics, Physical Anthropology and Animal physiology, Faculty of Science and Technology, University of the Basque Country, Leioa, Spain,* [3]*Virgen de Begoña Clinical Analysis Laboratory (Medikosta), Erandio, Spain.*

Objective: To analyze trends in the number of invasive procedures and the incidence of chromosomal abnormalities over a 20-year single institution experience
Methods: Data of 16,894 invasive prenatal procedures performed between 1993 and 2013 in Bizkaia were retrospectively reviewed, with particular emphasis on indications
and number and type of abnormal results. Results: Traditionally, maternal age has been the main referral reason for prenatal testing (69.3%) but during the last 3 years, prenatal screening has become the
most important clinical indication, decreasing the number of invasive procedures performed. Related to karyotype analysis, chromosomal abnormalities were detected in 348 out of the 16,894 (2.55%) cytogenetic studies. Among chromosome aneuploidies (1.55%), the most frequent ones were classical autosomal aneuploidies (1.09%): Trisomy 21, 18 and 13 were diagnosed in 115 (0.94%), 23 (0.07%) and 9 (0.06%) cases respectively. Sex chromosome neuploidies were found in 59 cases (0.46%), being Klinefelter Syndrome the most common sex aneuploidy diagnosed (0.16%). Balanced rearrangements corresponded to 0.67% of the structural abnormalities while unbalanced rearrangements were found in 16 cases (0.15%). Conclusion: Nowadays, positive prenatal screening has progressively replaced advanced maternal age as the main referral reason for amniocentesis. Our study based in 16,894 amniocentesis contributes to establish a standard reference incidence of chromosomal abnormalities in pregnancies. Our data also confirm the karyotype as a reliable method for detecting complex chromosome abnormalities, providing an important basis for prenatal counseling and for prenatal screening policy in the national strategy.

P01.028-M
Observations following commercial implementation of a cell-free DNA (cfDNA) and single-nucleotide polymorphism (SNP)-based non-invasive prenatal aneuploidy test (NIPT)

K. Curnow, **E. Valenti**, *A. Ryan, M. Banjevic, S. Shchegrova, M. Hill, B. Zimmermann, M. Hall, Z. Demko, M. Rabinowitz;*
Natera Inc., San Carlos, CA, United States.

Objective: To describe the clinical observations following implementation of a SNP-based non-invasive prenatal aneuploidy test in more than 28,000 pregnant women.
Methods: 28,709 consecutive cases reported since March 2013 for NIPT. Isolated cfDNA was amplified via multiplex PCR targeting 19,488 SNPs covering chromosomes 13, 18, 21, X, and Y. Sequencing data was analyzed the NATUS algorithm. Reports were issued describing risk for trisomy 21, trisomy 18, trisomy 13, and Monosomy X, and in a subset of cases triploidy, sex chromosomes trisomies and fetal sex. All reports included fetal cfDNA fraction. Follow-up information on samples receiving a high-risk result for trisomy 21, trisomy 18, trisomy 13, or Monosomy X was collected from providers.
Results: 510 (1.8%) cases received a high-risk NIPT result for any of the four main indications (325 trisomy 21, 83 trisomy 18, 41 trisomy 13, 61 Monosomy X). Of the 28,709 cases, 49% were under 35 years of age. 17,529 low-risk results and 358 high-risk results were reported to centers participating in follow-up efforts. A response to requests for follow-up information was received for 317/358 (88.5%) of the high-risk patients; including 120 calls (33.5%) with karyotype. These requests identified 21 false positives (8 trisomy 21, 1 trisomy 18, 8 trisomy 13, 4 Monosomy X). Two (0.01%) trisomy 21 false negative results were voluntarily reported.
Conclusions: Performance of this SNP-based approach in a clinical setting, when adopted by a large and diverse population and distribution base, appears consistent with previously reported validation performance characteristics.

P01.029-S
Non-invasive prenatal testing of fetal aneuploidies and follow-up

G. H. Schuring-Blom[1], *M. G. Elferink*[1], *P. van Zon*[1], *O. Akkermans*[1], *K. A. Kusters*[1], *W. van Haren-van ,t Woud*[1], *E. de Bruijn*[2], *G. C. M. L. Page-Christiaens*[3], *K. D. Lichtenbelt*[1], *M. J. A. van Kempen*[1], *I. J. Nijman*[1], *G. van Haaften*[1], *B. van der Zwaag*[1], *E. Cuppen*[1], *J. K. Ploos van Amstel*[1];
[1]*Department of Medical Genetics, University Medical Center Utrecht, Utrecht, Netherlands,* [2]*Hubrecht Instutute, University Medical Center Utrecht, Utrecht, Netherlands,* [3]*Department of Obstetrics, University Medical Center Utrecht, Utrecht, Netherlands.*

In the Netherlands the Minister of Health has licensed noninvasive prenatal trisomy testing (NIPT) as from April 1st 2014, for women with a risk above 1:200 based on the first trimester combined test . In anticipation, we validated the SOLiD WildFire on 154 blood samples obtained from pregnant women opting for invasive testing. We show a false negative result in a trisomy 18 case: a growth retarded fetus, small placenta, and maternal BMI of 29 may have resulted in a low fetal fraction. We also present a case of a super-

numerary derivative chromosome, partly consisting of chromosome 13 material: an example of unexpected findings with NIPT. In 2013, thousands of Dutch women had NIPT performed abroad, at their own expense. In one of these women, who had received normal NIPT results, fetal anomalies were seen at the 20 week ultrasound. Invasive testing showed a trisomy 18. NIPT was repeated in our centre prior to amniocentesis, and it clearly indicated a trisomy 18. Placental and fetal biopsies, investigated with FISH after termination of pregnancy, confirmed this finding. Data of the initial NIPT could not be shared with us, which prohibited tracing of the source of this false negative finding. False negative, false positive and unexpected results will be obtained with NIPT. For safeguarding and examining follow up samples, leading to a further understanding of possible underlying biological causes, close interaction between specialists involved is essential. This is also vital to ensure adequate care and counseling for couples confronted with such results.

P01.030-M
Dyscordant Chromosomal Finding in Monozygotic Twins

P. Losan, *M. Hasch;*
Genetika Plzen, Pilsen, Czech Republic.

Losan P.,Hasch M., Planetova S.Genetics-Pilsen, Pilsen, Czech Republic
We investigate a patient PL aged 34 after spontaneous pregnancy in 17 th weeks of her gestation with monozygotic twins having dyscordant chromosomes. Literature describes mosaicism only in over 20 cases if more foetal tissues were examined. Our case report refers to different twins chromosomal finding represented by lines 47, XXX/45, X. Amniocentesis because of patological NT (4,7mm) by fetus B proved fetus A (47, XXX/46,XX), and fetus B (45,X/46,XX). In our first genetic examination by QF PCR we demostrated trisomy of chromosome X in fetus A, and chromosome monosomy X in fetus B. Second FISH analysis of native amniocytes proved in fetus A chromosome X in 79% of its nuclei (21% with normal set of chromosome XX), in fetus B monosomy of chromosome X in 95% of nuclei (5% with normal set of chromosome XX). The 3 rd FISH exmination of cultured amniocytes confirmed in fetus A trisomy of chromosome X in 95% of its nuclei (5% with normal set of sex chromosome), in fetus B monosomy of chromosome X in 98% of nuclei (2% with normal set of sex chromosome). Pregnancy finished in 25 th week by spontaneous delivery (stillborn fetus B with monosomy X, 1120g/30cm, fetus A with trisomy X 675g/30 died 17 days after delivery owing to sepsis). Our case report is shrouded in question: at what stage of embryonic development occurred an error?

P01.031-S
Embryo quality and early pregnancy loss after IVF

P. Motyreva, M. Serkova, **K. Sinkov**, *S. Ustinov, I. Ayzikovich;*
Avicenna Medical Center, Novosibirsk, Russian Federation.

Genetic disorders are of the most common reasons of early pregnancy loss. Chromosome abnormalities can be found in up to 70% karyotypes of chorionic villi after miscarriages of both spontaneous and IVF pregnancies.
Here we find out if embryo quality is a sufficient criterion of successful pregnancy outcome after IVF, and identify the relationship between the embryo morphology and chromosomal pathology in spontaneous abortions or missed miscarriages.
We analyzed 45 samples from patients underwent dilation and curettage after IVF. Chromosome preparations were made using direct material processing, GTG-stained or FISH was performed on chromosomes 13,16,18,21,22,X,Y.
Embryo transfer (ET) was performed at the day 5 of embryo development. In the most (76%) cases 2 embryos per woman were transferred. All embryos were divided into groups based on their quality. Day 5 blastocysts AA were defined as 'excellent'; AB, BA, BB as 'good'; BC, CB, C as 'poor' quality. Chromosome abnormalities were found in 53% cases. In these cases 25% were ET of excellent embryos, 63% were ET of good, and 12% were ET of poor. In abortions with normal karyotype 33% of ETs were with excellent embryos, 66% with good. Control group was 53 cases of live birth after IVF at the same period of time. In these successful pregnancies 41% were ETs with excellent embryo quality, which is significantly higher than in pathology group. Otherwise, embryos of excellent and good quality also need preimplantation genetic diagnosis, because chromosomal anomalies in more than 70% cases could be identified using this technique.

P01.032-M
ESX1 gene expression is a predictive marker of residual spermatogenesis in azoospermic males

S. Tabano[1,2], *A. Pansa*[1,3], *S. Melis*[4], *S. M. Sirchia*[5], *E. Bonaparte*[2], *D. Giacchetta*[4], *M. Castiglioni*[4], *G. M. Colpi*[4], *M. Miozzo*[1,2];
[1]*Department of Pathophysiology and Transplantation; Università degli Studi di Milano, Milano, Italy,* [2]*Division of Pathology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy,* [3]*A.O. Papa Giovanni XXIII, Medical Genetics Unit, Bergamo, Italy,* [4]*Andrological-urology unit and IVF center, San Paolo Hospital, Milano, Italy,* [5]*Department of Health Sciences; Università degli Studi di Milano, Milano, Italy.*

ESX1 mRNA expression was previously investigated by our group in testicular biopsies of infertile men and correlated to the presence of residual spermatogenesis in Non Obstructive Azoospermic (NOA) patients. Here, we further deepen this issue investigating by real-time PCR ESX1 expression in both testicular fragments (TF) and seminal fluids (SF) of 78 NOA men. The aim was to verify whether a positive ESX1 expression in TF or even in SF was predictive of a successfully sperm recovery at TESE/microTESE. Concerning TF, ESX1 mRNA levels: 1) significantly decrease with the increasing of spermatogenesis defect, as classified by histology; 2) are higher in dilated tubules, likely containing spermatozoa, compared to thin ones. In addition, the presence of a positive or negative testicular expression of ESX1 strongly correlates ($p<0.0001$) with positive or negative sperm recovery at surgery. Regarding SF, ESX1 mRNA expression was detected in the ejaculate of 44/56 azoospermic men, at lower levels than normospermic men ($p<0.05$). No significant differences were found in ESX1 expression levels among samples with different degree of spermatogenic failure, based on histological classification. Regarding spermatozoa recovery and ESX1 expression in SF, the two variables were concordant in 33/56 (59%) of cases. The overall data reinforce a correlation between a positive ESX1 mRNA detection and residual spermatogenesis in testes of NOA patients, indicating a role of ESX1 as predictive spermatogenesis molecular marker. We can speculate that in SF discrepancies between ESX1 expression (+) and sperm retrieval (-) could be attributed to limitations in surgery techniques for sperm recovery.

P01.033-S
The importance of fœtal pathology. Regional assessment report for Montpellier for the years 2010 to 2012

P. Blanchet, *N. Bigi, Y. Musizzano, S. Doutre, D. Genevieve, P. Sarda, M. J. Perez;*
Genetic Center - Arnaud de Villeneuve Hospital, Montpellier, France.

The Languedoc-Roussillon region in the South of France has a population of about 2 800 000. Over the period extending from 2010 to 2012 the number of births in this region was 91 715. Over the 3-year period 910 requests for termination of pregnancy (TOP) were authorized. 92% of these TOPs were done for serious congenital anomalies. 50% of the TOPs were performed for serious malformation syndromes without a precise genetic cause determined during the prenatal period. In order to characterise fœtal anomalies, maternities in the region are encouraged to send fœtuses to the Fœtal Pathology Unit for genetic investigations and an autopsy. Over the 3-year-period 985 fœtuses were received for expertise either following accidental fœtal demise or TOP (n=436). In 30% of cases fœtal pathology showed additional anomalies undetected on fœtal ultrasound examination and in 7% of cases the pathology results considerably modified the initial prenatal ultrasound diagnosis. In fœtuses addressed for diagnosis of a syndrome, genetic investigations and autopsy revealed 20% chromosome abnormalities and in 6% of cases put a name on various malformation syndromes (VATER association, CHARGE, Smith Lemli Opitz syndromes, osteochondrodysplasias, ⋯). The malformations most commonly implicated were central nervous system anomalies (33%), skeletal anomalies (30%), heart defects (18%) and urinary tract malformations (14%). Fœtal pathology clarifies fœtal anomalies, determines whether a particular genetic syndrome is involved and reveals chromosome anomalies undiagnosed before TOP. This information is important for families (genetic counselling) and for the physicians who managed the interrupted pregnancy or decided on the TOP.

P01.034-M
Analysis of FMR1 and FMR2 genes in women with primary ovarian insufficiency from the Basque Country

M. Barasoain[1], *G. Barrenetxea*[2], *I. Huerta*[1,3], *M. Télez*[1,3], *A. Carrillo*[2], *C. Pérez*[2], *E. Ortiz-Lastra*[4], *J. González*[4], *B. Criado*[5], **M. Arrieta**[1];
[1]*Department of Genetics, Physical Anthropology and Animal Physiology. Faculty of Science and Technology. University of the Basque Country, Bilbao, Spain,* [2]*Center for Reproductive Medicine and Infertility Quirón Bilbao, Bilbao, Spain,* [3]*Virgen de Begoña Clinical Analysis Laboratory (Medikosta), Erandio, Spain,* [4]*Department of Medical-Surgical Specialities. Faculty of Medicine. University of the Basque Country, Bilbao, Spain,* [5]*Cooperativa de Ensino Superior Politecnico e Universitario, Porto, Portugal.*

Primary ovarian insufficiency (POI) is an ovarian dysfunction defined as irregular menses and elevated gonadotrophin levels before or at the age of 40 years. Several genes have been reported as having significance in POI but the FMR1 (intermediate and premutation alleles) is one of the most important genes associated with it. The FMR2 gene has also been related with the development of this condition. A group of 68 women with POI and 47 control women from the Basque Country has been analyzed. Considering the FMR1 gene, the number of women carrying at least one allele with >35 CGG

repeats (intermediate and premutation alleles) was statistically higher in patients (26.47% vs. 0%). The patient group was divided in three categories concerning their ovarian condition. Among patients with amenorrhea and elevated FSH levels, the frequency of alleles between 35 and 54 CGG was statistically higher than in controls (15% vs. 0%). This frequency is also statistically higher among women with irregular menses and elevated FSH levels (11.11% vs. 0%). Regarding the FMR2 gene, small alleles with fewer than 11 repeats have been associated with premature ovarian failure. The frequency of these alleles in this study is not statistically different (3.68% vs. 3.19%). The data suggest that carrying more than 35 CGG repeats in the FMR1 gene might be related with the development of POI. However, the FMR2 gene has not a clear association with this ovarian dysfunction.

P01.035-S

Follicle stimulating hormone receptor gene alterations and ovarian response to gonadotropins in Iranian infertile women

S. Zari Moradi[1], *A. Mohseni Meybodi*[1], *N. Masoudi*[1], *M. Totonchi*[1], *N. Mirghavam Aldin*[2], *M. Ashrafi*[2], *M. Akhound*[3], *H. Gourabi*[1];

[1]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for reproductive Biomedicine ,ACECR., Tehran, Islamic Republic of Iran,* [2]*Department of Endocrinology and Female Infertility at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR,, Tehran, Islamic Republic of Iran,* [3]*Department of Epidemiology and Reproductive Health at Royan Institute for Reproductive Biomedicine, Royan Institute for Reproductive Biomedicine, ACECR,, Tehran, Islamic Republic of Iran.*

Diminished Ovarian Reserve(DOR) and Ovarian Hyper Stimulation Syndrome(OHSS) are infertility disorders in which women's ovaries don't have proper response to gonadotropins. Follicle stimulating hormone(FSH) has a critical role in the maturation of the ovarian follicles from the antral to the graffian stage. FSH will start a signaling cascade in the granulosa cells after sitting on its receptor(FSHR). Alteration of this receptor may change follicle maturation and therefore result in improper response to gonadotropins. We investigated the association of FSH receptor gene alteration in DOR and OHSS patients. The presence of P.Ala307Thr, P.Ser680Ala, P. Ala665Thr and Mut.Val341Ala were analyzed in a case control study. 31 Iranian DOR and 34 Iranian OHSS patients were selected as the case group. 30 Iranian fertile women were enrolled as the control group. The patients DNA were extracted from their peripheral blood and amplified by relevant primers. For determining allelic variant status all PCR products were analyzed by Sequencing. The results were unexpected; the homozygous Ser680 and Ala307 variants seem to be significantly associated with OHSS. The FSHR P.Ala665Thr genotype frequency was similar in all patients and controls. The number of oocytes retrieved was comparable between patients with different FSHR genotype. Although data are accumulating with evidence suggesting that the ovarian response to gonadotropins is mediated by different genetic alterations, as in some previous studies homozygousity for Ser680 was significantly associated with DOR, the optimal biomarkers and the efficacy of the tests still remain to be evaluated.

P01.036-M

New molecular approaches for the detection of free fetal DNA

C. Germani[1], *M. V. Capogna*[2], *R. Cascella*[1], *M. Ragazzo*[1], *S. Zampatti*[1], *C. Strafella*[1], *G. Novelli*[1], *A. Pietropolli*[2], *E. Piccione*[2], *E. Giardina*[1,3];

[1]*Department of Biomedicine and Prevention, School of Medicine, University of Rome "Tor Vergata", Rome, Italy,* [2]*Section of Gynecology and Obstetrics, Academic Department of Biomedicine and Prevention, University Tor Vergata , Rome , Italy, Rome, Italy,* [3]*Laboratorio di Genetica Molecolare UILDM, Fondazione Santa Lucia, Rome, Italy.*

One of the major effort in medical genetics is the development of non-invasive prenatal diagnosis, aimed to replace current invasive methodologies. It is well known that the circulating free fetal cells may be employed as a new alternative source of DNA for prenatal diagnosis, in order to avoid the risks associated to invasive diagnosis. The cell free fetal DNA (cffDNA) in maternal plasma or serum allows the development of non-invasive method for the detection of chromosomal and molecular diseases. The same approach can be even applied to determine fetal sex and the risk for X-linked genetic disorders.

To date, several techniques, such as PCR, Real Time PCR, Next Generation Sequencing, have been employed for cffDNA analysis. Here we propose a new molecular technology (Plexor® HY System), based on Real Time PCR for fetal sex determination. The Plexor® technology takes advantage of the specific interaction between two modified nucleotides and the reduction in fluorescence. The qPCR approach allows the simultaneous quantification and detection of fetal sex in pregnant women. Peripheral blood samples were obtained from 50 pregnant women at the 12th to 14th gestational week and the cffDNA was isolated from maternal plasma.

Determination of fetal sex of all samples demonstrated a concordance of 100% with the results obtained by traditional method (karyotyping). We also observed, as expected, that cffDNA increases together with gestational age.

The experimental data demonstrate that non-invasive and molecular methodologies are able to determine the fetal sex and quantify the cffDNA.

P01.037-S

FSHB -211 G/T polymorphism affects hormonal levels and sperm parameters

L. Tamburino[1], *V. Tomaselli*[2], *N. Barone*[1], *R. Condorelli*[1], *L. Cimino*[1], *S. La Vignera*[1], *E. Vicari*[1], *A. Calogero*[1];

[1]*Department of Medical and Pediatric Sciences, Section of Endocrinology, Andrology and Internal Medicine. University of Catania, Catania, Italy,* [2]*Department of Political and Social Sciences, University of Catania, Catania, Italy.*

FSHB gene transcription is the rate-limiting step for FSH production. The *FSHB* -211 G/T single-nucleotide polymorphism (SNP) is the only genetic variant which has a major effect on serum FSH concentrations in men. The aim of this study was to evaluate the effects of this *FSHB* SNP on male infertility. The SNP was analyzed in 83 men with oligoasthenozoospermia/azoospermia (group 1) and in 82 normozoospermic controls (group 2). Genotyping of SNP was performed by Real-time PCR with TaqMan Genotyping Assay. The *FSHB* genotypes frequencies were: 74.4% (GG), 22.7% (GT) and 2.9% (TT). The distribution frequency of heterozygous and homozygous T carriers was significantly different between the two groups: 65.8% of GT heterozygotes and 100% of TT homozygotes were found in group 1 (Z-test, p=0.0057). The T allele frequency was statistically different in the two groups: 18,6% and 7,9% in group 1 and 2, respectively (Z-test, p=0.007). Moreover, the FSH serum levels were differently distributed with a trend from the highest values in the GG genotype to the lowest levels in the TT genotype (Kruskall-Wallis test: p=0.037). The T allele was associated with significant declining levels of LH, testosterone (GG+GT vs. TT and GG vs. TT (p<0.05, ANOVA) and sperm concentration (p<0.05, Median test). These results corroborate the observation that the highly conserved promoter regions of the *FSHB* gene have a regulatory function on the transcription of this gene and demonstrate convincingly that the promoter variant may be involved to the modulation of testicular functions both in healthy and infertile men.

P01.038-M

Noninvasive prenatal diagnosis of Huntington disease in the Netherlands; a validation study

J. M. E. van den Oever, *E. K. Bijlsma, E. Bakker, M. J. van Belzen, E. M. J. Boon; Leiden University Medical Center, Leiden, Netherlands.*

Huntington disease (HD) is a progressive neurodegenerative disorder, that presents with motor symptoms, cognitive impairment and psychiatric disturbances. HD is caused by the expansion of an unstable polymorphic trinucleotide $(CAG)_n$ repeat in exon 1 of the *HTT* gene.

Our facility is the only laboratory for diagnostics of HD in the Netherlands. About one third of the requests for molecular prenatal diagnostics we receive are for HD. However, molecular testing is performed on fetal DNA derived from invasive procedures. Therefore, there is a request for alternative, less invasive methods. Noninvasive prenatal diagnosis (NIPD) using total cell-free DNA (cfDNA) from maternal plasma for the detection of paternally inherited mutations in the fetus is achievable for a range of genetic disorders. In this study, we have explored the use of NIPD for HD. We have compared our methods to previously described methods and subsequently optimized and validated them.

Since 2010, n=17 couples have been included in this validation study, resulting in maternal blood samples from n=22 pregnancies. Using a combination of PCR and fragment analysis, paternally inherited fetal CAG repeat length was determined using total cfDNA. All results were confirmed on genomic DNA derived from chorionic villi.

The full range of fetal CAG repeats tested in this cohort was 15-70 repeats. We show that paternally inherited repeats in the intermediate and affected range can be detected in a large background of maternal cfDNA. In addition, ins and outs of detecting trinucleotide repeats in fragmented cfDNA from maternal plasma will be discussed.

P01.039-S

Perinatal hypophosphatasia: A case of extreme intrafamilial variability

D. Myles Reid[1], *K. Fong*[2], *S. Keating*[3], *S. Viero*[4], *K. Chong*[1];

[1]*Department of Obstetrics and Gynecology, The Prenatal Diagnosis and Medical Genetics Program, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada,* [2]*Department of Medical Imaging, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada,* [3]*Department of Pathology and Laboratory Medicine, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada,* [4]*Department of Pathology and Laboratories, North York General Hospital, Toronto, ON, Canada.*

Hypophosphatasia (HPP) is a clinically diverse condition characterized by defective bone and/or teeth mineralization in the presence of low activity of serum and bone alkaline phosphatase. Perinatal lethal and infantile forms of HPP have autosomal recessive mode of inheritance with prenatal ultrasound and postnatal x-rays showing extreme skeletal hypomineralization that often results in neonatal death. Intrafamilial variability for autosomal recessive conditions is rare and HPP is not an exception; however, occasionally unexplained variations have been noted among affected siblings. We report a family with extreme variability in the perinatal presentation of HPP. The couple had two pregnancies affected with HPP confirmed by DNA analysis showing compound heterozygous mutations in the ALPL gene. Fetal ultrasound in the first affected pregnancy showed short long bones, fractures and demineralization of the skull at 16 weeks gestation. The second affected pregnancy had normal skeleton and normal growth of long bones at both 16.5 and 19.5 weeks gestation ultrasound. Both pregnancies were terminated in the second trimester. Fetal autopsy on the first fetus confirmed the prenatal ultrasound findings while external examination and x-rays on the second fetus showed few significant findings of perinatal HPP. This case emphasizes that in HPP prenatal diagnosis should rely on molecular analysis rather than ultrasound and suggests that other genetic or prenatal environmental factors can significantly modify the phenotype even in known lethal skeletal dysplasias.

P01.040-M

Additional Genetic Testing in case of increased Nuchal Translucency and normal Karyotype

K. Muru[1,2], *T. Reimand*[1,2,3], *M. Sitska*[1], *R. Zordania*[1], *Ü. Murumets*[1], *P. Ilisson*[1], *K. Õunap*[1,2];
[1]*Department of Genetics, United Laboratories,Tartu University Hospital, Tartu, Estonia,* [2]*Department of Pediatrics, University of Tartu, Tartu, Estonia,* [3]*Department of Biomedicine, Institute of Biomedicine and Translation Medicine, University of Tartu, Tartu, Estonia.*

In fetuses with increased nuchal translucency (NT ≥ 3 mm), after exclusion fetal chromosomal anomaly, more than 100 different developmental/genetic syndromes are reported, most of them are unique and difficult to diagnose before birth. At the same time the anxiety of prospective parents needs to be reduced and exclusion of at least some genetic disorders may be helpful. Our study group consisted of 51 fetuses with increased NT and normal karyotype (analyzed at Tartu University Hospital in 2012-2013). For genetic testing the arrayed primer extension system was used, allowing to examine different genetic diseases with same test: Noonan syndrome (NS) (PTPN11, SOS1, KRAS, RAF, MEK1); Smith-Lemli-Opitz syndrome (SLOS); congenital adrenal hyperplasia (CAH); and spinal muscular atrophy (SMA). Of 51 tested pregnancies we found four positive for NS with the following mutations: one with p.Asp61Asn in PTPN11, and three with p.Pro655Leu in SOS1; and one case of CAH (homozygous mutation p. Pro454Ser in CYP21A2). The mutation p.Pro655Leu in SOS1 was inherited from healthy parent at least in two cases (in one case parental testing is ongoing); and in literature the mutation is proposed to be as polymorphism. No SMA or SLOS cases or carriers were detected and there were only two CAH carriers in our group. In conclusion: only in two cases (4%) the test gave valuable information for family; in three cases this test gave concern and uncertainty about fetus's health. Therefore it is questionable whether this particular test would be the best choice for additional testing.

P01.041-S

Two familial cases with interstitial deletion of chromosome 13 due to maternal germline mosaicism

A. Zagorac[1], *A. Blatnik*[1], *D. Krgović*[1], *B. Zagradišnik*[1], *F. Mujezinović*[1], *N. Kokalj Vokač*[1,2];
[1]*University Medical Centre Maribor, Maribor, Slovenia,* [2]*Medical Faculty Maribor, University of Maribor, Maribor, Slovenia.*

De-novo structural chromosome aberrations are usually interpreted as a result of a random event during parental gametogenesis and the recurrence risk therefore is estimated to be very low.
We report on a case in which the same supposedly de-novo deletion recurred in a second pregnancy.
The patient was referred to our institution for fetal karyotyping in her first pregnancy due to a positive first-trimester screening test. Karyotype after amniocentesis at 17 weeks gestation showed an interstitial deletion of chromosome 13: 46,XX,del(13)(q22q32). To define the exact deleted region an array-CGH was performed, indicated one copy of 13q31.1q32.1, 15,9 Mb in range. The ultrasound examination at 23 weeks of gestation showed cerebellar hypoplasia, severe ventriculomegaly as well as associated facial features – hypertelorism, midface hypoplasia and micrognathia. The pregnancy was terminated. Both parents were found to have normal karyotypes.
In the second pregnancy, chromosomal analysis of the fetus showed an identical interstitial deletion of chromosome 13 as the one found in the first pregnancy.
Microsatellite analysis of genomic DNA extracted from tissues of both fetuses as well as from the blood of both parents revealed loss of heterozygosity for two markers located inside the deleted region. Missing alleles originated from the mother.
The results of molecular and cytogenetic studies strongly suggest that the maternal gonadal mosaicism could be the cause for the increased risk of recurrence in described case.
The possibility of germline mosaicism is of particular concern when counselling the parents of a child with a de-novo chromosomal abnormality.

P01.042-M

Gene Expression Patterns in a disturbed Karyotype: Keys to the Clinical Conundrum of Klinefelter Patients

F. Tüttelmann[1], *R. Bongers*[2], *S. Werler*[2], *N. Bogdanova*[1], *J. Wistuba*[2], *S. Kliesch*[2], *J. Gromoll*[2], *M. Zitzmann*[2];
[1]*Institute of Human Genetics, Münster, Germany,* [2]*Centre for Reproductive Medicine and Andrology, Münster, Germany.*

Klinefelter Syndrome (KS) is the most common chromosome disorder in men (47,XXY), exhibiting marked phenotypic variation, frequent hypogonadism and increased mortality. It is unclear to what extent the genetic impact of the supernumerary X-chromosome contributes to the pathology.
EXAKT (Epigenetics, X-chromosomal features and Clinical Applications in Klinefelter syndrome Trial) involves 132 KS men and their parents assessing a wide range of clinical parameters in comparison to male and female controls (n=50 each) in relation to genetic investigations. The objective was to elucidate gene expression patterns in KS and whether these would be related to inherent pathologies.
Gene-expression was substantially disturbed in KS vs. both control groups. The differential expression of 36 not only X-chromosomal genes puts these phenotypical males into a genetic framework located between men and women with normal karyotypes. A range of these genes has previously been attributed to gender-specific modulations of immune responses. The KS cohort exhibited increased insulin resistance/inflammatory status, a procoagulatory state, higher waist circumference, dyslipidemia and an altered cardiac rhythmogenic setting. The extent of clinical dyshomeostasis was associated with the expression of dysregulated genes. Paternal origin of the supernumerary X-chromosome was an additional confounder regarding insulin resistance and cardiac phenotype.
In KS patients, the supernumerary X-chromosome contributes to a number of pathologies by altering gene expression patterns: insulin resistance, dyslipidemia, enhanced inflammation markers as well as altered cardiac rhythmogenic setting are involved; this was observable independently from testosterone substitution treatment which may have attenuated responses in KS.

Klinefelter Syndrome testicular gene expression profile by a whole transcriptome approach

V. Gatta[1,2], *M. D'Aurora*[3,2], *A. Ferlin*[4], *S. Franchi*[2], *S. Sperduti*[3,2], *L. D'Onofrio*[3,2], *R. Selice*[4], *C. Foresta*[4], *G. Palka*[5], *L. Stuppia*[1,2];
[1]*Department of Psychological, Humanities and Territorial Sciences, School of Medicine and Health Sciences, "G. d'Annunzio" University, Chieti, Italy,* [2]*Center of Excellence on Aging (Ce.S.I.), Chieti, Italy,* [3]*Department of Neuroscience and Imaging, "G. d'Annunzio" University, Chieti, Italy,* [4]*Centre for Male Gamete Cryopreservation, Department of Histology, Microbiology, and Medical Biotechnologies, "University of Padova", Padova, Italy,* [5]*Department of Oral Health and Biotechnological Sciences, School of Medicine and Health Sciences, "G. d'Annunzio" University, Chieti, Italy.*

Klinefelter Syndrome (KS) is the most common sexual chromosome abnormality (47,XXY) and represents the first genetic cause of male infertility. The mechanisms leading to KS testis degeneration are still unclear and no therapy is so far available for affected patients.
The present study is aimed to unravel information about molecules playing a key role in the disruption of the spermatogenesis.
Gene expression profiles analysis of KS azoospermic testis versus normal testis, could provide useful information about the molecular basis of the alteration of the spermatogenesis.
Transcriptome analysis was performed carrying out gene expression profile by a whole genome microarray approach on testis biopsies obtained from 6 azoospermic non-mosaic KS men and from 3 controls, for a total of 12 experiments. T-test and False Discovery Rate were used to evaluate differentially expressed genes. Identified transcripts were analysed by Ingenuity Pathways Analysis software to disclose genes biological functions.
Data analysis revealed the differentially up- and down-expression, in KS testis versus the control ones, of 656 and 247 genes related to Endocrine system development and function, Lipid metabolism, Reproductive disease, Free radical scavenging, and Cell death.

Take together these data show the presence of several genes involved in testis microenvironment deregulation leading to the spermatogenesis failure. This information, associated with an early diagnosis could help to unravel possible therapeutic targets for testis failure prevention and limitation.

P01.044-M
Immunoelectron microscopy reveals massive expression of laeverin in microvesicles in preeclamptic placentas

M. Nystad[1,2], *V. Sitras*[3], *G. Acharya*[1,2,4];
[1]*Women's Health and Perinatology Research Group, Department of Obstetrics and Gynaecology, University Hospital of North Norway, Tromsoe, Norway,* [2]*Women's Health and Perinatology Research Group, Department of Clinical Medicine, Faculty of Health Sciences, University of Tromsø, Tromsoe, Norway,* [3]*Department of Obstetrics and Fetal Medicine, Rikshospitalet, Oslo University Hospital, Oslo, Norway,* [4]*Department of Clinical Sciences, Intervention and Technology, Karolinska Institute, Stockholm, Sweden.*

Preeclampsia is a pregnancy-specific syndrome characterized by hypertension and proteinuria. It complicates 5-10% of pregnancies and is a major cause of maternal mortality world-wide. Laeverin (aminopeptidase-Q) is a plasmamembrane-bound aminopeptidase that is specifically expressed in the human placenta. We reported previously that the mRNA levels of laeverin gene are significantly up-regulated in preeclamptic compared to healthy placentas, indicating that laeverin might play a role in the pathophysiology of preeclampsia. Immunofluorescence studies have indicated that laeverin protein is highly expressed in the cytoplasm, instead of the plasmamembrane, of villous trophoblasts in preeclamptic placentas. In this study, we used immunoelectron microscopy to investigate the subcellular localisation of laeverin protein. Ultrathin sections of high pressure freezed (Tokyasu method) tissue samples of four placentas (two from healthy women and two from women with severe preeclampsia) were fixed and labeled with primary antibody raised against laeverin, followed by antibody conjugated with gold particles. Double labeling with markers for endoplasmatic reticulum (ER) and Golgi apparatus (GA) were also performed. We found laeverin in the ER, GA and massive expression in microvesicles within the cytoplasm of villous trophoblasts, extracellular space and in the fetal capillaries in preeclamptic placentas. Since the ER and GA in normal placentas did not show any evidence of accumulation of laeverin, we hypothesize that dysregulation of transport or folding of laeverin might have a role in the development of preeclampsia.

P01.045-S
Leri Weill syndrome findings in an infertile man with 45,X/46,X,derY, t(Y;Y)(p11.2;q11.21) and SHOXY deletion

K. Yararbas[1], *B. Saglam Ada*[2], *F. Alp*[2], *B. Cavdarli*[3], *A. Ocal*[2], *S. Gurkan*[1], *G. Karatas*[1], *I. Akin*[1], *K. Bilecen*[1], *E. Laleli Sahin*[1], *A. Tukun*[1];
[1]*Duzen Laboratories Group, Istanbul, Turkey,* [2]*Etlik Zubeyde Hanim Women Health Teaching and Research Hospital, Ankara, Turkey,* [3]*Ankara Numune Teaching and Research Hospital, Ankara, Turkey.*

Leri-Weill dyschondrosteosis (LWD) or syndrome is a rare genetic disorder with skeletal dysplasia characterized by short stature, mesomelia, and Madelung deformity. We report a 29-year-old male with Leri Weil Syndrome phenotype. The patient was referred from Urology department because of azoospermia. Infertility was the first complaint that forced him request medical achievement. The patient had short stature with macrocephaly, mesomelia, Madelung deformity, and exaggerated flattened vertebral spine adressing Leri Weill syndrome. Simultaneously regular consultations, radiographic and other procedures and genetic analysis was planned. Conventional cytogenetic analysis and Y chromosomal microdeletion scan was performed. No microdeletions were present on the loci sY14(SRY), sY84, sY86 (AZFa), sY127, sY134 (AZFb), sY254, sY255 (AZFc), sY152, sY153 (AZFd) and RBM1. Chromosomal analysis revealed a mosaic finding of two series: 45,X and 46,X, with a der(Y), possibly t(Y;Y)(p11.2;q11.21). Additional metaphase FISH analysis with a commercial probe mix targeting DXZ1, LSI SRY supported the mosaic numerical finding with 15% of the metaphases only showing one DXZ1 signal without LSI SRY and 45 chromosomes counted on DAPI stain. Whole chromosome painting FISH studies demonstrated that the derived Y chromosome consisted of only Y chromosomal material. SHOX analysis by FISH technique revealed absence of SHOX signal but 2 DYZ signals on derived Y chromosome. Finally, chromosomal microarray findings (Affymetrix Cytoscan 750K SNP Array platform) confirmed a SHOX deletion with no additional significant findings above cut-off values.

P01.046-M
The prevalence of luteinizing hormone beta-subunit gene polymorphisms in Czech population and patients with ovarian hyperstimulation syndrome

P. Peldová, **J. Chrudimská**, *M. Macek jr., M. Macek sr.;
Department of Biology and Medical Genetics, Charles University - 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic.*

There are two common polymorphisms in luteinizing hormone beta-subunit (LHβ) gene, which form the variant LHβ (v-LHβ). These polymorphisms change the amino acid sequence (Trp8Arg and Ile15Thr) of the protein. The hormone with v-LHβ (Arg8/Thr15) was shown to have higher bioactivity (tests in vitro) but shorter lifetime in vivo. The presence of v-LHβ is associated with reduced woman´s fertility, menstrual disorders and abortions. Female IVF patients with at least one v-LHβ allele tend to be hypo-responders to controlled ovarian hyperstimulation. Thus, we propose that women with v-LHβ would be in a lower risk to develop an ovarian hyperstimulation syndrome (OHSS).
In our study, 102 fertile male-controls, 149 fertile female-controls and 58 patients affected by OHSS type III-V were analyzed. The genotype was determined by restriction fragment length polymorphism (RFLP). The prevalence of v-LHβ allele was 10,1% in female controls, 14,7% in male controls and 6,0% in OHSS patients.
There was no statistical difference between Czech control men and women in genotype or allelic frequencies (P=0,22; P=0,12, respectively). The Czech population frequency of v-LHβ is closest to the prevalence from Iceland, Italy and The Netherland.
There was no difference between female controls and OHSS patients in genotype or allelic frequencies (P=0,41; P=0,25, respectively). The protective effect of the v-LHβ from OHSS was not confirmed, but this needs to be verified in a larger cohort.
Supported by grants IGA NT13770-4/2012, project for conceptual development of research organization 00064203 and OPPK CZ.2.16/3.1.00/24022.

P01.047-S
Genetic basis of male infertility: Belorusian Centrum of Reproductive Medicine data.

S. Zoukovskaya, *K. Mosse, N. Rumiantsava, L. Savenko;
Center of Reproductive Medicine, Minsk, Belarus.*

Genetic factors play an important role in male infertility etiology.
We present the data of spermatogenetic impairment infertile couples referred to ART. Results. 601 mentally normal men with azoospermia/severe oligozoospermia were examined using cytogenetic and moleqular methods. Klinefelter's syndrome (KS, 47,XXY) was found in 11 (1,8%) patients. Different AZF regions Yq microdeletions (DelAZF) were detected in 34 (5.6%) patients. AZFc deletion calculated for 29 cases (85,3%) with a chance of retrieving sperm by testicular biopsy (TESE) and performing ICSI: spermatozoa were received in 15 cases (51.7%) for following cryopreservation. Two AZFb and 3 AZFb+c deletion's patients showed sperm absence in testicular tissue. 2 men with complete AZFa+b+c region's deletion didn't undergo TESE/ICSI. 16 (2.6%) CFTR gene mutation's heterozygote carriers were identified: dF508del (10 cases), CFTR2,3del (3), 2184insA (2), 1677delTA (1). Counseling: Partners-carriers of CFTR gene mutations have 25% risk of affected outcome, DelAZFc male - 100% deletion's transmission risk for sons. We recommended donor sperm using or adoption for KS and DelAZFb; DelAZFb+c; DelAZFa+b+c's patients.ARTs: 12 DelAZFc patients underwent IVF+ICSI procedures. 5 couples (41.6%) got pregnancy: 3 pregnancies resulted in healthy girl delivery, two - ongoing (12 and 22 weeks gestation). Preimplantation testing was performed for 2 couples with CFTR gene mutations heterozygote's status for both partners. Two pregnancies were obtained: one is developing successfully, other resulted in miscarriage. Conclusion. KS/Yq microdeletions are specific for a severe spermatogenic failure. Genetic testing permits to establish the origin of azoospermia, prognoses, ART strategy's selection and to avoid unnecessary treatment.

P01.048-M
X chromosome-linked CNVs in male infertility: discovery of duplication load and recurrent deletions with potential clinical relevance

C. Chianese[1], *D. Lo Giacco*[2], *C. Giachini*[1], *G. Forti*[1], *E. Ars*[2], *E. Ruiz-Castañé*[3], *C. Krausz*[1];
[1]*Department of experimental and clinical biomedical sciences, University of Florence, Florence, Italy,* [2]*Molecular Biology Laboratory, Fundació Puigvert, Barcelona, Spain,* [3]*Andrology Service, Fundació Puigvert, Barcelona, Spain.*

The X-chromosome genetic content is predicted to be important in spermatogenesis but its role in male infertility remains unknown. We investigated whether X-linked copy number variations (CNVs) might have clinical significance in idiopathic infertile men. We previously detected by a-CGH a number of CNVs including 16 patient-specific gains and 3 recurrent deletions on Xq, exclusively (CNV67) and prevalently (CNV64; CNV69) found in infertile patients. Among the 14 gains, we selected 5 for further qPCR analyses on a larger study population including 276 idiopathic infertile patients and 327 normozoospermic controls. The difference in duplication load was statistically different (p=1.65x10-4). PAR1-linked DUP1A displayed the highest

frequency (1.44% of patients) and we hypothesize it may cause spermatogenic failure by disturbing meiotic X-Y pairing or by affecting the correct regulation of a gene potentially influencing spermatogenesis (PPP2R3B). Concerning the 3 deletions, 627 patients and 628 controls were tested for each deletion with PCR+/−. CNV64 and CNV69 were significantly more frequent in patients than controls (p>0.05). CNV67 was detected exclusively in patients (1.1%) and was maternally transmitted. The oligozoospermic phenotype of one carrier versus his normozoospermic non-carrier brother strongly indicates a pathogenic effect of the deletion on spermatogenesis. MAGEA9, an ampliconic gene reported as independently acquired on the human X chromosome with exclusive physiological expression in the testis, is likely to be involved in CNV67. Our investigation further indicates an association between X-linked CNV burden and spermatogenic impairment and identifies the first X chromosome-linked recurrent deletion and duplication with clinical significance.

P01.049-S
A novel m.9588G>A missense mutation in the mitochondrial COIII gene as a cause of low sperm motility in asthenozoospermic Tunisian infertile men

S. Baklouti-Gargouri[1,2], *M. Ghorbel*[3], *A. Sellami*[4], *F. Fakhfakh*[5], *L. Ammar-Keskes*[5], *L. Ammar-Keskes*[5];
[1]*Laboratory of Molecular, Human Genetics, Faculty of Medicine, University of Sfax, Sfax, Tunisia, Sfa, Tunisia,* [2]*Laboratory of Histology, Sfax Faculty of Medicine, University of Sfax, Tunisia., Sfax, Tunisia,* [3]*Laboratory of Molecular, Human Genetics, Faculty of Medicine, University of Sfax, Sfax, Tunisia, SfaX, Tunisia,* [4]*Laboratory of Histology, Sfax Faculty of Medicine, University of Sfax, Tunisia., sfax, Tunisia,* [5]*Laboratory of Molecular, Human Genetics, Faculty of Medicine, University of Sfax, Sfax, Tunisia, sfax, Tunisia.*

Infertility affects 10-15% of the population, of which, approximately 40% is due to male etiology consisting primarily of low sperm count (oligozoospermia) and/or abnormal sperm motility (asthenozoospermia). Furthermore, it has been demonstrated that mtDNA base substitutions can greatly influence semen quality.
In this study we performed a systematic sequence analysis of the mitochondrial genes (cytochrome oxidase III (COIII) gene in 64 infertile men suffering from asthenozoospermia (n=31) in comparaison to normozoospermic infertile men (n=33) and fertile men (n=150) from Tunisian population. A novel m.9588G>A mutation was found in the sperm's mitochondrial DNA (mtDNA) in all asthenozoospermic patient and was absent in the normozoospermic and in fertile men. The m.9588G>A mutation substitutes a highly conserved Glutamate at position 128 to Lysine. In addition, PolyPhen-2 analysis predicted that this variant is ''probably damaging''. This novel missense mutation (m.9588G>A) detected in the mitochondrial COIII gene as a cause of low sperm motility in asthenozoospermic Tunisian infertile men

P01.050-M
New candidate genes for oligoasthenoteratospermia as a potential cause of human male infertility

K. Veselá[1], *I. Hrdlicka*[1], *B. Chylikova*[1], *R. Mihalova*[1], *K. Rezabek*[2], *F. Liska*[1];
[1]*Institute of Biology and Medical Genetics, Charles University in Prague, First Faculty of Medicine and General University Hospital, Prague 2, Czech Republic,* [2]*Department of Obstetrics and Gynaecology, Charles University in Prague, First Faculty of Medicine and General University Hospital, Prague 2, Czech Republic.*

Oligoasthenoteratospermia (OAT) is a condition characterized by the presence of sperm with abnormal morphology. The causes of OAT are unknown in most cases. Routine genetic examination of patients with nonsyndromic male infertility (Y-chromosome microdeletions and *CFTR* mutations) does not cover this phenotype. Given the hundreds of genes identified as essential for male fertility in animal models it is probable that substantial fraction of cases with genetically caused OAT remains undetected. Our study aims for mutation screening of selected candidate genes which were linked to OAT in animal models.
We selected candidate genes whose mutation in model organism interfering with spermatogenesis and was demonstrated like OAT. We selected *CAPZA3, CDC42, CDC14B, CNTROB, CSNK2A2, GOPC, HOOK1, HRB, OAZ3, ODF1, RIMBP3* and *SPATA16.* We performed genealogy, karyotyping and mutation analysis of *CFTR* gene and Y-chromosome microdeletions. Control group are men with normospermia. PCR amplified exons of the selected genes were sequenced using GS Junior next generation sequencer.
To date we accumulated 131 cases and 88 controls. Sequencing is completed for 41 patients and 8 controls. We found 6 persons with chromosomal aberration and one man with Y-chromosome microdeletion. We detected 115 known sequence variants and 18 novel variants (in *CDC42*, *CNTROB, HOOK1* and *RIMBP3*). The clinical significance of the novel variants is uncertain, however, we identified two likely damaging frameshift variants (in *CNTROB* and *RIMBP3*).
The study is supported by Ministry of Health of the Czech Republic grant No. NT/12269-5

P01.051-S
Transcriptomic profiling of spermatozoa of infertile men with abnormal sperm morphology

B. Chylikova[1], *M. Hodulova*[1], *J. Ariagno*[2], *O. Seda*[1], *G. Mendeluk*[2], *A. L. Kierszenbaum*[3], **F. Liska**[1];
[1]*Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Praha, Czech Republic,* [2]*Laboratory of Male Fertility, Faculty of Pharmacy and Biochemistry, University Clinical Hospital "José de San Martin", University of Buenos Aires, Buenos Aires, Argentina,* [3]*Department of Pathobiology, The Sophie Davis School of Biomedical Education, The City University of New York, New York, NY, United States.*

The pathogenesis of oligo/astheno/teratospermia is unknown in most patients. Especially, the proportion of genetic and environmental factors has been hard to tease apart. However, transcriptomic or proteomic approaches can identify common dysregulated genes or pathways in sperm, that are substantial for their function, regardless the ultimate etiological factor.
We analyzed twelve semen samples according to WHO criteria (2010). Four of the participants were fertile donors, clinically and andrologically normal, who had achieved pregnancy in a period less that twelve months and got a live born baby in the last year. Seven samples were from infertile patients examined in our clinic that presented with oligospermia and abnormal sperm head morphology, including decapitation. We performed genome-wide expression analysis using Affymetrix HuGene2.1ST microaarays.
The principal component analysis revealed substantial overlap between normal and abnormal samples. These results indicate that despite the common result of morphologically abnormal spermatozoa, the underlying causes of the infertility might be diverse.
Surprisingly four genes were markedly different between fertile and infertile sperm samples: an uncharacterized gene, a small nucleolar RNA gene, a microRNA gene and *RIPK4.* Protein kinase RIPK4 is known to phosphorylate the adaptor protein DVL2 (dishevelled 2) to activate the Wnt signaling pathway. In fact, the ortholog DVL1 has a role in regulating spermiogenesis via Wnt signaling.

Aneuploidy of fetal chromosomes is one of the causes of pregnancy loss or congenital birth defects. It is known that the frequency of oocyte aneuploidy increases with maternal age in humans. Recent data have highlighted the contribution of cohesin complex in the correct segregation of meiotic chromosomes. In mammalian oocytes, cohesion is established during the fetal stage and meiosis-specific cohesin subunits are not replenished after birth. This raises the possibility that the long meiotic arrest of oocytes facilitates the deterioration of cohesion leading to the age-related increase in aneuploidy. We here examined the cohesin levels in dictyate oocytes from different age groups. Samples were obtained from the ovarian tissues of 8 women (age range: 19-49 years) and also from 2- and 10-month-old female mice. Ovarian tissue sections were immunostained using cohesin antibodies and the cohesin levels were determined by immunofluorescence. The levels of the meiosis-specific cohesin subunits, REC8 and SMC1B, were found to be decreased in women aged 40 and over compared with those aged around 20. An age-related decrease in meiotic cohesins was also evident in mice. Interestingly, SMC1A, the mitotic counterpart of SMC1B, was readily detectable in human oocytes but only barely in mice. The mitotic cohesin levels of mice slightly increased with age. These results suggest that, mitotic and meiotic cohesins may act in a coordinate manner in humans to maintain the levels of this protein over a sustained period. The decreased meiotic cohesin subunit levels with age impairs sister chromatid cohesion leading to increased segregation errors.

Maternal plasma miRNA analysis of fetuses with congenital heart defects

O. Biro, *L. Lazar, J. Rigo Jr., B. Nagy;*
Semmelweis University, 1st Dept. of Obstetrics and Gynecology, Budapest, Hungary.

Congenital heart defects (CHD) are common developmental malformations and often associated with chromosomal disorders. The major focus of current research is examining free fetal nucleic acids in maternal circulation aiming to create new noninvasive screening methods. The miRNAs are short, non-coding RNA molecules that play important part in regulation of eukaryotic gene expression. The aim of this study was to investigate the role of

miRNAs in heart development, measure miRNA concentration and expression in maternal blood.
Peripheral blood samples were collected from 53 women, 27 of them had healthy and 26 had fetuses with congenital heart defects. Blood samples were centrifuged and miRNA was extracted from plasma. MiRNA concentration was calculated by Nanodrop spectrophotometer. By using Gene Ontology and miRBase databases we searched for those miRNAs which can be detected in plasma and are associated with chromosomal and congenital heart defects. These criteria were fulfilled by *let-7c* miRNA of chromosome 21. qRT-PCR was carried out to validate the miRNA's expression.
There was no significant difference between the miRNA concentrations in the two groups (6.05 ng/µl vs 5.36 ng/ µl). We found significant differences in the *let-7c* concentrations between the control and patient group (1.12±3.19 ng/µl vs. 0.00047±0.00083 ng/µl; p<0.0001).
Fetal-derived miRNAs are part of the free nucleic acids found in maternal plasma, expression studies reveals new opportunities for congenital heart defect research and diagnosis. According to our study *let-7c* seems to be a potential biomarker for fetal CHD.

P01.055-S
Overexpression of mir-21 and mir-221 in preeclamptic placentas

M. Vazan[1], *I. Svecova*[2], *J. Danko*[2], *Z. Lasabová*[1];
[1]*Comenius University in Bratislava, Jessenius Faculty of Medicine in Martin, Dept. of Molecular Biology, Martin, Slovakia,* [2]*Comenius University in Bratislava, Jessenius Faculty of Medicine in Martin, Clinic of Gynecology and Obstetrics, Martin, Slovakia.*

Preeclampsia is a multisystem disorder with partial genetic and immunological etiology; the apoptosis is thought to play a role in the development of preeclampsia. The microRNAs are small noncoding molecules involved in regulation of cellular processes including apoptosis. Here we designed a 96-well reaction plate for the analysis of 21 microRNAs in duplicates which are known to be involved in the apoptosis regulation and are expressed in placenta - pro- apoptotic miR-1, let-7c, let-7g, mir-200c, mir-143, mir-205, mir-122, mir-409-3p, mir-449, mir-708, mir-149, mir-204,mir-133, anti-apoptotic - mir-214, mir221, and mir 222, and miRNAs with both the anti-apoptotic and apoptotic targets mir29a and mir29c. The normalization was performed against RNU44. The microRNAs were extracted from placental tissues obtained after delivery from preeclamptic women and healthy controls. After stem-loop primer reverse transcription in one tube, the samples were analyzed on the plates and evaluated by deltadelta Ct algorithm. The aberrantly expressed miRNA were validated by TaqMan MicroRNA Assay by relative quantitation with the standard curves The analysis of 21microRNAs revealed overexpression of mir-122, mir-21, mir-221, mir- 29a, mir- 29c and mir-449 The validation was performed on 13 additional preeclamptic placental samples collected after delivery and 6 placental samples from normal delivery; a significant overexpression of mir-21 and mir-221 with p=0.0055 (CI95% 25.2 to 123.47) and p=0.0047 (CI95% 12.16 to 57.20) was observed, respectively. Although the validation on larger number of samples is necessary, the analysis of miRNA deregulation can help in the identification deregulated signaling in preeclamptic placentas for detection of new biomarkers.

Analysis of micrornas expression profile in human placentas from pregnancies complicated by preeclampsia

A. S. Glotov[1], *V. S. Pakin*[1], *E. S. Vashukova*[1], *M. M. Danilova*[1], *E. S. Mihailin*[2], *O. N. Arzhanova*[1], *V. S. Baranov*[1];
[1]*Ott's Institute of Obstetrics&Gynecology, St.-Petersburg, Russian Federation,* [2]*State Budget Institution of Health „Maternity hospital №10", St.-Petersburg, Russian Federation.*

Preeclampsia is a main cause of maternal and neonatal mortality and morbidity However, the origin of this disease is rather obscure so far. MicroRNAs (miRNAs) as a key a regulators of gene expression in cell proliferation, apoptosis, and embryogenesis, whereas their abnormal expression has been suggested in various common disorders. The objective of this study was to compare expression profiles of miRNAs in placentas from preeclampsia patients with these ones from normal term pregnancies. The expression profiling of five patients was performed with Ion Torrent semiconductor sequencing. Fourteen miRNAs (miR-181a-5p, mir-143, miR-143-3p; miR-126-5p; mir-369, mir-136, miR-136-5p, mir-142, miR-142-3p; mir-516a-1, mir-516a-2, mir-519a-1, mir-518c and miR-518c-3p) were significantly overexpressed in preeclampsia placenta compared to these ones in the controls. The results are important prerequisite for further molecular studies of genetic and epigenetic contributors in preeclampsia.
The work was supported by grants of Russian Federation President № 16.120.11.5773-MC.

miRNA as potential universal fetal marker in NIPT

T. Sedlackova[1], *G. Repiska*[1], *G. Minarik*[1,2,3];
[1]*Comenius University in Bratislava, Faculty of Medicine, Institute of Molecular Biomedicine, Bratislava, Slovakia,* [2]*Comenius University in Bratislava, Faculty of Natural Sciences, Department of Molecular Biology, Bratislava, Slovakia,* [3]*Geneton, Ltd., Bratislava, Slovakia.*

Introduction: Circulating miRNA molecules are currently studied as potential diagnostic markers in many physiological and pathophysiological conditions such as oncological diseases, heart diseases and pregnancy. The aim of our study was to determine if circulating miRNAs can be used as potential universal fetal marker in NIPT. **Methods**: Circulating miRNAs were isolated from plasma of pregnant women and miRNA samples were divided into two groups depending on fetal gender. Firstly, expression levels of 91 miRNAs were established in three female and three male samples by two-step RT-qPCR. Five miRNAs (miR-378, miR-122, miR-20b, miR-320a, miR-320b) whose expression levels significantly differ between two groups were chosen for further analyses. Subsequently, expresion levels of five selected miRNAs were evaluated in 14 female and 15 male samples by two-step RT-qPCR. Differences between groups were tested using Student t-test with p<0.05 was consider as statistically significant. **Results**: After the first part of this study where panel of 91 miRNAs were investigated, five miRNAs significantly differ in their expression levels between two sample groups. However, there were no significant differences in expression levels of five selected miRNAs between sample groups, when expression levels of these miRNAs were determined in a greater number of samples. **Conclusion**: Our study showed, that none of evaluated miRNA molecules in this work is not suitable as the universal fetal marker. However, since our work addressed only limited number of miRNA molecules, for determination if circulating miRNAs can be used as universal fetal marker, further studies are needed.

P01.058-M
Arthrogryposis multiplex congenita caused by compound heterozygosity to Ashkenazi founder mutation and a novel splice mutation in *NEB* gene

M. Feingold Zadok[1], *R. Maymon*[1], *D. Chitayat*[2], *M. Injeyan*[2], *O. Reish*[1];
[1]*Assaf Ha'Rofe Medical Center, Beer Yaakov, Israel,* [2]*Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada.*

Background: Nemaline myopathy (NM) is a heterogenous disorder. A homozygote 2502bp deletion in *NEB* - had been detected in 1:40,000 Ashkenazi Jews (AJ). Most cases have congenital hypotonicity that might progress, but arthrogryposis is relatively rare.
Patients: Three affected siblings with arthrogryposis and an increased nuchal fold / cystic hygroma in two, were detected at 11-15 weeks of gestation. Parents were AJ with non-contributory family history.
Methods and Results: Histopathology with electron microscopy of muscle samples suggested NM on two siblings. DNA sequencing confirmed compound heterozygosity to the known Ashkenazi mutation (maternal) and splice mutation c.9619-2A>G (paternal) predicted to disrupt the intron 66 splice acceptor site.
Discussion: The splice site mutation revealed in our patients, has been previously detected in two unrelated affected AJ with clinical stigmata of arthrogryposis (*Ludtke et al*. ICHG 2011; *Yonath et al.* Prenatal Diagnosis, 2012). The detection of this mutation in several AJ families suggests it is either hot spot site or a new AJ founder mutation. Further studies should be performed to validate its carrier frequency among this population. Also, the severe stigmata in affected patients harboring this splice mutation, suggests its critical role in disease pathogenesis. In line with this, when arthrogryposis detected prenatally, screening of the *NEB* should be considered.

P01.059-S
Familial chromosomal translocation t(3;5)(q26.2;p14): clinical characterization of affected members with neural tube defect as a common clinical feature

E. Benusiene[1,2], *E. Preiksaitiene*[1,2], *V. Sliuzas*[1,2], *S. Tumene*[1,2];
[1]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania,* [2]*Centre for Medical Genetics, Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania.*

A 26-years-old woman was referred for prenatal diagnostics because of aggravated obstetric anamnesis. Her first child (male) was born at 34 weeks of gestation via S/C due to polyhydramnios and hypotrophy. Hypotonia, dysmorphic facial features and multiple congenital malformations were observed, including hypertelorism, epicanthal folds, micrognathia, hypoplastic cerebellum, congenital heart defect, optic nerve dysplasia, micropenis, hypospadias, syndactyly, and suspected spina bifida occulta. The newborn died at age of 1 month. According genealogy, proband's mother had a miscarriage at the 14th week of gestation and stillborn at 26 weeks of gestation

with uncertain gender and myelomeningocele.
During this pregnancy at the 27th week of gestation ultrasound scan showed polyhydramnios and multiple congenital anomalies in the fetus. On the 31st week of gestation the fetus died in the uterus. Autopsy findings were pulmonary atresia, transposition of the great vessels, horseshoe kidney, cerebellum hypoplasia, hydrocephalus, clubfoot, and spina bifida. Subtelomeric FISH was performed to the proband and balanced translocation ish t(3;5)(qter-,pter+;pter-,qter+) was detected. Karyotype was 46,XX,t(3;5)(q26.2;p14).
The clinical phenotype of affected family members is similar and could result from the combination of dup(3q) and del(5p) syndromes. Only few cases of (3;5) translocations have been reported to date. Detailed clinical description of affected family members brings new data for the characterization of this rearrangement.

P01.060-M
The Effect of Radiofrequency Waves on Pregnant Mice in association with Genes involved in Neuronal Migration

A. G. S. Yildirim[1], E. Karaca[2], O. Gozen[3], B. Durmaz[2], **O. Cogulu**[2]*, T. Yildiz[4], O. Yeniel[1], M. Ergenoglu[1], C. Gunduz[5], E. Koylu[3], S. Sagol[1];*
[1]Ege University, Faculty of Medicine, Department of Obstetrics and Gynecology, Izmir, Turkey, [2]Ege University, Faculty of Medicine, Department of Medical Genetics, Izmir, Turkey, [3]Ege University, Faculty of Medicine, Department of Physiology, Izmir, Turkey, [4]Ege University, Faculty of Science, Department of Physics, Izmir, Turkey, [5]Ege University, Faculty of Medicine, Department of Medical Biology, Izmir, Turkey.

The advancements in technology have improved human life in numerous ways, and concerns have been raised regarding health and safety issues in parallel with the spread of those developments. One of those concerns has been focused on radiofrequency waves because of common usage in daily life, such as mobile phones. The aim of this study is to evaluate change in expression levels of 7 genes (Dcx,Tuba1a, Ywhae, Arx, Reln, Large, Flna), which are involved in neuronal migration following the exposure of radiofrequency waves. A total of 16 mice were included in the study. They were divided into two groups as study and control. Each group consisted of 6 female and 2 male mice. Study group was exposed to 0.725 W/kg SAR value for 12 hours per day continuously by establishing an exposure system throughout pregnancy. A total of 29 offspring in the study group and 12 in the control group were achieved. Gene expression analyses were performed by using real time RT-PCR. Significantly increased expression levels were found in 5 (Arx, Dcx, Large, Reln, Ywhae) out of 7 genes in the study group. In conclusion exposure to radiofrequency waves in pregnancy may cause significant changes in those gene expressions involved in neuronal migration, which may also be related with brain anomalies.

P01.061-S
Confined placental mosaicism in a case of false positive NIPT result for trisomy 18

R. Raynova[1]*, I. Bradinova[1], K. Vladimirova[1], M. Panova[2], A. Savov[1];*
[1]National Genetic Laboratory, University Hospital of Obstetrics and Gynecology, Sofia, Bulgaria, [2]First Hospital of Obstetrics and Gynecology, Sofia, Bulgaria.

Non-invasive prenatal testing (NIPT) of cell-free fetal DNA (cffDNA) for fetal aneuploidy risk assessment has been shown to be both highly sensitive and highly specific. False positive rates can be as low as 0.1%. However, discrepancies between positive NIPT result and fetal karyotype on chorionic villus sampling or amniocentesis may occur. The source of aneuploidy may be due to maternal mosaicism, maternal malignancy, true fetal mosaicism, a demised co-twin, an anembryonic sac, confined placental mosaicism.
We present a case of a 38-year-old woman, pregnant in 16 gestational weeks, referred to our Unit for amniocentesis due to positive NIPT for trisomy18. The ultrasound scans were unremarkable.
DNA was extracted from uncultivated amniocytes, amplified with commercial QF-PCR kit Aneufast (Molgentix SL, Barcelona, Spain) and analyzed on ABI 3130xl. Karyotyping was performed on cultured amniocytes using standard protocol.
QF-PCR and cytogenetic analysis showed normal results, trisomy 18 was excluded.
The pregnancy was still ongoing, with no pathological findings on routine ultrasound scans. Cytogenetic and molecular-genetic analyses are to be done after delivery.
Since fetal cell-free DNA mostly originates from invading trophoblast cells, this false-positive result may be due to mosaicism confined to the placenta (CPM). CPM occurs in 2% of the viable pregnancies and before the introduction of NIPT was most often detected by direct analysis of chorionic villus sampling.
Our case illustrates that follow-up with diagnostic testing of chorionic villus sampling and/or amniotic fluid for abnormal NIPT results should be performed and that pre- and posttest counseling is important.

P01.062-M
Preliminary experience with the management of positive results of non invasive prenatal testing (NIPT) in a reference centre

V. Bianchi[1]*, B. Gentilin[1], C. Cesaretti[1], M. Calvello[1], R. Fogliani[2], S. Guerneri[3], M. Di Segni[3], L. Cerutti[3], P. Ilardi[3], F. Lalatta[1];*
[1]Clinical Genetics Unit Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy, [2]Obstetrics and Gynecology Unit, Prenatal Diagnosis Unit Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy, [3]Laboratory of Medical Genetics Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy.

During the past year techniques enabling non-invasive prenatal testing for the most common trisomies have become available clinically. An increasing number of women have been offered the test in connection with their first trimester screening, regardless of their level of risk. Pregnancies with a positive test are often referred to our Centre for genetic counseling and invasive procedures as recommended. To this end, we have created a flow-chart to assist these patients who are not receiving enough information at time of sampling. Clinical aspects of the test, its limits and reasons for false positives are discussed and a guaranteed follow-up is scheduled to collect data at time of birth. Between July 2013 and January 2014 6 patients with positive NIPT (2 trisomy 21, 1 trisomy 18, 1 monosomy X, 1 47,XXY, 1 triple X) were referred. All patients underwent an amniotic fluid procedure and only one case of trisomy 21, which had fetal anomalies at ultrasound, was confirmed. Normal results were obtained in the other 5. Two term placentas have been studied, the others being ongoing pregnancies. Since false positive cases of chromosome aneuploides after NIPT may have different underlying biological causes ,(the majority, however, are due to placental mosaicism) we believe that the cytogenetic analysis of term placentas should be acquired in all such cases so as to increase our knowledge about the relationship between cffDNA and the fetal genome. Genetic counselling should always be carried out before and after testing to reduce misinterpretation of test validity.

P01.063-S
Non-invasive prenatal detection of a mosaic trisomy 16

B. Bayindir[1,2]*, P. Brady[1], N. Brison[1], L. Dehaspe[1], S. Ardui[1], J. Houdt[1], K. Van Esch[1], E. Legius[1], T. Ravel[1], K. Devriendt[1], J. Vermeesch[1];*
[1]Center for Human Genetics, KU Leuven, Leuven, Belgium, [2]Universita degli studi di Pavia, Pavia, Italy.

The presence of cell free fetal DNA in the maternal circulation has allowed for the development of methods, which allow for non-invasive detection of fetal chromosomal aneuploidies. Our laboratory offers non-invasive prenatal testing (NIPT) with an innovative pipeline that utilizes all of the information provided by shallow depth whole genome sequencing to identify possible aneuploidies of all chromosomes. We have encountered one case, referred because of high trisomy 21 risk (1/14), with unusually high Z-score (5.7) for the chromosome 16 indicating the presence of a trisomy 16. Follow-up with direct FISH and array analysis of amniotic fluid cells showed a low-level mosaicism (between 7 and 20%). The finding of low level mosaicism is contrasting with the high Z-score which suggests the presence of trisomy 16 in the majority of the cells. This discrepancy could be explained by confined placental mosaicism and, if so, should be taken into account in subsequent counseling. Whereas the gynecologist suggested interruption, the family decided to continue the pregnancy with expert ultrasound monitoring of the fetal development following clinical genetic counseling.

P01.064-M
Non-invasive detection of fetal deletions or duplications by low coverage massively parallel sequencing

C. ZHANG, *W. Xie, X. Pan, F. Chen, Y. Gao, W. Wang;*
BGI-Shenzhen, Shenzhen, China.

To report the performance of fetal chromosomal deletions/duplications detection by the massively parallel sequencing (MPS) of maternal plasma DNA, we recruited 1,324 participants and performed the MPS test in a double-blind study. The peripheral blood of each participant was obtained before invasive sampling at 10-28 weeks' gestation with a median of 21 weeks. Plasma DNA was extracted and sequencing. About 0.08 fold sequencing data per sample was generated and the bioinformatics analysis was performed using FCAPS algorithm. Deletions / duplications, ranged from 3.07 Mb to 26.98 Mb, were suspected in 17 of the 1,324 samples, of which 16 were consistent with the results of fetal karyotyping / aCGH. In one case the suspected abnormality was not confirmed by karyotyping, representing a false positive case. No false negative case was observed in the remaining 1,307 low-risk samples. The sensitivity and specificity for detection of fetal chromosomal deletions / duplications were100% and 99.92%, respectively. Our study demonstrated the MPS-based test is feasible and of high sensitivity and specificity in detecting fetal chromosomal deletions / duplications.

Nonivasive prenatal KEL genotyping using TaqMan Real time PCR and by capillary electrophoresis minisequencing

J. Böhmova[1], *R. Vodicka*[1], *M. Lubusky*[2], *I. Holuskova*[3], *M. Studnickova*[2], *R. Kratochvilova*[1], *E. Krejcirikova*[1], *M. Janikova*[1], *I. Dhaifalah*[1];
[1]*Dept of Medical Genetics and Fetal Medicine University Hospital and Palacky University Olomouc, Olomouc, Czech Republic,* [2]*Department of Obstetrics and Gynecology University Hospital in Olomouc, Olomouc, Czech Republic,* [3]*Transfusion Department University Hospital Olomouc, Olomouc, Czech Republic.*

Introduction: There are two reasons for establishing a methodology for noninvasive determination of KEL genotypes in early pregnancy. To identify fetuses which are at risk of hemolytic disease of fetus and newborn by alloimmunized pregnant women and to prevent alloimmunization during pregnancy. Aim: KEL noninvasive determination of fetal genotype from cffDNA in plasma KEL negative pregnant women using TaqMan assay and minisequencing (SNaPshot). Project is supported by IGA MZ CR: NT12225. Material and methods: 1) TaqMan assay involving region of KEL (K/k) polymorphism and region of AMELY gene as an internal control was tested in DNA samples from leukocytes of k/k, K/K and k/K men. 2) SNaPshot: Determination of sensitivity threshold KEL calibration was performed using a dilution series. It was tested 141 samples of cffDNA from maternal plasma in the first trimester. Results: 1) TaqMan assay: KEL genotypes determined from leukocyte DNA were distinguishable, but there was fluorescence background. So there wasn´t able to exactly distinguish between false positive fluorescence background and fetal DNA admixture. 2) SNaPshot: On the basis dilution series it was possible to detect less than 0,78% admixture of K allele corresponding DNA concentration of 0,04 ng /µl. Seven fetuses with allele K were found in 113 k/k mothers, which corresponds to about 4-5 % of the population frequency. It wasn´t possible to determine KEL genotype at 8 fetal samples due to KEL maternal heterozygous genotype. Conclusion: SNaPshot assay is more suitable to distinguish fetal KEL genotyp, than TaqMan assay.

P01.066-M

Feasibility of utilization of semiconductor based low coverage genomic sequencing in noninvasive prenatal trisomy 21 detection

G. Repiska[1], *E. Nagyova*[2], *K. Soltysova*[2], *J. Budis*[3], *R. Sysak*[4], *M. Gerykova-Bujalkova*[5], *B. Vlkova-Izrael*[1], *T. Szemes*[2], *G. Minarik*[1,6], *I. Hudecova*[7], *D. Recent studies focused on utilization of next-generation sequencing (NGS) technology in non-invasive prenatal detection of trisomy of chromosome 21 (T21) showed high sensitivity and specificity if more than 10 milion of read per sample were used. For these analyses high-throughput NGS systems are needed. The aim of our study was to test feasibility of usage of NGS protocol with approx. 5 milion of reads per sample and to estimate sensitivity and specificity of such testing. In our study high-risk group samples of 42 pregnant women, represented by 37 samples without and 5 with trisomy 21 bearing fetus confirmed by previous invasive procedure were analyzed by low coverage genomic sequencing on IonTorrent PGM. For T21 detection Z-score calculation was used. In all 5 samples with T21 fetuses Z-score above 3 was recorded. In non-trisomic and trisomic samples on average 5 463 516 and 6 292 096 mapped reads per sample were used in Z-score calculation, respectively. In non-trisomic and trisomic samples Z-scores were -0.26 (SD = 1.15) and 7.65 (SD=3.73) on average, respectively. So in our small scale study 100% sensitivity and specificity were recorded. According to our results low coverage sequencing based on IonTorrent PGM sequencing is suitable for noninvasive prenatal trisomy testing, however, a further study based on data from larger sample cohort is needed for more precise calculation of sensitivity and specificity of our current protocol. The study continues on greater group of samples. This study was supported by grant ITMS 26240220067 funded by ERDF.

P01.067-S

Validating non-invasive prenatal testing (NIPT) using artificial and actual pregnancy plasmas: accurate detection of five microdeletions

M. P. Hall, *N. Wayham, J. Babiarz, J. Hu, J. Tong, P. Lau, S. Sigurjonsson, M. Hill, B. Zimmermann, M. Rabinowitz;*
Natera Inc., San Carlos, CA, United States.

Introduction: Microdeletions, which may result in mental and physical handicaps, are challenging to detect using cell-free DNA-based NIPT due to their smaller size. Additionally, sample rarity and the later gestational ages at which samples are generally collected complicate test performance validation. We created artificial pregnancy plasma DNAs (plasmArts) to circumvent these issues, demonstrating accurate detection of five microdeletions: 22q11.2, Cri-du-Chat, 1p36, Prader-Willi, and Angelman.
Methods: DNA isolated from cell lines, affected or unaffected children, and their unaffected mothers, was treated to generate nucleosomal ladders, mimicking maternal/fetal cfDNA fragment lengths. These "cfDNAs" were mixed to mimic fetal fraction distributions in the target gestational age population, and were analyzed alongside pregnancy plasmas using the PanoramaTM NIPT, which reports copy number and associated confidence for each chromosome. 469 samples (111 artificial mixtures of mother/child DNA derived from 5 affected and 1 unaffected children and their unaffected mothers, 6 affected and 352 unaffected pregnancy plasmas) mimicking various fetal fractions were tested.
Results: NIPT correctly distinguished affected and unaffected "pregnancy" plasmArts, suggesting that mixtures behaved similarly to maternal plasma cfDNA. This SNP-based assay detected deletions to as low as 3.9% fetal fraction. The anticipated false positive rate based on the observed fetal fraction distributions and unaffected pregnancy plasma measurements is ≤1%.
Conclusions: PlasmArt samples generated appropriate NIPT results, allowing robust test performance validation for rare conditions. This approach accurately identified pregnancies with a fetus affected by various microdeletions. This will increase NIPT clinical coverage and allow for earlier prenatal screening for sub-chromosomal deletions.

P01.068-M

Discordant results between non-invasive prenatal testing by maternal plasma sequencing and fetal ultrasound examination

E. Pelo, **G. Marseglia**, *C. Pescucci, D. Parrini, F. Marin, M. Betti, E. Lisi, F. Gerundino, F. Sbernini, E. Contini, M. Benelli, F. Torricelli;*
SOD Diagnostica Genetica AOUC, Firenze, Italy.

Over the past year, noninvasive prenatal screening (NIPS) based on massively parallel sequencing to align and count DNA fragments floating in the plasma of pregnant women, has become clinically available into prenatal care as an advanced screening test. We report here a case of discordant results in fetal sex determination between NIPS and ultrasound examination. The patient was referred to our clinical genetic service at 23 week of gestation due to discrepancies between NIPS results performed in a different center and fetal ultrasound examination. In particular, a first NIPS report was of a normal female fetal karyotype but subsequent ultrasound examination showed a fetal male gender. The result of a second NIPS analysis on a new plasma sample offered and performed by the same center was of increased risk for Turner syndrome. After genetic counseling, amniocentesis was performed at 23 wog. FISH analysis with a probe targeting SRY gene showed a single signal for SRY onto an almost intact X chromosome, revealing an X-Y cryptic chromosomal translocation: 46,XX.ish der(X)t(X;Y)(p22.3;p?)(SRY+). Array-CGH showed a subtelomeric deletion of about 2.28 Mb in Xp22.33 and the presence of the short arm of Y chromosome. To exclude the possibility of phenotypic consequences due to haploinsufficiency of SHOX gene, MLPA subtelomeric analysis was carried out. These case support the recommendation that NIPT should be regarded as a screening test and offered in the context of genetic pre-test counseling as well as post-test counseling for screen positive individuals. Diagnostic testing is recommended to confirm positive NIPS results.

P01.069-S

Older mother's perspectives on non-invasive prenatal testing for fetal abnormalities and adult-onset conditions in the United Kingdom

L. M. Jackson, *A. O'Connor, L. Goldsmith, H. Skirton, Applied Health Genetics Research Group;*
Plymouth University, Plymouth, United Kingdom.

Since the 1970's there has been a steady increase in England and Wales in the number of women having a baby at the age of 35 or over. Birth rates for this group have risen from 6% in 1974 to almost 20% in 2012.
The use of new technologies such as non-invasive prenatal testing and genome or exome sequencing may result in the opportunity for women to request fetal testing for a range of conditions. While there is considerable support from prospective parents and health professionals for non-invasive prenatal testing for single gene disorders, ethical concerns have been identified. It has been suggested that prenatal testing discriminates against people with disability and there are fears it may become routine. Detecting multiple genetic conditions in the fetus may facilitate detection of adult-onset conditions. This has serious implications for parental decision making.

In this study we aimed to explore the attitudes of mothers aged 35 or over towards new diagnostic techniques for prenatal diagnosis of foetal abnormality. Women who had given birth in the UK within the last 12 months were recruited using a novel recruitment strategy via Twitter. Here we present the initial findings relating to NIPT and testing for adult-onset conditions. Mother's considered the reduced risk to the pregnancy and extra time to make a decision as being major advantages of NIPT whilst voicing concerns regarding health service readiness and test accuracy. Concerns about testing for adult-onset conditions included increased psychological burden on parents and respecting the child's autonomy.

P01.070-M
Prenatal diagnosis and outcome in Noonan Syndrome

D. Liebrecht, *C. Daumer-Haas, S. Minderer, T. Schramm, C. Bagowski, M. Shoukier, K. P. Gloning;*
Pränatal-Medizin München, Munich, Germany.

Noonan syndrome (NS) is an autosomal dominant inherited disorder caused by heterozygous mutations of several genes within the RAS/mitogen activated protein kinase pathway. NS is characterized by short stature, minor facial and cardiac anomalies. Frequent prenatal ultrasound findings are increased nuchal translucency in addition with distended jugular lymphatic sacs, cystic hygroma, hydrops, hydrothorax, ascites, polyhydramnios, cardiac and renal anomalies. There is high variability of clinical symptoms even within single families. We present a retrospective study of 23 prenatally diagnosed cases with mutations in PTPN11, SOS1, RAF1 genes from a cohort of 330 fetuses with ultrasound findings indicating NS and normal karyotype. Cases were seen in a single tertiary center between 2005 and 2014 by an expert team of experienced sonographers and human geneticists. Prenatal ultrasound findings, molecular genetic data and postnatal phenoptype will be reported. Some cases are exemplified with clinical, ultrasound and molecular genetic data. In our study we want to emphasize the importance of prenatal molecular testing of Noonan genes (panel) in cases with an increased nuchal translucency and at least one additional feature mentioned above. Prognosis depends on molecular genetic findings in conjunction with ultrasound abnormalities which can change dramatically in the course of pregnancy. The occurrence of severe progredient hydrops or hydrothorax in the second or third trimester is associated with a high risk for an unfavourable outcome. Genetic counseling remains demanding due to the high variability in the prenatal and postnatal spectrum of symptoms in NS and the difficulty to give a reliable prognosis.

P01.071-S
Follow up of 30 prenatally diagnosed cases of osteogenesis imperfecta

G. Baujat, *K. Lambot, A. Lebre, T. Attie-Bitach, J. Bengoa, J. Bernard, B. Bessieres, A. Millischer, S. Monnot, L. Salomon, P. Sonigo, A. Munnich, M. Le Merrer, V. Cormier-Daire;*
Hôpital Necker-Enfants Malades, Paris, France.

Osteogenesis Imperfecta (OI) is a heritable connective tissue disorder, characterized by a wide clinical spectrum, ranging from few fractures in mild cases to perinatal lethality. During pregnancy, if severe forms are usually easily early recognizable, the mild and moderate forms may lead to notoriously difficulties in the evaluation of the postnatal prognosis. **Objective:** to evaluate the contribution of prenatal imaging, family history and molecular analysis in the postnatal prognosis in osteogenesis imperfecta. **Methods:** to analyze retrospectively the prenatal features (fetal ultrasound examination and 3D CT-scan), family history and postnatal outcomes (phenotype and genotype) of 30 cases diagnosed antenatally as OI in our hospital. **Results:** In 15 cases, the severe fetal presentation led to pregnancy termination. Among the 15 remaining cases that are still alive, 4 are considered as severe, 6 as moderate and 5 as mild. The family history appears to be the best prenatal predictor of postnatal severity. We emphasize the sensitivity of the 3D-CT scan. Molecular screening was not helpful in the prognosis given *a priori* to the parents. No correlation between the severity of skeletal phenotype and the genotype was demonstrated *a posteriori*. Importantly, in 3 cases with marked bowing of the long bones, a significant improvement of the bone deformities was observed after birth. **Conclusion:** OI is today easily diagnosed during pregnancy based on the improvement of the recent imaging tools; however, the postnatal prognosis is still often difficult to evaluate, highlighting the value of a family history.

P01.072-M
Prenatal diagnosis of de novo partial trisomy 4q3l→qter and partial monosomy 22q13.3→qter

K. Crkvenac Gornik, *I. Tonkovic Djurisevic, M. Miklos, S. Huljev Frkovic, L. Ljiljana, R. Lasan Trcic, D. Begovic;*
Division of Genetics, Department of Pediatrics, University Hospital Centre Zagreb, Zagreb, Croatia.

We report prenatal diagnosis of a fetus with partial trisomy of 4q31-qter and partial monosomy of 22q13.3-qter. A 35-year-old woman was referred for prenatal diagnosis at 28 weeks gestation because of fetal hydrothorax and polyhydramnios detected by ultrasound. Amniocentesis was performed and routine G-band analysis of cultured amniocytes showed additional material of unidentifiable origin at the long arm of one chromosome 22. Karyotype was 46,XX,der(22)add(22)(q13.3)?. Further molecular cytogenetic characterization of the additional genetic material was carried using FISH. Six commercial FISH were used: two centromeric chromosome probes 4(D4Z1) and 14/22(D14Z1/D22Z1); two whole chromosome paints 4 and 22; two locus specific probes 22q13.3(SHANK3) and 22q11.2(N25); two subtelomeric probes 4p(D4S3360) and 4q(D4S2283). The extra chromosomal material was found to be derived from chromosome 4 de novo and fetal karyotype was redesigned as 46,XX,der(22)t(4;22)(q31.3;q12)dn. A girl was delivered at 38 weeks of gestation with a birth weight of 3000g and AS 10/10. She has mild dysmorphic features including dolichocephaly, microretrognathia, small skin folds on ears, without other anomalies. At the age of one year she shows slight developmental delay especially in motor skills development. Reported children with distal partial trisomy 4q have the wide phenotypic variability which could be related to the location of the breakpoints and associated monosomies of the other chromosomal parts. Partial trisomies of 4q31 to 4qter in general were associated with only mild phenotypic anomalies like slight (mental) retardation and/or dysmorphism which is consistant with our case. Further follow up is necessary especially because of monosomy 22q13.3-qter.

P01.073-S
Prenatal diagnosis of UPD using genomic SNP array in a foetus with ultrasound abnormalities.

C. Castagnini[1], *G. Marseglia*[2], *C. Pescucci*[2], *U. Ricci*[2], *G. Traficante*[1], *F. Gerundino*[2], *C. Giachini*[2], *F. Marin*[2], *C. Romolini*[2], *M. Trafeli*[2], *F. Gensini*[1], *M. Genuardi*[1], *F. Torricelli*[2];
[1]*Department of Biomedical, Experimental, and Clinical Sciences "Mario Serio", University of Florence, Firenze, Italy,* [2]*SOD Diagnostica genetica, AOU Careggi, Firenze, Italy.*

We report the case of a 35-year-old gravida 1, para 0 referred at 18 weeks of gestation (wg) because of several fetal malformations. First trimester screening test showed an increased risk for trisomy 21 with a nuchal translucency of 4,1 mm; the fetal karyotype was 46, XY. Ultrasound scanning at 17 wg showed increased fetal biometry (>95°), small thorax, flaccid abdomen wall, ambiguous genitalia. At 19 wg the patient optioned for pregnancy termination and the fetal autopsy showed cleft palate, microglossia, edematous short neck with a prominent occipital region, low-set ears, ambiguous resembling male genitalia with hypospadias and short limbs with joint contractures. The fetal roentgenograms showed bell-shaped thorax with coat-hanger. SNP array analysis was performed on DNA from fetal tissue. Data analysis revealing two regions of runs of homozygosity in 14q: the first one is a subcentromeric region of about 10 Mb, the second is a subtelomeric region of about 9 Mb. Trio analysis performed by two computational tools (UPDtool and SNPtrio) for detection and classification of uniparental isodisomy (UPD) confirmed paternal uniparental iso/heterodisomy of chromosome 14. In particular, data revealed a region of isodisomy in 14q11.2-q12 from genomic position 20.2 Mb to 30.4 Mb, a region of heterodisomy in 14q12-q32.2 from 30.9 Mb to 97.9 Mb, and a terminal region of isodisomy from genomic position 98 Mb to telomere. Results was validated by the analysis of microsatellite markers across chromosome 14. This result may contribute to prenatal identification of similarly affected patients.

P01.075-S
Reporting the outcome of molecular PGDs from a single laboratory in Iran

S. Zeinali[1,2], *P. Fouladi*[2], *F. Rahiminejad*[2], *S. Sabeghi*[2], *K. Fatemi*[2], *L. Rejali*[2], *A. Sarhadi*[2];
[1]*Dep't of Molecular Medicine, Biotechnology Research Center, Pasteur Institute of Iran, Tehran, Iran, Tehran, Islamic Republic of Iran,* [2]*Medical Genetics Lab of Dr. Zeinali, Kawsar Human Genetics Research Center, Tehran, Iran, Tehran, Islamic Republic of Iran.*

Reporting results of preimplantation genetic diagnosis (PGD) for single gene disorders, gender typing, HLA matching and chromosomal aneuploidies from 2009. We used mainly multiplex nested PCR containing several short tandem repeats (STR) and sometimes gene fragments for sequencing. PGD were mainly offered for families with common genetic disorder in Iran specially beta-thalassemia, HLA matching, PKU, sex typing, chromosomal aneuploidies and Hemophilia A. In total we have performed PGD for 29 cases (total of 158 blastomers). For ladies with advanced age only few (1-4) eggs could be retrieved. In total only 46 blastomers could be implanted.
Our results show that in total 36 blastomers were tested for F8 linked STRs, 5 for PKU (BH4, PTS gene), 8 for PKU (PAH gene), 8 for Deafness (GJB2 gene), 8 for Epidermolysis Bollusa and HLA matching, 20 for β-Thalassemia, 84 for aneuploidies and finally gender selection was done on 132 blastomers. Some of these figures belong to two or three types of simultaneous testing

(e.g. thalassemia and sex selection or thalassemia and HLA typing).
Implantation was succeeded to pregnancies and child births in 3 families and one is still pregnant. The birth outcome was a twin healthy boys for hemophilia A (born on May 2011), a triplet boys for gender and aneuploidies selections (born on December 2013), a carrier boy for β-thalassemia was born on February 2014 and another twin hemophilia A pregnant at 8 weeks.

P01.076-M
Pre-case haplotyping of the two monogenic diseases in one family in Gennet: Marfan syndrome and SMA

I. Soldatova, *M. Putzová, L. Krautová, D. Rašková, L. Vykysalá, J. Míka, P. Potužníková, R. Křen, D. Stejskal;*
GENNET, Prague, Czech Republic.

Genetic pre-case haplotyping (PGH) is an important constituent of the preimplantation genetic diagnosis (PGD). In our center we have performed haplotyping studies for 86 different monogenetic diseases of all types - X-linked, autosomal recessive, autosomal dominant, translocation and small deletions. The list of diagnosis for which we can offer PGD is being continually extended. PGD is available for a large number of monogenic disorders. For most couples requiring PGD, common pre-case haplotyping analysis of disease-associated haplotype is derived from family anamnesis. We are presenting a case in which affected haplotype will be determined by standard PGH analysis . In this family 2 affected haplotypes were detected which are associated with AD disease - Marfan syndrome - OMIM # 154700 and AR disease- Spinal Muscular Athrophy(SMA) - OMIM # 253300. During the first PGD cycle in the year 2013 (11.2013): 11 cumulus-oocyte-complexes (COCs) were retrieved. 9 blastomeres were biopsied. All tested embryos were analysed .2 embryos were affected of SMA , 3 embryos were affected of Marfan syndrome .2 embryos were diagnosed as monosomy of chr.5 carrying high risk paternal haplotype SMN1 gene. 2 embryos did not show PCR-amplification. The embryos were not re- analysed because they didn´t show optimal development. In this first PGD cycle no embryos were transferred . While there was no transfer in this case during the first PGD cycle, PGD still increases the chances of families at risk of transmitting serious genetic disorders to plan a healthy offspring.

P01.077-S
Targeted capture and massively parallel sequencing for PGD of monogenic diseases

Y. T. Du[1], *J. Li*[2], *X. D. Zhang*[2], *J. L. Li*[2], *S. J. Liu*[2], *Y. W. Xu*[3], *C. Q. Zhou*[3];
[1]*BGI healthcare, Shenzhen, China,* [2]*BGI Research, Shenzhen, China,* [3]*The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

PGD is an important option for known carriers of monogenic diseases to deliver healthy babies. Polymerase chain reaction (PCR) is the most widely used method in PGD for monogenic disorders. However, in order to establish a robust PCR based PGD protocol, extensive preclinical experiments are needed to ascertain the efficiency and reliability of the procedure, which is a labor-intensive, time-consuming and costly process.
Many clinical applications based on targeted Massively parallel sequencing (MPS) have been reported. In this study, we explored the applicability of targeted MPS for PGD of monogenic disease. Isolated single lymphocytes were used to evaluate the genotyping accuracy of target-MPS at single-cell level at first. Then two families carrying mutation of the HBB causing β-thalassemia were tested using targeted MPS.
Pedigree haplotype analysis was applied in the following analysis and double-blind design was used in the study.
Over hundred of informative SNPs flanking both sides of the disease causing mutation were detected for each embryonic haplotype. The average interval between informative SNPs and gene mutation was within 10 kb. The final result was 100% consistent with the diagnosis provided by the reference laboratory, and the whole test was finished within a week.
The new targeted MPS based method will make the PGD for monogenic disease more accurate, faster and more affordable, providing benefit to many patients requiring PGD for monogenic disease.

P01.078-M
Single cell segmental aneuploidy detection is compromised by S phase

E. S. Dimitriadou[1], *N. Van der Aa*[2], *J. Cheng*[1], *T. Voet*[2], *J. R. Vermeesch*[1];
[1]*Laboratory for Cytogenetics and Genome Research, Department of Human Genetics, KU Leuven, Leuven, Belgium,* [2]*Laboratory of Reproductive Genomics, Department of Human Genetics, KU Leuven, Leuven, Belgium.*

Carriers of balanced translocations are at high risk for unbalanced gametes which can result in recurrent miscarriages or birth defects. Preimplantation genetic diagnosis (PGD) is often offered to select balanced embryos. This selection is currently mainly performed by array comparative genomic hybridization (aCGH) on blastomeres. Current methodology does not take into account the phase of the cell cycle, despite the variable copy number status of different genomic regions in S phase. To evaluate the accuracy of single cell array CGH, different cell cycle phases from three cell lines derived from patients with different chromosomal imbalances were sorted by flow cytometry. Ten single cells were picked per cell line per cell cycle phase, whole genome amplified and analyzed by BAC arrays, the most commonly used platform for PGD purposes. In contrast to G phase, where the imbalances were efficiently identified, the log2 intensity ratios of less than half of the probes in the regions of interest were above the detection threshold in 17/26 analyzed S phase cells. The results demonstrate that the accuracy to detect segmental chromosomal imbalances is reduced in S-phase cells, which could be a source of misdiagnosis in PGD. Hence, the determination of the cell cycle phase of the analyzed cell is of great importance and should be taken into account during the analysis. This knowledge may guide future technological improvements.

The aim of the study was to verify the possibility to predict preeclampsia (PE) after the 20th week of gestation by reliable cut-off levels based on PlGF analysis at the time of pregnancy termination within weeks 24-41. Control PlGF levels for weeks 9-19 were derived from 800 cases; 100 PE sera comprised: 17 - PE weeks 24-29, 24 (30-33), 34 (34-37) and 25 (38-41). PlGF was examined by DelphiaXPress Tm platform (PerkinElmer). Reliable PlGF control levels (3, 5, 25, 50, 75 and 95 percentiles) were established for weeks 9-19. For 1st trimester PE risk determination commercial software was used, for weeks 14-19 levels < 3 or 5 pecentiles were applied. Inverse relationship of decreased PlGF levels to the onset of PE and its clinical impact was documented. PlGF median level increase during pregnancy is significantly retarded. Levels of PlGF for PE (weeks 24-29) correspond to medians of the 11th week, PE (weeks 30-33) to week 15 and intermediate/late PE to week 17. PlGF cut off levels for 100%/95% detection rate success for PE weeks 24-29,30-33, 34-37, 38-41 are 61.6/46.2, 267.8/19.5, 262.3/180.3, 168.3/146.0 (all pg/ml). Combination of 1 st trimester PE screening with software prediction of early intermediate and late PE with 2nd/3rd trimester PlGF examination could improve the complex care not only for PE, but also for other adverse risks of HELLP syndrome, SGA, preterm delivery and IUGR including increased efficacy of 1st trimester aneuploidy screening. Supported by FN Motol (00064203, Modern Therapy), IGA NT13770 and OPPK CZ.2.16/3.1.00/24022.

Integrative transcriptome-based approach for association studies: identification of new genetic markers for preeclampsia

E. Trifonova[1], *N. Ershov*[2], *T. Gabidulina*[3], *V. Serebrova*[1], *V. Stepanov*[1];
[1]*Institute for Medical Genetics, Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation,* [2]*The Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Sciences, Novosibirsk, Russian Federation,* [3]*The Institute for Obstetrics and Gynecology, Siberian Branch of Russian Academy of Medical Sciences, Tomsk, Russian Federation.*

Preeclampsia is a common pregnancy-specific disorder with unknown etiology diagnosed in 5-17% of pregnancies. It is the leading cause of maternal and perinatal morbidity and mortality. Our prior genome-wide transcriptional profiling of placental tissue led to a novel set of 63 preeclampsia candidate genes (differentially expressed genes, (Fold Change >1.5, FDR<0.1)). In this report, we present preliminary study on the role of variability in some of these genes in the genetic susceptibility to preeclampsia. We analyzed 51 tagging single nucleotide polymorphisms (tagSNPs) in 12 genes (ANKRD37, BCL6, BHLHE40, CCSAP, CORO2A, DGKG, GPT2, PLIN2, RDH13, SIGLEC6, SYDE1 and ZNF175) in 514 patients with preeclampsia and 627 women with uncomplicated pregnancies from Russian, Buryat and Yakut populations using MassArray iPLEX (Sequenom). We have detected significant associations for preeclampsia with tagSNPs in PLIN2, BHLHE40, DGKG, RDH13, SYDE1 genes in Russian and Buryat population. In Yakut population, only three genes (BHLHE40, CORO2A, GPT2) are associated with increased risk of preeclampsia. tagSNPs in ANKRD37 and ZNF175 genes were associated with preeclampsia in Buryat population only. Interestingly, we found an association with preeclampsia for twenty out of the fifty-one studied polymor-

phism. This results demonstrate the high informative value of the integrative approach in studies of the genetic components of preeclampsia and show that allelic variations of the differentially expressed genes in placental tissue are associated with preeclampsia in different ethnic groups. Nevertheless, the clinical significance of these findings remains to be determined. This work was supported by the Russian Foundation for Basic Research (grant №14-04-01467).

Molecular understanding of the FMR1 premutation and Fragile X-associated Premature Ovarian Failure

C. Caslini, *A. Crespi, G. Pietrini, A. Marozzi;*
MEDICAL BIOTECHNOLOGY AND TRANSLATIONAL MEDICINE, Milan, Italy.

CGG repeats expansion (55-200 units, premutation range) in the 5'UTR of FMR1 gene (Xq27.3) is associated with Fragile-X Tremor/ Ataxia Syndrome and Premature Ovarian Failure (POF). FMR1 premutation represents the most significant single gene variant associated with POF, however no studies are available to evaluate its pathogenic effect in the ovary context. As for FXTAS, an RNA-mediated toxic gain of function could be hypothesized for FX-POF. Human granulosa cell line were transfected with plasmid containing 76CGG repeat elements in the 5'-UTR of EGFP reporter under the control of CMV immediate early promoter (CMV-76CGG-EGFP), or with CMV-EGFP as control. By RNA immunoprecipitation, the interaction of 76rCGG for rCGG-Repeat Binding Proteins (rCGG-RBPs), previously identified, was tested. 76rCGG solely immunoprecipitate with heat shock proteins, some hnRNPs and proteins involved in paraspeckles formation such as SFPQ and hnRNPM, suggesting that in vivo premutated FMR1 mRNA differs from the wild type in making RNA-protein complexes. In this regard in premutated granulosa cells a deregulation of structural components paraspeckles was observed suggesting an alteration of splicing. Furthermore an "heat shock like" response associated with a reduced cell viability in human ovary granulosa cells expressing expanded CGG mRNA was observed, indicating a toxic role of premutated mRNA itself in the ovaries. This work is supported by Telethon grant GGP009126.

DNA copy number variations in women with premature ovarian insufficiency

O. Tšuiko[1,2,3], *O. Žilina[1], M. Nõukas[1,4], K. Haller-Kikkatalo[3,5], A. Salumets[3,2,5], A. Kurg[1];*
[1]Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia, [2]Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia, [3]Competence Centre on Reproductive Medicine and Biology, Tartu, Estonia, [4]Estonian Genome Centre, University of Tartu, Tartu, Estonia, [5]Department of Obstetrics and Gynaecology, University of Tartu, Tartu, Estonia.

The cause of premature ovarian insufficiency (POI) remains unknown in many cases. In recent years many studies have focused on the genetic factors of POI. Conventional karyotyping analyses have identified several X chromosome regions that harbour genes critically required for normal functioning of the ovaries. Due to rise of DNA microarray technology, it has been shown that in addition to X chromosome rearrangements, POI is associated with aberrations in autosomal chromosomes. Single-nucleotide polymorphism (SNP) arrays are useful in identifying single genes and genome regions responsible for the onset of POI. The present study included 700 women with idiopathic POI with the cessation of ovarian function before 40 years of age. Women with a history of gynaecological surgery, cancer treatment and genetic syndromes were excluded. Genomic DNA samples were provided by Tartu University Hospital and Estonian Genome Centre and analysed for copy number variations (CNV) and runs of heterozygosity (ROH) using high-resolution SNP arrays. The majority of detected CNVs fall within the common polymorphic regions, while others have clinical significance and harbour previously reported and novel POI candidate regions and genes. Identified aberrations include a 24Mb Xp22.33-p21.3 hemizygous deletion and a novel microdeletion in 15q21.3. In addition to CNV, numerous ROH regions were detected, which may possibly contain homozygous mutations in POI associated genes. DNA microarrays are a suitable tool for evaluating genomic imbalances in POI patients when compared to the conventional cytogenetic methods. The present study provides novel data on associations between the genomic variants and aberrations and POI phenotype.

Prenascan in Gennet, non-invasive prenatal test trisomy

S. Horáčková, *J. Vávrová, F. Zembol, I. Marešová, M. Putzová, D. Stejskal;*
Gennet s.r.o., Praha 7, Czech Republic.

Prenascan project was created in the Czech Republic in cooperation with Health BGI Europe. Project introduced into clinical practise non-invasive prenatel test for trisomy of chromosomes 13, 18, 21 with the possibility of sex determination and determining defects in sex chromosomes X and Y. The method is based on the evaluation of fragment's relative abundance of cell-free DNA (cffDNA) in maternal plasma. The fetal fraction of the total free DNA is 5-25 %, according to the stage of pregnancy. Extraction of cffDNA exploits the fact that cffDNA is significantly smaller than the maternal DNA, with fragments approximately 200bp in size. cffDNA subsequently subjects to whole-genome sequencing using next-generation sequencing platform based on the semiconductor sequencing technology. Examination method Prenascan is perfomable between 10 and 21 weeks of pregnancy, only after genetic counseling. Diagnostic sensitivity of the method is about 96 % to detect the tested trisomy. The specificity of the test exceeds 99,7 %. Efficiency of the test is 99,9 % for the cases of trisomy 21, 98,8 % for trisomy 18 and 98,7 % for trisomy 13. The main limitation of the test is low concentration of cffDNA in maternal plasma. Test results can be distorted by foreign DNA if the mother received transfusion or transplantation of stem cells.
From October 2012 to December 2013 1263 patients were tested . Positivity was found in 22 cases, false pozitivity in 4 cases. False-positive patients were tested by amniocentesis or chorionic villus sampling with normal results.

A unique ring chromosome 20 in a fetus with a complex heart malformation

M. J. V. Hoffer[1], *M. Koopmans[1], K. Teunissen[2], L. Groenewegen[1], I. Bogerd[1], S. Bhagwandien-Bisoen[1], M. H. Breuning[1], N. S. den Hollander[1], M. C. Haak[2];*
[1]Dept. of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands, [2]Dept. of Obstetrics, Leiden University Medical Center, Leiden, Netherlands.

A 31-year old woman was referred at 20+6 weeks gestational age because of abnormalities at the standard anomaly scan. Advanced ultrasography showed a double outlet right ventricle with transposition of the great arteries and a hypoplastic left ventricle. Furthermore a mandibular retrognathia was noticed. Amniocentesis was performed for RAD and array analysis. The pregnancy was terminated at the parents request and external post-mortem examination revealed mild dysmorphic facial features including mild micrognatia and low set ears. SNP-array analysis showed a duplication deletion rearrangement in the long arm of chromosome 20. The interstitial duplication was 20,5 Mb and the adjacent deletion was 240 kb in size. Karyotyping revealed a ring chromosome 20 in all analysed cells. Fluorescence in situ hybridisation analysis demonstrated that the duplication was inverted. Parental chromosomes were normal indicating that this unbalanced rearrangement occurred de novo. Only a few cases with a ring chromosome with a telomere deletion and an additional inverted duplication have been described so far. These inv dup del chromosomes are the result of an asymmetric breakage of a dicentric chromosome that has been formed to stabilize a broken chromosome. The ring formation represents a new mechanism, in addition to telomere capture, through which inv dup del chromosomes can stabilize. In conclusion this study presents a prenatal case with a ring chromosome 20, which presented with ultrasonographic anomalies initially.

P01.085-S
A 3 years worldwide experience with Prenatal BACs-on-BeadsTM for prenatal diagnosis in over 9.500 pregnancies

Chromosomal microarrays are the gold standard in prenatal cases with ultrasound abnormalities+normal karyotype. In low-risk pregnancies their use is still controversial because of their diagnostic yield in relation to that of variants of unclear significance. Consequently some laboratories, for low-risk pregnancies, adopted PNBoBs™ (in combination with karyotype) a transitional test investigating 9 critical-regions associated with dominant microdeletion syndromes with known genotype-phenotype correlations. We present the experience of 12 worldwide laboratories using PNBoBs™+karyotype. The purpose was to evaluate the usefulness of PNBoBs™ in pregnancies with low *a priori* risk of microdeletion/microduplication syndromes (advanced maternal age,AMA; maternal anxiety,MA; increased risk after maternal serum screening for Down syndrome,MSS-DS; soft marker/s). 9648 samples were analyzed: 17.4% AMA, 22.2% MSS-DS, 8.1% MA, 36.0% ultrasound abnormalities and 7.1% for unknown origin. Successful rate was 96.7%; false negative incidence 0.56% related to chro-

mosome abnormalities not covered by PNBoBs™ but detectable by karyotype. In 0.31% of cases PNBoBs™ was reflexed by FISH for further characterization. Overall abnormal results (PNBoBs™+karyotype) were observed in 9.1% of cases; a microdeletion/microduplication was retrieved in 0.7% of cases (n=69); the majority of them (68.1%) involved Di George syndrome critical-region (deletion=32; duplication=15). 23 cryptic imbalances were found in low risk pregnancy leading to an additional diagnostic yield of about 1/246 in the low-risk pregnancies; 41 were detected in high risk pregnancies providing a 1.8% of additional detection rate (1/54). We will present incidence of cryptic unbalances stratified by indication for prenatal diagnosis that was surprisingly higher than expected basing on theoretical incidence (1/1700).

Detection of 7p14 deletion in a fetus with aortic coarctation: genetic and fetal morphology data

L. Cardarelli[1], *I. Mammi*[2], *F. Di Giovanni*[3], *E. Nalesso*[1], *S. Gomirato*[1], *L. Michelotto*[1], *K. Marchioro*[1], *M. Duca*[1], *G. Abatangelo*[1];
[1]*Lab Citotest - Consorzio GENiMED, Sarmeola di Rubano (PD), Italy,* [2]*Dolo Hospital - ULSS 13, Dolo (VE), Italy,* [3]*Mirano Hospital - ULSS13, Mirano (VE), Italy.*

We present the case of a fetus with aortic coarctation suspected by ultrasounds at 26th gw, in which an interstitial deletion 7p12.3p14.2 was identified on amniotic fluid. The deleted region, confirmed by FISH and aCGH analyses, spanned in the range chr7:36,671,630-46, 039.765bp, and involved several genes, as GLI3, ccm2, GCK, txndc3.
Decipher db shows at least 5 subjects with a microdeletion involving this region, all with delayed psychomotor development, dysmorphisms and abnormalities of the extremities. One of the subjects also presented coarctation of the aorta.
The literature also reports some cases of del(7)(p14) and Greig Cephalopolysyndactyly, an autosomal dominant disorder associated with GLI3 aploinsufficiency, characterized by a distinct combination of craniofacial, foot and hand malformations. Digilio et al reported a deletion 7p14 with cardiac anomalies (non-compacted myocardium, VSD, ASD and aortic valve dysplasia). Five other subjects, with cytogenetically visible deletions 7p14, had more severe findings as microcephaly, dysmorphism and mental retardation.
After several genetic counseling sessions with the equipe of the prenatal center, the parents decided for ToP.
Fetal autopsy identified cranio-facial dysmorphisms, a complex CHD with aortic coarctation, ASD, VSD and left ventricle hypertrophy, Meckel's diverticulum, accessory spleen and horseshoe kidney.
This case underlies that ultrasound, genetic testing (including aCGH) and genetic counselling should be included in the protocol of pregnancies with fetal malformations, once again reinforcing the necessity for the different specialists involved in prenatal diagnosis to cooperate in the identification of a complex fetal phenotype, to offer a prognosis that may help parents in their pregnancy options.

Prenatal diagnosis and Preimplantation Genetic Diagnosis for inherited cardiac diseases in the Netherlands: an overview

E. A. Nannenberg[1], *J. J. van der Smagt*[2], *M. W. Wessels*[3], *J. P. van Tintelen*[4], *A. A. M. Wilde*[1], *R. H. Lekanne Deprez*[1], *C. E. de Die-Smulders*[5], *I. Christiaans*[1], *Y. Arens*[5];
[1]*Academic Medical Center, Amsterdam, Netherlands,* [2]*Utrecht Medical Center, Utrecht, Netherlands,* [3]*Erasmus Medical Center, Rotterdam, Netherlands,* [4]*University Medical Center Groningen, Groningen, Netherlands,* [5]*Maastricht University Medical Center, Maastricht, Netherlands.*

Inherited cardiac diseases are associated with an increased risk of sudden cardiac death (SCD). Common hallmark is the variable disease expression and incomplete penetrance. Therefore the phenotype varies widely between and within families. PND and PGD provide carriers of a mutation that causes an inherited cardiac disease the possibility of having a child without the familial gene mutation and reduce the risk of SCD in their children. The advice from the National Board for PGD indications is to be hesitant with PGD in inherited cardiac diseases due to reduced penetrance and variable expression of the phenotype.
In this study, we evaluated the number of PND and referrals for PGD for inherited cardiac diseases in the Netherlands in the past 15 years.
PND was performed for three different inherited cardiac diseases: Hypertrophic cardiomyopathy (HCM) (n=2), Dilated cardiomyopathy (DCM) (n=1) and Long QT syndrome (LQTS) (n=1). Couples came for PGD intake for HCM (n=9), Arrhythmogenic right ventricular cardiomyopathy (ARVC) (n=3), DCM (n=9), NCCM (n=1), LQTS (n=2), Brugadasyndrome (n=2), and idiopathic VF (n=3). After intensive counseling one couple (DCM) choose to continue the PGD procedure. Another couple (idiopathic VF) started the procedure, but withdrew after the genetic test was made, because of ethical considerations. The other couples choose to fulfill their child wish by other means. The families opting for PND or PGD for inherited cardiac diseases have experienced a severe phenotype or a severe family history of SCD. Nevertheless, the number of patients continuing with PND and PGD is low.

Zimmermann*[2], *A. Rauch*[1];
[1]*Institute of Medical Genetics, University of Zurich, Zurich, Switzerland,* [2]*Division of Obstetrics, University Hospital Zurich, Zurich, Switzerland,* [3]*Swiss Perinatal Institute, Zurich, Switzerland,* [4]*Department of Gynecology and Obstetrics, Kantonsspital Frauenfeld, Frauenfeld, Switzerland,* [5]*Division of Gynecology and Obstetrics, Hospital of Männedorf, Männedorf, Switzerland,* [6]*Obstetric clinic, Winterthur, Winterthur, Switzerland,* [7]*Department of Gynecology and Obstetrics, Kantonsspital Winterthur, Winterthur, Switzerland.*

Objective: The objective of this study was to determine for the first time the reliability and the diagnostic power of high-resolution microarray testing in routine prenatal diagnostics. Methods: We applied high-resolution chromosomal microarray testing in 464 cytogenetically normal prenatal samples with any indication for invasive testing.
Results: High-resolution testing revealed a diagnostic yield of 6.9% and 1.6% in cases of fetal ultrasound anomalies and cases of advance maternal age (AMA), respectively, which is similar to previous studies using low-resolution microarrays. In 3 (0.6%) additional cases with indication AMA an aberration in susceptibility risk loci was detected. Moreover, one case (0.2%) showed an X-linked aberration in a female fetus, a finding relevant for future family planning. We found the rate of cases, in which the parents had to be tested for interpretation of unreported copy number variants (3.7%), and the rate of remaining variants of unknown significance (0.4%) acceptably low. Of note, these findings did not cause termination of pregnancy after expert genetic counseling. The 0.4% rate of confined placental mosaicism was similar to that observed by conventional karyoytyping and notably involved a case of placental microdeletion.
Conclusion: We conclude that high-resolution prenatal microarray testing is a reliable technique that increases diagnostic yield by at least 17.3% when compared with conventional karyotyping, without an increase in the frequency of variants of uncertain significance.

P01.089-S
Noninvasive detection of a balanced fetal translocation from maternal plasma

S. Kim[1], *T. Jensen*[1], *D. van den Boom*[2], *C. Deciu*[1], *M. Ehrich*[2];
[1]*Sequenom Laboratories, San Diego, CA, United States,* [2]*Sequenom Inc., San Diego, CA, United States.*

Noninvasive prenatal testing based on massively parallel sequencing (MPS) of circulating cell free DNA (ccfDNA) from pregnant plasma offers a powerful tool for detecting fetal chromosomal aneuploidies and other copy number variations; however, copy neutral structural rearrangements have proven challenging. We aimed to detect and characterize a balanced fetal specific translocation event by sequencing ccfDNA from maternal plasma. Simulations were used to develop an algorithm which leverages base incremental changes in mapping characteristics of ccfDNA to identify paired end reads potentially harboring structural rearrangements. We then applied this methodology on high coverage 100bp paired end data from ccfDNA isolated from a 38 year-old pregnant donor carrying a fetus with a balanced translocation. Our algorithm identified the known translocation (p=1.21e-8) and discounted the likelihood of others, enabling the base specific localization of the breakpoints. Furthermore, while no evidence of chromothripsis existed, we identified a 6bp deletion present within der(8) which is absent from the der(11) reciprocal rearrangement after de novo assembly of 76 chimeric reads. Overall, we have demonstrated here the first proof of concept study detecting and characterizing a balanced fetal specific translocation by sequencing ccfDNA from maternal plasma.

Prenatal diagnosis and follow-up of a Patient with ASPM primary microcephaly MCPH

Y. Tunca[1], *C. Badoer*[2], *E. S. Cakar*[3], *F. Libert*[4], *H. Akar*[1], *M. Abramowicz*[5];
[1]*Medical Genetics Department, GATA, Gulhane Military Medical Faculty, Ankara, Turkey,* [2]*IRIBHM, ULB, Université Libre de Bruxelles, Brussels, Belgium,* [3]*Medical Genetics Department, Zekai Tahir Burak Women's Health Education and Research Hospital, Ankara, Turkey,* [4]*Genetics Department, Hopital Erasme - ULB, Université Libre de Bruxelles, Brussels, Belgium,* [5]*IRIBHM, ULB and Genetics Department, Hopital Erasme - ULB, Université Libre de Bruxelles, Brussels, Belgium.*

Primary microcephaly is a heterogeneous disorder of brain development

where the brain is too small since birth but otherwise normally formed. It results from an insufficient production of mature neurons during neurogenesis. Many genetic defects have been identified in primary microcephaly, the common pathobiological endpoint being an alteration in the cell-cycle timing and fate determination of neural progenitors. *ASPM* is the most frequently involved gene in the Microcephaly, Primary Hereditary (MCPH), autosomal recessive phenotype. Detailed prenatal and postnatal phenotypic reports are currently lacking. We report on a Turkish family where the second child, a 36 months old boy, presented with typical MCPH. The parents were first cousins, and the mother was in the 9th week of her third pregnancy. Next generation sequencing of the proband's DNA showed a homozygous *ASPM* mutation, a 1bp insertion in exon 18 causing a frameshift and premature stop codon, c.6513dupA (p.Val2172SerfsX7). Both parents were heterozygous for the mutation. They opted for prenatal diagnosis, and amniocytes DNA showed homozygosity for the mutation. The pregnancy was continued, and the parents declined further examinations. This case illustrates the power of high throughput sequencing for rapid prenatal diagnosis of MPCH, where phenotypic correlations should eventually help understand how MCPH genes shape various parts of the cortex, central gray matter, and other parts of the encephalon.

Identification of rare CNVs involving genes acting in oocyte maturation and differentiation in a cohort of patients affected by Primary Ovarian Insufficiency

I. Bestetti[1,2], *C. Castronovo[1], M. Crippa[1], R. Rossetti[3], A. Pistocchi[2], C. Caslini[2], C. Sala[4], D. Toniolo[4], L. Persani[3,5], A. Marozzi[2], P. Finelli[1];*
[1]Laboratory of Medical Cytogenetics and Molecular Genetics, IRCCS Istituto Auxologico Italiano, Milano, Italy, [2]Department of Medical Biotechnology and Translational Medicine, University of Milan, Milano, Italy, [3]Laboratory of Endocrine and Metabolic Research and Division of Endocrine and Metabolic Diseases, IRCSS Istituto Auxologico Italiano, Milano, Italy, [4]Division of Genetics and Cell Biology, San Raffaele Research Institute and Vita Salute University, Milano, Italy, [5]Department of Clinical Sciences and Community Health,University of Milan, Milano, Italy.

Primary Ovarian Insufficiency (POI) is a heterogeneous group of disorders with an incidence of 1:10,000 women by age 20, 1:1,000 by age 30, 1:100 by age 40. Despite the identification of numerous candidate genes in POI women, the genetic origin has been clarified only in about 20% of the patients. The patients showing the most severe phenotype, characterized by the absence of pubertal development and primary amenorrhea (PA) and 46,XX ovarian dysgenesis, are indeed rare but the search for genetic variations in this extreme phenotype may be more effective in identifying novel pathogenic mechanisms.
To unveil new POI causative genes we searched for rare high-penetrance CNVs involving genes essential for ovarian function in a cohort of 46,XX patients affected by PA. Forty-three patients were processed by high resolution array-CGH. Thirty-seven patients were found to bear 98 CNVs not reported to date in healthy subjects according to the Database of Genomic Variants (DGV), and 11 CNVs already reported in DGV but relevant to gene content, for a total of 109 CNVs. Several of these genomic alterations include genes implicated in: meiotic resumption, oogonia maintenance, first-polar-body extrusion, DNA repair, follicle adhesion/migration regulation, actin remodelling, cholesterol endocytosis, Ca2+ homeostasis.
Once characterized by other molecular and bioinformatics approaches, the results of this study are promising to expand the knowledge about the molecular pathways involved in POI pathogenesis and probably provide the basis for a more accurate genetic diagnosis of POI patients.

P01.092-M

Conflicting results QF-PCR and karyotyping due to structural aberration of the Y-chromosome

K. B. M. Hansson[1], *N. S. den Hollander[1], M. E. van Huizen[2], J. Lind[3], L. Groenewegen[1], M. Hoogenboom[1], J. Zonneveld[1], M. J. V. Hoffer[1];*
[1]Leiden University Medical Center, Leiden, Netherlands, [2]Dept. of Gynaecology and Obstetrics, Haga Hospital, location Red Cross, The Hague, Netherlands, [3]Dept. of Gynaecology and Obstetrics, Haga Hospital, location Westeinde, The Hague, Netherlands.

Quantitative fluorescent polymerase chain reaction (QF-PCR) is an accurate and efficient technique for rapid prenatal diagnosis of trisomy 13, 18 and 21 and aneuploidies of the sex chromosomes. Discordant results between QF-PCR and karyotyping have occasionally been reported, mostly due to mosaicism.
A 20-year old female underwent chorionic villus sampling at 13 weeks' gestation because of an increased risk of a chromosomal aberration after first trimester screening. Ultrasound investigation demonstrated no abnormalities. The results from the QF-PCR analysis were interpreted as a possible mosaic 45,X/46,XY because of the low contribution of the Y chromosome. Conventional karyotyping of the LTC demonstrated a non-mosaic 45,X. Since no abnormal findings were detected on ultrasound, a confined placental mosaicism was suggested as a possible explanation for the discordant findings. A subsequent amniocentesis revealed a normal male genotype with QF-PCR. Karyotyping, on the contrary, demonstrated a mosaic pattern with 45,X and a structural rearranged Y chromosome, probably an i(Yp). Additional FISH confirmed the presence of an isochromosome of the short arm of the Y chromosome. The case presented here demonstrates that caution should be taken when conflicting results are observed in CVS - even if a normal profile is obtained with QF-PCR in a follow-up amniocentesis. This case further illustrate that mosaicism for an abnormal cell line can result in a normal QF-PCR profile.

Persistent Elevated Population-based Rates of Congenital Malformations (CM) and Elevated Whole Body Counts (WBC) of 137Cs among Pregnant Women in the Polissia Region of the Rivne Province in Ukraine.

W. Wertelecki[1,2], *B. Ievtushok[1,3], L. Yevtushok[1,3], N. Zymak-Zakytnia[4,5], Z. Sosyniuk[1,3], S. Lapchenko[6], I. Kuznetsov[6];*
[1]OMNI-Net Ukraine Birth Defects Programs, Rivne, Ukraine, [2]Division of Dysmorphology and Teratology, University of California-San Diego., San Diego, CA, United States, [3]Rivne Regional Medical Diagnostic Center, Rivne, Ukraine, [4]OMNI-Net Ukraine Birth Defects Programs, Khmelnytsky, Ukraine, [5]Khmelnytsky Perinatal Center, Khmelnytsky, Ukraine, [6]OMNI-Net Ukraine Birth Defects Programs, Lutsk, Ukraine.

Background: We established a population-based surveillance of CM in the Rivne (R) province of Ukraine. The northern half of R or Polissia (P) is polluted by Chornobyl ionizing radiation. Analyses of observations during 2000-2009 demonstrated elevated population-based rates of specific CM; that prenatal exposure to alcohol was an unlikely cause as well as WBC Bq counts of pregnant women residing in P that often were above the officially set safe limits (Wertelecki et al., in Congenital Anomalies, 2014 in press).
Objectives: determine the degree of persistence of population-based rates of CM, patterns of alcohol use during pregnancy and of WBC patterns among pregnant women.
Methods: adherence to procedures of the European CM monitoring consortium (EUROCAT); analysis of CM patterns among 180,559 births in R during 2000-2011; and analysis of WBC obtained from 9,169 pregnant women in R during 2008-2012.
Results: persistence of higher rates in P than in non-P of conjoined twins, teratomas, neural tube defects, microcephaly, and microphthalmia; less prevalent prenatal exposures to alcohol in P; and persistence of elevated WBC (above 3750 Bq) in 19% of pregnant women residing in P and nearly 0.2% among those residing in non-P.
Conclusions: Higher rates of specific CM, for the most part blastopathies, and elevated WBC of incorporated 137Cs by pregnant women are persistent in the P region of the Rivne province. The evidence is sufficiently compelling to call for a shift from descriptive epidemiology toward cause-effect investigations of IR impacts on CM in Rivne-Polissia.

P01.094-M

The VEGF+405 G/G Genotype may Influence Embryo Implantation in ART

Z. Rokhsattalab[1], *H. Gourabi[2], M. Hasanzad[1];*
[1]Islamic Azad university Medical Science Branch of Tehran, Tehran, Islamic Republic of Iran, [2]Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR,, Tehran, Islamic Republic of Iran.

Repeated implantation failure (RIF) is the main problem after using assisted reproductive techniques (ART). The main causes of RIF as a multifactorial problem include decrease in endometrial receptivity, defects of embryo or combinational. Successful embryo implantation depends on trophoblast proliferation, migration and invasion to the endometrium, all associated with vascular endothelial growth factor (VEGF) as the major protein in stimulating of angiogenesis. This study aimed to determine the association betweenVEGF+405G/C polymorphism and RIF in infertile women. The patients group included 74 women with >3 RIF and the control group consisted of 149 healthy fertile women. Genotypes and allele frequencies of VEGF+405G/C polymorphism were determined by PCR-RFLP method and verified by Sanger sequencing. The frequencies of GG, GC and CC genotypes in patients group were 31.1%, 48.6% and 20.3%, respectively while those frequencies in controls were 2.0%, 47.0% and 51.0% respectively. The frequency of GG genotype was significantly higher in patients than controls ($p<0.001$). CC genotype frequency was higher in controls than patients ($p<0.001$). The frequency of GC genotype did not show any difference between groups. C as the wild allele was more frequent in controls while frequency of G as the mutant allele was higher in patients ($p<0.001$). The VEGF+405 G/G genotype may influence embryo implantation and lead to

RIF in ART candidates. Since this is the second report on association of this polymorphism with RIF, further studies in different ethnic populations require for determining this association.

P01.095-S

Gene-gene interactions and the risk of recurrent miscarriages in EG-VEGF and its receptor genes

M. Su;
Department of Obstetrics and Gynecology, National Cheng-Kung University Hospital, Tainan, Taiwan.

Endocrine gland-derived vascular endothelial growth factor (EG-VEGF) and its receptor genes (PKR1 and PKR2) play an important role in human early pregnancy. Our previous study showed that PKR1 and PKR2 polymorphisms are associated with recurrent miscarriages (RM). This study was conducted to find EG-VEGF, PKR1 and PKR2 variants in the coding regions of idiopathic RPL patients and further evaluate gene-gene interactions in 3 genes. Two hundred and ninety one blood samples from 142 RPL women and 149 controls were nucleotide sequenced in the coding regions of EG-VEG, PKR1 and PKR2. Gene-gene interaction was evaluated in 3 gene variants using multifactor dimensionality reduction (MDR) method. One each nonsynonymous variant of 3 genes were identified, and PKR1(I379V) and PKR2(V331M) were significantly associated with idiopathic RM (p=0.006 and p=0.002, respectively). Genetic interactions were founded not only between PKR1(I379V) and PKR2(V331M), but also among EG-VEGF (V67I), PKR1(I379V) and PKR2(V331M) (p=0.01 and p=0.01, respectively). Women carried low-risk genotypes reduced 77% risk of experiencing miscarriages compared with those carried high-risk genotypes. The present study corroborates the clinical relevance of the EG-VEGF system in human early pregnancy, and provides evidence for the gene-gene interactions of EG-VEGF and PKR variants.

Study of chromosomal alterations and polymorphisms of MTHFR, Factor V and Prothrombin genes in patients with recurrent miscarriage referred to Royan Institute

K. Farahmand[1], *H. Kalantari*[2], *M. Totonchi*[2], *M. Hashemi*[1], *S. Shahzadeh-fazeli*[2], *f. Reihani*[2], *H. Gourabi*[2], *A. Mohseni Meybodi*[2];
[1]*Islamic azad university tehran medical science branch, Tehran, Islamic Republic of Iran,* [2]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive biomedicine, ACECR, Tehran, Iran, Tehran, Islamic Republic of Iran.*

Introduction: Recurrent miscarriage(RM) is defined as two or more consecutive pregnancy losses before 20 weeks of gestation which is an important clinical problem, with an incidence of 1%-3% among couples wishing to have children. There are several factors in the etiology of RM. One of the main genetic causes involve in the pathogenesis of RM is balanced chromosomal rearrangements in one or both of partners. In 4%-8% of couples with RM, at least one of the partners has chromosomal abnormality. After chromosomal abnormalities, thrombophilia was identified as a major cause of RM, with a rate of up to 40%, especially in the first half of pregnancy.
Methods: The patients group included 1100 Iranian couples(2200 individuals) referred to Royan Institute between 2004 and 2013. Karyotyping was performed using standard cytogenetic techniques. Besides, thrombotic gene polymorphisms were studied in 128 women who had a normal karyotype .The results were compared with 70 healthy women as control group.
Results: Abnormal karyotypes were found in 124 people, 83 women (3.77%) and 41 men (1.86%). The frequencies of *FV Leiden*, *Prothrombin*-G20210A, *MTHFR*C677T and *MTHFR*A1298C mutations in patients were 10.93%,4.68%,43.75% and60.15%, respectively. These frequencies in control group were 2.85%,2.85%,34.28% and5.71% respectively.
Conclusion: Sex chromosome mosaicism is the most commonly detected chromosomal abnormality in couples with RM who are candidates for offering PGD.Patients with combined thrombophilic mutations are at higher risk for RM than women without these mutations.The most important issue with hereditary thrombophilia's is the prevention of maternal thrombosis.

Polymorphisms in oxidative stress related genes and recurrent miscarriage

I. V. Volodin[1], *M. B. Khadzhieva*[2];
[1]*Moscow State Universitet, MOSCOW, Russian Federation,* [2]*N.I. Vavilov Institute of General Genetics, MOSCOW, Russian Federation.*

Recurrent miscarriage (RM) is one of the important problems of modern reproductive medicine. RM affects approximately 1 – 5 % of all couples trying to conceive. Various factors have been identified that influence miscarriage, including parental chromosomal abnormalities, endocrine dysfunction, and others. However 50% of cases fail to reveal an identifiable cause and are therefore classified as idiopathic.
We investigated the association of polymorphisms in oxidative stress related genes with idiopathic RM. 331 idiopathic RM patients and 197 controls were genotyped for *ABCB1* rs1045642, *CYP1A1* rs1048943 and rs4646903, *COMT* rs4680, *CAT* rs17880664, *GCLC* rs17883901, *GPX4* rs713041, *NRF2* rs6721961, *SOD2* rs4880, and *OGG1* rs1052133. A protective effect of *COMT* rs4680-G allele on RM was shown in individual SNP analysis: P = 0.0016, OR = 0.47, 95% CI 0.29 - 0.75. The multi-factor dimensionality reduction (MDR) approach revealed gene-gene interactions for *ABCB1*, *COMT, GPX4*, and *OGG1* genes. Cumulative gene risk score analysis demonstrated that more than three risk alleles in the genes *ABCB1*, *COMT*, *GPX4*, and *OGG1* were associated with idiopathic recurrent miscarriage P = 1.2 x 10-3, OR =1.97, 95% CI 1.31- 2.97. In silico data interpreting by GeneMANIA analysis revealed genetic, physical, pathway and coexpression networks for these four genes.
The current study shows that cumulative effects of genetic variability in oxidative stress-related genes may play a role in the recurrent miscarriage with no known etiology.

P01.098-M

Results of conventional karyotyping and 5 thrombophilic gene mutations in a Turkish population with recurrent pregnancy loss

Y. Özen, *H. Gürkan, H. Tozkır, S. Ulusal, E. Göncü, D. Eker;*
Trakya University, Edirne, Turkey.

Recurrent pregnancy loss (RPL) is the spontaneous loss of clinically established intra-uterine pregnancy before the fetus has reached viability
Here we present the cytogenetic data of couples and prevalence of 5 thrombophilic gene mutations among 175 women referred with RPL to our center.
Chromosome analyses were performed in 179 couples with two or more consecutive miscarriages before 24 weeks' gestation between 19.10.2011-31.12.2013 using GTL banding. MTHFR c.677C>T and c.1298A>C, Factor II c.20210G>A, FactorV (Leiden) c.1691G>A and plasminogen activator inhibitor-1 (PAI-1) 4G/5G genotypes were determined using SNP primers designed by the manufacturer (NLM Diagnostics, Italy). Melting curve
analysis has been performed with labeled probes using Real-Time PCR method (Qiagen, Rotor Gene).
Table 1 shows the detail of the cytogenic findings of couples with RPL. The frequencies of studied 5 thrombophilic gene mutations in women referred with RPL were summarized in Table 2.
The prevalence of parental chromosomal aberrations was greater in our study (8.4%) than in most studies in the literature, which quote a 3% - 5% prevalence.
Comparing our results of 5 thrombophilic gene mutations with other studies we suggest considering the mutations in FV Leiden G1691A, MTHFR C677T and PAI-1 4G/5G genes in women with RPL.

P01.099-S
The role of HLA-genes in complex immunogenetic preconditions for idiopathic recurrent pregnancy loss

K. Sosnina, O. Terpylyak, **D. Zastavna**, *N. Helner;*
Institute of Hereditary Pathology, NAMS of Ukraine, Lviv, Ukraine.

Influence of HLA-system on reproductive losses is considered from the standpoint of search for specific HLA genes, the similarity of spouses in HLA-antigens, or the study of modulating properties of HLA-system in the gene network complex. Aim. To analyze the distribution of allelic polymorphism of the HLA-DRB1, DQA1, DQB1 genes and HLA-G 14-bp insertion/deletion polymorphism in married couples with RPL. Results. Complex analysis of distribution and frequency of allelic variants of genes HLA-DRB1, HLA-DQA1 and HLA-DQB1 was conducted for 200 married couples with recurrent pregnancy loss of undefined genesis. It was determined that allele DRB1*0301 is an allele-aggressor in the group of women with RPL, and possessing this allele presents three-fold increased risk of idiopathic pregnancy loss for a woman (OR = 3.4;CI95%:1.0-11.1). The results demonstrated probable significant increase in frequency of genotype +14 bp/+14 bp of HLA-G 14-bp insertion/deletion polymorphism ($p < 0.05$) in women with RPL against the control group. The study demonstrated over two-fold increase of the risk of pregnancy loss for women-carriers of homozygous genotype by allele of insertion(+)14 bp 3' UTR region of HLA-G gene (OR = 2.65;CI 95%:1.06-6.68).
It was determined that the increase in total homology of spouses by 50% and more in allelic polymorphism in loci HLA-DRB1, HLA-DQA1 and HLA-DQB1 presents twelve-fold increased risk of idiopathic pregnancy loss for a woman (OR =12.8;CI95%:1.63-100.27).Conclusions. Changes in the major hystocompatibility complex genes can cause the failure of female reproductive function and lead to the early fetal loss.

P01.100-M
Association study of miR-196a2 rs11614913 polymorphism with risk of idiopathic recurrent pregnancy loss in Iranian women

M. Amin-Beidokhti[1], *F. Karamaldin*[2], *R. Mirfakhraie*[1], *S. Zare-karizi*[3], *M. D. Omrani*[1];
[1]Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran, [2]Shafa Hospital, Semnan, Islamic Republic of Iran, [3]Islamic Azad University Varamin Pishva Branch, Varamin, Islamic Republic of Iran.

Introduction: Recurrent Pregnancy Loss (RPL) is defined as the occurrence of two or more consecutive pregnancy loss prior to 20th week of gestation. There are several leading causes of RPL including uterine anatomical defects, genetic factors, infectious, immunological, environmental and blood dyscariasis. However, despite in a large number of cases no cause has been identified and is classified as idiopathic. Recent studies have implicated miRNAs in endometriosis, preeclampsia, infertility and RPL. Therefore; the aim of the present study was to investigate the association of miR-196a2C>T (rs11614913) with RPL.
Methods: We conducted a case-control study of 185 Iranian women: 85 patients with at least two unexplained consecutive pregnancy losses and 100 healthy controls with at least one live birth and no history of pregnancy loss. Patients with recurrent pregnancy losses due to anatomic, hormonal, chromosomal, infectious, autoimmune, or thrombotic causes were excluded from the study group. Genotyping was performed using tetra-primer amplification refractory mutation system PCR (T-ARMS-PCR).
Results: Significant difference in distribution of miR-196a2 rs11614913 genotypes was found in RPL patients in comparison to controls, with P-value of 0.04 and odds ratio equal to 2.69 (95% CI: 1.03-7.03).
Conclusion: We provide evidence for association between genetic variation in miR-196a2 and recurrent pregnancy loss. Further studies will be required to validate the significance of the studied genetic variation in diverse ethnic populations.

P01.101-S
Genetic variation in Circadian Rhythm Genes are associated with Recurrent Spontaneous Abortions

P. Lavtar, *M. Volk, L. Zemljič, A. Maver, B. Peterlin;*
Clinical Institute of Medical Genetics, Ljubljana, Slovenia.

Recurrent spontaneous abortion (RSA), the occurance of three or more consecutive pregnancy losses before the 24th week of pregnancy, occurs in approximately 0,5-3% of reproductive-aged women. Results from animal model studies demonstrate the importance of circadian rhytms in reproductive health. The aim of this study was to examine whether there is an association between genetic variability in the primary clock genes CLOCK and ARNTL and RSA in the Slovene population. The study group consisted of 152 unrelated women with RSA and control group of 170 age-matched women. Altogether, 8 SNPs were tested, 4 in CLOCK (rs6811520, rs6850524, rs11932595 and rs13124436) and 4 in ARNTL gene (rs3789327, rs1481892, rs4757144 and rs12363415). The significance of association for individual SNP was calculated to compare the allelic frequency and genotype distribution in patients and control subjects using the Chi-Square test ($\chi 2$). After using Bonferroni correction significant difference in distribution of CLOCK rs6850524 polymorphism genotypes were found in patients with RSA in comparison to controls, with P-value of $2.90 \cdot 10^{-6}$ and odds ratio equal to 2.65 (95% CI: 1.68 to 4.18). Other SNPs in CLOCK and ARNTL genes did not display any significant association with RSA susceptibility. We provide evidence for association between genetic variation in CLOCK gene and RSA. Further studies are required to validate the results obtained in the Slovenian population.

P01.102-M
Prenatal diagnosis for hereditary cancer in the Netherlands

C. J. Dommering[1], *L. Henneman*[1], *A. Van der Hout*[2], *M. A. Jonker*[3], *A. C. Moll*[4], *H. Meijers-Heijboer*[1], *DNA-diagnostic laboratories the Netherlands;*
[1]Department of Clinical Genetics, VU University Medical Center, Amsterdam, Netherlands, [2]Department of Genetics, University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [3]Department of Mathematics, Faculty of Sciences, VU University, Amsterdam, Netherlands, [4]Department of Ophthalmology, VU University Medical Center, Amsterdam, Netherlands.

Background Since the 1980s the genetic cause of many hereditary tumor syndromes has been elucidated. As a consequence, carriers of a deleterious mutation in these genes can opt for prenatal diagnoses (PND). We investigated uptake of PND in the Netherlands for retinoblastoma (Rb) and compared this with use of PND for five other hereditary tumor syndromes, i.e. familial adenomatous polyposis (FAP), Von Hippel-Lindau's disease (VHL), hereditary breast ovarian cancer (HBOC), neurofibromatosis type 2 (NF2), and Li-Fraumeni syndrome (LFS). **Methods** A questionnaire was mailed to all DNA-diagnostic laboratories assessing: 1) Number of independent mutation positive families identified until January 2013 2) Number of PNDs performed for these syndromes until that date One-sided Fishers-exact test was used to compare uptake of PND for Rb with the other five tumor syndromes. **Results** 11.8% of mutation positive Rb families used PND, whereas uptake for the other syndromes was between never and 6.5%. For Rb PND was used both by couples with a 50% risk and by healthy couples with a child with a *de novo* mutation (2-3% risk). Overall uptake for PND was significantly higher for Rb than for FAP, HBOC and NF2. If just Rb couples with a 50% risk were taken into account, only a significant difference was found between Rb and FAP and HBOC. **Conclusion** Large differences in the use of PND between tumor predisposing syndromes were observed. Highest uptake was observed for Rb and other childhood hereditary tumor syndromes, which is of relevance for physicians caring for these families.

P01.103-S
Double Robertsonian translocation of chromosomes 13, 14 and 15: a case report

A. Vizule[1,2], *I. Grinfelde*[2,3], *J. Bars*[3], *A. Stamere*[4], *I. Teilane*[4];
[1]Faculty of Continuing Education, Rīga Stradiņš University, Riga, Latvia, [2]Medical genetics clinic, University Children's Hospital, Riga, Latvia, [3]Prenatal diagnostic department, Medical genetics clinic, University Children's Hospital, Riga, Latvia, [4]Laboratory Department, University Children's Hospital, Riga, Latvia.

Introduction. Robertsonian translocations (RT) are among the most common balanced structural rearrangements in humans that occurs in the acrocentric chromosome pairs (chromosomes 13-15, 21-22). Robertsonian translocations comprise complete centromere fusion of the long arms of two acrocentric chromosomes, and the two short arms are lost.
Materials and methods. Trisomy 13 with double RT was characterised by standart karyotype analysis and fluorescence in situ hybridization method (FISH) with probes for chromosomes 13, 18, 21, X and Y with critical regions (RB1, D18Z1, D21S259/D21S341/D21S342, DXZ1, DYZ3) from Abbott Molecular, Inc. Vysis AneuVysion DNA Probe Kit.
Case report. A pregnant 22-year old woman was referred to the prenatal genetic counseling after ultrasonography performed at 13 weeks of gestation revealed congenital fetal abnormalities, including polydactyly of both upper limbs and bilateral cleft lip and palate. First trimester biochemical screening showed decreased pregnancy-associated plasma protein A (PAPP-A) and human chorionic gonadotropin (HCG), calculated risk for trisomy 18

was 1:105. Triple marker screening showed decreased alpha-fetoprotein (AFP) and HCG, and normal free estriol levels. Risk recalculation with the FMF-2012 software (Fetal Medicine Foundation) adjusted risk for trisomy 13 showed 1:55. Diagnostic amniocentesis performed at 15/16 weeks of gestation revealed trisomy 13 by FISH and later 45,XX,+13,der(13;14)(q10;q10),der(14;15)(q10;q10) using standart karyotype analysis.
Conclusions. Currently the estimation of recurrence risk for future pregnancies is impossible because parents refused to investigate their karyotypes. There could be several possible explanations for double Robertsonian translocation.

P01.104-M
Sex chromosome classification by cell free DNA analysis of maternal plasma in a general obstetrical population

C. M. Coffeen, *P. L. Devers, D. Chudova, K. Jones, R. P. Rava, A. J. Sehnert;*
Illumina, Redwood City, CA, United States.

Objective: To examine the performance of noninvasive prenatal testing (NIPT) by sequencing maternal plasma cell-free DNA for fetal sex chromosome classification in a general obstetrical population.**Study Design:** Blood samples were prospectively collected from pregnant women at 21 US sites in the Comparison of Aneuploidy Risk Evaluation (CARE) study (clinicaltrials.gov NCT01663350). Patients undergoing serum screening for fetal aneuploidy were followed to birth. Sex chromosome status was classified blindly by NIPT and compared to clinical outcome based on newborn physical examination, or karyotype if performed. Sensitivity, specificity and exact 95% confidence intervals based on the Clopper-Pearson method were calculated. **Results:** Sex chromosome classification by NIPT and outcomes were available for 1,948 subjects. 1,935 (99.3%) were classified as XX or XY by NIPT. Sensitivity and specificity for predicting female were 97.7% (CI:96.6-98.6) and 99.2% (CI:98.4-99.6), respectively, and 99.2% (CI:98.4-99.6) and 97.7% (CI:96.6-98.6) for predicting male. Two fetuses classified XY by NIPT had ambiguous genitalia at birth; one showed mosaic karyotype 45,X/46,XY. NIPT classified 13 (0.67%) samples with sex chromosome aneuploidy (SCA). Nine with Monosomy X (MX) - all bearing normal-appearing female infants; one had prenatal karyotype 46,XX. Three cases classified XXX by NIPT appeared female at birth and one classified XXY appeared male.
Conclusion: Results demonstrate that NIPT has excellent performance in the general obstetrical population for sex chromosome classification. Mosaicism, maternal contribution or co-twin demise may explain discordance. NIPT is useful in cases of ambiguous genitalia, pregnancies at-risk for sex-linked disorder, or when SCA is not readily detectable by ultrasound/newborn examination.

P01.105-S
The XY female: prenatal discrepancy between phenotype and genotype in bichorial diamniotic twin, what's the differential diagnosis?

E. Pompilii;
Medical Genetics Unit, St Orsola Malpighi Hospital, University of Bologna, BOLOGNA, Italy.

Sexual differentiation depends upon a series of complex events. A 32aa, healthy pregnant woman underwent a routine prenatal ultrasonographic examination at 12 weeks' gestation that showed a bichorial diamniotic twin pregnancy with female sex fetuses. Upon personal desire of the mother, amniocentesis was performed at 15+1 weeks of gestation. Ultrasonographic examination at the time of the procedure confirmed, in both fetuses, normal fetal anatomy with female external genitalia. However, amniotic fluid karyotype analysis was discordant with the female ultrasonographic sex, revealing a 46,XY male karyotype in both of them. Fetal re-exanimation was performed with 3D and 4D ultrasound for fetal sex, and a female genitalia was confirmed again. One hypothesis was the search for the presence of mutation on SRY gene on chromosome Yp11.3, causing 46,XY complete gonadal dysgenesis or XY sex reversal. the analysis has revealed no mutation in the analyzed gene. The other hypothesis was the analysis of androgen receptor (AR) gene. The molecular analysis showed a single nucleotide deletion in codon 766, that resulted in a frame-shift mutation in the steroid binding domain of the androgen receptor P766fsX. As expected, the carrier mother had both normal and mutant AR genes. After genetic counseling the couple decided upon voluntary termination of the pregnancy at the 20th week of gestation. The autoptic examination of both fetuses confirmed the external female genitalia and revealed the presence of sever hypoplasic uterus and abdominal testes that confirmed by histopathological examination.

P01.106-M
Prenatal detection of a case with Simpson- Golabi-Behmel syndrome as a consequence of GPS3 and GPS4 gene duplications

N. Kokalj Vokac[1,2], *N. Tul Mandić*[3], *D. Krgović*[1], *A. Blatnik*[1], *F. Mujezinović*[1];
[1]University Medical Centre Maribor, Maribor, Slovenia, [2]Medical Faculty, University of Maribor, Maribor, Slovenia, [3]University Medical Centre Ljubljana, Ljubljana, Slovenia.

We describe the case of Simpson-Golabi-Behmel syndrome (SGBS) discovered prenataly. Fetal scan in 23rd week of pregnancy identified male fetus with macrosomia, macrocephalia, dilatation of 3rd and 4th ventricle, hyperechogenic gut, agenesis of corpus callosum, cistical dilatated interhemispheric fissura, macrosomic kideny and liver, and kidney polyhydramnion.
Amniocentesis was performed. Molecular kariotyping using ISCA 4x180K arrays reveled two interstitial microduplications on Xq26.2 in size of 574 kb and 115kb. A larger microduplications encompassed four OMIM genes, including whole GPC4 gene. A smaller microduplications was located within the GPC3 gene and embraced exons 6 and 7 of the longest transcript of this gene. CNVs were inherited from the mother.
Persons with this SGBS are frequently affected by embrogenic tumors of kidneys. Also the mother had Wilms tumor in her childhood. The pregnancy was terminated because of ruptured amniotic membrane and amniotic leakage. An autopsy of the infant confirmed organomegaly seen on ultrasound. In addition, a ventricular septal defect, a complete agenesis of the corpus callosum, cerebellar hypoplasia were observed. Distinct facial features were also present, including hypertelorism, short nose with broad nasal bridge, macrostomia and macroglossia, nail hypoplasia, and an extra rib.
GPC3 and GPC4 are the two genes in which mutations are known to cause SGBS. There are only few reports on duplications of GPC3 gene and one report of duplication of CPG4 gene causing SGBS in the literature. Mostly deletions and mutations of GPC3 gene are described. In our presentation possible role of two genes involved in SGBS is discussed.

P01.107-S
The correlation between transcript expression levels of nuclear encoded and mitochondrial encoded genes in single human oocytes during oocyte maturation

A. Allahveisi[1], *M. noruzinia*[2], *M. ghaffari novin*[3], *A. Dehghanifard*[4];
[1]Kurdistan University of Medical Sciences, Sanandaj, Islamic Republic of Iran, [2]Department of medical genetic, Faculty of Medical sciences, Tarbiat Modares University, tehran, Islamic Republic of Iran, [3]Department of Biology and Anatomical Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran, [4]Sarem Cell Research Center (SCRC), Sarem Women's Hospital, Tehran, Islamic Republic of Iran.

Introduction: Impairment of human oocyte maturation during oocyte maturation is a cause of infertility in infertile women. Therefore, Oocyte maturation is important in successful reproductive outcome of assisted reproduction technologies (ART). Mitochondria,which are the most organelle in the oocytes,have in important role during oocyte maturation. Little is known about mitochondrial genomes during oocyte maturation .This aim was to identify the correlation between transcript expression levels between mitochondrial and nuclear encoded genes included the cytochrome C oxidase1 (MT-CO1) gene and the nuclear respiratory factor 1(NRF1) as well as the mitochondrial transcription factor A (TFAM) genes , which using by single-cell real-time PCR during human oocyte maturation. 27 consenting women aged 21-35 years, with male factors were selected for ovarian stimulation and ICSI procedures.
Results:at the germinal vesicle (GV) stage oocytes ,no significance correlation between the relative expression levels ($P>0.05$),whereas there was significant correlation between the relative expression levels of nuclear (TFAM,NRF1) and mitochondrial (MT-CO1) encoded genes at the stages of metaphase I (MI)and metaphase II (MII)stages of oocytes ($P<0.05$).
Conclusion:human oocyte maturation is associated with the increased correlation between transcript expression levels of nuclear (TFAM , NRF1) and mitochondrial (MT-CO1)encoded genes. Thus, any defect correlation between transcript expression levels of nuclear mitochonderial genes leads to impaired developmental oocyte competence.

P01.108-M
Prenatal molecular diagnosis of skeletal dysplasias - a single center experience

T. Schramm, *S. Minderer, K. P. Gloning, C. Daumer-Haas, M. Shoukier, M. Lindner, C. Bagowski;*
Pränatal-Medizin München, Munich, Germany.

Skeletal dysplasias are a large, heterogeneous group of conditions involving the formation and growth of bone. Some skeletal dysplasias are associated with additional abnormalities in other organ systems.
Prenatal diagnosis relies primarily on fetal ultrasound findings, but molecular analysis is used to confirm the presumptive diagnosis and to determine the recurrence risk.

The diagnosis of a substantial number of the most frequent skeletal dysplasias can be confirmed in a short period of time by molecular genetic analysis of the involved genes (e.g. thanatophoric dysplasia, diastrophic dysplasia, campomelic dysplasia, Ellis-van Creveld syndrome or hypophosphatasia).
We present a retrospective analysis of 300 cases diagnosed prenatally by an expert team of experienced sonographers and human geneticists. The study was carried out at a single tertiary center during the last 20 years.
We demonstrate clinical findings and molecular genetic data and construct work-ups for the diagnosis of „difficult" cases (e.g. short rib-polydactyly syndromes, Filamin B associated skeletal dysplasias). Molecular genetic testing was conducted in 186 cases. We were able to establish a final diagnosis in 118 cases - which is equivalent to a detection rate of 65%. Some cases are exampflified with clinical, radiological, pathological and molecular genetic data.
We want to point out the importance of molecular genetic diagnosis for confirming the clinical diagnosis of skeletal dysplasias and providing exact information for genetic counselling.

P01.109-S
Susceptibility loci for neurodevelopmental disorders - genetic counseling and pregnancy management

L. Govaerts, *M. Srebniak, K. Diderich, M. Joosten, S. Riedijk, S. van der Steen, S. van der Steen, F. de Vries, D. Van Opstal, R. Galjaard;*
Erasmus Medical Center, Rotterdam, Netherlands.

Objectives: SNP genomic array may detect susceptibility loci for neurodevelopmental disorders (SL), with possibly an increased but unquantified phenotypical risk. This study evaluates the effect of releasing the SL to pregnancy management. Psychological aspects will be reported separately.
Method: Every patient received *pre-test counseling* with "all pathogenic results will be communicated".
The *post-test genetic counseling* concentrated on the phenotype of the particular SL, its incidence in the normal and affected postnatal population and the difference between postnatal and prenatal ascertainment. Targeted parental array testing was offered. Extensive ultrasound (US) examination was offered when the SL (postnatally ascertained) was associated with physical abnormalities. Psychological help was available in all cases if needed.
Results: In 36 cases out of 2108 ongoing pregnancies a SL was found.
1. Two couples with an increased risk for aneuploidy and no US abnormalities opted for TOP. Both couples already had "a bad feeling" about the pregnancy before testing. They received psychological help. Pathological examination (N=1) revealed no structural abnormalities.
2. For parents with fetal US abnormalities the SL was usually considered as less important. The US abnormalities were the reason for TOP.
3.The inherited nature of SL seemed reassuring.
Conclusions: In 5,5 % (2/36) of the SL cases the pregnancy was terminated due to the presence of the SL. Further follow up of the families and their children is needed to evaluate the significance of prenatal diagnosed SL, to offer early intervention when neurodevelopmental disorders emerge and to evaluate the psychological impact of prenatally discovered SL.

P01.110-M
Origin of multilocus methylation defects of imprinted genes in first-trimester spontaneous abortions

M. V. Lepshin, *E. A. Sazhenova, I. N. Lebedev;*
Research Institute of Medical Genetics, Siberian Branch of Russian Academy of Medical Science, Tomsk, Russian Federation.

Genomic imprinting is one of the most important epigenetic mechanisms of fetal growth regulation. Our studies demonstrated that multilocus methylation defects (MLMD) at imprinted genes may be responsible for pathology of early embryonic development. The aim of the present research was analysis of origin of MLMD in first-trimester spontaneous abortions (SA). Chorionic villus samples (CVS) and extraembryonic mesoderm (EM) were collected from 217 SA from women who underwent abortion procedures. Induced abortion (IA) with normal karyotype (n = 60) were investigated as a control group. The DNA methylation patterns of 7 imprinted genes were analyzed in both tissues using MS-PCR, including analyses of 51 imprinted genes from 15 SA and 4 IA by GoldenGate Methylation Cancer Panel I microarray. Comparative analysis of epimutations distribution between studied tissues allows the identification its somatic or germinal origin. Presence of epimutations in both tissues indicates about mistake reprogramming in the primordial germ cells during gametogenesis. Whereas tissue-specific compartmentalisation of epimutations allows suggesting independent sporadic epigenetic events in various embryonic germ layers after its divergence. No epimutations were found in the 60 IA samples. Somatic MLMD in SA occurred more frequently than germinal epimutations (129 epimutations per 1808 alleles vs. 32/904; p<0.001). Multiple somatic epimutations were found more frequently in the EM (52/904; 31/904) than in the CVS (32/904; 14/904; p<0.05). Multiple hypomethylation in both tissues occurred more frequently than hypermethylation (96/1808; 33/1808; p<0.001). Thus, abnormalities of imprinting maintenance in the EM cells derived from epiblast progenitors are associated with fetal loss in first-trimester.

P01.111-S
Gonadal mosaicism for structural autosomal rearrangements with non-centromeric breaks: data from 76 carriers suggests male-specific selection against abnormal cell lines and association of clinical manifestation with a high proportion of abnormal cells

N. V. Kovaleva[1], *P. D. Cotter*[2,3];
[1]*The Turner's Scientific and Research Orthopaedic Institute for Children, St.Petersburg, Russian Federation,* [2]*University of California San Francisco, San Francisco, CA, United States,* [3]*ResearchDx, Irvin, CA, United States.*

Mosaicism for chromosomal structural rearrangements (Rea) is rare. There is much to learn about the timing and mechanisms of Rea formation and maintenance, and clinical manifestation. The question as to whether the proportion of abnormal cells in cultured blood is significant remains open. A recent study showed a strong female preponderance among carriers of mosaicism for Reas with pericentromeric breaks indicating female-specific instability in early embryos (Kovaleva NV. AJMG,136A:401-13). Objectives: (i) Comparative analysis of the male/female ratio in carriers of gonadal mosaicism (GM) for balanced and unbalanced Reas, (ii) comparative analysis of the proportion of cells with unbalanced Rea in blood cultures of asymptomatic and affected carriers. Method: Review of mosaicism for normal line/structural Rea cases of known sex identified from the literature. Results: (1) Among carriers of GM for balanced Rea (all asymptomatic) there was a typical male predominance, 18M/15F, unlike the strong female predominance among carriers of GM for unbalanced Rea (both asymptomatic and affected), 9M/34F, p<0.001. (2) Only one of eight male carriers with poor reproductive history was reported to have sterility, the others had partners with spontaneous/habitual abortion. (3) Seven of eight (88%) affected carriers of unbalanced Rea displayed a high proportion (≥50%) of abnormal cells compared to 2/27 (8%) in asymptomatic carriers, p<0.01. Conclusions: A strong female prevalence among carriers of GM for unbalanced Rea suggests male-specific selection against abnormal cells rather than impairment of male gametogenesis. A high proportion of abnormal cells detected in cultured T-lymphocytes is associated with clinical manifestation of chromosomal imbalance.

P01.112-M
Parental subfertility is not associated with an increased risk of a *de novo* mutation or microdeletion in the offspring

M. L. Haadsma, *J. Seggers, J. E. H. Van Kammen - Bergman, A. Hoek, H. Groen, H. E. K. De Walle;*
University of Groningen, University Medical Center Groningen, Groningen, Netherlands.

Background Children born after *in vitro* fertilisation (IVF) with or without intracytoplasmic sperm injection (ICSI) are at increased risk for congenital anomalies. Recent publications suggest that the underlying parental subfertility is mainly responsible for this risk increase, rather than the IVF/ICSI procedures, but it is unclear how. Our study aimed to identify whether offspring of subfertile couples are at increased risk for a *de novo* mutation or microdeletion.

Materials and methods Data were used from the birth defects registry Eurocat Northern Netherlands. We included malformed foetuses and children born between 1997-2010 (N=5709). Of those, 5249 were born to fertile couples and 460 to subfertile couples (83 after IVF, 95 after ICSI, 282 conceived naturally after a time to pregnancy >12 months). We analysed whether parental subfertility was associated with *de novo* mutations or microdeletions.

Results From the 5709 malformed cases, 156 (2.7%) had a monogenic condition resulting from a *de novo* mutation and 61 (1.1%) had a *de novo* chromosomal microdeletion. Parental subfertility was not associated with *de novo* mutations (OR 0.88, 95%CI 0.47-1.63) or microdeletions (OR 1.04, 95%CI 0.41-2.60). Subgroup analyses showed that IVF or ICSI alone were not associated with a *de novo* event either. Adjustment for paternal and maternal age did not change the results.

Conclusion Parental subfertility, IVF and ICSI are not associated with *de novo* mutations or microdeletions in offspring. These results suggest that the previously established increased risk of congenital anomalies after IVF/ICSI is not explained by an increase in *de novo* events.

P01.113-S
Prenatal detection of TAR syndrome

V. Cejnova[1], *V. Harmas*[1], *M. Wilimska*[1], *M. Putzova*[2], *L. Krautova*[2], *J. Stekrova*[3], *K. Hirschfeldova*[3], *J. Lastuvkova*[1];
[1]*Regional Health Corporation, Usti nad Labem, Czech Republic,* [2]*GENNET, Prague, Czech Republic,* [3]*Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University, Prague, Czech Republic.*

Thrombocytopenia-absent radius (TAR) syndrome is a rare genetic disorder that is characterized by the absence of the radius bone in each forearm and a markedly reduced platelet count that results in life-threatening bleeding episodes (thrombocytopenia).
Rare proximal microdeletions of 1q21.1 are found in the majority of patients but are also found in unaffected parents. Recently it was shown that TAR syndrome is caused by the compound inheritance of a low-frequency non-coding SNP and a rare null allele in *RBM8A.*
We present chromosomal, molecular, fetal ultrasound and pathological findings in a case of TAR syndrome diagnosed prenatally. In the first pregnancy (2010), ultrasound examination at 22 weeks of gestation revealed bilateral absence of the radii, pregnancy was terminated. A 1q21.1 microdeletion including *HFE2*, *PEX11B* and *CD160* genes was found using MLPA. Both parents were analyzed in order to determine the parental origin of the deletion, which was subsequently identified in the healthy mother. The second pregnancy (2012) ended in miscarriage. The third pregnancy (2013) with the same ultrasound findings, was terminated. Then the Sanger sequencing was used to analyze the DNA sequence of the region spanning the 5′UTR and the first intron of the *RBM8A* gene in the fetuses (2010, 2013) and parents. Genotyping of the sequence demonstrated the presence of compound heterozygote for the 5′UTR (rs139428292) and intronic (rs201779890) SNPs in the father. Both fetuses had compound inheritance of an *RBM8A* SNP (rs201779890 G>C) and a deletion in the 1q21.1 region. Now is the family in the PGD process.

Tetrasomy 13q31.3q34 due to two marker chromosomes in a fetus with increased nuchal translucency

A. Stembalska[1], *G. Jagielska*[2], *J. Gil*[1], *A. Jarczynska*[1], *E. Szmida*[1], *I. Laczmanska*[1];
[1]*Department of Genetics, Wroclaw, Poland,* [2]*1st Department and Clinic of Gynaecology and Obstetrics, Wroclaw, Poland.*

Small supernumerary marker chromosomes (sSMC) are a group of structurally rearranged chromosomes that cannot be identified by conventional cytogenetic techniques. Prenatally sSMC are present in about 0.075% of the tests and postnatally in 0.044% of live born children. An overall risk of an abnormal phenotype is about 30%.
We report on a 31-year-old woman (first pregnancy, after IVF) referred for genetic counselling because of increased foetal nuchal translucency (5,5mm at CRL 55,9mm) and increased risk of trisomy 21 (1:11) and trisomy 18 (1:207) in first-trimester combined prenatal screening. Ultrasound scanning at 17th week of gestation revealed no heart defects but an increased nuchal fold, left-sided diaphragmatic hernia and hydronephrosis.
Cytogenetic studies of amniocytes showed a karyotype as follows: 48,XX,+mar1,+mar2. Parents' karyotypes were normal. To determine the origin of the markers, array comparative genomic hybridization (aCGH) was used (Agilent SurePrint G3 Human CGH Microarray Kit 4 x 180K platform). Tetrasomy of the region 13q31.3 to 13q34 - arr[hg19] 13q31.3q34(92507936-115092648) was showed.
The pregnancy was terminated at 18th week of gestation. Post mortem examination revealed dysmorphic facial features, head and body disproportion (head diameter: 8cm, CRL 12,5cm), wide neck, ambiguous genitalia. No other malformations of the internal organs, except listed above, were found.
It is known that a risk of an abnormal phenotype associated with de novo sSMC derived from chromosome 13 (or 14, 21, 22) is about 7%. Molecular characteristic of sSMC is important for genetic counselling and genotype/phenotype correlation.

P01.115-S
Additive effect of thromobhilic gene polymorphisims is associated with recurrent pregnancy loss

I. Joksic[1], *M. Sopic*[2], *J. Joksic*[2];
[1]*Clinic of Gynecology and Obstetrics, Belgrade, Serbia,* [2]*Faculty of Pharmacy, Belgrade, Serbia.*

Recurrent pregnancy loss (RPL) is a heterogeneous condition affecting up to 5% of women of reproductive age. Thrombophilias (acquired and inherited) have been postulated as one of the causes of RPL. Here we examined the prevalence of nine thrombophilic gene polymorphisims among women with history of recurrent miscarriages and fertile controls. The study included 70 women with history of at least two early pregnancy losses (before 20th gestation week) and 30 fertile controls with no miscarriages. We investigated mutations in genes responsible for cloating and fibrinolysis, including FV Leiden, FV H1299R, FII G20210A, MTHFR C677T and A1298C, F XIII V34L, PAI -1 4G/5G and EPCR H1 and H3 haplotypes using reverse PCR Vienna lab CVD StrippAssays. Our results showed no statistically significant difference in prevalence of specific gene mutations between two tested groups. However, prevalence of heterozygous mutations as well as total number of mutations (homozygous and heterozygous) was significantly higher in RPL group than in control group (40% vs 24% and 26% vs 15% respectevly, p <0,01). Each woman with RPL had at least three mutations in examined genes, while the average number of mutations in control group was 1.75. Several studies have proposed that risk for RPL may be associated with additive effect of several mutations in genes involved with coagulation process rather than to some specific mutations. Our findings confirm these assumptions. Pregnancy itself represents a protrhrombotic state, which combined with multiple thrombophilic gene polymorphisms may contribute to adverse pregnancy outcome.

P01.116-M
Trisomy 16 Detected In Chorionic Villous Samples; Evaluation of 10 New Cases

S. Basaran[1], *B. Karaman*[1], *M. Kirgiz*[2], *I. H. Kalelioglu*[3], *R. Has*[3], *H. Kayserili*[1], *A. Yuksel*[3];
[1]*Medical Genetics Dep, Istanbul Medical Faculty, Istanbul, Turkey,* [2]*Premed, Genetic Diagnosis Center, Istanbul, Turkey,* [3]*Gynecology and Obstetrics Dep., Istanbul Medical Faculty, Istanbul, Turkey.*

Since trisomy 16 (T16) is a lethal chromosomal abnormality, it is very rarely diagnosed in ongoing pregnancies, even in the first trimester.
We present ten new T16 cases detected in chorionic villous samples. Referral indication was increased first trimester-screening test (FTST) risk in eight cases, with additional pathological ultrasound (US) findings in two, pathological US in one, and positive triplet test results in the other. Pathological US findings included intrauterine growth retardation, generalized edema, cystic hygroma, omphalocele, oligohydramnios, echogenic intracardiac focus, choroid plexus cyst, and hyperechogenic bowels.
Combined risk of FTST in eight cases ranged between 1:2 to 1:62. PAPP-A levels were decreased in six cases (range 0,05-0,29 MoM). $_{\beta}$hCG levels were over 2,10 MoM in five cases.
T16 was detected by karyotyping using direct preparation and/or long term cell culture (LTCC) techniques in all cases, showing mosaic status in only one. Two cases (one unsuccessful DP, and one with normal DP results) were further investigated with I-FISH using centromeric chromosome 16 probe, and T16 mosaicism was demonstrated.
Eight cases were followed up by amniocentesis. Mosaic T16 was detected in only one of six by karyotyping, and I-FISH indicated mosaicism in four cases and normal results in two.
Our results are compatible with the literature, showing that the most sensitive screening test for T16 is the FTST, with the most reliable parameter being PAPP-A. I-FISH studies are helpful in the clarification of low-level mosaicism in AF cells, when T16 was found in chorionic villous samples.

P01.117-S
Non-invasive prenatal testing (NIPT): Laboratory experiences of PrenaTest®

W. Hofmann, *U. Schoeck, J. Bonnet, S. Groemminger;*
LifeCodexx AG, Konstanz, Germany.

Non-invasive prenatal testing (NIPT) is an emerging new option in prenatal care. The commercially available PrenaTest® has been introduced in Europe in August 2012 and exhibits sensitivities and specificities over 99%. The laboratory experiences from routine application of NIPT are reported and test accuracy, limitations as well as patient profiles are discussed.
Within the past eighteen months about 8,000 successful PrenaTest® analyses have been reported, with 98.0% negative results. 1.7% were positive for trisomy 21, 0.4% positive for trisomy 18 and 0.1% positive for trisomy 13. According to ad hoc feedback from ordering specialists there were one false-negative result for trisomy 18 and 13 false-positive results (one T13, ten T18 and two T21) up to now. Further analysis revealed that one discordant positive T21 case was caused by a fetus papyraceus as determined by investigation of the placenta after birth, the other discordant T21 case was reported back by the responsible doctor as a known case of a vanishing twin. For one discordant positive T18 case, the fetus had a euploid karyotype after amniocentesis, but placental material exhibited 80% cells with trisomy 18 in FISH analysis.
It is intriguing that the majority of discordant results of NIPT and invasive diagnosis seem in fact to be consequences of fetal vs. extra-fetal cytogenetic discrepancies or due to undiscovered vanished twins. These findings suggest that biological reasons rather than methodical failures play the major role.

This confirms a strong collaboration between geneticists and gynecologists specialized in ultrasonography and further analysis of discordant results.

P01.118-M
Performance of in-house non-invasive aneuploidy test using benchtop next generation sequencing system

M. Hýblová[1], *G. Minárik*[2], *R. Sysák*[3], *M. Geryková-Bujalková*[4], *B. Vlková*[2], *L. Striešková*[1], *J. Budiš*[5], *S. Bokorova*[1], *J. Turňa*[1], *T. Szemes*[2];
[1]*Department of Molecular biology, Faculty of Natural Sciences, Comenius University, Bratislava, Slovakia,* [2]*Geneton Ltd., Bratislava, Slovakia,* [3]*Department of Gynecology and Ostetrics, St. Cyril and Method Hospital, Bratislava, Slovakia,* [4]*Department of Clinical Genetics, Medirex Inc., Bratislava, Slovakia,* [5]*Faculty of Mathematics, Physics and Informatics, Natural Sciences, Comenius University, Bratislava, Slovakia.*

Since the discovery of cell-free fetal DNA in 1997 by Dennis YM Lo, the main goal was formulated - a reliable method for non-invasive fetal aneuploidy detection. The arrival of next generation sequencing technologies finally gave scientists a proper tool to reach this goal. Today, so called large next generation sequencing instruments are used for the so called non-invasive prenatal aneuploidy testing. Few years ago, so called benchtop next generation sequencers were introduced, which allowed researchers worldwide to start adopting wide range of novel methods benefiting from next generation sequencing. However, they were generally considered not to be sufficiently parallel for non-invasive aneuploidy test.
In our study, we used one of benchtop next generation sequencers, the Mi-Seq by Illumina, to test its ability to detect aneuploidy. Plasma DNA from pregnant was isolated, fragment libraries were prepared and sequenced in multiplex setup. Data was analysed using in-house pipeline. A set of 20 samples (average read count 2 870 322 with SD 603 708) high risk group pregnancies with confirmed euploid fetus was used for training of our analysis pipeline. Analysis of testing set including 5 samples with T21 fetus resulted in 100% specificity and 100% sensitivity. Based on our results we believe that performance of benchtop next generation sequencers is sufficient for non-invasive prenatal aneuploidy testing. In addition, the inherently higher flexibility of benchtop systems could be of benefit for short turnaround and low sample throughput demands. This research was supported by ERDF grant with ITMS 26240220067.

P01.119-S
12 Mbp chromosomal gain on 7p detected prenatally without major dysmorphic features

H. Duba[1], *D. Müller*[1], *M. Maurer*[1], *F. Lausegger*[2], *C. Herbst*[2], *R. Kraschl*[3], *D. Kuchernig*[3], *S. Deutschbauer*[4], *G. Webersinke*[4];
[1]*Humangenetische Untersuchungs- und Beratungsstelle, Landes- Frauen- und Kinderklinik, Linz, Austria,* [2]*Gynäkologie- und Geburtshilfe, Perinatalzentrum, Klinikum Klagenfurt am Wörthersee, Klagenfurt, Austria,* [3]*Kinder- und Jugendheilkunde, Klinikum Klagenfurt am Wörthersee, Klagenfurt, Austria,* [4]*Labor für Molekularbiologie und Tumorzytogenetik, Krankenhaus Barmherzige Schwestern, Linz, Austria.*

We describe a prenatally detected 12 Mbp chromosomal gain on 7p. Amniocentesis was performed due to risk for a chromosomal abnormality after first trimester screening.
Cytogenetic analysis revealed a duplication on chromosome 7p in the foetus. A SNP array was carried out showing a 12 Mbp gain - ISCN: arr[hg19]7p21.3p15.3(13,146,026-25,348,884)x3.
A literature review revealed one report from Miller et al. (Am J Med Genet 1979;4(4):323-32), describing a man with a duplication of the segment 7p21 to 7p25 with severe mental deficiency but normal growth.
In order to exclude a balanced rearrangement of the parents, conventional chromosome analysis was performed. The mother showed the same duplication as the foetus. A SNP array confirmed the cytogenetic result.
The mother presented without major dysmorphic signs and showed no intellectual disability. She had finished basic education.
Pregnancy was continued due to missing ultrasound abnormalities and the inheritance of the maternal duplication.
After caesarean section at 34+6th gestation week the premature infant presented with a weight of 2340g (P38), length 46.0cm, OFC 31.7cm and APGAR 9/10/10.
The slightly cyanosed girl showed mild facial dysmorphisms as deep set ears, mild retrognathia and mild hyperplasia of the clitoris. No further clinical abnormalities were reported. 19 days after birth the girl left the hospital in a good general state of health (weight 2486g). Two subsequent controls revealed no major clinical abnormalities.
The case report shows the importance of testing parents after a pathological prenatal result and that a 12 Mbp 7p duplication not necessarily causes a major malformation.

P01.120-M
Partial Trisomy 6q detected in Prenatal Diagnosis

R. Pinto Leite[1], *P. Botelho*[1], *M. Souto*[1], *R. Nogueira*[2,3], *A. Carvalho*[1], *O. Moutinho*[1], *M. Martins*[1];
[1]*Centro Hospitalar de Tras-os-Montes e Alto Douro, Vila Real, Portugal,* [2]*Centro de Genética Clínica, Porto, Portugal,* [3]*Universidade do Minho, Braga, Portugal.*

Partial distal trisomy 6q is a rare event and is characterized by a distinct phenotype which includes microcephaly, acrocephaly, joint contractures and profound psychomotor retardation. The authors present a case of a 30-year-old pregnant woman referred to prenatal diagnosis due to ultrasound anomalies. It was the first pregnancy of a non-consanguineous couple with no familial or personal story of anomalies. Parents karyotype was performed. Cytogenetic analysis revealed a chromosome 15 with an increase p arm similar to a variation in length of heterochromatic stalks on the short arm. Both parents presented a chromosome 15 with satellites but different from the one detect at the amniocytes. Subtelomeric FISH analysis revealed a trisomy of 6q27-qter present at p arm of chromosome 15 - it was a *de novo* rearrangement. The parents decided to terminate the pregnancy and foetal autopsy was required. Several polymorphic variants were described in human chromosome 15 including increased amounts of short arm hetrochromatin (ph+), interpreted as a normal polymorphism. In the majority of cases partial trisomy 6q results from a balanced chromosomal rearrangement in one of the parents, usually of maternal origin. There have also been rare cases in which partial trisomy 6q has appeared from spontaneous (*de novo*) errors very early in embryonic development. The authors compared the cytogenetic and the foetal autopsy findings with those described in the literature. Every new case of a rare chromosomal alteration should be reported in order to establish a genotype/ phenotype correlation, improving risk evaluation and genetic counseling.

P01.121-S
Assessment of chromosomal changes in trophectoderm cells in relation to maternal age

M. Hruba[1], *D. Brotanova*[1], *R. Vlckova*[1], *L. Hradecky*[1], *P. Novakova*[1], *N. H. Zech*[2];
[1]*IVF Zentren Prof. Zech, Pilsen, Czech Republic,* [2]*IVF Zentren Prof. Zech, Bregenz, Austria.*

Unbalanced chromosomal changes in embryos are one of the main causes of low human fecundity, with their incidence presumably increasing with maternal age. In the aim to assess the frequency of whole chromosomal and segmental changes in relation to maternal age, we evaluated 224 trophectoderm samples by aCGH (for details see table below). Our results showed a statistically significant increase in embryos with abnormal chromosomal results with advancing maternal age. Overall, 539 chromosomal changes involving similarly all chromosomes, with slightly higher frequency on chromosomes 15, 16, 21, 22, were described. The frequencies of losses and gains were not significantly different. The rising complexity of changes with higher maternal age was caused predominantly by increasing numbers of whole chromosomal abnormalities whereas frequency of segmental changes was shown to be independent on maternal age.

Group (according to maternal age)	No of abnormal embryos / No of analyzed embryos	No of segmental changes / No of chrom. changes	No of whole chromosomal changes / No of chrom. changes	Mean No of chromosomal changes per abnormal embryo	Mean No of segmental changes per abnormal embryo	Mean No of whole chrom. changes per abnormal embryo

Our contribution to rescue line hypothesis for a case of Turner syndrome.

M. Libik[1], *N. Ptáková*[1,2], *J. Paděrová*[1,2], *D. Novotná*[1], *J. Chudoba*[1], *J. Drábová*[1,2], *V. Krulišová*[1,2], *M. Vlčková*[1], *M. Macek jr.*[1,2], *M. Macek sr.*[1,2];
[1]*University Hospital Motol, Prague, Czech Republic,* [2]*Charles University 2nd Faculty of Medicine, Prague, Czech Republic.*

Turner syndrome (45,X) is the only viable monosomy in humans, about 1% of recognized conceptus with this karyotype survive to livebirth. Ultrasound examination in 12th week of gestation disclosed hygroma coli cysticum with initial signs of hydrops. The NT was 6,2 mm. The QF-PCR analyses from na-

tive CVS was 46,XY. The long-term CVS cultivation revealed 45,X as well as QF-PCR and FISH. The same results were found in post mortal examination of muscule cells cultures. These findings suggest that in trophoectoderm initiated mosaicism with the 46, XY clone and loss of Y chromosome must occurred after fertilization. XY clone persisted in the embryo as a minor cell population and its prevalence increased in further chorion formation. It explains that in QF-PCR analysis of biopsied samples 46, XY represented at least 80% cells, while the second line 45,X was under detectable limit for this method (less than 20%). Our findings confirm recently published data, describing similar situation for 45,X genotype derived from 46,XX. This "rescue line" implies an origin of this disorder in mitotic loss. We also proved that syncytiotrophoblast is a strong candidate for the location of the rescue cell line. Most probably this may not be detected in extensive search for cryptic mosaicism. Our casuistic point out the importance of complex molecular genetics testing in native and long-term cultured fetal cells to provide the best reliable results allowing to make final conclusions properly. Supported by grants IGA NT13770-4/2012, project for conceptual development of reasearch organization 00064203 and OPPK CZ.2.16/3.1.00/24022.

P01.123-S
SNP-based non-invasive prenatal testing identifies vanishing-twin pregnancies

M. Stosic, *K. Curnow, A. Ryan, E. Kirkizlar, S. Sigurjonsson, M. Hall, Z. Demko, M. Rabinowitz;*
Natera, Inc., San Carlos, CA, United States.

Objective: To determine the ability of single nucleotide polymorphism (SNP)-based non-invasive prenatal testing (NIPT) to identify unrecognized vanishing twin pregnancies that could otherwise confound NIPT results.
Method: 30,795 consecutive reported commercial samples that were received for NIPT for fetal whole-chromosomal aneuploidies; known multiple gestations were excluded. Cell-free DNA was isolated from maternal blood samples, amplified, and sequenced. Sequencing results were analyzed using the NATUS algorithm to determine the fetal chromosomal copy number and presence of additional fetal haplotypes. Clinical follow-up for cases with additional fetal haplotypes is reported here.
Results: 130 (0.42%) cases with additional fetal haplotypes were identified, indicative of fetal triploidy or molar, vanishing twin, or undetected twin pregnancy. Clinical confirmation was available for 76 cases (58.5%); including 31 (40.8%) vanishing twin, 37 (48.7%) viable twin, 2 (2.6%) molar pregnancies, 3 (3.9%) triploid pregnancies, and 3 (3.9%) non-triploid pregnancies. Of the 5 vanishing twin losses with a known date of demise, 100% of losses occurred in the first trimester, and up to 8 weeks elapsed between the loss and detection by NIPT.
Conclusions: This SNP-based approach successfully identified previously unrecognized vanishing twin, viable twin, molar, and triploid pregnancies. Vanished twins have been identified in the literature as a significant cause of false positive results in NIPT. As vanished twins are more likely to be aneuploid, and residual cfDNA could bias NIPT results, the unique ability of this method to identify additional fetal haplotypes has the potential to decrease the false positive rate.

P01.124-M
Case-control analysis of VKORC1 gene polymorphisms (G1639A, C1173T) in women of reproductive losses from Republic of Moldova

E. V. Plingau[1,2], *N. Sirocova*[1], *K. Boiciuc*[1], *N. Usurelu*[1], *S. Gatcan*[1], *V. Sacara*[1], *M. Duca*[2];
[1]*Institute of Mother and Child, Chisinau, Moldova, Republic of,* [2]*University of AS RM, Chisinau, Moldova, Republic of.*

VKORC1 reactivates the reduced form of vitamin K- essential cofactor in the γ-carboxylation of blood coagulation factors. Decreased enzyme activity leads to blood clotting disorders that can cause reproductive problems. Aim of our research was to determine the prevalence of VKORC1 variant alleles G1639A (rs9926231) and C1173T (rs9934438) and correlate genotypes with recurrent pregnancy loss (RPL)
Materials and methods: Were tested 91 women with two or more (case) RPL, 69 women with two normal births (control) and 67 DNA samples of healthy Moldavian population. There was used PCR-RFLP assay to identify the VKORC1 rs 9926231 and rs9934438 with MspI and HinfI enzymes respectively. The distribution of genotypes was tested for deviation from Hardy-Weinberg equilibrium (HWE).
The results: All evaluated genotype frequencies were conformed to HWE expectation for VKORC1 polymorphisms. There was identify no significant difference in frequency in case and control groups for heterozygous state of rs9926231 (46.2%vs54.4%).The evidential differences of VKORC1 T1173T genotype frequency in case and control groups (19.8%vs7.4%). There was identified statistically significant that patients with T1173T genotype have increased risk of complications during pregnancy (OR 3.26; 95% CI 1.07, 9.91;p=0.032).
Comprising the allele frequencies of VKORC1 gene rs9926231 across different populations revealed that its are relatively close in Moldovan populations to those reported for Caucasians and Turkish. The allele frequencies of VKORC1 gene rs9934438 are statistically significant different from data available on NCBI-site, NCP, MASSource.
Conclusion: VKORC1gene rs9934438 is statistical associated with recurrent pregnancy loss and increasing the risk of complications during pregnancy

P01.126-M
The application of post-light semiconductor-based next-generation sequencing in clinical cases of preimplantation aneuploidy screening (PGS) with fresh embryo transfer

K. Lukaszuk, *S. Pukszta, J. Liss, C. Cybulska;*
Invicta sp. z o.o., Gdansk, Poland.

Screening of all chromosomes is now a gold standard in PGD. Although NGS techniques are today best method of choice they require more than 24 hours to perform, consequently blastocyst vitrification is needed. 8 couples with the average maternal age of 34,4 was referred to PGS procedure from 08/2013. All together 28 blastomeres were biopsied. The short duration of the procedure allowed fresh embryo transfer without need of blastocyst vitrification. 7 out of 8 cases resulted in pregnancy in first cycle giving pregnancies rate of 87,5%. 3,5 blastomers on average per cycle were biopsied, resulted in 1,25 blastomers on average per cycle with no aneuploidy detected. 35,7% of embryos were euploid. We not only used cutting-edge technology in the field of PGD but we went further and designed and preformed in clinical IVF-PGD procedure innovative protocol adjusted to single blastomere biopsy and fresh transfer. The additional benefit is the cost 3 times lower in comparison to aCGH. Developing PLS-NGS technology require use of the latest chemistry and software updates to improve analysis quality. The highest standards and stringency in quality system of results is required to avoid diagnosis failure. New technology of PLS-NGS possess strong research potential allowing for generation of large amount of data in scale of hours. Our innovative single-plot short-time protocol require only single blastomere biopsy and is adjusted to fresh embryo transfer. We put efforts in increase of reproduction success rate by increase implantation and decrease miscarriages rates and this aspect need to be followed up.

P01.127-S
Analysis of the AZF region of Y chromosome in Slovak men with azoospermia

J. Bernasovska, *I. Boronova, E. Petrejcikova;*
University of Presov, Presov, Slovakia.

Y chromosome microdeletions are the most common genetic cause of male infertility and screening for these microdeletions in azoospermic men is now standard practice. Analysis of the Y chromosome in men with azoospermia or severe oligozoospermia has resulted in the identification of three regions in the euchromatic part of the long arm of the human Y chromosome (Yq11) that are frequently deleted in men with otherwise unexplained spermatogenic failure. PCR analysis of microdeletions in the AZFa, AZFb and AZFc regions of the human Y chromosome is an important screening tool.
The aim of this study was to analyse type of microdeletions in men with fertility disorders in Slovakia. We evaluated 123 patients with azoospermia and with normal karyotype. All patient samples were analyzed cytogenetically. For PCR amplification of sequence-tagged sites (STS) of the AZFa, AZFb and AZFc regions of the Y chromosome was used Devyser AZF set. For all markers in one multiplex PCR reaction fluorescently labeled primers were used. For automated visualization and identification of the STS markers we used genetic analyzer 3500xL (Applied Biosystems). We reported 9 cases of deletions in the *AZF* region (7,32%). We have recorded particular types of deletions in each region *AZFa,b,c* but also a complete deletion of the whole *AZF* region. The most frequent was microdeletion(s) in the AZFc region. In Slovak azoospermic patients the percentage of microdeletions in the AZF region is low, but their detection is important for subsequent therapeutic procedures. This work was supported by grants APVV-0716-10 and ITMS 26220120041.

Indisputable double paternity in twins caused by superfecondation

W. Manoubi, *A. Mili, A. M'sakni, I. Ben Charfeddine, A. Amara, I. Chatti, D. Hmida, I. Miniaoui, A. Saad, M. Gribaa;*
Laboratory of Human Cytogenetics, Molecular Genetics and Reproductive Biology Farhat Hached Universi, Sousse, Tunisia.

Introduction: Paternity tests enable to establish the biological relationship between a child and his alleged father. Today, this test is based on DNA fingerprinting using mainly short tandem repeats (STRs) markers. Indeed, each

individual receives half of its genetic heritage from his biological mother and the other half from his biological father. Rare cases of twin pregnancy were induced by fertilization from two different parents. In this case, we speak about a "superfecondation". This situation is exceptionally confirmed.
Here, we report a case of genetically confirmed superfecondation in the context of paternity test by DNA fingerprinting.
Observation: In the context of paternity, we performed a genetic study of 4 members: a mother, her 2 twin infants, and a supposed father. This study involved the analysis of 15 STRs markers by „PowerPlex 16 System" kit. Results were analyzed by Genotyper® v 3.7.
Results: Genetic analyzes were performed under the same technical conditions and showed that one of the twins share the same alleles with the alleged father, while the other infant has different alleles in 11 of the 15 STRs studied. Therefore, despite that these two children are twins, their biological fathers are different.
Discussion and conclusion: The superfecondation is a rare and special obstetric situation. It is secondary to the fertilization of two eggs from the mother by two sperm each from a different father.
In this study, we have confirmed this situation by molecular genetics tools. However, their clinical and biological implications remain unknown.

P02.01-S
IL-8 is associated with age-related macular degeneration in Italian samples

M. Ragazzo[1], *R. Cascella[1], S. Zampatti[1], F. Ricci[2], G. Staurenghi[3], F. Missiroli[2], P. Borgiani[1], F. Viola[4], C. Eandi[5], A. Cusumano[2], F. Sangiuolo[1], G. Novelli[1], E. Giardina[1,6];*
[1]Department of Biomedicine and Prevention, School of Medicine, University of Rome "Tor Vergata", Rome, Italy, [2]UOSD Patologia retinica Fondazione PTV "Policlinico Tor Vergata", Rome, Italy, [3]Eye Clinic, Department of Clinical Science „Luigi Sacco", Sacco Hospital, University of Milan, Italy, Milan, Italy, [4]UO Oculistica Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy, [5]Department of Clinical Physiopathology, Eye Clinic, University of Torino, Torino, Italy, [6]Laboratorio di Genetica Molecolare UILDM, Fondazione Santa Lucia, Rome, Italy.

Age-related macular degeneration (AMD) is a macular degenerative disease, representing one of the main socio-economical health issues for the elderly population worldwide. The increasing prevalence of AMD is related to progressive aging of the population and affects more than one million Italian people. AMD presents a multifactorial etiology with several risk factors (age, cigarette smoking, diet).
Genes in the complement pathway (CFH) and a chromosome 10 region (ARMS2) showed to be the most involved loci in the disease. Several studies confirmed the crucial role of inflammation and angiogenesis in AMD pathogenesis and progression. Given these data a screening of IL8 gene has been proposed (4q12-q13) to evaluate the association of AMD with rs2227306 (C/T), that is an intronic SNP in the IL8 gene. The results demonstrated a strong association of T allele (p = 4.15*10-5, OR = 1.39, 95% CI = 1.19-1.62) in a cohort composed of 721 cases and 660 controls, suggesting the sequencing of the entire IL8 gene. Sequencing analysis revealed two haplotypes associated with AMD development (A-T-T-T, p = 2.08*10-9,OR = 1.68, 95% CI = 1.43-1.97 and T-C-C-A, p = 7.07*10-11, OR = 0.60, 95% CI = 0.51-0.70). It is notably that in human coronary atherosclerosis, IL-8 is an important mediator of angiogenesis and may contribute to plaque formation via its angiogenic properties. In this context IL-8 could represent a candidate gene to link the development and progression of AMD, the smoke habits and the occurrence of cardiovascular events in these patients.

P02.02-M
Molecular investigations in patients with oculocutaneous albinism.

F. Morice-Picard[1,2], E. Lasseaux[1], C. Plaisant[1], J. Bouron[1], C. Rooryck[1,2], D. Cailley[1], P. Fergelot[1], D. Lacombe[1,2], **B. Arveiler**[1,2];
[1]Bordeaux Universitary Hospital, Bordeaux, France, [2]University of Bordeaux, Bordeaux, France.

Oculocutaneous albinism is characterized by both ocular and skin and hair features. In addition to *TYR, OCA2, TYRP1, SLC45A2*, a locus in 4q25 (OCA5) and two new genes, *SLC24A5* (OCA6) and *C10ORF11* (OCA7) were recently discovered. Ocular (OA1) and syndromic albinism are also known. When studying 400 patients, we found 36 % OCA1, 25% OCA2, 2 % OCA3, 11% OCA4, 1.25% OCA6, 0% OCA7, 6% OA1 et 1% *HPS1*. Deletions represent 5.6% of the anomalies. In two patients we found a complex rearrangement of *OCA2* that comprised the deletion of exons 2 to 19, followed by the reinsertion, after reshuffling, of most of the deleted segment in intron 1 of the gene.
17.5% of patients remain without molecular diagnosis. A first hypothesis is that mutations are located in the introns or regulatory regions of the genes. We undertook the sequencing of the entirety of the OCA1-4 genes to search for alterations not only affecting the exons. A second hypothesis is that new OCA genes remain to be discovered. We have sequenced the exome of 11 patients.
In our diagnostic laboratory we have used NGS to analyze the 6 OCA, OA1 and HPS1 genes. This was efficient in terms of both finding mutations and rapidity. We are designing a larger panel including all syndromic albinism genes.
The extensive analysis of all albinism genes will allow us to better characterize gene interactions in this disease that may not be purely monogenic.

P02.03-S
Two novel (p.E930X and p.C2278X) mutations in ALMS1 leading to Alström Syndrome

T. Piñeiro-Gallego, *M. Álvarez-Satta, S. Castro-Sánchez, D. Valverde;*
Departamento de Bioquímica, Xenética e Inmunoloxía, Vigo, Spain.

Alström syndrome (AS, OMIM#203800) is an extremely rare, autosomal recessive disorder with a significantly shorter life expectancy. It is mainly characterized by sensorineural hearing loss, early onset blindness due to retinal dystrophy, and obesity. Other reported features include recurrent pulmonary infections, progressive renal and hepatic dysfunction, cardiomyopathy, short stature, and endocrinological features. AS is caused by mutations in the ALMS1 gene, which encodes a protein of unknown function that localizes to the basal bodies of cilia, playing a role in intracellular trafficking. Here we report two AS cases born to unrelated healthy parents. The diagnosis of AS was performed accordingly to the criteria previously defined by Marshall et al. (2007). We ascertained two families with seemingly AS. Molecular analysis was performed by direct sequencing of the known hot spots in the ALMS1 gene (exons 8, 10 and 16) according to the mutational load described in AS. We identified a homozygous mutation (c.2788G>T, p.E930X) in patient 1 and a homozygous mutation (c.6834C>A, p.C2278X) in patient 2 that co-segregate with the disease phenotype in family 2. Both mutations cause a truncated protein and had not been previously described in literature. We show that direct sequencing of exons 8, 10 and 16 of the ALMS1 gene could represent a useful tool for molecular diagnosis of AS, whilst the mutations described here may contribute to extend the mutational spectrum in AS.

P02.04-M
Exome sequencing in 32 patients with anophthalmia/microphthalmia and other developmental eye defects

A. Slavotinek[1], *S. T. Garcia[2], G. Chandratillake[2], T. Bardakjian[3], R. Lao[4], P. Tang[4], E. Wan[4], D. Wu[1], K. Umeda[1], J. Tirch[2], R. Tischler[2], J. Harris[2], M. J. Clark[2], S. Chervitz[2], A. Patwardhan[2], J. M. West[2], A. Schneider[3], P. Kwok[4], S. Baranzini[5], R. M. Chen[2];*
[1]Department of Pediatrics, University of California, San Francisco, San Francisco, CA, United States, [2]Personalis, Inc., Menlo Park, CA, United States, [3]Division of Medical Genetics, Einstein Medical Center, Philadelphia, PA, United States, [4]Cardiovascular Research Institute, University of California, San Francisco, San Francisco, CA, United States, [5]Department of Neurology, University of California, San Francisco, San Francisco, CA, United States.

Anophthalmia/microphthalmia (A/M) is a genetically heterogeneous birth defect for which the etiology remains unknown in more than 50% patients. A/M can occur without other structural eye defects (simplex A/M), or can be present with other ocular findings (complex A/M), such as anterior segment dysgenesis (ASD). We used exome sequencing (ACE ExomeTM, Personalis, Inc., 18 exomes; UCSF Genomics Core, 20 exomes; 6 were run twice) to sequence DNA from 32 children with A/M or other developmental eye defects for pathogenic mutations. In 19 patients with simplex A/M, we identified mutations in STRA6 (1 patient), RARB (1 patient; p.Arg387Cys), GDF6 (1 patient; p.Ala249Glu) and OTX2 (1 patient; p.Gln91His) and in 9 patients with complex A/M, we found mutations in STRA6 in 2 patients. Putative causative variants were identified in 3 out of 4 patients with other developmental eye defects - a homozygous mutation in GCNT2, p.Tyr347Cys, in a female with cataracts and microtia and a de novo mutation in COL4A1, p.Gly773Arg, in a female with cataracts and cardiomyopathy. In a male with a chorioretinal defect, microcephaly, seizures and sensorineural deafness, we identified a maternally inherited splice site mutation and a paternally inherited missense mutation, p.Ala507Ser, in PNPT1 which is critical for mRNA import into mitochondria and has not been associated with eye defects. In one child with ASD, no mutation was identified. Our overall detection rate for A/M was 6/28 (21%), illustrating high genetic heterogeneity and the need for further gene discovery.

P02.05-S
Molecular study of Brazilian patients with auditory neuropathy

P. Z. Ramos[1], *G. M. Carvalho[2], A. C. Guimarães[2], A. M. Castilho[2], E. L. Sartorato[1];*
[1]CBMEG, Universidade Estadual de Campinas (UNICAMP), Campinas, Brazil, [2]ENT Department, Universidade Estadual de Campinas (UNICAMP), Campinas, Brazil.

Auditory neuropathy (AN) is characterized by an absent or abnormal auditory brainstem responses and preserved otoacoustic emissions and/or cochlear microphonics. To date, four loci associated with nonsyndromic AN were mapped: DFNB9 (*OTOF* gene) and DFNB59 (*PJVK* gene), responsible

for autosomal recessive pattern; AUNA1 (*DIAPH3* gene) for autosomal dominant; and AUNX1 for X-linked. Connexin 26 mutations were also reported in subjects with AN. The main goal of the study was to investigate genetic mutations in patients with clinical diagnosis of AN, to verify its importance and involvement in the etiology of AN in Brazilian patients. Clinical information and genetic evaluation of 39 patients were analyzed. We investigated the most common causes of genetic hearing loss, including pathogenic variants in the *GJB2* gene, deletions in the *GJB6* gene and m.1555A>G mutation in the *MTRNR1* gene. Additionally, direct sequencing is performing for mutation screening of *OTOF* gene. The common Spanish p.Q829X mutation in the otoferlin gene was not detected in our cohort. The c.35delG mutation in the *GJB2* gene was found in two patients in homozygous genotypes. However, it is not established if pathogenic variants in connexin 26 could be involved with AN or if the otoacoustic emissions that were recorded from these subjects only represent the residual activity of few outer hair cells that still alive. Further investigation is needed to clarify the link between *GJB2* mutations and AN. The study of AN genetic basis is extremely important to improve the diagnosis, management, therapy and genetic counseling of the affected subjects.

P02.06-M
Targeted high-throughput sequencing for mutation detection in Bardet-Biedl Italian patients

I. Passerini[1], *S. Palchetti*[1], *A. Mariottini*[1], *C. Pescucci*[1], *G. Marseglia*[1], *S. Bardi*[1], *M. Benelli*[1], *S. Falconi*[1], *E. Contini*[1], *A. Sodi*[2], *F. Marin*[1], *U. Menchini*[2], *F. Torricelli*[1];
[1]*AOU Careggi, Florence, Italy,* [2]*Eye Clinic, University of Florence, Florence, Italy.*

Bardet-Biedl syndrome (BBS) is characterized by truncal obesity, polydactyly, hypogonadism, developmental delay, learning disabilities, progressive retinopathy, renal disease and susceptibility to diabetes mellitus. Although BBS is mainly transmitted in an autosomal recessive manner, few families exhibit a tri-allelic mode of inheritance. To date, 16 different BBS genes (BBS1-BBS16) are known and BBS1 and BBS10 show the highest mutation frequency in BBS patients.
Six unrelated patients evaluated by standard ophthalmologic examination and with a clinical diagnosis of BBS were analyzed by targeted re-sequencing of 130 retinopathies-related genes on HiScanSQ Illumina platform (mean coverage 500X). Bioinformatic analysis identified a mean of 1100 sequence variants per sample. Filtering pipeline (exonic function, frequency, prediction and inheritance model) leads to distil a mean of 10 candidate variants per sample. The candidate variants were independently validated by Sanger sequencing and segregation analysis was performed.
We identified two known causative deletions in BBS9 (c.1877_1880del) and BBS7 (c.712_715del) genes and a novel frameshift deletion in BBS10 (c.804_805del). Morever, a patient is compound heterozygote for two novel variants in BBS10 (c.1677_1678insA and c.1220T>C); one patient present a homozygous variant in BBS2 gene (c.209A>G) and one novel heterozygous variant (c.538C>T) in BBS3 gene. The last patient has two variants in BBS12 gene both in homozygous status [c.1044del (novel) and c.61T>C (described)].
NGS approach has enabled us to detect variants in BBS genes. Although for described variants and ins/del frameshif variants the genotype-phenotype correlation is clear, in order to clarify tri-allelic variants' role in BBS-onset, further association studies are required.

P02.07-S
Neuro-developmental genes may underlie human congenital general anosmia

T. Olender[1], *A. Alkelai*[1], *P. Tatarskyy*[1], *R. Isseroff*[1], *V. Boyko*[1], *E. Ben-Asher*[1], *D. Oz-Levi*[1], *E. K. Ruzzo*[2], *D. B. Goldstein*[2], *E. Pras*[3], *D. Lancet*[1];
[1]*The Weizmann Instiute of Science, Rehovot, Israel,* [2]*Duke University, Durham, NC, United States,* [3]*Sheba Medical Center, Ramat Gan, Israel.*

The neuronal and cell-biological mechanisms underlying vertebrate olfaction have been studied in considerable detail, but there is a gap in our understanding of the molecular genetic basis of olfactory monogenic disorders. Congenital general anosmia (CGA) affects <0.1% of the general population, and appears in isolated or syndromic forms. We have recruited a large cohort of isolated CGA, with 66 affected families of Jewish origin. We applied whole-exome sequencing to 43 selected individuals from 8 multiply affected families. We identified in three members of one family with a rare X-linked mutation in the TENM1 (teneurin 1) gene, a neuronal signal transducer that functions in synaptic-partner-matching between olfactory sensory neuronal axons and target projection neurons in drosophila. The mutation affects a highly conserved Proline residue in one of the YD domains of TENM1. In another family we identified candidate variants in the genes FGFR1 (heterozygous mutation) and SEMA3A (heterozygous mutation). Affected individuals in this family obligatorily carry both mutations, suggesting a di-genic model of inheritance. Both FGFR1 and SEMA3A are implicated in Kallmann's syndrome, where GnRH neuronal migration developmental abnormalities typically lead to syndromic anosmia, associated with sterility. Our patients are unusual in having isolated anosmia. All mutations are currently under further scrutiny. The results suggest that decyphering CGA pathogenic variants might shed light on the embryonic development of the olfactory neuronal system.

P02.08-M
Prevalence of GJB2 (CX26) gene mutations in Turkish patients with autosomal recessive nonsyndromic sensorineural hearing loss

M. Gunduz[1,2], **E. Uctepe**[2], *S. Unsal*[3], *A. Ozdek*[4], *D. Demiral*[5], *M. Korkmaz*[4], *A. Erdoğan*[3], *E. Gunduz*[1], *N. Ark*[2];
[1]*Turgut Ozal University, Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey,* [2]*Turgut Ozal University, Faculty of Medicine, Department of otolaryngology head and neck surgery, Ankara, Turkey,* [3]*Turgut Ozal University, Graduate School Of Health Sciences, Department of Medical Genetics,Department of Audiology And Speech Pathology, Ankara, Turkey,* [4]*Department of Otolaryngology, Ministry of Health, Dıs¸kapı Yıldırım Beyazıt Training and Research Hospital,, Ankara, Turkey,* [5]*Department of Audiology And Speech Pathology, Ministry of Health, Dıs¸kapı Yıldırım Beyazıt Training and Research Hospital,, Ankara, Turkey.*

Hearing impairment is the most common sensory impairment in humans, affecting 2:1,000 births. At least 50%of the cases are inherited. Non-syndromic hereditary hearing loss accounts for the 70% of the hereditary hearing loss. It is a genetically heterogeneous disorder.
The single-nucleotide guanine deletion (35delG) of the GJB2 gene coding for connexin 26 was shown to be the main genetic cause of autosomal recessive deafness among Europeans. The purpose of our study was to evaluate the prevalence of GJB2 mutations among affected individuals from Turkey. To provide appropriate genetic testing and counseling to families, we searched fifty patients presenting with autosomal recessive non-syndromic hearing loss from Turkey for variations in GJB2 gene by direct sequencing. Mutations were detected in 9 out of 28 people from 20 different families (9/28, 32 %). Four different mutations were identified; three of them were previously identified (35delG, V27I, E114G). The remaining one alleles, K221N was novel variants which determined 'uncertain significance' in different database. However, it is reported disease causing variant by 'Mutation Taster Database'. The most common mutations were 35delG followed by V27I with an allele frequency of 21 and 7 %, respectively. There is no correlation between mutation types and clinical findings of patients.
In conclusion, we determined GJB2 gene mutations responsible for 32 % of autosomal recessive non-syndromic hearing loss in Turkish people. This is higher than earlier studies which reported that the overall frequency of GJB2 mutations in comparable families in Turkey is 18.9%.

P02.09-S
A novel GJB6 mutation causes autosomal dominant palmo-plantar hyperkeratosis with hearing loss

E. Trevisson[1], *M. Doimo*[1], *M. Cassina*[1], *C. Cerqua*[1], *G. Crispino*[2], *F. Mammano*[2], *L. Salviati*[1], *M. Clementi*[1];
[1]*Clinical Genetics, Department of Women's and Children's Health, Univeristy of Padova, Padova, Italy,* [2]*Fondazione per la Ricerca Biomedica Avanzata, Istituto Veneto di Medicina Molecolare, Padova, Italy.*

We report a boy affected by bilateral sensorineural deafness and palmoplantar hyperkeratosis. The pedigree suggests an autosomal dominant pattern of inheritance with variable expressivity. Molecular analysis of GJB2 was negative and GJB6 deletions were also excluded. GJB6 encodes connexin 30, which is highly expressed in the inner ear and in keratinocytes. Therefore, we sequenced the entire coding region of this gene in the proband and identified the c.175 G>A mutation, causing a substitution of glycine 59 with an arginine residue. The same missense mutation had been previously reported in a single patient affected by post-lingual deafness and palmoplantar hyperkeratosis (Nemoto-Hasebe et al, 2009). The G59R mutation affects a highly conserved amino acid, it was absent in 100 healthy ethnically matched controls and segregates with the phenotype in our family. The analysis by molecular modelling revealed that the residue is located at the top of the channel formed by the hemiconnexons. All these findings strongly indicate a pathogenetic role for the novel variant. To explore the functional consequence of the missense mutation, we expressed the mutated version of GJB6 in HeLa cells lacking connexins. We showed that GJB6 mutated protein is localized to the plasma membrane only when co-expressed with the wild type form. This model was employed to test the electrophysiological properties of the connexons formed by both the mutated and the wild-type connexin 30.

P02.10-M

Hearing and ageing: a complex genomic strategy leading to new genes/variants identification in European and Central Asian populations

D. Vuckovic[1], *S. Dawson*[2], *M. P. Concas*[3], *M. Ciullo*[4], *T. Nutile*[4], *S. Cappellani*[5], *M. Pirastu*[3], *P. Gasparini*[1,5], *G. Girotto*[1];

[1]*Dep. Medical Sciences - University of Trieste, Trieste, Italy,* [2]*UCL Ear Institute, University College London, London, United Kingdom,* [3]*Institute of Population Genetics, National Council of Research, Sassari, Italy,* [4]*Inst. Genetics and Biophysics "A.Buzzati-Traverso", CNR, Naples, Italy,* [5]*Inst. Maternal and Child Health-IRCCS "Burlo Garofolo", Trieste, Italy.*

The lack of knowledge on the molecular basis of Normal Hearing Function (NHF) and Age-related Hearing Loss (ARHL), prompted us to develop a combined multiphase strategy using approx. 3000 individuals from isolated populations of Europe, Caucasus and Central Asia. Starting from our past experience on GWAS meta-analysis combined with expression studies (Girotto et al. 2014), the following strategy was designed: PHASE1: GWAS meta-analysis for common tag-SNPs and common functional variants, PHASE2: replication in independent cohorts, PHASE3: SKAT gene-based test for rare functional variants, PHASE4: Whole Exome Sequencing (WES) in a selected subgroup of 250 ARHL cases/controls. During PHASE1 the following strongly significant associations were identified: ITFG2 (p=6.92E-11), PCDH20 (p=4.71E-10), SLC28A3 (p=2.39E-09). The last two belong to gene-families already known as being involved in hearing-loss and expressed in the cochlea. During PHASE2 four SNPs within the PCDH20 gene were replicated at nominal level (p<0.05) in the 1958 British Birth Cohort. Applying PHASE3, the SKAT gene-based test for rare functional variants (0.001<MAF<0.05) revealed highly suggestive associations (ranging from 7.97E-06 to 1.90E-05) for the following genes: PTPRCAP, FN1, EAF1, METRNL, PDP2, ARRDC1, HDGF, TMOD1.

Finally, thanks to PHASE4 (carried out in collaboration with CRG, Spain), WES data are now available to identify population disease-specific rare variants. In vitro and in vivo functional studies will be carried out in the future to confirm the role of the whole list of genes/variants identified through the above-described phases. Up-to-date results will be presented and discussed.

P02.11-S

Targeted exome sequencing method identified Myo15A gene mutations as a frequent cause of non syndromic autosomal recessive hearing loss in Iran

A. Bushehri[1], *M. Babanejad*[1], *N. Bazazzadegan*[1], *N. Nikzat*[1], *K. Kahrizi*[1], *R. J. H. Smith*[2], *H. Najmabadi*[1];

[1]*Genetics Research Center , University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Molecular Otolaryngology & Renal Research Laboratories, Department of Otolaryngology Head and Neck Surgery, Iowa, IA, United States.*

Human MYO15A is located on chromosome 17p11.2 and encodes unconventional myosin XV, which is critical for the formation of stereocilia. Mutations of MYO15A are associated with profound autosomal recessive nonsyndromic hearing loss (ARNSHL) in humans, and with deafness and circling behavior in Shaker-2 mice. To date, more than 50 mutations have been reported in MYO15Amost of which have been found by linkage analysis in consanguineous families from countries like Pakistan, Turkey, Iranand India.

In present study, we used targeted genomic enrichment and massively parallel sequencing to identify the cause of ARNSHL in probands from 94 families segregating recessive deafness. In eight probands, we identified MYO15A mutations as the cause of ARNSHL. Of the eight mutations, 6 were present in the homozygous state, 2 in compound heterozygous state and of them 7 were novel. This study implicates MYO15A as an extremely important cause of ARNSHL in Iran. With a mutation frequency of 8.5% in our cohort,MYO15A mutations are the most frequent cause of ARNSHL after GJB2 mutations.

P02.12-M

Whole exome sequencing identifies new causative mutations in Tunisian families with non-syndromic deafness

Identification of the causative mutations in patients affected by autosomal recessive non syndromic deafness (DFNB forms), is demanding due to genetic heterogeneity. After the exclusion of GJB2 mutations and other mutations previously reported in Tunisian deaf patients, we performed whole exome sequencing in patients affected with severe to profound deafness, from four unrelated consanguineous Tunisian families. Four biallelic mutations were identified in three different genes, i.e. a nonsense mutation, c.208C>T (p.R70X), in LRTOMT, a missense mutation, c.5417T>C (p.L1806P), and splice site mutations, c.7395+3G>A, in MYO15A, c.2260+2T>A, in TMC1. We thereby provide evidence that whole exome sequencing is a powerful, cost-effective screening tool to identify mutations causing recessive deafness in consanguineous families.

DNA diagnostics of hereditary hearing loss (HL) is complicated considerably because of the genetic and phenotypic heterogeneity of the disease. Currently, only 10-20% of the patients receive a clear genetic diagnosis, because only two genes are analysed regularly. We developed a Next-Generation Sequencing (NGS) panel for HL, consisting of 79 known genes for all nonsyndromic sensorineural forms HL and Usher-, Stickler- and Jervell en Lange-Nielsen syndrome. 114 patients with presumed autosomal recessive nonsyndromic HL and ten patients with autosomal dominant nonsyndromic HL were analyzed using this panel. Target enrichment and sequencing was performed using the Illumina TruSeq Custom Enrichment and HiSeq2000. In total 307 variants were identified in the 124 different patients. In order to deal with the large amount of variants, a classification system was set up to assign the most plausible disease causing variant to each patient. Variants with a MAF below 0.003 were classified according to the variant type and predictions based on different prediction programs, in five groups ranging from definitely pathogenic (class 5) to not pathogenic/no clinical significance (class 1) at all. Approximately 3.7% of the patients had variants in two or more groups. In addition there was one patient with two variants in class four. The current diagnostic setting is likely to be less reliable than generally assumed. In addition, our study shows that a straightforward, reliable and a validated classification system is necessary to use targeted resequencing in the diagnostics of hearing loss in the future.

Molecular diagnosis of Italian patients affected by hereditary Retinal Dystrophies, using targeted high-throughput sequencing

S. Palchetti[1], *I. Passerini*[1], *A. Mariottini*[1], *C. Pescucci*[1], *G. Marseglia*[1], *L. Berti*[1], *M. Benelli*[1], *E. Contini*[1], *A. Sodi*[2], *F. Marin*[1], *V. Murro*[2], *U. Menchini*[2], *F. Torricelli*[1];

[1]*AOU Careggi, Florence, Italy,* [2]*Eye Clinic, University of Florence, Florence, Italy.*

Hereditary Retinal Dystrophies (RD) represent one of the most frequent genetic causes of blindness in the Western world. Because of their high clinical and genetic heterogeneity, an exhaustive classification of RD is difficult. The progressive forms may have an onset in early childhood, as Leber congenital amaurosis, or later in life, as Retinitis Pigmentosa (RP). There are also described many syndromic forms, as Usher syndrome (USH), and Bardet-Biedl syndrome (BBS).

RD can be inherited as autosomal recessive (ar) or autosomal dominant (ad), as well as X-linked (xl), or mitochondrial traits. Nevertheless, the majority of cases are sporadic.

In this study, we analyzed 115 retinopathies-related genes by targeted next-generation sequencing (NGS) in a cohort of 78 patient with sporadic RP, 10 patients with USH and 10 patients with BBS.

Sequence target enrichment was performed using SureSelect XT kit (Agilent). Sequencing of each library was carried out on HiScanSQ Illumina platform (mean coverage 500X).

We obtained a detection rate of 100% for BBS patients, 80% for USH patients, and 69% for RP patients. The candidate variants were independently validated by Sanger sequencing and segregation analysis was performed.

Were also identified 3 large deletions in the genes EYS, RPGR and USH2A, using method CONTRA and confirmed by MLPA.

This study confirms that NGS-based mutation analyses are reliable and cost-

efficient approaches in molecular diagnosis of genetically heterogeneous diseases like RD. NGS allows also a considerable reduction of costs and an early intervention for diseases for which there are available appropriate therapeutic strategies.

P02.15-S
Identification of three novel homozygous variants in the GJB2 gene in Mexican patients with hereditary sensorineural hearing loss

M. MIrna[1], *M. Rivera-Vega*[1], *F. Loeza-Becerra*[1], *L. Gonzalez-Huerta*[1], *H. Urueta-Cuellar*[1], *P. Berruecos*[2], *S. Cuevas-Covarrubias*[1];
[1]*Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico D.F., Mexico,* [2]*Audiologia y Foniatria, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico D.F., Mexico.*

Background: Hereditary sensorineural hearing impairment (HSHI) is a genetically heterogeneous disorder worldwide. Mutations in the GJB2 gene are a frequent cause of hereditary SNHL. Individuals that are homozygous for the GJB2 gene mutations manifest a wide spectrum of clinical data that ranges from moderate to profound SNHL; this suggests the participation of epigenetic and environmental factors in the phenotypic expression Objective: To describe three novel homozygous mutations in the GJB2 gene with HSHI. Materials and methods: Three subjects with prelingual HSHI were included in the study. Genomic DNA was extracted by conventional methods and all exons of GJB2 gene were analyzed through PCR and the DNA was sequenced on an ABI 3730XL automated sequencer. Results DNA sequencing analysis showed three novel homozygous mutation in the GJB2 gene that corresponded to p.V84M/p.F31I/p.W44X; /p.V84M/p.F31I/p.R32S and p.E47X/p.R32S/p.S19R. Parents were tested for this molecular defect and they present an heterozygous state that allows to confirm the recessive inheritance pattern. These mutations were searching in 100 normal controls to discard a possible polymorphism. Conclusion: We describe three novel varieties of homozygous mutations in patients with HSHI. All patients presented profound hypoacusia with no other anomalies. These data show that the genesis of HSHI is complex and that the genetic defects are greater than expected.

P02.16-M
Regional distribution of the GJB2/GJB6 gene mutations in Mexican population with hereditary hearing impairment

F. LOeza-Becerra[1], *M. Refugio-Rivera*[1], *M. Martinez-Saucedo*[1], *L. Gonzalez-Huerta*[1], *H. Urueta-Cuellar*[1], *P. Berruecos*[2], *S. Cuevas-Covarrubias*[1];
[1]*Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico D.F., Mexico,* [2]*Audiologia y Foniatria, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico D.F., Mexico.*

Background: Hereditary sensorineural hearing loss (SNHL) is a genetically heterogeneous disorder worldwide. Mutations in the GJB2 gene are a frequent cause of hereditary SNHL. There is a prevalence of certain mutations in various populations which suggests that specific mutations may be influenced by ethnic background. Objective: To analyze the prevalence of GJB2, GJB6 mutations in several geographic areas of Mexico in patients with hereditary SNHL. Materials and methods: One hundred and forty Mexican unrelated propositi with prelingual SNHL were included in the study. All patients had three previous generations born in Mexico and belonged to no specific ethnic group. Analyses of the GJB2 and GJB6 genes and mt.A1555G were performed in all subjects. Results Twenty three homozygous mutations, 57 heterozygous mutations, 1 double heterozygous (GJB2/GJB6) and 59 wild-type genotypes in the GJB2 gene were observed. Three patients had the homozygous del35 mutation whereas 26 patients were heterozygous for this gene defect. Only one patient with the GJB6 gene deletion was present (it includes the double heterozygous GJB2/GJB6). The mt.A1555G mutation was not detected. Conclusion: We found a great variety of mutations depending on the analyzed region in patients with SNHL; 57.86% of patients had affection in one or two alleles in GJB2 or GJB6 genes whereas 42.14% were wild-type. In some cases, allele distribution depended on region. Molecular studies of more genes involved in hereditary non-syndromic SNHL are required to completely confirm the molecular basis of hearing loss in Mexican population.

P02.17-S
Panel base on next-generation sequencing for molecular diagnosis of inherited heterogeneous eye diseases

M. Qi, *H. Huang, X. Yi, Y. Chen;*
BGI-Shenzhen, Shenzhen, China.

Background: Inherited eye diseases are a leading cause of blindness in children and adults, a typical monogenic disease of which is retinitis pigmentosa (RP) that cause visual impairment. An accurate, econimical, and high throughput molecular diagnosis system can be very helpful in clinical diagnosis and essential in gene therapy in the future. **Methods:** We developed a panel based on next generation sequencing (NGS) that captures the exons of 283 inherited eye disease genes, which includes 58 known RP disease-causing genes. We applied 180 samples in this panel, 64 of these samples are previous tested by Sanger sequencing, and 99 of these samples are unselected patients with clinical diagnosis of retinitis pigmentosa. **Results:** We presented data on our first 99 probands with RP with systematic evaluation of our method and comprehensive molecular diagnosis. 96.85% of each targeted regions in 4,381 exons covered by at least 20 folds. In the 99 RP patients, 66.7% molecular diagnosis rate for RP disease was achieved, while in 5 patients, molecular diagnosis were not consistent with their initial clinical diagnosis. We revisited these 5 patients and reclassified the clinical diagnosis of them. In addition, altogether 3 patients were found to carry copy number variant (CNV). **Conclusions:** We have systemic evaluated and compared our method with Sanger sequencing, and have identified a large number of novel mutations. The results show that our method is sufficiently accurate for molecular diagnosis, and suggest the importance of molecular diagnosis in clinical diagnosis.

P02.18-M
An integrated next-generation sequencing approach identifies causative mutations in a family with syndromic and non-syndromic retinitis pigmentosa

C. Méndez-Vidal[1,2], *N. Bravo-Gil*[1,2], *M. González-del Pozo*[1,2], *A. Vela-Boza*[3], *J. Pérez-Florido*[3], *J. Santoyo-López*[3], *S. Borrego*[1,2], *G. Antiñolo*[1,2,3];
[1]*Department of Genetics, Reproduction and Fetal Medicine, Institute of Biomedicine of Seville, Virgen del Rocio University Hospital/CSIC/University of Seville, Seville, Spain,* [2]*Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Seville, Spain,* [3]*Genomics and Bioinformatics Platform of Andalusia (GBPA), Seville, Spain.*

Routine molecular testing of Inherited Retinal Dystrophies (IRD) generally involves mutational screening of hundreds of clinically relevant IRD genes. Comprehensive analysis with available techniques has been challenging due to the extensive clinical and genetic heterogeneity present in this group of disorders. Here, we describe the clinical application of an integrated next-generation sequencing approach to determine the underlying genetic defects in a Spanish family with a provisional clinical diagnosis of autosomal recessive Retinitis Pigmentosa (arRP). Exome sequencing of the index patient and immediate family members resulted in the identification of the homozygous *BBS1* p.M390R mutation. Sanger sequencing confirmed the presence of this variant in this family branch but did not segregate in extended family members. Clinical reanalysis showed co-ocurrence of two different phenotypes in this family: Bardet-Biedl syndrome in the family harboring the *BBS1* mutation and non-syndromic arRP in the extended family members with unknown causal genetic defects. To identify possible causative mutations in the arRP family branch, we applied targeted resequencing on 26 IRD genes in one of the affected members using the 454 GS Junior system. The in-house custom panel was validated using 18 DNA samples known to harbor mutations in relevant genes and allowed us to reliably identify two novel heterozygous mutations in *RP1* (c.5962dupA; p.I1988Nfs*3 and c.4582_4585delATCA; p.I1528Vfs*10) as the most likely disease-causing variants in these arRP patients. Taken together, these results demonstrate the value of this combined next-generation sequencing-based approach as an efficient screening and diagnostic tool for complex genetic disorders.

P02.19-S
Partial *NMNAT1* deletions cause Leber Congenital Amaurosis

F. Coppieters[1], *T. Fujimaki*[2], *M. De Bruyne*[1], *A. Baert*[1], *M. Kondo*[3], *A. Murakami*[2], *E. De Baere*[1];
[1]*Center for Medical Genetics Ghent, Ghent University, Ghent, Belgium,* [2]*Department of Ophthalmology, Juntendo University Graduate School of Medicine, Tokyo, Japan,* [3]*Department of Ophthalmology, Mie University Graduate School of Medicine, Mie, Japan.*

In 2012, *NMNAT1* was identified as a novel disease gene for Leber Congenital Amaurosis. The mutation spectrum contains both coding and regulatory mutations. The starting point of this study was pseudohomozygosity of a known *NMNAT1* mutation (p.Arg237Cys, exon 5) in two unrelated Japanese families (F1 and F2), assuming hemizygosity. Here, we aimed to identify the putative *NMNAT1* deletions.

Copy number variation (CNV) screening was performed for all exons using qPCR. Subsequently, identified deletions were refined with additional qPCR amplicons located in the breakpoint regions. Finally, the junction product was amplified with long-range PCR and sequenced (Nextera XT, MiSeq, Illumina).

In F1, CNV analysis showed a heterozygous deletion of exon 4 and 5, which was subsequently refined to a region of 13.0-18.7 kb. In F2, the amplicon for exon 4 was deleted, whereas the copy number for exon 5, located downstream of the p.Arg237Cys mutation, was normal. Subsequent refinement at

the 5'end delineated the deletion to a region of 1.5-6.7 kb. Long-range PCR revealed a band of 2.4 kb and 2.1 kb in F1 and F2, pointing to two different deletions of approximately 16.6 kb and 4.8 kb, respectively. Sequencing analysis of the junction products is currently ongoing.
In conclusion, we report the first deletions in *NMNAT1*, expanding the mutation spectrum of this gene. Hence, we presume that the high number of patients in which only a single heterozygous mutation could be identified, can be explained by structural variations, requiring additional strategies apart from resequencing of the coding region.

P02.20-M
Prevalence and mutation analysis of *NMNAT1* gene in Leber Congenital Amaurosis in Spanish population

R. Sanchez-Alcudia[1], *S. Tatu[1], F. Blanco-Kelly[1], N. Reyes[1], M. Lopez-Molina[2], R. Perez-Carro[1], A. Avila-Fernandez[1], M. Corton[1], C. Ayuso[1];*
[1]Department of Genetics, Instituto de Investigacion Sanitaria-Fundacion Jimenez Diaz (IIS-FJD), Madrid, Spain, [2]Department of Ophthalmology, IIS-Fundacion Jimenez Diaz University Hospital, Madrid, Spain., Madrid, Spain.

Leber Congenital Amaurosis (LCA) is the most severe blinding retinal dystrophy that represents near 5% of cases. At the moment 20 genes have been associated to this disease, more of them expressed in the photoreceptors or in the retinal pigment epithelium, explaining around 70% of LCA cases. The ubiquitous gene encoding nicotinamide nucleotide adenylyltransferase 1 (*NMNAT1*) was recently associated to this pathology using exome sequencing. The aim of this work was to screen the *NMNAT1* gene in our Spanish cohort of uncharacterized LCA families. We were selected a total of 96 LCA families previously screened for known mutations to cause LCA using a commercial genotyping chip with negative results. Index cases of these families were analyzed by direct Sanger sequencing of the coding *NMNAT1* sequence. This screening allowed us to identify five novel mutations in the *NMNAT1* gene and to characterize 6 of the 96 total families (6.25%), carrying all of them compound heterozygous mutations. As described in other populations, the p.E257K variation which was not found in any of the 176 Spanish controls tested, is the most frequent variation. Five additional families were found to carry the p.E257K common variation in heterozygosity with no other apparently change in the second allele. In order to fully characterized these families other studies (RNA expression in peripheral total blood and lymphoblast cell line, intronic sequencing and others) should be performed.

P02.21-S
Mutation hotspot sequencing reveals RPE65 as the most frequently mutated LCA gene in Denmark

G. D. N. Astuti[1,2,3], *M. Bertelsen[4,5,6], R. W. J. Collin[1,2], T. Rosenberg[4,6], S. M. H. Faradz[3], F. P. M. Cremers[1,2];*
[1]Department of Human Genetics, Radboud University Medical Centre, Nijmegen, Netherlands, [2]Radboud Institute for Molecular Life Sciences, Radboud University Medical Center, Nijmegen, Netherlands, [3]Division of Human Genetics, Center for Biomedical Research, Faculty of Medicine, Diponegoro University, Semarang, Indonesia, [4]National Eye Clinic for the Visually Impaired, Kennedy Center, Glostrup, Denmark, [5]Department of Ophthalmology, Glostrup Hospital, Glostrup, Denmark, [6]Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark.

Leber congenital amaurosis (LCA) represents the most severe and earliest onset form of inherited retinal dystrophies, and affects 1 per 50,000 individuals worldwide. Presently, mutations in twenty genes with diverse roles in the retina are known to be associated with LCA. The large number of LCA genes necessitates a systematic genotyping approach in a cost- and time-effective manner. Previous studies in LCA have described some recurrent mutations and mutational hotspots in particular exons of LCA-associated genes, i.e. an intronic variant in *CEP290* (c.2991+1655A>G), a nonsense mutation in *AIPL1* (p.W278*), a missense change in *GUCY2D* (p.R768W), and various mutations clustering in exons 7 and 9 of *CRB1*. As gene-specific therapies are emerging, identifying mutations in *RPE65* and *LRAT* can also be of tremendous importance for patients. Sanger sequencing of these mutation hotspots, and all protein-coding exons of *RPE65* and *LRAT* in 64 Danish LCA probands revealed one or two variants in 22 (34%) cases. Upon the identification of heterozygous variants, Sanger sequencing was performed in the relevant genes to identify the second allele, *RPE65* was shown to be the most frequently mutated gene in Denmark (20% vs. 8% in other Caucasian populations). This is important as 9-*cis*-retinoid supplementation and *RPE65* gene augmentation therapies have been developed.

P02.22-M
Propensity for localized provoked vulvodynia by *TRPV1* and *NGF* polymorphisms

T. C. Falik-Zaccai[1,2], *L. Kalfon[1], A. Azran[1], Y. Farajun[1], O. Hemo[1], E. Tubin[1], L. Abramov[3], A. Yeshaya[4], J. Bornstein[1,2];*
[1]Western Galilee Medical Center-Naharia, Naharia, Israel, [2]The Galilee Faculty of Medicine, Bar Ilan University, Safed, Israel, [3]Lis Women's Hospital, Tel-Aviv, Israel, [4]Shnaider Women's Hospital, Beilinson Medical Center, Petah-Tikva, Israel.

Localized provoked Vulvodynia (LPV) is a prevalent chronic pain condition. Familial occurrence (FO) suggests genetic susceptibility in its etiology. We studied possible associations between LPV in 70 affected women and seven Single Nucleotide Polymorphisms (SNPs) in the genes Transient Receptor Potential Vanilloid type-1 (*TRPV1*), Nerve Growth Factor (*NGF*) and *heparanase*, hypothesized to be involved in the pathophysiology of LPV. Prevalence of SNPs was compared between women with severe primary LPV and 132 healthy, ethnically matched controls. Women participating in the study have answered a detailed questionnaire, addressing possible FO of LPV and comorbid pain conditions.
SNaPshot™ genotyping revealed a novel statistically significant high prevalence of non-synonymous polymorphism rs222747 of *TRPV1* and rs11102930 located in the promoter region of *NGF,* , in women with LPV, especially those from Ashkenazi Jewish ancestry compared to the control group. Logistic regression model for rs222747 and rs11102930 frequent alleles indicates significant risk for LPV in all affected women and Ashkenazi Jewish group, respectively. Significant higher rate of FO of LPV, Temporo mandibular joint (TMJ) symptoms, recurrent vaginitis and irritable bowel syndrome was found in affected women compared to healthy controls.Ad hoc analysis compared pain conditions with frequent alleles among the 202 women studied. Interestingly, rs222747 minor allele of *TRPV1* was found in association with women presenting TMJ and women with recurrent vaginitis, suggesting a possible common genetic predisposition to pain comorbidities. These data open a new horizon for understanding the pathophysiology of LPV and might lead to the development of new personalized therapeutic modalities.

P02.23-S
Genetic Disorder with Diverse Modes of Inheritance Implicates Sporadic Form of Mild to Moderate Sensorineural Hearing Loss in a Pediatric Population

N. K. D. Kim[1], *K. Park[2,3], A. Kim[2], S. Kim[2], M. Kim[4], S. Oh[2], J. Joung[1], W. Park[5,6], B. Choi[4];*
[1]Translational Bioinformatics Laboratory, Samsung Genome Institute, Samsung Medical Center, Seoul, Korea, Republic of, [2]Otorhinolaryngology, Seoul National University Hospital, College of Medicine, Seoul National University, Seoul, Korea, Republic of, [3]Seoul ENT clinic, Gimhae, Korea, Republic of, [4]Department of Otorhinolaryngology, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of, [5]Translational Genomics Laboratory, Samsung Genome Institute, Samsung Medical Center, Seoul, Korea, Republic of, [6]Department of Molecular Cell Biology, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of.

arNSHL (autosomal recessive Nonsyndromic Hearing Loss), the most frequent mode of hereditary hearing impairment, is typically severe or profound. In contrast with severe or profound hearing loss of which genetic etiologies have been intensively investigated, relatively less attention into mild to moderate hearing loss has been paid. This study was designed to delineate genetic contributions, if any, to moderate hearing loss in a pediatric population using the next generation sequencing technologies. We performed whole exome sequencing (WES) for 12 unrelated children with moderate degree of hearing loss. Hearing loss from 11 of 12 probands was sporadic. We performed bioinformatic analyses of the WES data and selected the candidate variants compatible with either autosomal recessive inheritance pattern or *de novo* autosomal dominant pattern. Strong candidate variants were detected in 6 (50%) of 12 probands, suggesting a strong genetic contribution to moderate degree of hearing loss in a pediatric population. Diverse mode of inheritance pattern was observed in this disease population unlike in severe to profound hearing loss. Compound heterozygotes from deafness genes, *OTOGL,* and *SERPINB6* were detected. One proband segregated moderate degree of hearing loss as a digenic inheritance involving two deafness genes, *GPR98* and *PDZ7.* In addition, strong candidates from another three subjects were selected as a *de novo* mutation from *MYH14*, *MYO7*, and *P2RX2*, respectively. This study, for the first time in the literature reveals a strong genetic contribution to sporadic forms of moderate hearing loss in a pediatric population.

Identification of genes and related mutations in 10 Iranian families with non-syndromic autosomal recessive hearing loss by whole exome sequencing

M. Babanejad[1], *M. Akbari*[2], *H. Najmabadi*[1], *K. Kahrizi*[1];
[1]*Genetics Research Center , University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Women's College Research Institute, Women's College Hospital, University of Toronto, Toronto, ON, Canada.*

With prevalence figures close to 0.2% at birth, hearing loss (HL) is the most frequent sensory impairment in childhood. In developed countries, genetic causes account for more than 60% of congenital HL, most often resulting in non-syndromic deafness, which is usually autosomal recessive.
Hereditary nonsyndromic hearing loss (NSHL) in Iran is highly heterogeneous, and more than 50% of patients with a presumed genetic etiology lack a specific molecular diagnosis with STR analysis. Whole-exome sequencing (WES) has recently opened a new page in Mendelian disease gene discovery - enabling to study autosomal recessive HL in a new way.
The aim of this study is to find more causative genes and their mutations for NSARHL in Iranian families by WES. After ruling out any association to prevalent genes for NSARHL in Iran, ten families will be subjected to WES.
Until now, WES has been performed with genomic DNA from affected individuals of two consanguineous families with profound deafness. Analysis of these data revealed a novel homozygous mutation in MYO7A gene in one family but co-segregation study failed to confirm this variant as the only cause of HL in this family. Additional clinical investigation revealed that an intra-familial phenotypic variation and existence of both syndromic and non-syndromic HL in this family is possible. Further studies to find the other variants which may be associated with HL in this family, the data analysis of the second family and also WES of remaining families are underway.

Nonsyndromic hearing loss in Moravia: one fifth due to GJB2, no mutations in SERPINB6, TMIE, COCH, ACTG1, KCNQ4, GJB3

P. Tvrda[1], *P. Plevova*[1], *P. Turska*[1], *B. Kantorova*[1], *E. Mrazkova*[2], *D. Grecmalova*[1], *A. Gregorova*[1], *A. Hladikova*[1], *E. Silhanova*[1], *N. Dvorackova*[1];
[1]*Department of Medical Genetics, Faculty Hospital, Ostrava, Ostrava, Czech Republic,* [2]*Department of Epidemiology and Public Health, Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic.*

GJB2 gene mutations are the most frequent cause of nonsyndromic hearing loss. There are many other genes less frequently causing this disorder. The aim of our study was to look for other genes mutated in Moravian population of patients with deafness. We have performed sequencing of *GJB2* coding region on ABI3130 and Δ(GJB6-D13S1830) detection using PCR and gel electrophoresis in 142 patients with nonsyndromic hearing loss. Biallelic pathogenic *GJB2* mutations were found in 31 patients (22%) thus explaining their hearing defect. In 9 patients (6%) only one pathogenic *GJB2* mutation was found. No patient carried Δ(GJB6-D13S1830). Sequencing of *SERPINB6, TMIE, COCH, ESPN, ACTG1, KCNQ4* and *GJB3 g*enes was performed on ABI3130 in 13, 13, 13, 30, 20, 14 and 30 patients without *GJB2* mutation, respectively. No pathogenic mutation was found in *SERPINB6, TMIE, COCH, ACTG1, KCNQ4* and *GJB3* genes. In *ESPN* gene, two variants with unknown pathogenicity were found in two unrelated patients: c.337C>T, p.Arg113Cys (Polyphen score 1.00) and c.1797_1808delCCCACCGCCGCC, p.Pro600_Pro603del. Both variants were inherited from parents without hearing loss. We cannot exclude big genomic deletion/duplication of *ESPN* gene on the other allele in the patients. There may also be bigenic mechanism of hearing loss pathogenesis. So far, however, we cannot conclude that these variants are causal in our patients. We are going to analyze *WHRN* gene encoding the whirlin protein, functionally associated with *ESPN* gene product espin.

Comprehensive genetic diagnosis of non-syndromic hereditary hearing loss by targeted resequencing of 32 genes with use of Haloplex design and IonTorrent PGM sequencer

E. Nagyova[1], *D. Dvorska*[1], *T. Szemes*[1,2], *L. Kadasi*[1,3], *G. Minarik*[4,1,2];
[1]*Department of Molecular Biology, Comenius University in Bratislava Faculty of Natural Sciences, Bratislava, Slovakia,* [2]*Geneton Ltd., Bratislava, Slovakia,* [3]*Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia,* [4]*Institute of Molecular BioMedicine, Comenius University in Bratislava Faculty of Medicine, Bratislava, Slovakia.*

Non-syndromic hearing loss (NSHL) is one of the most common hereditary diseases with incidence higher than 1:1000. It is characterized by high genetic heterogeneity as causal mutations in more than 70 genes were found to be associated with it. Altough mutations in single gene - GJB2, are the most prevalent worldwide in remaining cases screening for causal mutation will be expensive and time consuming by conventional gene by gene approach. Therefore simultaneous sequencing of multiple genes with utilization of next-generation sequencing (NGS) should be the right solution.
In our pilot study 5 samples with familial incidence of autosomal dominant or recessive non-syndromic hearing loss without causal mutations in GJB2 gene were analyzed. The NGS was performed on IonTorrent PGM with use of customized Haloplex assay covering coding sequence of 32 most frequently mutated NSHL associated genes.
In 3 of 5 cases candidate causal mutations were identified and its presence was verified with Sanger sequencing. The detected mutations were p.H455Q in KCNQ4, p.G662E in MYO1A and p.T1866M in TECTA.
According to our results the multiparallel resequencing of panel of NSHL candidate genes could significantly improve genetic diagnosis of this geneticaly heterogeneous hereditary disease. Nevertheless, the lack of information about functional consequencies of low frequency variants could complicate the variant validation process and lead to false positive results.

Evidence for genetic linkage of a North Carolina-like macular dystrophy phenotype in association with digit anomalies to chromosome 5p15.32 or 9p24.1

V. Cipriani[1,2], *A. Kalhoro*[1,2], *S. Defoort-Dhellemmes*[3], *G. Arno*[1], *M. Michaelides*[1,2], *A. Webster*[1,2], *V. Plagnol*[4], *A. Moore*[1,2], *B. Puech*[3];
[1]*UCL Institute of Ophthalmology, London, United Kingdom,* [2]*Moorfields Eye Hospital, London, United Kingdom,* [3]*Service d'Exploration de la Vision et Neuro-Ophtalmologie, Hôpital Roger Salengro, Lille Cedex, France,* [4]*UCL Genetics Institute, London, United Kingdom.*

Introduction: Developmental macular disorders are a rare cause of visual impairment in children, but identifying the causative genes will help understand the biological pathways involved in human macular development. One such disorder is North Carolina macular dystrophy (NCMD), an autosomal dominant fully penetrant developmental macular dystrophy. NCMD has been mapped to chromosome 6q16 (MCDR1) and NCMD-like disorder has been mapped to chromosome 5p13.1-5p15.33 (MCDR3). To date, the genes underlying NCMD are unknown. The case of a British family affected by a dominant macular dystrophy resembling NCMD in association with digit anomalies was presented by A. Sorsby in 1935. We present a second unrelated family of French origin affected by the same phenotype and report the results of genetic linkage studies in both families. Methods: Fifteen members of the two families, including 11 affected, were genotyped using the Affymetrix 250K Sty array (238,304 single nucleotide polymorphisms). Parametric linkage analysis under a dominant model with complete penetrance was performed. Results: Linkage analysis identified two loci at 5p15.32 and 9p24.1 with LOD score of 2.7. Given the involvement of other ADAMTS proteins in several different ocular phenotypes, all exons of gene ADAMTS16 (5p15.32) were sequenced in affected individuals and no mutations were found. Discussion: The linkage overlap with the MCDR3 locus on 5p might indicate allelism or more likely the presence of mutations in two different adjacent developmental genes. Exome sequencing is undergoing and expected to shed light on the genetic basis of this disorder.

Inherited nonsyndromic sensorineural hearing loss (NSHL) is characterized by a high level of genetic heterogeneity, making extremely challenging to obtain a molecular diagnosis with traditional screening methods. Whole exome sequencing (WES) has been recently introduced as an alternative approach to search for alleles underlying Mendelian disorders and has been successfully applied for gene/mutation discovery. In this study, we used WES to identify the pathogenic mutations responsible for NSHL in three families (NSHL6, 11, and 12), with a recessive inheritance pattern and at least two affected siblings. A total of 9 individuals were subjected to WES using the SeqCapEZ Exome capture kit (Roche) and the HiSeq 2000 sequencer (Illumina). In particular, the NSHL6 patients were compound heterozygous for two novel mutations within the TMPRSS3 gene (DFNB8/10 locus). Both variants segregate with post-lingual, bilateral, high-frequency NSHL and affect evolutionary conserved amino acids located within the TMPRSS3 catalytic domain. In the NSHL11 family, two novel missense variants were found in the heterozygous state in OTOGL, a gene that was only recently associated with NSHL (otogelin-like protein, DFNB84 locus). Finally, in the consanguineous

NSHL12 pedigree, WES coupled with homozygosity mapping analysis pointed out a known missense variant (rs74315438) in the CLDN14 (DFNB29 locus) gene, coding for the claudin 14 protein. In conclusion, we provide evidence of the usefulness of WES for the diagnosis of NSHL and increase the knowledge on the genetic defects underlying this disease. This study was supported by: Italian Telethon Foundation (grant#GGP11177) and Fondazione Cariplo, grant N°2013-0825.

P02.29-S
Phenotypic and genotypic variability of Pendred syndrome

R. Birkenhäger, *S. Arndt, W. Maier, E. Löhle, A. Aschendorff, R. Laszig;*
Department of Otorhinolaryngology, Head and Neck Surgery, University Medical Center Freiburg, Freiburg, Germany.

Pendred Syndrome (PDS) is an autosomal-recessive disorder characterized by progressive sensorineural hearing impairment and goiter. PDS is associated with temporal bone abnormalities ranging from isolated enlargement of the vestibular aqueduct (EVA) to Mondini dysplasia. Hearing loss is prelingual in the majority of the cases; a minority of patients has a progressive hearing loss later in life.
EVA and PDS are caused by mutations in the SLC26A4 gene. The SLC26A4 gene is expressed in the non-sensory epithelia of the inner ear. Additionally the genes FOXI1 and KCNJ10 may also be responsible for PDS and inner ear malformations. The FOXI1 gene is involved in the transcriptional control of the SLC26A4 gene. The KCNJ10 gene encodes for a K+-channel located in the stria vascularis. In this study we analysed 167 patients with PDS and EVA hearing loss to accomplish a phenotype genotype correlations for PDS related deafness.
Individual exon and intron transitions of the SLC26A4, FOXI1 and KCNJ10 genes of patients were sequenced. Audiometric thresholds were performed, and radiologically, the vestibular aqueduct midpoint and opercular width were measured.
In the analysed patients with PDS, a total of 34 different SCL26A4 mutations were detected, mutations could not be detected in 64 % of the cases. FOXI1 and KCNJ10 analyses reveal no mutation.
The present results obtained in patients with PDS indicate that this phenotype is likely to be complex. Moreover, analysis of FOXI1 and KCNJ10 genes in our cohort suggests a minor implication of these two genes in the phenotype of EVA and PDS.

P02.30-M
The 965insA in SLC26A4 gene is a founder mutation in Azeri families from western Iran

M. Mohseni, *B. Davarnia, M. Babanejad, N. Nikzat, K. Kahrizi, H. Najmabadi;*
Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran.

Background: Mutations in the *SLC26A4* gene cause both Pendred syndrome [sensorineural hearing loss (SNHL), enlarged vestibular aqueduct (EVA), and goiter] and autosomal recessive nonsyndromic hearing loss (ARNSHL) at the DFNB4 locus. Pendred syndrome is the most common type of syndromic HL.
Materials/Patients and Methods: We performed comprehensive clinical and genetic evaluations of 15 patients from four unrelated families from the Ardebil Province in western Iran. After testing STR markers to confirm linkage to the *SLC26A4* locus, we sought to identify genetic mutations in *SLC26A4* by Sanger sequencing all 21 exons, exon-intron boundaries and the promoter region of this gene.
Results and Conclusions: A known frameshift mutation (965insA, p.N322Fs7X) in exon 8 was identified in all four families. Three families were homozygous for this mutation and one family was compound heterozygote (L597S/965insA). To date, this mutation has been reported only in the Iranian population, so we investigated the possibility of a founder effect. Haplotypes were constructed by genotyping seven single nucleotide polymorphisms throughout the *SLC26A4* gene, thus identifying a single haplotype that co-segregated with the 965insA mutation. We conclude that this mutation originates from a common founder in the west province of Iran.

P02.31-S
Identification by whole-exome sequencing of two novel *LARS2* mutations in an Italian family with Perrault syndrome

G. Soldà[1], *M. Robusto*[1], *P. Castorina*[2], *U. Ambrosetti*[2], *R. Asselta*[1], *S. Duga*[1];
[1]*Dipartimento di Biotecnologie Mediche e Medicina Traslazionale, Università degli Studi di Milano, Milan, Italy,* [2]*Dipartimento di Scienze Cliniche e di Comunità, Università degli Studi di Milano and Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, UO Audiologia, Milan, Italy.*

Perrault syndrome (PRLTS) is a rare autosomal recessive disorder characterized by ovarian dysgenesis and premature ovarian failure (POF) in females, and by progressive hearing loss in both genders. Recently, mutations in four genes (i.e. HSD17B4, HARS2, CLPP, and LARS2) were found to be responsible for PRLTS, although they do not account for all cases of this genetically heterogeneous condition.
In this study, we used whole-exome sequencing (WES) to identify the pathogenic variants responsible for PRLTS in an Italian pedigree with two affected siblings (one female and one male). All five family members were subjected to WES using the SeqCapEZ Exome v2 kit (Roche) and the HiSeq2000 platform (Illumina). Data analysis highlighted compound heterozygosity, in both patients, for two novel missense variations, p.Thr300Met (c.899C>T) and p.Glu638Lys (c.1912G>A) within LARS2, encoding the mitochondrial leucyl-tRNA synthetase,. The segregation of the two mutations in the pedigree is compatible with the autosomal recessive inheritance of the disease. Both Thr300 and Glu638 residues are evolutionary conserved, and are respectively located within the editing domain and immediately before the KMSKS sequence, a unique signature of the catalytic domain of class 1 aminoacyl-tRNA synthetases. The identified mutations were confirmed to be absent in an in-house database of about 3500 ethnically-matched control exomes.
Apart from the original report in 2013, to our knowledge, this is the first study confirming the role of LARS2 mutations in PRLTS pathogenesis.
This study was supported by: Italian Telethon Foundation (grant#GGP11177) and Fondazione Cariplo, grant N°2013-0825.

Plateau iris configuration (PIC) is a unique subtype of angle-closure glaucomas presenting in younger patients. PIC has been recognised as one of the anatomical mechanisms of angle closure development along with papillary block. The diagnosis is always based on gonioscopic and ultrasound biomicroscopy (UBM) findings. PIC-associated anterior chamber characteristics include a normal central anterior chamber depth (ACD), a flat iris plane, an iris root that angles sharply forward, and anteriorly positioned or large ciliary processes. Peripheral iridotomy is proposed as a treatment. Post-iridotomy complications, such as persistent angle narrowing or occlusion with intraocular pressure elevation, give rise to the plateau iris syndrome (PIS). An autosomal dominant pattern of inheritance with incomplete penetrance was proposed by Etter et al. in 2006 because of a higher prevalence of PIC in first-degree family members. To our knowledge, no familial case has been reported to date.
Here we described a multiplex family of seven affected members in two generations. Two members have PIC and five have PIS with early-onset and severe prognosis for some of them. Whole-exome sequencing was performed in five of the cases. Among the about 50 candidate variants left after filtering out by segregation, frequency and pathogenicity, the four more relevant ones -according to their function- were validated by Sanger sequencing in the two remaining affected members. Further experimental investigations and/or sequencing of additional families with a similar phenotype are needed to highlight the causative gene.

Two Tumor Necrosis Factor promoter polymorphisms in Romanian patients with Primary Open Angle Glaucoma Results from a pilot-study

R. Simionescu[1,2], *R. Caisan*[3], *L. Voinea*[2], *A. Popa Cherecheanu*[2], *C. Bara*[2], *R. Sfrent-Cornateanu*[2];
[1]*OCULUS, Bucharest, Romania,* [2]*Carol Davila University of Medicine and Pharmacy, Bucharest, Romania,* [3]*National Hematology Institute prof C.T. Nicolau, Bucharest, Romania.*

Glaucoma is a complex group of optic neuropathies, characterized by the degeneration of the optic nerve, eventually leading to blindness. Primary Open Angle Glaucoma (POAG) is the most common form of disease, affecting 8 million people. The risk factors for POAG include genetic background. TNF-alpha polymorphisms were studied in different populations regarding their influence on susceptibility of POAG.
We aimed to investigate two TNF-α polymorphisms regarding susceptibility to POAG. To our knowledge, this is the first study of TNF polymorphisms

in Romanian POAG patients. We assessed 258 subjects (112 POAG patients and 146 healthy unrelated matched controls) for -857C/T (rs1799724) and -308 G/A (rs1800629) TNF-alpha polymorphisms. These were genotyped by Real Time PCR (Taqman SNP Genotyping Assays C_2215707_10 and C_7514879_10 respectively, Applied Biosystems, USA). Statistical analysis was performed using the SNPStats program for genetic association studies (http://bioinfo.iconcologia.net/SNPstats); p-values ≤0.05 were considered significant.
All studied groups were in HWE for both polymorphisms. The frequencies of minor alleles -857T and -308A were similar in POAG patients and controls (0.22/0.10 and 0.21/0.13 respectively). There was no significant difference in SNPs regarding the allele carriage or genotype frequency between POAG and control subjects. Three main haplotypes were constructed with similar frequencies in patients and controls -857C/-308G/, 857T/-308G and -857C/-308A: 0.683/0.661; 0.218/ 0.205 and 0.98 / 0.133 respectively. There was no significant association between the global haplotype and POAG (p-value = 0.5).
Conclusion: TNF-alpha polymorphisms (-857C/T and -308G/A) seem not to influence susceptibility of POAG. These results should be confirmed on larger patients' cohort.

P02.34-M
Genetic screening for disease-associated mutations in human retinal diseases using whole exome sequening (WES)

A. Tiwari[1], *A. Bahr*[1], *S. Feil*[1], *J. Neidhardt*[1], *W. Berger*[1,2,3];
[1]*Institute of Medical Molecular Genetics, University of Zürich, Schlieren, Switzerland,* [2]*Zurich Center for Integrative Human Physiology (ZIHP), Zürich, Switzerland,* [3]*Neuroscience Center Zürich (ZNZ), University of Zürich and ETH Zürich, Zürich, Switzerland.*

Monogenic diseases of the retina and vitreous affect approximately 1 in 2000 individuals. They are characterized by tremendous genetic heterogeneity and clinical variability of symptoms involving more than 20 different clinical phenotypes and mutations in more than 200 genes. Clinical manifestations of retinal degenerations (RD) range from mild retinal dysfunctions to severe congenital forms. A detailed clinical diagnosis and identification of the underlying mutations are crucial for genetic counseling of affected patients and their families, for understanding genotype-phenotype correlations and developing therapeutic interventions.
We make use of WES and have established a reliable and efficient high-throughput analysis pipeline of next generation sequencing (NGS) data to identify disease-causing mutations in RD. Our data indicate that this approach enables us to genetically diagnose approximately 56% of the patients (N=28) with mutation(s) in known disease-associated genes. Thus, 44% of the cases, that do not carry mutation(s) in a known gene, are crucial for identification of novel candidate genes and biological pathways underlying the disease phenotype. Amongst identified mutations, 47% were previously described in the literature while 53% are novel. The types of mutations included missense mutations (47.4%), frameshift insertions or deletions (26.3%), stop gains (15.8%) and mutations predicted to interfere with splicing (10.5%). In conclusion, WES can rapidly identify mutations in various families affected with different forms of RD. Functional studies of the identified mutations are needed to understand the underlying disease mechanisms, which in future might aid in the development of therapeutic approaches.

P02.35-S
Large number of new mutations found in patients with inherited retinal dystrophies using Panel-based Next Generation Sequencing

N. Gloeckle[1], *S. Kohl*[2], *J. Mohr*[1], *F. Battke*[1], *A. Sprecher*[1], *M. Schubach*[1], *K. Hoertnagel*[1], *A. Bernd*[3], *B. Wissinger*[2], *J. Neidhardt*[4], *W. Berger*[4,5,6], *S. Biskup*[1];
[1]*CeGaT GmbH, Tübingen, Germany,* [2]*Molecular Genetics Laboratory, Centre for Ophthalmology, University of Tübingen, Tübingen, Germany,* [3]*Clinic for Hereditary Retinal Degeneration, University Hospital Tübingen, Tübingen, Germany,* [4]*University of Zurich, Institute of Medical Molecular Genetics, Schlieren, Switzerland,* [5]*Zurich Center for Integrative Human Physiology (ZIHP), University of Zurich, Zurich, Switzerland,* [6]*Neuroscience Center Zurich (ZNZ), University and ETH Zurich, Zurich, Switzerland.*

In inherited retinal dystrophies (RD) genetic heterogeneity is a well known feature. Therefore, we used next generation sequencing (NGS) technology as a tool to identify known as well as unknown mutations in RD.
More than 150 genes associated with RD were selected from literature or databases. A custom target-in-solution-enrichment was used, followed by sequencing on either the SOLiD 5500xl or the Illumina HiSeq 2500 platform. Variants were annotated using transcript, variant, medical as well as population frequency databases. Identified mutations were validated using Sanger sequencing.
We analyzed 300 patients with all forms of RD including syndromic forms such as Usher-syndrome and Bardet-Biedl syndrome. The detection rate of solved cases was 56.7%. Interestingly, in 54% of the solved cases we were able to detect mutations which were not previously described in literature at the date of the medical report. 70% of these cases show exclusively a new mutation in case of dominant or x-linked inheritance and two new mutations in case of recessive inheritance. 30% show one new and one previously described mutation.
Therefore, we conclude that NGS is the most promising tool to identify known as well as unknown mutations for this genetically highly heterogeneous disease entity. New mutations were found in 47 different genes. Genes most frequently affected by mutations were *USH2A* and *EYS* followed by *RPGR, PRPF31* and *CDHR1*.
The high number of novel mutations detected in our cohort shows the advantage of NGS over often used conventional chip-array analysis that assay only known mutations.

P02.36-M
Splice factor-based gene therapy to correct mislocalization of the ciliary protein RPGR in retinal degeneration

R. Da Costa[1], *E. Glaus*[1], *A. Tiwari*[1], *B. Kloeckener-Gruissem*[1,2], *W. Berger*[1,3,4], *J. Neidhardt*[1];
[1]*Institute of Medical Molecular Genetics, University of Zurich, Schlieren, Switzerland,* [2]*Department of Biology, ETHZ, Zurich, Switzerland,* [3]*Zurich Center for Integrative Human Physiology (ZIHP), University of Zurich, Zurich, Switzerland,* [4]*Neuroscience Center Zurich (ZNZ), University and ETH Zurich, Zurich, Switzerland.*

Retinal degenerations (RD) and other genetic diseases are often caused by splice site mutations. This type of mutation accounts for approximately 20% of all pathogenic sequence variants associated with retinal degeneration.
Previously, we reported the identification of an X-linked RD patient that showed skipping of exon 10 in the RPGR mRNA. To treat this mutation-induced splice defects, we applied mutation-adapted splice factors. In case of the splice factor U1snRNA, the adaptation yielded an increase in its affinity towards the mutated splice site. This novel gene therapeutic approach was highly efficient in increasing the amount of correctly spliced RPGR transcripts in minigene splicing assays and patient-derived fibroblasts.
In this study, we aimed at evaluating the efficacy of the U1-based therapy on the protein level. We established an assay to locate the RPGR protein in patient-derived and control skin fibroblasts. In control fibroblasts, we found that the RPGR protein locates along the primary cilia including basal body, transition zone and axoneme. In contrast, patient-derived cells showed mislocalization of the RPGR protein restricted to the basal body and transition zone. Upon treatment with mutation-adapted U1, localization of RPGR along the axoneme was significantly increased compared to control treatments.
We conclude that the efficacy of the U1-based gene therapy is sufficient to correct not only misspliced transcripts but also their translated proteins. Thus, the adaptation of U1snRNA is a promising technique to treat patients who carry pathogenic splice defects.

P02.37-S
Homozygous deletion of glutamate receptor gene *GRID2* causes new human hotfoot mutant phenotype, characterized by early-onset cerebellar ataxia and retinal dystrophy

K. Van Schil[1], *M. Karlstetter*[2], *F. Meire*[3], *M. Bauwens*[1], *H. Verdin*[1], *F. Coppieters*[1], *E. Scheiffert*[2], *N. Deconinck*[4], *T. Langmann*[2], *E. De Baere*[1];
[1]*Center for Medical Genetics, Ghent University and Ghent University Hospital, Ghent, Belgium,* [2]*Department of Ophthalmology, University of Cologne, Cologne, Germany,* [3]*Department of Pediatric Ophthalmology, Queen Fabiola Children's University Hospital, Brussels, Belgium,* [4]*Department of Pediatric Neurology, Queen Fabiola Children's University Hospital, Brussels, Belgium.*

It was our aim to identify the genetic cause of early-onset autosomal recessive cerebellar ataxia (ARCA) associated with retinal dystrophy in a consanguineous family.
Homozygosity mapping and copy number analysis revealed a homozygous deletion of exon 2 of *GRID2*, p.(Gly30_Glu81del), in the proband, compatible with mouse hotfoot mutant *ho15J*. *GRID2* encodes an ionotropic glutamate receptor known to be selectively expressed in cerebellar Purkinje cells. Here, we demonstrated *GRID2* mRNA expression in human adult retina and retinal pigment epithelium. In addition, *Grid2* expression was demonstrated in different stages of murine retinal development. GRID2 protein expression was observed in both murine and human retina, more specifically in photoreceptor inner segments, the outer plexiform layer and ganglion cell layer.
In order to rule out involvement of mutations in another gene, whole exome sequencing was conducted but did not reveal any other disease-causing mutations, supporting the phenotype observed here represents a single clinical entity.
We identified *GRID2* as underlying disease gene of early-onset ARCA with retinal dystrophy, expanding the clinical spectrum of *GRID2* deletion mutants, which thus far only involved cerebellar but no retinal phenotypes. We demonstrated, for the first time, GRID2 mRNA and protein expression

in human and murine retina, providing evidence for a novel functional role of GRID2 in the retina. To the best of our knowledge *GRID2* is the second glutamate receptor gene, apart from *GRM6*, leading to retinal disease when mutated. Finally, we provided further evidence for evolutionary conservation of a hotfoot fragile site between mouse and human.

P02.38-M
Homozygosity mapping and whole exome sequencing identified four novel candidate retinal dystrophy genes

M. M. Alrashed[1,2];
[1]*Department of clinical laboratory sciences, College of Applied Medical Sciences, King Saud University, Riyadh, Saudi Arabia,* [2]*Department of genetics, King Faisal specialist hospital and research center, Riyadh, Saudi Arabia.*

Inherited retinal dystrophies (IRD) are a remarkably genetically and phenotypically heterogeneous group of inherited eye diseases, with over 190 causative genes identified to date. In the highly consanguineous Saudi population, autosomal recessive forms of IRD are thought to account for the overwhelming majority of cases. Consanguinity is known to increase the frequency of recessive disorders since it increases the coefficient of inbreeding, which is a measure of the percentage of the genome that is identical by descent. Homozygosity mapping, targeted candidate gene analysis and whole exome sequencing were used to identify the causes of IRD in the Saudi population. Mutations in RP1 were found to be a common cause of recessive RP in the Saudi population. Novel and previously identified homozygous mutations in the KCNV2 gene were identified in a cohort of patients with a distinct recessive retinal disorder, 'cone dystrophy with supranormal rod response,' demonstrating phenotype/genotype correlation. In addition, a founder homozygous CABP4 mutation was identified . Causative homozygous mutations were also found in the IRD genes RBP3, RDH12, CRB1, BBS4, CNGA3, CNGB1, EYS, RLBP1, ABCA4 and PCDH12. Four novel candidate genes for retinal degeneration were identified in this study. Potentially pathogenic homozygous variants were identified in EMC1 (c.G430A, p.A144T), KIAA1549 (c.2399_2400insAA, p.T800fs809X), GPR125 (c.C2504G, p.S835C) and DHX29 (c.C2738T, p.A913V). In the majority of cases (31 families) the genetic cause of IRD was identified, demonstrating the power of homozygosity mapping and whole exome sequencing.

Next-generation sequencing for retinal dystrophy: two years' clinical experience

T. Gale, *S. Barton, S. Ramsden, G. Black, G. Hall;*
Manchester Centre for Genomic Medicine, Manchester, United Kingdom.

Retinal dystrophy (RD) is a genetically and phenotypically heterogeneous group of conditions; it can be syndromic or non-syndromic and follow dominant, recessive or X-linked inheritance. Since April 2012 we have been using next-generation sequencing (NGS) technology with a panel of 105 known retinal genes; genetic testing and the potential identification of causative mutations is now available for a much broader range of patients with RD than was previously possible.
We are currently conducting a notes-based review to evaluate our clinical delivery of this service and its impact on families; we will present data on a cohort of 40+ patients who have undergone NGS testing for retinal dystrophy. Analysis so far shows a wide age range (2-87 years) of patients, around 50% of whom have no family history.
A common reason for testing is to clarify the mode of inheritance for the sake of children or other relatives. Patients also underwent testing to clarify a diagnosis or prognosis, for example, whether the co-occurrence of hearing loss in the family was due to Usher syndrome.
We have reported a range of results: clearly pathogenic mutations (50-60% detection rate), negative test results, and unclear or ambiguous results requiring additional family samples and careful genetic counselling.
We will present data on the impact and value of NGS testing for families and clinicians, including incidental carrier findings and unexpected results such as altered inheritance pattern or change in management. Our experience suggests NGS testing for retinal dystrophy is relevant for a significant number of patients.

Retinitis pigmentosa (RP) is a heterogeneous group of inherited retinal dystrophies ultimately characterized by the loss of photoreceptors leading to blindness. The molecular diagnosis of RP has long been hampered by the large genetic heterogeneity of this group of disorders. The clinical application of next generation sequencing (NGS) techniques may overcome, in part, these limitations. In this study, we conducted whole exome sequencing (WES) to uncover the genetic cause of arRP in a consanguineous Spanish family, in which genotyping and resequencing microarrays failed to identify the genetic defect. This strategy allowed the detection of one rare homozygous mutation located in exon 1 of C2ORF71 gene (c.1795T>C, p.Cys599Arg). Although this variant has been previously annotated (rs377190272), it has only been detected in heterozygosity in one control individual out of 6304 exomes from the Exome Variant Server database, being probably an asymptomatic carrier. Moreover, the variant co-segregated with the disease in the extended family and was absent in 400 matched chromosomes. Clinically, patient with mutation p.Cys599Arg shows signs of typical RP and resembles other patients with missense mutations in this gene. Taking into account the high prevalence of carriers of deleterious mutations in RP genes among the control population, and the growing number of experiments in which new variants identified by exome sequencing are reported, identifying real novel mutations is an increasingly difficult task. All together this data allow us to conclude that rs377190272 is the most likely causative mutation underlying the phenotype arRP in this family.

Inherited retinal disorders affect approximately 1 in 2000 individuals worldwide. Symptoms and associated phenotypes are really variable and, to date, more than 150 genes have been implicated. Retinitis pigmentosa (RP), a degenerative disease of the retina, accounts for approximately one-half of cases. Molecular diagnostics for RP patients by Sanger sequencing is hampered by genetic and clinical heterogeneity. Next generation sequencing (NGS) technology provides a new approach for RP genetic testing, allowing for the screening of other known retinal disease genes in addition to RP genes, particularly important due to their clinical and genetic overlap. To test NGS potential for RP molecular diagnosis, we analyzed a panel of 123 retinal disease genes by targeted NGS in a cohort of 95 Italian probands with non-syndromic RP. All identified genetic variants entered a systematic data analysis pipeline for their prioritization and prediction of pathogenicity, followed by direct sequencing validation. Here, we report preliminary results on 52 probands, for which data analysis and Sanger validation have been completed. Our screening resulted in a molecular diagnosis for 47 RP patients, comprising 18/20 recessive, 11/11 dominant, and 18/21 sporadic cases. A total of 92 likely causative variants in 45 different genes were identified; 46/92 are novel mutations. The genes *USH2A*, *ABCA4*, *EYS*, *NR2E3* and *RP1* were more frequently affected than others. In this group of 52 patients, NGS proved to be an efficient (diagnostic rate: 90%), faster and less time consuming method compared to conventional ones for molecular diagnosis of genetically heterogeneous diseases such as RP.

P02.43-S
Hypomorphic variants in the splice factor genes DHX38 and SNRNP200 are associated with autosomal recessive retinitis pigmentosa

M. Khan[1,2], *M. Ajmal*[1,2], *K. Neveling*[1], *S. Micheal*[1,3], *M. Azam*[1,2], *A. I. den Hollander*[1,3], *R. W. J. Collin*[1,4], *R. Qamar*[2,5], *F. P. M. Cremers*[1,2,4];
[1]*Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands,* [2]*Department of Biosciences, COMSATS Institute of Information Technology, Islamabad, Pakistan,* [3]*Department of Ophthalmology, Radboud University Medical Center, Nijmegen, Netherlands,* [4]*Nijmegen Institute for Molecular Life Sciences, Radboud University Nijmegen, Nijmegen, Netherlands,* [5]*Al-Nafees Medical College & Hospital, Isra University, Islamabad, Pakistan.*

Purpose: To identify the underlying genetic defects in two consanguineous families with autosomal recessive retinitis pigmentosa (arRP).
Methods: Ophthalmologic analysis was performed in selected persons from both families, that included visual acuity assessment, fundoscopy and electroretinography. Genome-wide homozygosity mapping was performed for multiple affected and unaffected individuals using single nucleotide polymorphism arrays. After exclusion of arRP-associated genes residing in homozygous regions, the probands were analyzed using whole exome sequen-

cing. Pathogenicity of the candidate disease-causing variants in the homozygous regions was assessed by in-silico analysis.
Results: Ophthalmologic examination revealed typical features of RP in both families. In the first family a homozygous missense variant, c.3269G>A;p.(Arg1090Gln), was identified in SNRNP200, which previously was implicated in autosomal dominant RP (adRP) and shown to impair splicing. In the second family a missense mutation, c.995G>A;p.(Gly332Asp), was identified in DHX38, which encodes the pre-mRNA splicing factor PRP16 and previously has not been associated with arRP. The DHX38 variant shows a lod score of 3.25, which is highly suggestive of linkage. Segregation analysis indicated that both variants segregated with RP in respective families, in an autosomal recessive manner. In-silico analysis supported the causality of the p.(Arg1090Gln) and p.(Gly332Asp) variants.
Conclusions: Since the SNRNP200 variant p.(Arg1090Gln) appears only to be causative when present homozygously, we hypothesize that it is a hypomorphic mutation. So far mutations in pre-mRNA splicing factor genes have only been associated with adRP, thus this is the first report that implicates defects in the splicing machinery proteins DHX38 and SNRNP200 to be associated with arRP.

P02.44-M
RS1 gene exon 2 deletion in a large Pedigree with X-linked juvenile retinoschisis

A. Nicoletti[1], *L. Ziccardi*[2], *L. D'Agruma*[3], *S. Cecchin*[1], *O. Palumbo*[3], *S. Benedetti*[1], *M. Rendina*[3], *M. Bertelli*[1];
[1]MAGI Human Genetics Institute, Rovereto (TN), Italy, [2]Neurophthalmology Unit – IRCCS Fondazione Bietti, Rome, Italy, [3]Medical Genetics Unit, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo (FG), Italy.

Juvenile retinoschisis (XLRS) is a vitreo-retinal disorder characterized by early-onset cystic macular dystrophy that can evolve in central atrophy, thus leading to blindness. More than 200 disease-causing mutations have been reported in the X-linked gene *RS1* (Xp22). The clinical diagnosis is based on instrumental ocular examination and can be confirmed by molecular genetic testing. In this report, we present the molecular characterization of an XLRS family with 4 affected males and a pedigree suggestive of an X-linked inheritance. **Methods:** *RS1* gene point mutations screening was performed by PCR e direct sequencing. *RS1* gene copy number variation was assessed by "home made" MLPA analysis and by SNP-array analysis using CytoScan HD Array (Affymetrix, Santa Clara, CA). **Results:** the exon 2 fragment of *RS1* gene failed to amplify in the proband; given the strong suspicion of a deletion a confirmation was made by MLPA and SNP-array: all affected males were positive for exon 2 deletion of *RS1* gene. Carrier females were also identified. SNP-array analysis showed a deletion of less than 7 kb including exon 2. **Conclusion:** this is the first report of a deep characterization of a whole exon deletion in the *RS1* gene, accounting in 10% of XLRS. SNP-array analysis mapped the deletion breakpoint in an intronic region rich of several repeated elements, thus prone to rearrangements. Female carriers can be easily detected by MLPA analysis that represents a useful test in terms of time and costs for copy number detection.

P02.45-S
Spectrum of SLC26A4 gene mutations in Slovak NSHL patients

M. Pecimonova[1], *K. Ottonellova*[1], *A. Soltysova*[1,2], *L. Kadasi*[1,2];
[1]Faculty of Natural Sciences, Comenius University, Department of Molecular Biology, Bratislava, Slovakia, [2]Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia.

Nonsyndromic hearing loss is characterized by hearing impairment that is not associated with other signs and symptoms. This form of deafness accounts for 70% of all inherited hearing loss and it is caused mostly by malformations of structures in the inner ear. A large number of genes is associated with nonsyndromic hearing loss, including CLDN14, COL11A2, GJB2, GJB3, GJB6, KCNQ4, MYO1A, MYO15A, MYO6, MYO7A, POU3F4, SLC26A4, TECTA, TMPRSS3, and many others.
In the Slovak population, mutations in GJB2, GJB6 and mitochondrial genes were only screened to date. In our work we focused on the mutation screening of the SLC26A4 gene, which was found as another of the most prevalent disease genes in NSHL. The SLC26A4 gene encodes a protein called pendrin, which functions as an anion transporter of mostly chloride, iodide and bicarbonate ions across the membranes of cells of the thyroid, inner ear, and kidneys. Recessive mutations in this transporter are associated with hearing loss DFNB4, which is accompanied by an enlargement of vestibular aqueduct. Mutated pendrin affects the levels of fluid in the inner ear that leads to malformation and hearing loss.
In our work, we screened 324 patients for mutations in the SLC26A4 gene. We found several missense mutations, of which the most frequent were G6V (probably non-pathogenic), R185T, R409H, T416P, L445W, R470H, Y530S, L597S, and two splicing mutations c.919-2 A>G and c.2089+1G>A. In two patients we confirmed Pendred syndrome by identifying genotypes R409H/c.919-2 A>G and L445W/c.2089+1G>A.

Ammosov North-Eastern Federal University, Laboratory of Molecular Biology, Yakutsk, Russian Federation, [6]Institute of Cytology and Genetics, Siberian Branch of the Russian Academy of Sciences, Laboratory of Human Molecular Genetics, Novosibirsk, Russian Federation, [7]Novosibirsk National Research State University, Department of Cytology and Genetics, Novosibirsk, Russian Federation.

Usher Syndrome (US) is an autosomal recessive condition characterized by a combination of congenital hearing impairment and retinitis pigmentosa. To date, ten genes have been associated with US, representing up to 90% of cases. Three types of US are known and differ by onset of the symptoms, severity and progressiveness of deafness and additional vestibular dysfunction. Patients with type II US have congenital bilateral sensorineural hearing loss that is mild to moderate in the low frequencies and severe to profound in the higher frequencies, intact vestibular responses, and bilateral retinitis pigmentosa.
40 unrelated Usher II type families (60 patients) from Volga-Ural Region of Russia were studied using genotyping microarray (Usher, Asper-Biotech) for screening 614 mutations in genes CDH23, MYO7A, PCDH15, USH1C, USH1G, USH2A, GPR98, CLRN1, DFNB31 and automatic sequencing of Usher's genes. Diagnosis was based on pedigree data, ophthalmologic, audiological and vestibular examination.
We revealed homozygous and heterozygous genotypes for the c.11864G>A (p.Trp3955X) mutation (USH2A) in six unrelated families among Russian, Tatar and Chuvash patients with Usher II syndrome. We found four pathogenic mutations in coding region of 8 patients (p.Glu4458fs, p.Trp3955X, p.Glu4078fs, and p.Gly1392X), confirming their clinical diagnosis. The most frequent USH2A gene mutation was c.11864G>A (9/80 alleles; 11,25%). Mutation c.11864G>A in heterozygous state was also found in one Russian subject out of 1066 examined individuals from 16 various populations of Eurasia: Bashkirs, Tatars, Chuvashes, Udmurts, Komi-Permyaks, and Mordvins, Russians, Belarusians, Ukrainians, Veps, and Karelians, Abkhazians, Kazakhs, Uzbeks, Yakuts, Altaians. Study was supported by grants (№12-04-00342_a, №12-04-98520_r_vostok_a, №14-04-97002_r_povolgie_a, №14-04-97007_r_povolgie_a,№14-04-01741_A).

P02.47-S
SOX2 whole gene deletion without ocular malformation but with isolated bilateral third degree microtia : a new manifestation of SOX2-related disorders?

E. Ranza[1], *K. Varvagiannis*[2], *E. Stathaki*[1], *S. Gimelli*[1], *S. E. Antonarakis*[1,2], *A. Bottani*[1], *F. Sloan Béna*[1];
[1]HUG, University Hospitals of Geneva, Geneva, Switzerland, [2]Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland.

SOX2-related eye disorders are characterized by anophthalmia and/or microphthalmia, which is usually bilateral and severe. Molecular genetic testing of this gene, including sequence analysis and MLPA (for large gene deletions), identifies mutations in about 10-20% of individuals with such ocular involvement. Other common findings include brain malformations, oesophageal atresia and male genital abnormalities. Postnatal growth failure with pituitary insufficiency, seizures, sensorineural hearing loss, delayed motor development and learning difficulties are described. Recent studies have demonstrated a broader ocular phenotype in cases with missense mutations, consistent with a role for *SOX2* in both posterior and anterior segment development. Severe *SOX2* (OMIM 184429) mutations (whole gene deletion/nonsense mutation) with complete loss-of-function alleles, almost uniformly result in anophthalmia/microphthalmia.
We report the case of a newborn female, evaluated at birth for isolated bilateral third degree microtia. All investigations (cardiac, abdominal, cerebral, ophthalmologic) were normal.
Array-CGH analysis has shown a *de novo* 40 kb deletion of 3q26.33 (chr3:181407035-181442290) [hg19] deleting the entire *SOX2* gene.
More detailed ophthalmologic evaluations confirmed the absence of any ocular abnormality. The girl benefits from osseous conduction hearing aids. Is there a link between *SOX2* deletion and microtia, consistent with results

of a recent study showing under-expression of *SOX2* in human auricular chondrocytes from microtia samples ? Our case also confirms the reduced penetrance of the ocular phenotype, even in severe *SOX2* mutations, and raises the question of a further broadening of *SOX2*-related disorders….

Exome sequencing identifies POU3F4 p.Ala116fs mutation among family with hearing loss

U. Lechowicz[1], *A. Pollak*[1], *P. Stawinski*[1], *A. Podgorska*[1], *M. Mueller-Malesinska*[1], *M. Oldak*[1,2], *L. Korniszewski*[1], *H. Skarzynski*[1], *R. Ploski*[3];
[1]*World Hearing Center, Institute of Physiology and Pathology of Hearing, Kajetany/ Warsaw, Poland,* [2]*Department of Histology and Embryology, Medical University of Warsaw, Warsaw, Poland,* [3]*Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland.*

One of the most common genetic diseases in human is hearing loss (HL). The majority of cases are nonsyndromic (70%) and 1-5% are nonsyndromic X-linked. Most cases are due to mutations in a single gene. Nevertheless, DNA diagnostics for hearing loss are challenging, since it is an extremely heterogeneous trait. Although more than 70 causative genes have been described for the nonsyndromic hearing loss alone, diagnostic application of the scientific progress has lagged behind. Some previous reports have shown that „next-generation DNA sequencing techniques" have the potential to offer a novel testing platform that could test all known genes in a sensitive, specific and cost-efficient manner. In this study, whole exome sequencing (WES) for direct genetic diagnosis in NSHL was used. Sequential filtering of variants obtained from WES, bioinformatic analyses, and Sanger sequencing validation identified premature termination p.Ala116fs mutation in POU3f4 gene as the candidate disease-causing mutation in the family. POU3F4 belongs to a subfamily of transcription factors, which are characterized by 2 conserved deoxyribonucleic acid-binding domains, a 75- amino acid POU- specific domain and a 60-amino acid homeodomain, both helix-turn-helix structural deoxyribonucleic acid-binding motifs. In this study clinical features and genetic analysis of a male child from a Polish family with congenital deafness and POU3F4 p.Ala116fs mutation is described. Usually clinical features of DFNX2 (DFN3) often include a mixed, progressive hearing loss, temporal bone anomalies, and stapes fixation.

Common copy number variations on the origin of disease

P. Rendeiro[1], *M. Amorim*[2], *R. Lemos*[1], *C. Ventura*[1], *Á. Pereira*[1], *A. Sousa*[1], *R. Cerqueira*[1], *J. Sá*[1], *J. Pinto Basto*[1], *L. Nunes*[2], **P. Tavares**[1];
[1]*CGC Genetics, Porto, Portugal,* [2]*Serviço de Genética Médica, Hospital D. Estefânia, Lisboa, Portugal.*

Introduction: It is well established the relation between CNV and intellectual disability and/or autism, as it is the existence of a large number of CNV not associated with disease. These polymorphisms although benign, could represent a risk of disease when occurring in homozigosity, or when combined, depending of its genetic content. Objective: We present a case of a girl with congenital deafness, and homozygous deletion of OTOA gene, resulting from the presence of a benign CNV in each chromosome. Method: PAMS, 8 yo was referred for genetic analysis because of congenital deafness. Conexin 26 and conexin 30 sequence analysis was done using Sanger sequencing, conexin 30 deletions was done using MLPA. Exclusion of additional genetic mutations was done using a proprietary mutation panel (312 mutations on 32 genes). Array CGH analysis was performed using Affymetrix Cytoscan 750K. Results: Conexin results were negative and CGC Mutation panel and direct sequencing results demonstrated absence of amplification on OTOA. Parents testing with array CGH revealed the presence of a CNV (heterozygous deletion) on 16p12.2 in each. Both CNV are registered on DGV as normal variants. However, each CNV encompasses the OTOA gene, thus leading to the conclusion that the co-existence of two overlapping (individually benign) CNVs was the mechanism leading to congenital deafness on the index case. Conclusions: This case reveals the utility of array CGH as a complement technique in the investigation of molecular mechanisms of genetic disease that allowed establishing the molecular diagnosis and proper genetic counseling to this family.

11ß-hydroxylase deficiency (11ß-OHD) represents the second most common cause of Congenital Adrenal Hyperplasia (CAH). It is caused by mutations in the *CYP11B1* gene localized in 8q21, 40 kb distant from its highly homologous *CYP11B2* gene codifing for aldosterone synthase. Pathological alleles derived from the asymmetric recombination of these two genes have been described. The formation of a chimeric *CYP11B2/CYP11B1* gene leads to 11ß-OHD; instead the chimeric *CYP11B1/ CYP11B2* gene causes the glucocorticoid-remediable aldosteronism (GRA). As the detection of these rearrangement is still laborious or indirect, our objective was to project a synthetic probe set for multiplex ligation-dependent probe amplification (MLPA) analysis in order to simplify the detection of these chimeric genes and other variation in the copy number of these genes. We disegned a set of 8 specific probes for both *CYP11B1* and *CYP11B2* genes to be used with the commercial control kit SALSA MLPA P300 Human DNA reference (MRC-Holland). The methods was tested on 15 control samples and then applied to 6 patients with the suspition of 11ß-OHD. The analysis with the CYP11 probe set has led to the identification of one copy number variation in an adult patient with adrenal rests misdiagnosed as 21-hydroxylase deficiency and not properly treated. He resulted compound heterozygous for a novel chimeric *CYP11B2/CYP11B1* gene, with the breakpoint region locolized within intron 2, and the known A306V mutation. In conclusion, the described MLPA kit represents an optimal complement to DNA sequence analysis in patients with 11ß-OHD, enabling detection of deletions, duplications or chimeric genes.

Aarskog-Scott syndrome (AAS), also known as facio-digito-genital dysplasia is a rare, clinically and genetically heterogeneous condition characterized by short stature, and facial, limb, and genital anomalies. The best characterized form of the syndrome which was caused by mutations in *FGD1* is inherited as an X-linked trait (MIM#305400). This gene located on the short arm of chromosome X (Xp11.21), includes 18 exons. The population prevalence of AAS is probably lower or equal to 1/25 000. The clinical singns may range from mild to severe. Herein, clinical features and intrafamilial heterogeneity of four affected individuals in a Turkish AAS family with a novel mutation were presented. Only one of these patients had received growth hormone therapy and this treatment provided height velocity gain in our patient.

P03.03-S
Deciphering variability of PKD1 and PKD2 genes in Italian patients affected by Autosomal Dominant Polycystic Kidney Disease (ADPKD)

P. Carrera[1,2], *S. Calzavara*[2], *P. Messa*[3], *A. Edefonti*[3], *R. Magistroni*[4], *F. Scolari*[5], *P. Manunta*[6], *A. Boletta*[7], *M. Ferrari*[1,2,6];
[1]*Ospedale San Raffaele, Center for Translational Genomics and Bioinformatics, Milano, Italy,* [2]*Ospedale San Raffaele, Laboratory of Clinical Molecular Biology, Milano, Italy,* [3]*IRCCS Policlinico,, Milano, Italy,* [4]*University of Modena, Modena, Italy,* [5]*University of Brescia, Brescia, Italy,* [6]*University Vita-Salute San Raffaele, Milano, Italy,* [7]*Ospedale San Raffaele, Division of Genetics and Cell Biology, Milano, Italy.*

ADPKD is the most common genetic nephron-pathology in humans, affecting about 1/1000 individuals. Aim of the present work was to define genetic variation of PKD1 and PKD2 in Italian patients affected by ADPKD. Analysis of PKD1 and PKD2 variation would allow to: confirm the diagnosis in clinically uncertain/atypical cases; offer genetic counseling in at risk families; exclude the presence of a mutation in related donors for kidney transplantation; define gene variability in Italian patients. 576 subjects has been analyzed with a semi-automated Sanger protocol: 298 unrelated patients belonging to families and 171 relatives; 72 patients with no familiarity and 35 cases with no data about familiarity. In 90% of the 405 probands, variants were present: PKD1 80%; PKD2 4%; PKD1+PKD2 6%. 84.5% of the identified variants have never been described. An average of 12 SNPs/patient in PKD1 and 2 SNPs/patient in PKD2,was observed. By combining results for truncating and known variants we classified variants as pathogenic in 65.4% (265/405) of patients. For unclassified variants, a prediction was attempted according to PKDB criteria. Concordance of the results obtained with SIFT, AGVGD and PolyPhen2 allowed calling of 18 likely-neutral and 12 highly-likely-pathogenic variants. In many cases interpretation of additional information becomes relevant (i.e. family segregation increases the score for pathogenicity). In patients with no mutations detected, MLPA analysis has been performed: we identified 2 patients with a huge deletion in PKD1 (ex2-

46); 1 patient with a deletion spanning exons 2-4 in PKD1; 1 patient with the deletion of the whole PKD2 gene.

P03.04-M
Scattered deletion of Pkd1 in mouse kidneys causes a cystic snowball effect and recapitulates human polycystic kidney disease

W. N. Leonhard, *M. Zandbergen, K. Veraar, L. Van der Weerd, E. de Heer, M. H. Breuning, D. J. M. Peters;*
Leiden University Medical Center, Leiden, Netherlands.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) patients carry a germline mutation in *PKD1* or *PKD2*, leading to thousands of kidney cysts. It is poorly understood why a rapid progression of the disease is preceded by a lag-phase of several decades. Studies in which *Pkd1* is inactivated in large percentages of cells in animal models, led to the presumption that inactivation of the remaining allele initiates cystogenesis, and that the progression can be accelerated by renal injury. To mimic human ADPKD, we lowered this percentage and found important characteristics of cystogenesis that have not been described before. **Methods:** The percentage of *Pkd1*-deficient cells in Tamoxifen-inducible kidney-specific *Pkd1*-deletion mice was controlled by varying the tamoxifen dose, visualized with reporter mice and quantified by eMLPA. Several renal injuries were applied. Cyst progression was followed by MRI-analysis and PKD-related signaling was analyzed by Immuno-histochemistry. **Results:** Interestingly, no pathological changes occurred for six months after scattered-*Pkd1*-deletion and renal injury did not trigger rapid PKD. However, in the following 3-4 months, clustered cyst formation led to a severe human-like PKD phenotype. This shift was preceded by increased pSTAT3, pCREB, pERK1/2, LCN2 and Ki-67 expression near the initial cysts. **Conclusions:** Our data argue against the presumption that renal injury is the major trigger for cystogenesis but suggests that initial cysts themselves, by imposing persistent stress on surrounding tissue, triggers a ‚snow-ball' effect driving the formation of new cysts. In addition, our model mimics human ADPKD more precisely and can be used for pre-clinical testing.

P03.05-S
Identification and characterisation of six novel SERPINA1 null mutations

S. Ottaviani[1], *I. Ferrarotti[1], T. P. Carroll[2], A. M. Fra[3], G. O'Brien[2], K. Molloy[2], D. Medicina[3], N. G. McElvaney[2], M. Luisetti[1];*
[1]IRCCS Fondazione Policlinico San Matteo, Pavia, Italy, [2]Beaumont Hospital, Dublin, Ireland, [3]University of Brescia, Brescia, Italy.

Alpha-1 antitrypsin (AAT) is the most abundant circulating antiprotease and is a member of the serine protease inhibitor (SERPIN) superfamily. The gene encoding AAT is the highly polymorphic SERPINA1 gene, found at 14q32.1. Mutations in the SERPINA1 gene can lead to AAT deficiency (AATD) which is associated with a substantially increased risk of lung and liver disease. The most common pathogenic AAT variant is Z (Glu342Lys) which causes AAT to misfold and polymerise within hepatocytes and other AAT-producing cells. A group of rare mutations causing AATD, termed Null or Q0, are characterised by a complete absence of AAT in the plasma. While ultra rare, these mutations confer a particularly high risk of emphysema. We report here the identification and characterisation of 6 new SERPINA1 Null mutations.

P03.06-M
Chromosome Microarray and non-coding DNA copy number variants - a case of Alveolar Capillary Dysplasia at FOXF1 locus

K. Schlade-Bartusiak[1,2], *E. Gagne[1], G. Hendson[1], M. L. McKinnon[3];*
[1]Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada, Vancouver, BC, Canada, [2]Child and Family Research Institute, Vancouver, Canada, Vancouver, BC, Canada, [3]Department of Medical Genetics, University of British Columbia, Vancouver, BC, Vancouver, BC, Canada.

Chromosome microarray (CMA) analysis typically focuses on coding DNA (RefSeq and OMIM genes). Although non-coding intergenic and intronic variants may be critical in disease pathogenesis, copy number variants (CNV) in these regions are usually interpreted as variants of unknown clinical significance. We present a case of a lethal neonatal condition in which the pathogenic CNV lies in a distant, upstream non-coding region. It highlights the importance of relevant clinical information for CMA interpretation, and the importance of the analysis of flanking regions if an identified CNV does not initially appear pathogenic. A term female, with a prenatal diagnosis of AVSD, presented with severe neonatal respiratory distress out of keeping with her cardiac issues. The clinical picture and early lethality suggested congenital surfactant deficiency (CSD). Sequencing of a CSD-gene panel was normal. CMA analysis revealed a *de novo* 1.5 Mb deletion at 16q24.1. None of the 16 RefSeq genes mapping within the deleted region appeared causative. However, this deletion is located 157 kb upstream of *FOXF1*, a gene responsible for congenital alveolar capillary dysplasia with misalignment of pulmonary veins (ACDMPV). The observed deletion encompasses a recently characterized distant regulator/enhancer of the *FOXF1* gene. The pathological diagnosis of ACDMPV was confirmed posthumously. As our knowledge of epigenetics and the genomic landscape improves, an increasing number of non-coding CNVs are poised to gain clinical relevance. We suggest that a database of well-characterized non-coding regulatory regions be developed and incorporated into CMA analysis.

P03.07-S
Novel mutations of PKD1 gene in autosomal dominant polycystic kidney disease (ADPKD)

F. Khadangi, *M. A. Kerachian;*
Medical Genetics Research Center, Department of Medical Genetics, Mashhad University of Medical Scie, Mashhad, Islamic Republic of Iran.

Background Polycystic kidney disease (*PKD*) can be inherited as an autosomal dominant (*ADPKD*) or an autosomal recessive trait (*ARPKD)*. *ADPKD* is one of the most common genetic diseases in humans affecting all ethnic groups worldwide with an incidence of 1 in 500 to 1 in 1,000. *ADPKD* is genetically heterogeneous and can arise from mutations in two genes, named *PKD1* and *PKD2*. Mutations of *PKD1* located on chromosome 16p13.3 are responsible for 85% of cases. **Aim** Although there is no hotspots reported in *PKD1*, most mutations are seen in the downstream exons of this gene. So, we developed a clinical assay for *PKD1* gene analysis using sequencing of 16 exons from 31 to 46 in 22 patients. **Material and Method** This study was carried out with a total of 22 patients. Genomic DNA was extracted from blood lymphocytes (5ml of whole blood) with standard methods and fragments were amplify using PCR. Screening of *PKD1* mutations was performed by direct Sequencing. **Result** Sequencing result of exons 44 and 45 showed one completely pathogenic mutation causing Gln4005Arg change. Two novel non-synonymous variation including Arg4091Glu and Val4035Ilu and five likely neutral SNP including rs10960, rs3087632, rs3087632, rs10960, rs3087632, rs3087632 are detected. There was no any variation in exons 35, 36 and 37. **Conclusion** It is expected that confirmation of pathogenic mutations can be useful for studies on disease molecular pathways. Early and prenatal diagnosis and personalized treatments recommended for family members after genetic consoling.

P03.08-M
Molecular diagnostics of autosomal recessive polycystic kidney disease by next-generation sequencing

L. Obeidová[1], *J. Stekrova[1], T. Seeman[2], A. Puchmajerova[3], J. Reiterova[4], V. Tesar[4], M. Kohoutova[1];*
[1]Institute of Biology and Medical Genetics of the First Faculty of Medicine, Charles University in Prague and General University Hospital, Prague, Czech Republic, [2]Department of Paediatrics, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic, [3]Department of Biology and Medical Genetics, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic, [4]Department of Nephrology, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic.

Autosomal recessive polycystic kidney disease (ARPKD) is a severe form of PKD with typical occurrence in neonates and infants. It is characterized by cystic dilations of the collecting ducts and congenital hepatic fibrosis. Perinatal mortality has been estimated to account 30-50% of ARPKD neonates and the majority of patients develop renal failure within 5 years, however presentation of ARPKD at later age and survival into adulthood have been also described. The aim of this work was to establish molecular diagnostics of ARPKD which could be used in "at-risk" families, as fetal ultrasonography has limited reliability in early pregnancy and some abnormalities typical for ARPKD become evident after 20 weeks of gestation. ARPKD is caused by mutations in PKHD1, whose longest transcript comprises 67 exons. Conventional mutational detection methods are therefore time-consuming and relatively expensive. For this reason next-generation sequencing has been chosen as a suitable method. After the setting up of NGS for PKHD1 gene, the analysis of 9 infants/children and 1 fetus from interrupted pregnancy, all with clinically suspected ARPKD, was carried out. Two mutations were found in 5 patients and one mutation in 3 patients. No mutation was identified in two patients, which could be caused by misdiagnosis. Interesting combination of p.G2705fsX and p.S2861G in cis appeared 3 times in our group of patients. Next-generation sequencing seems to be relatively fast, sensitive and cheaper in comparison to other methods and allows us molecular diagnostics of ARPKD. Supported by the grant project IGA MZCR NT 13090-4 and PRVOUK- P25/LF1/2.

Dysregulation of cytoskeleton organization, carcinogenesis and immune response pathways involved in Balkan endemic nephropathy development

R. Staneva[1], *B. Rukova[1], S. Hadjidekova[1], D. Nesheva[1], O. Antonova[1], P. Dimitrov[2], V. Simeonov[3], R. Cukuranovic[4], J. Cukoranovic[4], V. Stefanovic[4], M. Polenakovic[5], I. Dimova[1], R. Hlushchuk[6], V. Djonov[6], A. Galabov[7], D. Toncheva[1];*
[1]Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria, [2]National Center of Public Health and Analyses, Sofia, Bulgaria, [3]Vratza District Hospital, Vratza, Bulgaria, [4]Faculty of Medicine, Institute of Nephrology, University of Nis, Nis, Serbia, [5]Macedonian Academy of Sciences and Arts, Skopje, Macedonia, The Former Yugoslav Republic of, [6]Institute of Anatomy, Bern University, Bern, Switzerland, [7]Institute of Microbilogy, Bulgarian Academy of Sciences, Sofia, Bulgaria.

Background: Balkan endemic nephropathy (BEN) is a chronic interstitial nephritis with endemic distribution, spreading over territories of several Balkan countries. The intricate interplay between genetic background and environmental factors is believed to be at the basis of this progressive disease leading to chronic kidney failure and associated with high incidence of upper urinary tract uroepithelial cancer.
DNA methylation is the most studied primary epigenetic mechanism that is involved in processes such as cancer, genomic imprinting, tissue differentiation etc. Epigenetic alterations could be a major contributing factor to BEN's elusive etiopatogenesis.
Materials and methods: We performed whole genome DNA methylation analysis on DNA blood samples from 159 affected individuals and 170 healthy controls assigned to 8 DNA-pools based on gender and ancestral origin (Bulgarian and Serbian). After determining the methylation status of ca.27000 CpG-islands throughout the whole genome (Agilent DNA methylation array 1x244k) we defined the differently methylated regions (DMRs) between patients groups and respective control groups. We then compared DMRs across different ancestral and gender groups.
Results: Analysis of the common DMRs between patient-control pairs revealed that genes involved in major biological processes appear to be affected in BEN - cell adhesion and cytoskeleton organization/regulation of cell cycle - 14.8% of DMRs in both Bulgarians(BG)/Serbians(SER), carcinogenesis and metastasis - 7.41%(BG)/8.8%(SER) and immune response - 14.8%(BG)/6.4%(SER) respectively.
Conclusions: Data obtained from our experiments suggest that dysregulation of multiple major pathways such as cytoskeleton organization; cell cycle regulation and immune response could contribute to BEN pathogenesis.
Acknowledgements: funded by BNSF grant DMY03/35

Balkan endemic nephropathy (BEN) is a familial chronic tubulointerstitial disease with insidious onset and slow progression leading to terminal renal failure. The results of molecular biological investigations propose that BEN is a multifactorial disease with genetic predisposition to environmental risk agents.
Exome sequencing of 22 000 genes with Illumina Nextera Exome Enrichmen kit was performed on 22 DNA samples (11 Bulgarian patients and 11 Serbian patients). Software analysis was performed via NextGene, Provean and PolyPhen. The frequency of all annotated genetic variants with deleterious/damaging effect was compared with those of European populations. Then we focused on non-annotated variants (with no data available about them and not found in healthy Bulgarian controls).
There is no statistically significant difference between annotated variants in BEN patients and European populations. From non-annotated variants with more than 40% frequency in both patients' groups, we nominated 3 genes with possible deleterious/damaging variants - CELA1, HSPG2 and KCNK5.
Mutant genes (CELA1, HSPG2 and KCNK5) in BEN patients encode proteins involved in basement membrane/extracellular matrix and vascular tone, tightly connected to process of angiogenesis. We suggest that abnormal process of angiogenesis plays a key role in the molecular pathogenesis of BEN.

P03.11-S

Whole exome sequencing reveals rare homozygous ARID1B and heterozygous MTOR missense variants in a patient with bilateral cystic-dysplastic kidneys and features of Coffin-Siris syndrome and tuberous sclerosis

A. Kosfeld, *M. Kreuzer, C. Scholz, V. Riehmer, D. Horstmann, L. Pape, D. Haffner, R. G. Weber;*
Hannover Medical School, Hannover, Germany.

ARID1B variants have recently been described as a major genetic cause of Coffin-Siris syndrome, a developmental disorder associated with anomalies of the kidneys and urinary tract (CAKUT). Of 82 patients with Coffin-Siris syndrome carrying an ARID1B variant and examined for renal anomalies that have been described in the literature to date, 6 (7%) presented with a non-severe CAKUT phenotype. The causative ARID1B mutations detected in patients with Coffin-Siris syndrome so far were all heterozygous truncating variants. Here, we report a rare homozygous ARID1B missense variant detected by whole exome sequencing in a patient with bilateral cystic-dysplastic kidneys, bilateral vesicoureteral reflux grade IV, and a septal myocardial tumor. Stage 4 chronic kidney disease was diagnosed at 6 months of age, arterial hypertension developed, and pre-emptive kidney transplantation was performed at age 3.5 years. Additionally, the patient presented with a number of features frequently described in patients with Coffin-Siris syndrome carrying ARID1B mutations, such as thick eyebrows, synophris, thick eyelashes, strabism, anteverted nares, long philtrum, high arched palate, sandal gap, and behavioral anomalies. However, unlike all patients with heterozygous truncating ARID1B mutations, our patient had normal intelligence. Interestingly, whole exome sequencing also revealed a rare deleterious heterozygous MTOR missense variant inherited from a healthy mother in our patient. mTOR is regulated by TSC1/TSC2, encoded by genes that when mutated can cause tuberous sclerosis associated with renal cystic disease and myocardial tumors. Therefore, the MTOR and ARID1B variants may have acted together to cause the severe bilateral cystic-dysplastic kidneys present in our patient.

New genetic abnormalities underlying chronic intestinal pseudo-obstruction (CIPO)

F. Bianco[1], *L. Cordeddu[2], M. D'Amato[2], M. Bamshad[3], L. Francescatto[3], V. Stanghellini[1], G. Lindberg[2], Z. Mungan[4], C. Graziano[1], T. Pippucci[1], N. Katsanis[5], M. Seri[1], G. Romeo[1], R. De Giorgio[1], E. Bonora[1];*
[1]University of Bologna, St Orsola Malpighi, Bologna, Italy, [2]Karolinska Institutet, Stockholm, Sweden, [3]Center for Mendelian Disorders,University of Washington, Seattle, WA, United States, [4]Koc University School of Medicine, Istanbul, Turkey, [5]Depts of Cell Biology and Pediatrics,Duke University, Durham, NC, United States.

Background and Objective: CIPO is a severe motility disorder affecting the entire gut. Most patients are sporadic, however some CIPO cases show a familial clustering suggesting genetic components. The aim of this study was to identify a CIPO cause in a consanguineous family with several affected members. Results: Whole exome sequencing in the affected individuals revealed a novel homozygous mutation, p.622 Ala>Thr in RAD21, cohesin complex subunit regulating cell replication and gene expression. RAD21 screening in 33 sporadic CIPO patients did not show coding mutations. *RUNX1* expression, a RAD21 target, was decreased in the patient's cell line. *Rad21* morpholino knockdown in zebrafish embryos resulted in incomplete or absent expression of *Runx1*, in severe reduction of enteric neurons and delayed intestinal transit. These defects could be rescued only by wild-type *Rad21* cDNA, indicating that the mutation found in the CIPO pedigree extinguishes RAD21 functionality. Several binding sites for RAD21 were present in apolipoprotein A/C gene cluster and its altered binding to the regions dysregulated apolipoprotein expression levels. We studied APOB promoter and identified two RAD21-putative binding sites. EMSA assays showed that RAD21 wild-type, but not mutant, binds these regions. We therefore measured APOB protein levels that were increased in all CIPO patients, including the syndromic patient carrying the RAD21 mutation. Conclusion: The study of these two previously unlinked pathways in patients and in model organisms is contributing to clarify the pathogenesis of CIPO and will bear clinical implications for the diagnosis and prognosis of this disabling condition.

P03.13-S

Genotype-phenotype discrepancy in congenital adrenal hyperplasia due to trimodular haplotype of the RCCX module: the case of two Italian families

R. Santacroce, *A. Leccese, V. Longo, C. Dimatteo, G. D'Andrea, R. Trunzo, G. De Girolamo, M. Margaglione;*
Università degli Studi di Foggia, Foggia, Italy.

Congenital Adrenal Hyperplasia (CAH) due to 21-hydroxylase deficiency, encoded by CYP21A2 gene, is an autosomal recessive disorder with variable

incidence among the various groups. The CYP21A2 gene, is localized in a genetic unit defined RCCX module and is considered one of the most polymorphic of human genes.
We considered new evidences about the presence of a RCCX trimodular haplotype with a CYP21A2-like gene to explain the lack of a genotype-phenotype correlation in two patients referred to our centre for a suspected Non Classical form of CAH (NC21OH).
To identify the presence of deletions/duplications we used Multiplex Ligation Probe-Dependent Amplifications (MLPA) and to confirm the presence of a CYP21A2-like gene downstream TNXA gene we used previously described amplification and restriction strategy followed by the sequencing of the CYP21A2 gene downstream TNXB gene.
We validated the methods developed by recent studies and we found a good concordance with their results. The amplification strategy, direct sequencing and restriction analysis of CYP21A1P/CYP21A2-TNXA PCR product in association with MLPA assay and sequencing of CYP21A2 gene downstream TNXB gene, were able to identify the presence of more than one copy of CYP21A2 gene.
The strategy suggested is useful to screen cases where there is no genotype-phenotype correlation. We validated the modified screening strategy to facilitate molecular testing of CAH patients, considering the new evidence about possible different haplotypes.

P03.14-M
Familial mediterranean fever (FMF): genetics and role of S100A4

T. F. Sarkisian[1], *H. Hayrapetyan[1], M. Grigorian[2], N. Ambartsumian[2], M. T. Hansen, B. Forst, J. Klingelhofer, M. Hansen[3], B. Forst[3], J. Klingelhofer[4];*
[1]Center of Medical Genetics and primary health care, Yerevan, Armenia, [2]University of Copenhagen, Copenhagen, Denmark, [3]Danish Cancer Society, Copenhagen, Denmark, [4]Danish Cancer Society, Copenhagen, Armenia.

Number of patients with FMF in Armenia is dramatically increasing due to genetic drift and better professional competence, treatment, genetic counselling. Clinical and genetic investigations of FMF are "forced" by the high social and public health problems. Common MEFV mutations account for 98,71% of FMF patients and 1:3 in healthy population. 18.72% of heterozygote carriers have abortive or mild features; no mutations detect in 1.29% of FMF patients. Particular MEFV mutations (M694V homozygotes) have significant correlation with renal amyloidosis (RA). The risk of male patients to develop RA is four times higher than that of female patients. Colchicinotherapy delays RA progression, but patients with M694V-homozygous genotype present a more severe phenotype and a limited response to colchicine at the nephrotic stage of RA. Patients with other genotypes have a good chance to escape the nephrotic syndrome and to maintain renal function.
Serum amyloid A1 (SAA1) α/α with M694V homozygous genotypes are associated with a seven-fold increased risk of developing RA, compared to other SAA1 genotypes. The presence of one SAA1 α/α allele does not suggest an increased susceptibility to RA.
Association of pro-inflammation with pathogenesis of neoplasia, inflammatory, autoinflammatory diseases is confirmed. Correlation of S100A4 concentration with a pattern of MEFV mutations has been analyzed. Data demonstrating a significant increase of S100A4 in plasma of 100 FMF patients likely implicating of S100A4 in the pathogenesis of the disease. These findings suggest that chronic inflammation is mediated by S100A4 and SAA proteins, thus therapeutic targeting of pro-inflammatory pathways should be effective.

P03.15-S
Mutations in PAX2 Are Associated with Adult-onset FSGS

E. Stellacci[1], *M. Barua[2], L. Stella[3], A. Weins[4], G. Genovese[2,5], V. Muto[1], V. Caputo[6], H. R. Toka[2,7], V. T. Charoonratana[2], M. Tartaglia[1], M. R. Pollak[2];*
[1]Istituto Superiore di Sanità, Rome, Italy, [2]Beth Israel Deaconess Medical Center, Boston, MA, United States, [3]Università di Roma Tor Vergata, Rome, Italy, [4]Brigham and Women's Hospital, Boston, MA, United States, [5]Stanley Center for Psychiatric Research, Cambridge, MA, United States, [6]Università „La Sapienza", Rome, Italy, [7]Brigham and Women's Hospital, Boston, MA, United States.

Focal and segmental glomerulosclerosis (FSGS) is a histologically defined form of kidney injury characterized by the presence of partial sclerosis of some but not all glomeruli. Studies of familial FSGS have been instrumental in identifying podocytes as critical elements in maintaining glomerular function. Exome sequencing in members of an index family with dominant FSGS revealed a nonconservative, disease-segregating variant in the PAX2 transcription factor gene. Sequencing in probands of a familial FSGS cohort revealed seven rare and private heterozygous single nucleotide substitutions (4% of cases). Further sequencing revealed seven private missense variants (8%) in a cohort of individuals with congenital abnormalities of the kidney and urinary tract (CAKUT). As predicted by in silico structural modeling analyses, in vitro functional studies documented that several of the FSGS-associated PAX2 mutations perturb protein function by either affecting proper binding to DNA and transactivation activity, or altering the interaction of the transcription factor with repressor proteins, resulting in enhanced repressor activity. Thus mutations in PAX2 contribute to adult-onset FSGS in the absence of overt extrarenal manifestations. We expand the phenotypic spectrum associated with PAX2 mutations, which have been shown to lead to CAKUT as part of papillorenal syndrome. PAX2 mutations can cause disease through haploinsufficiency and dominant negative effects, which could have implications for tailoring individualized drug therapy in the future.

P03.16-M
Genetic and bioinformatics analysis of four novel GCK missense variants detected in Caucasian families with GCK-MODY phenotype

G. Malerba[1], **S. Costantini**[2], *G. Contreas[2], M. Corradi[2], S. P. Vargas[3], A. Giorgetti[3], C. Maffeis[2];*
[1]Section Biology and Genetics, University of Verona, Verona, Italy, [2]Regional Center for Pediatric Diabetes, Clinical Nutrition and Obesity, Department of Life and Reproduction Sciences, University of Verona, Verona, Italy, Verona, Italy, [3]Applied Bioinformatics Lab., Department of Biotechnology, University of Verona, Verona, Italy, Verona, Italy.

Heterozygous loss-of-function mutations in the glucokinase (GCK) gene cause a subtype of maturity-onset diabetes of the young (MODY) known as GCK-MODY/MODY2 . Diagnostic GCK sequencing identified 16 distinct mutations (13 missense, one nonsense and one splice-site substitutions, and one frameshift deletion) in 23 out of 25 unrelated GCK-MODY probands, all of which showed to co-segregate with hyperglycaemia. Four of the 13 missense substitutions (c.718A>G/p.Asn240Asp, c.757G>T/p.Val253Phe, c.872A>C/p.Lys291Thr, and c.1151C>T/p.Ala384Val) were novel, and the nonsense mutation (c.76C>T/p.Gln26*) segregated in seven families from north-eastern Italy, suggesting a founder effect in this geographical region. We focused on the novel missense variants to test whether an accurate and multi-level bioinformatics approach could satisfactorily strengthen family-genetic evidence for potential pathogenicity of such a type of variants in the routine diagnostic field, where wet-lab functional assays are generally not viable. In silico analyses of the novel missense variants (orthologous sequence conservation, SIFT, PolyPhen-2 and MutationTaster2 predictors, structural modeling, and splicing predictors) suggested that the encoded amino acid substitutions and/or the underlying nucleotide changes are likely to affect GCK structure/function. In conclusion, this study shows how a careful and multi-level bioinformatics analysis could provide effective suggestions to help a molecular-genetic diagnosis in the absence of wet-lab validations.

P03.17-S
Genetic spectrum of growth hormone deficiency: Findings from the Indian patient population

S. Birla, *R. Khadgawat, V. P. Jyotsna, V. Jain, M. K. Garg, A. Sharma;*
All India Institute of Medical Sciences, New Delhi, India.

Background: Isolated growth hormone deficiency (IGHD) and combined pituitary hormone deficiency (CPHD) result in significant short stature caused by mutations in *GH1, GHRHR PROP1, POUIF1* and *HESX1* genes. The present study describes the mutation profile of Growth Hormone Deficiency (GHD) patients from India. One hundred each of patients (60 IGHD, 40 CPHD) and controls were recruited for screening of G*H1, GHRHR, PROP1* and *POU1F1.*
Results: Consanguinity, family history and mutations were present in 20%, 8% and 35% of the cases respectively. Five novel and four reported mutations were identified (Table-1). *GHRHR* mutations were the most common change in IGHD followed by *GH1* cluster deletion. A novel *GH1* coding region deletion and three promoter SNPs were identified. These SNPs are reported to induce differential transcriptional activity resulting in reduced secretion of growth hormone. Novel insertion and nonsense *PROP1* mutations identified lead to frameshift and a truncated protein leading to GHD. Novel *POU1F1* splice site mutation in three patients from the same geographical region implies possible presence of founder effect.
Conclusion: This is the first report demonstrating genetic contribution to GHD in our population wherein 'Glu72Term', the most common change and five novel mutations were identified. Hotspot mutations reported worldwide were absent suggesting a distinct profile. Results of the study will facilitate timely diagnosis, counseling and intervention thereby reducing the stigma associated with GHD.

Table-1 Mutations/SNPs identified in the present study

S.No	Type of GHD (N=100)	Gene	cDNA position	Amino acid position	Nature of mutation/SNP	Frequency
1	IGHD (n=60)	*GH1* gene cluster	Gross deletion	-	Reported	15%
2		*GH1*	Deletion of exons 3-5	-	**Novel**	2%
3		*GH1* promoter	rs2005171	-	Reported	20%
4		*GH1* promoter	rs2005172	-	Reported	15%
5		*GH1* promoter	rs11568828	-	Reported	18%
6		*GHRHR*	c.214G>T	Glu72Term	Reported *(Nonsense)*	10%
7		*GHRHR*	c.527C>T	Ala176Val	Reported *(Missense)*	3%
8		*GHRHR*	c.920insC	-	**Novel** *(Insertion)*	2%
9	CPHD (n=40)	*PROP1*	c.112_124del13	-	Reported *(deletion)*	2.5%
10		*PROP1*	c.45C>T	Arg16Term	**Novel** *(Nonsense)*	2.5%
11		*PROP1*	c.128InsA	-	**Novel** *(Insertion)*	2.5%
12		*POU1F1*	c.605-1G->A	-	**Novel** *(Acceptor splice site)*	7.5%

Hirschsprung disease (HSCR) is a disorder of the enteric nervous system (ENS) and is characterized by the absence of enteric neurons along a variable length of the intestine. HSCR most commonly presents sporadically, although it is familial in 5-20% of the patients. The sporadic form of the disorder is believed to be a genetically complex disease. To assess the role of *de novo* mutations in sporadic HSCR, we performed exome sequencing on 20 HSCR patients, predominantly females with long segment HSCR and their unaffected parents. We identified and confirmed 24 *de novo* mutations (18 SNVs, 6 Indels) in 17 different genes (1.2 per trio). Non-synonymous *de novo* mutations were identified in RET in 8 out of 20 patients, corroborating previous findings that RET is the major genetic contributor in long-segment HSCR. A replication study in independent

HSCR patients, gene burden tests and functional analysis in both cell lines and zebra fish are currently being conducted. Interestingly, some of the genes harboring *de novo* mutations are members of pathways involved in the development of the ENS and the encoded proteins interact with known key signaling molecules. We will present all data which will enable us to make conclusion on whether, *de novo* mutations in genes other that RET also contribute to the development of sporadic HSCR.

RET and EDNRB mutations screening in Indonesian patients with HSCR, functional study and its implication in diagnostic

T. Widowati[1], *Y. Sribudiani*[2,3], *S. Melhem*[2], *J. Dijkhuis*[4], *M. Viel*[4], *P. Rochadi*[5], *S. Y. Patria*[1], *A. H. Sadewa*[6], *R. Sinke*[4], *Y. Soenarto*[1], *R. M. W. Hofstra*[2];

[1]*Department of Pediatric, Faculty of Medicine Universitas Gadjah Mada, Prof. Dr. Sardjito Hospital, Yogyakarta, Indonesia,* [2]*Department of Clinical Genetic, Erasmus Medical Center, Rotterdam, Netherlands,* [3]*Department of Biochemistry, Faculty of Medicine Universitas Padjadjaran, Dr. Hasan Sadikin Hospital, Bandung, Indonesia,* [4]*Department of Genetic, University Medical Center Groningen, Groningen, Netherlands,* [5]*Department of Pediatric Surgery, Faculty of Medicine Universitas Gadjah Mada, Prof. Dr. Sardjito Hospital, Yogyakarta, Indonesia,* [6]*Department of Biochemistry, Faculty of Medicine Universitas Gadjah Mada, Yogyakarta, Indonesia.*

Hirschsprung disease (HSCR) is a majority cause of chronic constipation in children. HSCR is an inherited disease and germline mutations are frequently identified in *RET* and *EDNRB.* However, defining causality of mutations in this genetic complex disorder is difficult. Therefore, in this study we combined sequence analysis of *RET* and *EDNRB* with functional studies to determine causality. We screened a total of 61 HSCR children and identified 8 rare RET coding variants (R79W, R144H, P270L, R694Q, A756V, G533S, Y1062C,D489N) and one possible splice-site variant. No rare variant in EDNRB were identified. The mutation frequency (15%) is comparable to previous studies. Four missense variants and one possible spice site variant have never been reported before. Four of the nine arose *de novo*, while the remaining variants are all inherited from an unaffected parent. One patient harbor two RET coding variants, one coming from each unaffected parent. Functional studies showed that 7 out of 8 coding RET variants resulted in significant lower expression of the phosphorylated-RET protein. Only 4 RET variants (R144H, R694Q, A756V, Y1062C) resulted in significantly lower expression of phosphorylated-ERK, a downstream component of the RET pathway, when compare to wild type RET. The possible splice-site variant (IVS 1880-4A>G) did not disturb the splicing process and, therefore, is not considered pathogenic. Our data suggest that 7 of the 9 identified RET variants are pathogenic and that not all rare RET variants are pathogenic, hence functional studies are essential to prove pathogenicity.

P03.20-M

Translating genetic findings in functional defects: functionomics of hypomagnesemia-causing genes

J. H. de Baaij, *F. Arjona Madueño, E. Bongers, R. Bindels, J. Hoenderop;*
Radboud University Medical Centre, Nijmegen, Netherlands.

The recent improvements of next generation sequencing techniques allow relatively rapid and cheap identification of new gene mutations in patients with familial hypomagnesemia. However, translating the genetic findings into functional assays to examine the function of the affected genes remains challenging because of inadequate cell models, the absence of an Mg2+ radioisotope and limited availability of animal models.

For example, we have identified new mutations in the gene CNNM2 in five families suffering from mental retardation, seizures, and hypomagnesemia. For the first time, a recessive mode of inheritance of CNNM2 mutations was observed and mutations in CNNM2 are associated with mental disability. Using stable Mg2+ isotopes, we demonstrated that CNNM2 increases cellular Mg2+ uptake in HEK293 cells and that this process occurs through regulation of the Mg2+-permeable cation channel TRPM7. In contrast, cells expressing mutated CNNM2 proteins did not show increased Mg2+ uptake. Knockdown of cnnm2 isoforms in zebrafish resulted in disturbed brain development and reduced body Mg content. These phenotypes were rescued by injection of mammalian wild-type Cnnm2 cRNA, whereas mammalian mutant Cnnm2 cRNA did not improve the zebrafish knockdown phenotypes. Altogether these data show that CNNM2 is fundamental for brain development, neurological functioning and Mg2+ homeostasis.

By establishing a novel Mg2+ transport assay using stable Mg2+ isotopes and the loss-of-function zebrafish model, we provide a unique system to examine the function of novel genes in Mg2+ homeostasis. These new in vitro and in vivo models may aid to explain the function of electrolyte transporters in the future.

P03.21-S

Family genomics reveals disease genetics: Inflammatory bowel disease

A. Stittrich, *S. Ament, D. Mauldin, M. Brunkow, L. Rowen, G. Glusman, J. Roach, L. Hood;*
Institute for Systems Biology, Seattle, WA, United States.

By definition, complex diseases are caused by many different genes, but this might hold true only at the population level. We hypothesize that within families with a high disease burden, complex diseases can arise from only a few high-effect risk variants. Assuming that all or most affected family members share the genomic region(s) that harbor the risk variant(s), whole-genome sequencing is the most precise method for determination of identical-by-descent segments to narrow down the search space for disease genes. Family genomics is especially powerful in multi-generation pedigrees. In some of the pedigrees we analyze diseased individuals are separated by more than 10 meioses each of which narrows the number of candidate alleles by approximately half, per Mendel's law of segregation. Family genomics furthermore permits identification of sequencing errors and detection of rare variants with high confidence.

In addition to our identical-by-descent detection tools we have created an analysis workflow to identify and score variants according to their inheritance pattern, population frequency and predicted function. We are currently analyzing over 200 families in over 30 studies that cover a wide range of diseases, from rare congenital diseases to common neurodegenerative and chronic inflammatory diseases. We present here our methods for identifying high confidence candidate variants for inflammatory bowel disease in families with high disease burden.

P03.22-M

A hemizygous mutation in retinitis pigmentosa GTPase regulator (*RPGR*) is a potential novel cause of congenital renal tract malformations

G. van de Hoek[1], K. Neveling[2], T. Klasson[1], M. R. Havenith[1], E. M. H. F. Bongers[2], N. V. A. M. Knoers[1], R. H. Giles[1], **K. Y. Renkema**[1];
[1]University Medical Center Utrecht, Utrecht, Netherlands, [2]Radboud university medical center, Nijmegen, Netherlands.

Congenital anomalies of the kidney and urinary tract (CAKUT) comprise a range of structural malformations and constitute the principal cause of end-stage renal disease in children. Although several genes have been linked to CAKUT pathogenesis, the genetic background remains unclear in many patients. We performed whole exome sequencing in the patient's DNA (SureSelect, Agilent / SOLiD5500™ System, Life Technologies). Through whole exome sequencing we identified a novel hemizygous dinucleotide frameshift deletion in the X-linked retinitis pigmentosa GTPase regulator (*RPGR*) gene of a male patient with unilateral kidney dysplasia. This mutation was confirmed through Sanger sequencing and was found to be inherited from the mother. Mutations in *RPGR* are frequently reported in patients with progressive retinal degeneration, however its potential role in kidney pathogenesis has not previously been observed. At present, we investigate the effect of *RPGR* dysfunction on kidney development *in vivo*, by generating zebrafish mutants using transcription activator-like effector nucleases (TALENs). Subsequently, complementation assays will be performed to study the specific effect of the human *RPGR* mutation in this vertebrate system. Also, we aim to characterize both wild-type and mutant RPGR *in vitro*, using patient-derived cell-lines isolated from urine and IMCD3 (murine inner medullary collecting duct) 3D cellular spheroids. To conclude, by identifying novel players in the aetiology of CAKUT, we will enhance our knowledge on the molecular networks underlying normal and disrupted kidney development. Identification of the genetic aetiology of CAKUT will improve DNA diagnostics and genetic counselling for CAKUT patients.

P03.23-S

The Prognosis of Abnormal Fetal Kidneys

M. Rasmussen[1], *M. Olsen[2], O. B. Petersen[3], L. Sunde[1];*
[1]Department of Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark, [2]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, [3]Department of Gynecology and Obstetrics, Aarhus University Hospital, Aarhus, Denmark.

Introduction: With the advent of high-resolution ultrasound scanners and the offer of a 20-week ultrasound scan to all pregnant women in Denmark, a suspicion of abnormal kidneys in the fetus is raised more frequently now than earlier. The prognosis of a fetus with abnormal kidneys is often not known, which complicates decision-making and causes anxiety to parents.
Methods: A population-based cohort of fetuses diagnosed with abnormal kidneys in the period 1st of January 2007 - 31st of December 2012 and a population-based matched comparison cohort of foetuses examined in the 20-week screening programme were established.
A national query identified fetuses with cystic kidneys, echogenic kidneys, multicystic kidneys, renal agenesia and/or severe hydronephrosis. Severe hydronephrosis was included in the query to avoid missing cases of multicystic kidneys, as the primary finding may have been interpreted as hydronephrosis.
All Danish departments of obstetrics and fetal medicine use the same software for prenatal diagnostics and ultrasound examination. These data were merged into a national dataset of around 1000 pregnancies. Prenatal fetal data were linked to their mothers' data using the mothers' civil registration numbers. This allows unambiguous individual-level linkage to all relevant data sources in Denmark, including the Danish National Patient Registry and medical journals.
Results: The prevalence of the various types of abnormal fetal kidneys, the prevalence of terminated pregnancies and measures of prognosis will be discussed. This study may facilitate that parents having a fetus with kidney abnormalities can be counselled based on valid and comprehensive data on prognosis.

P03.24-M

Targeted sequencing of 208 candidate genes in 460 CAKUT patients facilitates the inclusion of a novel gene set in diagnostics

N. Nicolaou[1], I. J. Nijman[1], S. van Lieshout[1], G. Monroe[1], A. M. van Eerde[1], W. F. Feitz[2], I. A. L. M. van Rooij[3], L. F. M. van der Zanden[3], N. Roeleveld[3,4], E. M. H. F. Bongers[5], R. H. Giles[6], E. Cuppen[1], **K. Y. Renkema**[1], *N. V. A. M. Knoers[1];*
[1]Medical Genetics, UMC Utrecht, Utrecht, Netherlands, [2]Urology, Radboud university medical center, Utrecht, Netherlands, [3]Health Evidence, Radboud university medical center, Nijmegen, Netherlands, [4]Paediatrics, Radboud university medical center, Nijmegen, Netherlands, [5]Genetics, Radboud university medical center, Nijmegen, Netherlands, [6]Nephrology and Hypertension, UMC Utrecht, Utrecht, Netherlands.

Congenital anomalies of the kidney and urinary tract (CAKUT) comprise a spectrum of structural malformations. CAKUT occur in 1:500 live-births and form the most common cause of end-stage renal failure in children. We aim to identify rare mutations in CAKUT candidate genes and elucidate involvement in CAKUT aetiology. After in-solution enrichment (SureSelect, Agilent), 208 candidate genes were sequenced (SOLiD5500™, Life Technologies) in 460 sporadic CAKUT patients. All genes were known to play a role in human CAKUT or to disrupt nephrogenesis in animal models. We demonstrated coverage depth of 120X and 65% enrichment efficiency on average. After variant calling, filtering was performed based on sequencing depth (≥15X) and allele frequency, excluding common variants. We identified 47 indels, 20 nonsense, 22 essential splice-site mutations, as well as 150 novel missense variants in 82 genes that were predicted to be pathogenic. Of these, 71 variants in 39 genes were previously reported in The Human Gene Mutation Database as causal mutations for kidney-related disorders. The variants are currently being validated in patients and parents by Sanger sequencing. Preliminary data show that the majority of variants are inherited, except for a well-known frameshift variant in *PAX2* and a novel variant in *LZTS2*, which occurred *de novo*. We conclude that our approach provides knowledge on the frequency of known disease-causing mutations and underlines the heterogeneity of CAKUT. Results indicate the value of including novel genes in an NGS based genetic test for CAKUT, facilitating early diagnostics and genetic counselling for CAKUT patients and their relatives.

P03.25-S

Renal fibrosis is the common feature of Autosomal Dominant Tubulointerstitial Kidney Diseases (ADTKD) caused by MUC1 or UMOD mutations

A. B. Ekici[1], *T. Hackenbeck[2], V. Moriniere[3], A. Pannes[4], M. Buettner[5], R. Janka[6], S. Uebe[1], A. Wiesener[1], I. Hermann[2], S. Grupp[2], M. Hornberger[7], T. B. Huber[8,9], N. Isbel[10], G. Mangos[11], S. McGinn[12], D. Soreth-Rieke[13], B. B. Beck[4], M. Uder[6], K. Amann[5], C. Antignac[14,15], A. Reis[1], K. Eckardt[2], M. S. Wiesener[2];*

Nephrology and Hypertension, Offenburg, Germany, [8]Renal Division of the University Hospital, Freiburg, Germany, [9]BIOSS Centre for Biological Signalling Studies, Albert-Ludwigs-University, Freiburg, Germany, [10]Dept. of Renal Medicine, Princess Alexandra Hospital, Brisbane, Australia, [11]Dept. of Renal Medicine, St. George Clinical School UNSW, Sydney, Australia, [12]Dept. of Renal Medicine, Royal North Shore Hospital, Sydney, Australia, [13]KfH Nierenzentrum, Miesbach, Germany, [14]Inserm, U983, Necker Hospital, Paris, France, [15]Université Paris Descartes, Sorbonne Paris Cité, Institut Imagine, Paris, France.

For decades, clinically ill-defined autosomal-dominant renal diseases originating from tubular cells and leading to tubular atrophy and interstitial fibrosis were reported. Patients exhibit mutations in at least 4 genes: UMOD, HNF1B, REN, MUC1, but are clinically indistinguishable all associated with renal fibrosis and renal failure the 3rd and 6th decade of life. In contrast to what the frequently used term "Medullary Cystic Kidney Disease" (MCKD) implies, development of medullary cysts is neither an early, nor a typical feature, as analyzed by MRI.
We now investigated 10 such families. In two large families we performed genome-wide linkage and haplotype analyses confirming linkage to a known 3.4 Mb locus MCKD1 locus on chromosome 1q21. Targeted genomic sequencing of the complete linkage locus in affected and healthy individuals of these two families and affected individuals of further families failed to uncover any segregating variant in any of the genes, including MUC1. The VNTR region in the coding sequence of the MUC1 was masked in these analyses due to its high GC-content and repetitive nature. After the recent publication of one MUC1-VNTR insertion mutation we established SNaPshot-minisequencing confirming this MUC1 mutation in 4 families. Further 3 families carried an UMOD mutation, leaving 3 families unsolved to date. On the basis of clinical and pathological characteristics we propose the term "Autosomal Dominant Tubulointerstitial Kidney Disease" (ADTKD) as a new name for this entity. This new terminology should enhance recognition and correct diagnosis of affected individuals, facilitating genetic counseling and stimulating research into the underlying pathomechanisms.

Hospital of Verona, Verona, Italy, [6]Pediatric Nephrology Unit Meyer Children's University Hospital, Firenze, Italy, [7]Department Of Biomedical Experimental And Clinical Sciences University Of Florence, Firenze, Italy.

Medullary sponge kidney (MSK) is a rare, developmental congenital disease characterized by diffuse ectasia or dilation of precalyceal collecting tubules. It is generally considered a sporadic disorder, but an apparently autosomal dominant inheritance has also been observed. The diagnosis of MSK is radiographic: typical pictures reveal collections of contrast medium in dilated papillary ducts, giving the appearance of a blush or linear striations in the mildest cases, or of bouquets of flowers when cystic dilation of the collecting ducts is seen. We previously described the association of MSK with mutations in ATP6V1B1 and ATP6V0A4, responsible of distal renal tubular acidosis (dRTA), a condition characterized by hypokalemia, hyperchloremic metabolic acidosis, nephrocalcinosis, nephrolithiasis, osteomalacia and rikkets. In this disorder the α-intercalated cells in the collecting duct are unable to secrete H+ and to acidify urine. The aim of our study was to investigate, on the basis of family history and clinical presentation at various ages, the relationship between MSK and dRTA: we studied first the possible role of the B1 and a4 apical subunits of the H+ATPase pump (at present 8 patients show pathogenetic variations in these two subunits) and afterwards whether other genes could be causative of this condition. We investigated, by high throughput sequencing, 25 patients classified as having MSK and we studied, in addition to the role of the above mentioned genes, other genes encoding proteins expressed in the tubules and genes implicated in the collecting duct system development. We will show the results of this new pilot study.

P03.27-S
MODY/Type 2 Diabetes: molecular analysis of a large cohort of patients by Next Generation Sequencing

R. Artuso[1], *A. Provenzano[2], L. Giunti[1], B. Mazzinghi[1], E. Andreucci[1], L. Lenzi[3], B. Piccini[3], P. Mandich[4], A. Blasetti[5], E. Mannucci[6], S. Toni[3], S. Giglio[1,2];*
[1]Medical Genetic Unit, Meyer's Children University Hospital, Firenze, Italy, [2]Medical Genetics Unit, Department of Clinical and Experimental Biomedical Sciences, University of Florence, Firenze, Italy, [3]Diabetology Unit, Meyer Children's University Hospital, Firenze, Italy, [4]DINOGMI, University of Genoa, Genoa, Italy, [5]Department of Pediatrics, University of Chieti, Chieti, Italy, [6]Diabetes Agency, Careggi Hospital, Firenze, Italy.

Maturity-onset diabetes of the young (MODY) is a phenotypically and genetically heterogeneous group of diabetes caused by single defects in at least thirteen genes, characterised by autosomal dominant inheritance, a young age of onset and pancreatic β-cell dysfunction. Genetic testing for MODY has become a routine procedure allowing to set up proper treatment and discriminate from type 2 diabetes (T2D) whose symptoms are often overlapping. We analysed, in the last 5 years, more than 300 Italian families with MODY/T2D diagnosis by direct sequencing of genes GCK, HNF1α, HNF4α, IPF1 and HNF1β, and only about 40% of the cases resulted positive. Mutations in GCK gene account for up to 80% for all Italian MODY cases according to literature data.
We then reanalysed the negative subjects through Next Generation Sequencing technology. We excluded common, non-coding and synonymous gene variants, and performed in-depth analysis on filtered sequence variants in a pre-defined set of 102 genes implicated in glucose metabolism. We found, in association with known heterozygous SNPs associated with diabetes, rare and pathogenetic variants, demonstrating that this approach leads to a genetic diagnosis in most of patients. For example, we identified new variants in the RFX6 gene and in two of these cases we also detected rare variants in WFS1 and ABCC8. All patients showed a good therapeutic response to dipeptidyl peptidase-4 (DPP4) inhibitors.
This approach may help in understanding the molecular aetiology of diabetes and in providing a more personalised treatment for each genetic subtype.

P03.28-M
A molecular genetic analysis of nephrotic syndrome in a cohort of Tunisian families

M. Trabelsi[1], O. Naija[2], M. Trabelsi[3,1], R. Meddeb[3,1], H. Safraou[3], N. Arfaoui[1], F. Maazoul[3], T. Gargah[4], F. ben Moussa[5], A. Khedher[6], H. Bouhamed Chaabouni[3,1], **R. Mrad**[3,1];
[1]Human Genetic Laboratory Faculty medicine tunis Tunis el Manar University, Tunis, Tunisia, [2]Pediatric department Charles Nicolle Hospital, Tunis, Tunisia, [3]Congenital and hereditary diseases Charles Nicolle Hospital, Tunis, Tunisia, [4]Pediatric department Charles Nicolle Hospital, Tunis, Tunisia, [5]Nephrology Department, La Rabta Hospital, Tunis, Tunisia, [6]Nephrology and internal medicine department, Charles Nicolle hospital, Tunis, Tunisia.

Background: Nephrotic syndrome (NS) is a renal disease characterized by heavy proteinuria, hypoalbuminemia, edema and hyperlipidemia. Its presentation within the first 3 months of life or in multiple family members suggests an underlying inherited cause. Mutations in the NPHS1 and NPHS2 genes are among the main causes of early-onset and familial steroid resistant nephrotic syndrome. This study was carried out to assess the frequencies of mutations in these two genes in a cohort of Tunisian pediatric NS patients.
Methods:Mutation analysis was carried out by direct sequencing of the NPHS1 and NPHS2 genes in 18 nephrotic syndrome (NS) families. This cohort included 6 families of congenital NS, and 12 infantile onset steroid resistant NS or familial cases.
Results: We detected likely causative mutations in 5 out of 6 families of congenital NS studied. A total of 5 different mutations were found in the NPHS1 gene. 3 homozygous mutations were found in the NPHS2 gene in 3 out of 12 infantile onset NS or familial cases.
Conclusions: Our results show a high prevalence of disease causing mutations in the NPHS1 (80% congenital, 30% overall) and NPHS2 (25% early onset and 16% overall) genes in the Tunisian NS children as compared to the European or Asian populations

P03.29-S
Gene Expressions In Glomerulopathies

M. Safarikova[1,2], *E. Pazourkova[2], A. Horinek[1], J. Reiterova[1,2], J. Stekrova[1], M. Kohoutova[1], V. Tesar[2];*
[1]Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University in Prague a, Prague, Czech Republic, [2]First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Czech Republic, Prague, Czech Republic.

The nephrotic syndrome is connected with both primary and secondary glomerulopathies. The expressions of 47 genes associated with different kidney diseases in patients with primary and secondary glomerulopathies were studied. The aim of this study is to find prognostic factors from renal biopsy. Our study was performed on the set of 118 patients. There were five different biopsy-proven diagnoses: FSGS, IgAN, MCD, MGN and SLE. The expressions were analysed using the real-time PCR and normalized by the endocontrol GAPDH gene. The obtained data were analysed using software STATISTICA 10. At the beginning three genes had to be excluded for no patient's sample had showed the expression in these genes. The statistical analysis using Kruskal-Wallis ANOVA was divided into three parts. The p value of following genes was lower than 0.01. Firstly, all the diagnoses were compared with each other. The statistically significance was identified in nine genes mostly between FSGS and SLE patients. Secondly, patients with SLE and IgAN were sorted out according to their histological foundations and the gene expressions were compared in each diagnosis. The only significant gene was in the comparison of IgAN patients. Finally, it was made comparison between groups of SLE and IgAN patiens, MCD, FSGS and MGN patients. The statistically significant differences were identified in ten genes. The differences were mostly between one group of SLE patients and patients with FSGS. Our study demonstrated the differences in gene expressions not only inter-diagnosis, but also intra-diagnosis. Supported by the grant project PRVOUK- P25/LF1/2.

P03.30-M
Next-Generation-Sequencing-based molecular diagnostics for congenital and inherited kidney disease

B. van der Zwaag, *A. M. van Eerde, M. G. Elferink, P. H. A. van Zon, M. F. Stokman, K. Y. Renkema, N. N. Nicolaou, H. K. Ploos van Amstel, N. V. A. M. Knoers;*
Department of Medical Genetics, UMC Utrecht, Utrecht, Netherlands.

Congenital and inherited kidney diseases constitute the leading cause of chronic kidney disease in children. Molecular diagnostic analysis of heterogeneous renal disorders has long been hampered by the size and numbers of genes involved, but has become feasible with the advent of Next-Generation-Sequencing (NGS). We set up and implemented an NGS-based test in our ISO15189 certified laboratory to enrich and sequence 376 genes known to be causal in or associated with kidney and urinary tract disorders. Based on the enrichment 23 disease related genepanels covering 175 genes were formed, including renal cysts (50 genes), Bardet-Biedl syndrome (14 genes), Joubert syndrome (21 genes), nephronophthisis (15 genes), congenital anomalies of the kidney and urinary tract (40 genes) and nephrotic syndrome (16 genes). To reach a genotyping accuracy of at least 99%, a minimal vertical coverage of 15 individual reads per base is required. To deliver a comprehensive analysis of the genepanel, a horizontal coverage of at least 98% of targeted bases is requested. When coverage by NGS drops below requested coverage thresholds, additional "Sanger"-based sequencing is performed to fill in the gaps. In this fashion, a mutation detection rate of >95% is achieved for the genes analysed. Initial diagnostic sequencing results will be presented. To conclude, comprehensive genetic testing by NGS will boost the diagnostic yield to potentially >40-50% molecular diagnoses within one clinical genepanel analyzed. Thereby delivering a swift answer to the patient and a leap in efficacy and cost reduction for healthcare providers.

P03.31-S

Epistasic Association of CTRC and SPINK1 Gene Variants Combination with Recurrent Pancreatitis in Lipoprotein Lipase Deficiency

K. Tremblay, *C. Dubois-Bouchard, D. Brisson, D. Gaudet;*
Université de Montréal and ECOGENE-21 Research Center, Chicoutimi, QC, Canada.

Background: Lipoprotein Lipase deficiency (LPLD) is a rare autosomal recessive disease associated with severe hypertriglyceridemia and increased risk of pancreatitis or other co-morbidities. There are important unexplained inter-individual variations in the incidence and severity of acute pancreatitis episodes in LPLD patients. Several genes involved in proteolytic networks are associated with pancreas and lipoprotein functions and could influence pancreatitis risk in LPLD. **Objective:** To evaluate the association between two genes regulating serine proteases, chymotrypsin C (*CTRC*) and serine peptidase inhibitor kazal type1 (*SPINK1*), and recurrence of hospitalizations for acute pancreatitis among LPLD subjects. **Methods:** *CTRC* and *SPINK1* have been sequenced in a sample of 38 LPLD patients and 100 controls. In LPLD, 18 (47%) presented a history of recurrent (≥5) hospitalizations for acute and severe abdominal pain, whereas 8 (21%) had not yet been hospitalized for this condition. Comparisons between studied groups were done with chi-square tests and multinominal regression analyses. **Results:** Gene sequencing identified 15 SNPs. Genotype-stratified analyses in LPLD subjects and controls suggested an epistasic association between rs545634 (*CTRC)* and rs11319 (*SPINK1)* SNPs combination and recurrence of hospitalizations ($p<0.001$) in LPLD. Regression analyses, controlling for age, gender and smoking status, suggest that the risk of frequent and recurrent hospitalizations for acute pancreatitis is significantly increased in LPLD in presence of this *CTRC-SPINK1* SNPs combination (OR = 41.4 [CI: 2.0-848.0]; $p=0.016$). **Conclusion:** These results suggest that modifier genes involved in protease pathways could influence the trajectory of pancreatitis risk in LPLD.

P03.32-M

Towards introduction of exome sequencing in pediatric liver transplant program

D. Marchetti, *C. Lodrini, L. Pezzoli, M. E. Sana, A. R. Lincesso, K. Migliorati, M. Iascone;*
Ospedale Papa Giovanni XXIII, Bergamo, Italy.

Pediatric cholestasis shows different etiology, clinical course and prognosis. Early recognition of the causes allows an appropriate treatment and management and plays a central role in decision-making about pediatric liver transplantation. Although each of genetic forms of cholestasis is rare, they collectively represent a frequent causes of liver transplantation. Starting in 2012, we enrolled and analyzed by exome sequencing 44 pediatric patients with isolated or syndromic forms of liver disease. The exonic region of 2,761 known disease-causing genes were assessed on patient and their parents using the TruSight Exome kit and 2X150 PE sequencing on MiSeq. Data analysis was focalized on phenotypic features and expected inheritance model. We obtained 32,799,211 reads/sample, the mean coverage was 200X and 98.54% of target regions were >20X. We identified the genetic causes in 21 patients (diagnostic yield:47.7%). Sixty seven percent of detected mutations were well known and previously described, while the remaining mutations satisfied criteria for molecular diagnosis. Alagille syndrome and progressive familial intrahepatic cholestasis were the most frequent diagnosis (42.8% and 28.6% respectively). Two patients were affected by a fructose intolerance while galactosemia, Niemann-Pick disease type C and Gaucher syndrome each have been diagnosed in a single patient. These results show that the diagnosis of children with intrahepatic cholestasis sometime is clinically challenging. Our data further expand the use of exome sequencing also in restricted subtype of pediatric patients, with a strong clinical impact also in liver transplant program.

P03.33-S

Success of liver transplantation in patients with progressive familial intrahepatic cholestasis: is there an association between genotype and outcome?

S. M. Herbst[1], *J. Vermehren*[2], *M. Melter*[2], *U. Hehr*[1];
[1]*Center for and Institute of Human Genetics, University Regensburg, Regensburg, Germany,* [2]*Children´s Hospital, University Hospital Regensburg, Regensburg, Germany.*

Study aim
Characterization of the genotype-phenotype correlation in patients with progressive familial intrahepatic cholestasis (PFIC) and identification of prognostic genetic parameters for long term outcome and success of liver transplantation in order to improve individual treatment options.
Method
Genetic testing was performed for 57 PFIC index patients, including NGS panel diagnostics for 5 children with infantile cholestasis and atypical liver histopathology. Long term data (2-35 years) of 8 patients with genetically confirmed PFIC will be presented to illustrate their specific medical problems.
Results
Most pathogenic mutations were identified in ABCB11 (56%), followed by ATP8B1 (32%) and ABCB4 (12%); including 73% missense mutations, 17% truncating mutations, 7% splice mutations and 3% small deletions.
Response to pharmacological therapy was insufficient in 87% of patients, thus, biliary diversion and/or liver transplantation was performed in 75%. One additional patient is currently listed for transplantation.
Perioperative complications observed in patients with missense mutations were mild and included bleeding and coagulation problems (n=2). Life threatening complications (organ rejection requiring retransplantation, death) occurred in two patients with at least one truncating ABCB11 mutation. Severe long term complications were observed in 3 ATP8B1 mutations carriers including severe diarrhea, renal failure, deafness and polyneuropathy.
Conclusion
Truncating mutations may be associated with a higher rate of severe perioperative complications in liver transplantation, possibly due to a stronger immune reaction towards the wild type protein. With an ongoing study we are currently evaluating this hypothesis in a larger cohort including application of NGS panel sequencing to search for additional causative genes.

P03.34-M

Genetic analysis of *PKD1* and *PKD2* genes in Korean patients with autosomal dominant polycystic kidney disease

R. Choi[1], *H. Park*[2], *Y. Hwang*[3], *C. Ki*[1], *K. Lee*[1], *J. Kim*[1], *C. Ahn*[2];
[1]*Department of Laboratory Medicine and Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,* [2]*Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of,* [3]*Department of Internal Medicine, Eulji General Hospital, Seoul, Korea, Republic of.*

Autosomal dominant polycystic kidney disease (ADPKD) is most common inherited kidney disorder with progressive cyst growth and renal enlargement, resulting in renal failure. Mutations in the *PKD1* and *PKD2* genes account for 85% and 15% of all ADPKD cases, respectively. Although there are a few studies on the frequency and spectrum of mutations in the *PKD1* and *PKD2* genes in Korean patients with ADPKD, they did not sequenced entire exons of the *PKD1* gene but analyzed only for exon 36-46 excepting the pseudogene region, which made it difficult to evaluate the accurate frequency and the spectrum of mutations. Therefore, we performed sequence analysis of 20 consecutive unrelated ADPKD patients for kidney transplantation by using long-range PCR to avoid pseudogene amplification followed by exon-specific PCR and sequencing of the entire exons of the two genes. All patients met the diagnostic criteria of ADPKD based on the ultrasonographic findings and family history of PKD and 14 patients (70%) were revealed to have mutations; 11 with *PKD1* and 3 with *PKD2* mutations, respectively. Among 10 novel mutations, eight mutations were found in *PKD1* gene while two mutations in *PKD2* gene. All were deleterious mutations except one missense mutation. It is of note that 6 out of 11 *PKD1* mutations (54.5%) were located outside the range of exon 36-46. Considering the mutation spectrum in Korean patients with ADPKD, long-range PCR followed by direct sequence analysis of pseudogene region should be performed for accurate molecular diagnosis of the disease.

P03.35-S

Primary hyperoxaluria: analysis of GRHPR, HOGA1 genes and the promoter-sequence of AGXT gene in the Italian population

A. Pelle[1], *G. Mandrile*[1,2], *A. Cuccurullo*[1], *C. Mancini*[3], *R. Sebastiano*[2], *S. Varacalli*[2], *D. F. Giachino*[1,4], *M. De Marchi*[1,2];
[1]*University of Torino, Department of Clinical and Biological Sciences, Torino, Italy, Orbassano (TO), Italy,* [2]*Medical Genetics, San Luigi University Hospital, Orbassano, Italy, Orbassano (TO), Italy,* [3]*University of Torino, Department of Medical Sciences, Torino, Italy, Torino, Italy,* [4]*Medical Genetics, San Luigi University Hospital, Orbassano, Italy, Orbassano, Italy.*

Primary hyperoxaluria (PH) is a rare autosomal recessive disease, commonly arising in childhood with nephrolithiasis, nephrocalcinosis, chronic renal failure. Mutations in *AGXT, GRHPR* and *HOGA1* genes are responsible of type 1, 2 and 3 respectively. Our laboratory, member of the European PH consortium (OxalEurope), is the only Italian center offering these genetic analyses.
Currently, 81 *AGXT*-PH1 and 1 *GRHPR*-PH2 patient are known in Italy.
In this study the entire coding sequence of *GRHPR* and *HOGA1* genes and the *AGXT* promoter was sequenced in 15 patients with high clinical suspicion of PH, negative for *AGXT* mutations. No point mutations were detected.
One patient resulted homozygous for the c.341-81delT *HOGA1* variant in intron 2. This variant is not reported in literature and was evaluated as pathogenic by *in silico* prediction, generating a new acceptor splicing site (AG in c.341-79). The minigene *in-vitro* assay demonstrated that this variant did not interfere with splicing.

Two patients were heterozygous for two different *AGXT*-promoter variants (c.-647C>T, c.-424C>T), not reported in the scarce literature nor in 1000Genomes Database. These variants have been evaluated as not pathogenic because they do not lie in any known regulatory-transcription site.
The negative results in those patients with high clinical suspicion of PH could be explained by undetected deletions (investigable by MLPA analysis of the two major genes) or mutations in other genes involved in oxalate metabolism, or differential diagnosis.

P03.36-M
Screening of a large cohort of Italian patients with Albright hereditary osteodystrophy and/or Pseudohypoparathyroidism phenotype for subtelomeric deletions of chromosome 2

F. M. Elli[1], *P. Bordogna*[1], *L. de Sanctis*[2], *V. Boldrin*[1], *A. Spada*[1], *G. Mantovani*[1];
[1]*Università degli Studi di Milano - IRCCS Cà Granda H Maggiore Policlinico, Milano, Italy,* [2]*Università di Torino - Ospedale Infantile Regina Margherita, Torino, Italy.*

Pseudohypoparathyroidism (PHP) is a heterogeneous group of rare genetic disorders due to end-organ resistance to the actions of PTH caused by genetic and/or epigenetic defects within or upstream the GNAS locus. The classification in different subtypes is based on the presence of specific somatic and developmental abnormalities, referred to as Albright hereditary osteodystrophy (AHO), and of resistance to other hormones acting via G protein coupled receptors.
Despite the advances in the study of PHP molecular determinants, about 30% of patients still lack a molecular diagnosis and, in the last years, independent groups found in a subset of PHP/AHO patients causative defects classically associated to diseases with partially common phenotype, such as deletions of 2q37.2 associated with the AHO-like syndrome (or brachydactyly-mental retardation syndrome, BDMR).
In this study, we screened by a multiplex ligand-dependent probe amplification (MLPA) assay targeting the chromosome region 2q our series of AHO/PHP pts negative for GNAS defects (n=56) and we detected 3 different deletions of 2q37, overlapping but smaller than those previously described. Ongoing studies will define the inheritance pattern of such deletions and will allow to narrow the common critical region associated with the AHO phenotype.
In conclusion, our data further confirm the molecular and clinical overlap between PHP/AHO and BDMR and will hopefully help to define genes involved in the AHO phenotype. Furthermore, all PHP/AHO pts negative for GNAS genetic/epigenetic defects should be considered for further molecular investigations to optimize genetic counselling.

P03.37-S
Exome sequencing reveals TPO mutations in Pseudo-Pendred syndrome

A. Denomme-Pichon[1], *E. Colin*[1,2], *S. Marlin*[3], *L. Jonard*[3], *S. Rouleau*[4], *S. Kury*[5], *S. Dumont*[5], *R. Coutant*[4], *D. Bonneau*[1,2];
[1]*Department of Biochemistry and Genetics, CHU Angers, Angers, France,* [2]*UMR CNRS 6214 INSERM 1083, Angers, France,* [3]*Department of Genetics, CHU Necker-Enfants-Malades, Paris, France,* [4]*Department of Pediatrics, CHU Angers, Angers, France,* [5]*Department of Genetics, CHU Nantes, Nantes, France.*

Pseudo-Pendred syndrome (PPDS) is defined by the association of sensorineural deafness, hypothyroidism due to iodide organification defect, absence of inner ear malformation and absence of mutation in SLC26A4, the gene responsible for classical PDS.
In order to determine the cause of PPDS, we performed whole exome sequencing (WES) in a family with two children affected with hypothyroidism, developmental delay, positive perchlorate test and absence of inner ear malformation on CT-scan. Parents were healthy and non-consanguineous and direct sequencing of SLC26A4 was normal in both patients.
WES was performed in both patients and their father. Variants were ranked by segregation, allele frequency, protein change and degree of conservation to assess likelihood of causation. Both patients were found to be compound heterozygous for missense mutations (Y453D and W233C) in TPO and the father was heterozygous for the Y453D mutation.
In silico prediction tools determined a deleterious mutational impact of both variants on protein function. Sanger sequencing confirmed the mutation segregation and found that the mother was heterozygous W233C. The latter mutation was novel and both were absent in the control population.
TPO encodes thyroperoxidase which catalyzes key reactions in thyroid hormone synthesis and mutations in TPO are responsible for thyroid dyshormonogenesis 2A. Mutations in TPO have been reported in 4 patients with hypothyroidism and deafness in a series of Israeli patients with iodide organification defect (Tenenbaum-Rakover, 2007) but their phenotype was not described as PPDS.
These cases together with the present report suggest that mutations in TPO can be responsible for pseudo-PDS.

P03.38-M
Renal function decay after nephrectomy: role of surgery and impact of hypertension gene polymorphisms

L. Zagato[1], *S. Delli Carpini*[1], *M. T. Sciarrone Alibrandi*[1], *F. Trevisani*[2], *P. Manunta*[2,1];
[1]*Ospedale San Raffaele, Milano, Italy,* [2]*Università Vita-Salute San Raffaele, Milano, Italy.*

The loss of nephronic mass leads to the development of hypertension and chronic renal failure, but the frequency and the rate at which this takes place after radical nephrectomy (RN) or nephron sparing surgery (NSS) is extremely variable and the mechanisms have not been clarified to date.
To evaluate the progression rate of renal function decay within a population undergoing kidney surgery and to assess the influence of polymorphisms of genes involved in essential hypertension (HT).
162 patients were followed at the Outpatient Clinic of Nephrology after a surgery for renal carcinoma, 75 RN and 87 NSS. The eGFR (estimated Glomerular Filtration Rate), an indicator of renal function, was evaluated for a mean follow-up of 23.5 months. 128 genetic polymorphisms located in 70 loci candidate for HT have been tested by TaqMan OpenArray system. Statistical analysis was performed using a General Linear Model covarying for sex, age, BMI, blood, therapy, basal renal function and type of surgery.
About the different surgical techniques, NSS patients displayed a significant decrease of eGFR variation significantly lower than that observed in RN ones (-5.7 ml/min vs. -23.9 ml/min P <0.05). Two SNPs, located in SIK1 and in PRKG1 genes, associated with a quicker decay of renal function (p=0.009) -20 mL/min/1.73m2 after 12 months in carriers of SIK1 T/PRKG1 GG (n=8) vs. -4 at the same time in all the other groups (n=154).
The progression of renal function decline after kidney surgery depends both on surgery type (80%) and on genetic background (15-20%).

P03.39-S
Hereditary renal hypouricemia causing by defect in URAT1: a new insight into molecular pathology

B. Stiburkova[1], *J. Stekrova*[2], *M. Nakamura*[3], *K. Ichida*[4,3];
[1]*Institute of Inherited Metabolic Disorders, First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic,* [2]*Institute of Biology and Medical Genetics of the First Faculty of Medicine, Charles University, Prague and General University Hospital, Prague, Czech Republic,* [3]*Department of Pathophysiology, Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan,* [4]*Division of Kidney and Hypertension, Jikei University School of Medicine, Tokyo, Japan.*

Renal hypouricemia is a rare heterogeneous inherited disorder characterized by impaired tubular uric acid transport with severe complications, such as acute kidney injury. So far, more than 100 patients with a loss-of-function mutation in the *SLC22A12* gene (URAT1, OMIM #220150) and more than ten patients with defects in the *SLC2A9* gene (GLUT9, OMIM #612076) have been described. The serum uric acid concentration in the proband was 1.1 mg/dL and expressed as an increase in the fractional excretion of uric acid 43%. The *SLC22A12* gene analysis for the patient revealed compound heterozygous variants of p.G366R and p.R477H. Functional and immunocytochemical analysis of URAT1 mutants was performed in *Xenopus laevis* oocytes. The urate uptake ability decreased to similar levels seen in mock samples in p.G366R mutant expressed oocytes. The p.R477H variant showed almost the same activity as the URAT1 wild type. In the co-expression samples, both variants p.WT/G366R and p.G366R/R477H lost their urate uptake activities. Variants p.WT/R477H tended to decrease urate transport compared to WT single expression; however, it was superior to the other two co-expression patterns (significant to WT/G366R, $^{\dagger}P<0.05$). Co-localization studies showed an accumulation of URAT1 in the endoplasmic reticulum of the p.G366R variant and mainly retention of wild type protein by variants p.G366R and p.R477H. The findings suggest that not only a loss-of-function mutation of URAT1 but also the dominant-negative effect cause renal hypouricemia *via* loss of uric acid absorption, partly due to protein misfolding caused by accumulation of URAT1 protein in the endoplasmic reticulum.
Support: LH13245 and PRVOUK-P25LF1/2.

SHORT syndrome is defined by its acronym: short stature (S), hyperextensibility of joints and/or inguinal hernia (H), ocular depression (O), Rieger abnormality (R) and teething delay (T). We and others recently identified the *PIK3R1* gene, encoding for the regulatory subunits of phosphatidylinositol-3-kinase (PI3K) and playing a key role in insulin signaling, as responsible of SHORT syndrome. In total, 22 cases with a *PIK3R1* and a variable phenotype have been reported. Only 15/22 patients presented at least 3 of 5 signs of the SHORT acronym. Indeed, the Rieger abnormality was found in less than half patients (8/21), but other ophthalmological manifestations such as hypermetropia can be present. Hyperextensibility of joints and/or inguinal hernia (3/18) were also rarely reported. At contrary, some features not part of the acronym are found at a high frequency: facial dysmorphism was typical with enophtalmia (20/20), lipodystrophy (19/19), insulin resistance (11/12), as well as diabetes mellitus in adolescence or adulthood (8/11). In conclusion, clinical reappraisal of SHORT syndrome at the light of the *PIK3R1* gene discovery permitted to revise the diagnostic criteria for SHORT syndrome. The presence of lipodystrophy and insulin resistance permit to classify SHORT syndrome among the rare syndromic forms of insulin resistance.

P03.41-S

Multiple SNP score associated to chronic renal disease risk predicts the eGFR of patients with newly diagnosed type 2 diabetes

C. Zusi[1], *S. Bonetti[1], M. Trombetta[1,2], M. L. Boselli[1], D. Travia[2], G. Zoppini[2], E. Bonora[1,2], R. C. Bonadonna[3];*
[1]Università di Verona, Verona, Italy, [2]AOUI di Verona, Verona, Italy, [3]Università di Parma, Parma, Italy.

Genome-wide association studies (GWAS) have identified several loci associated with risk of cardiovascular disease (CVD), nephropathy and reduction of glomerular filtration rate (eGFR). Moreover, albuminuria and eGFR reduction are independent predictors of CVD.
The aim of this study is to explore the relationship between SNPs and CVD and impaired renal function phenotype in Verona Newly Diagnosed type 2 Diabetes Study (VNDS) patients.
We studied 45 CVD and 44 eGFR and/or CKD predictors SNPs in 529 GAD-Ab negative subjects, (mean±SEM age: 58.8±0.41 years; BMI: 30.0±0.22 kg/m2; FPG: 7.17±0.08 mmol/L; HbA1c: 6.86±0.05%). The association analysis was performed on 5 phenotypes: 3 CVD phenotypes (carotid arteries ultrasound, lower-limb arterial ultrasound, ECG) and 2 kidney disease phenotypes (eGFR, microalbuminuria). For both genetic risks was generated a genetic load score (GLS), by summing up the number of risk alleles carried by each patient. Both GLS were considered in the analysis as natural values and as tertiles. Cardiovascular GLS was not associated with any of the cardiovascular phenotypes (p = 0.30-0.70). Nephropathic GLS, was not associated with albuminuria, while was significantly associated with decreased eGFR, with the score expressed both as natural value (p <0.01) and as tertiles (respectively: 84.3±1.3, 81.7±1.5 and 78.9±1.5 ml/min/1.73 m2 p<0.02), even after age, sex, BMI, antihypertensive therapy and HbA1c adjustment.
Conclusions: In patients with type 2 diabetes at diagnosis, genotype predicts the residual glomerular function, suggesting that nephropathic genetic risk clock starts ticking long before hyperglycemia.

P03.42-M

A genome-wide search for factors contributing to thyroid hemiagenesis

B. Budny[1], *E. Szczepanek-Parulska[1], W. Szaflarski[2], T. Zemojtel[3], M. Rydzanicz[4], L. Handschuh[3], J. Podkowinski[3], E. Wrotkowska[1], N. Derebecka[4], H. Bluijssen[4], J. Wesoly[4], M. Figlerowicz[3], M. Zabel[2], K. Wolinski[1], K. Ziemnicka[1], M. Ruchala[1];*
[1]Chair and Department of Endocrinology, Metabolism and Internal Diseases, Poznan University of Medical Sciences, Poznan, Poland, [2]Department of Histology and Embryology, Poznan University of Medical Sciences, Poznan, Poland, [3]Institute of Bioorganic Chemistry PAS, Poznan, Poland, [4]Department of Human Molecular Genetics, Institute of Molecular Biology and Biotechnology, Adam Mickiewicz University, Poznan, Poland.

Thyroid dysgenesis is the major cause of congenital hypothyroidism in humans. Hemiagenesis of the thyroid (TH) is a rare congenital malformation presenting developmental failure of only one thyroid lobe, and an incidence of 1/2000 for general population. Majority of cases are sporadic, but the reported familial cases are suggestive for existence of genetic, heritable contributors. Molecular background of the disorder remains unclear. The aim of the project was a screening for abnormalities in genes playing an important role in thyroid organogenesis. A microarray and exome sequencing approaches were employed to identify novel genetic factors contributing to the disorder. Thirty-nine TH patients participated in the study. The genetic analysis were conducted in all patients and encompasses sequencing of TPO, PAX8, FOXE1, NKX2-1 and TSHR genes as well as copy number investigation using Multiplex Ligation Dependent Probe Amplification (MLPA). The MLPA analysis did not reveal any unbalanced rearrangements. In selected cohort of patients a missense mutations in PAX8 and TBX1 sequences were found. Microarray examination resulted in identification of a several regions potentially involved TH aetiology. Two genomic regions show recurrence in the cohort of sporadic, unrelated TH patients. This is a first report presenting comprehensive screening of genes contributing to severe forms of thyroid dysgenesis, in TH patients. Mutations in those genes confirm their importance for organ development but cannot explain the abnormal phenotype and bilobation disturbance for majority of TH sporadic cases. Further studies on molecular background of the disorder are necessary.

P03.43-S

Further delineation of Tenascin-X-related Ehlers-Danlos Syndrome in patients with Congenital Adrenal Hyperplasia

A. Wischmeijer[1,2], *S. Menabò[3], M. Romagnoli[1], G. Rodella[1], A. Gambineri[4], O. Prontera[4], M. Seri[1], L. Baldazzi[3];*
[1]Department of Medical Genetics, Policlinico S.Orsola-Malpighi, University of Bologna, Bologna, Italy, [2]Clinical Genetics Unit, Arcispedale S. Maria Nuova - Istituto di Ricovero e Cura a Carattere Scientifico, Reggio Emilia, Italy, [3]Molecular Genetics Laboratory – Pediatric Department, Policlinico Sant'Orsola-Malpighi, University of Bologna, Bologna, Italy, [4]Department of Endocrinology, Policlinico Sant'Orsola-Malpighi, University of Bologna, Bologna, Italy.

Congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency is an autosomal recessive disorder characterized by cortisol with/without aldosterone deficiency, and androgen excess. The severity of clinical manifestations depends on the degree of 21-hydroxylase impairment caused by mutations in the CYP21A2 gene. Its classic form has an overall incidence of 1 per 15000 live births. CYP21A2 is flanked by the TNXB gene, encoding the extracellular matrix protein tenascin-X. Both, haploinsufficiency and complete loss of tenascin-X have been associated with phenotypes similar to Ehlers-Danlos syndrome (EDS). A significant portion of CAH-patients presents deletion of mostly one CYP21A2-allele, and up to 13% of these might be a contiguous deletion extending into TNXB.
We report two brothers (20 and 29 years old) with classic CAH and homozygous deletion encompassing CYP21A2 and TNXB, who were evaluated for clinical evidence of EDS: both present skin hyperextensibility, joint hypermobility and clinical history of multiple joint subluxations, without evidence of atrophic scars or other classic EDS features. The younger brother underwent surgery for inguinal hernia and rectal prolapse during adolescence. Cardiac ultrasound examination revealed bicuspid aortic valve, mild aortic dilatation and mitral valve insufficiency in the older brother; cardiologic follow-up was advised.
The parents, heterozygous carriers of the contiguous deletion of CYP21A2 and TNXB, don't show clear features of EDS.
To our knowledge, bicuspid aortic valve has not been observed in CAH with tenascin-X-related EDS yet. Our findings confirm that clinical evaluation for connective tissue pathology should be considered in CAH patients, especially those harboring CYP21A2 deletion.

P03.44-M

Tricho-rhino-phalangeal syndrome type III: an autonomous clinical entity or a clinical variant of type I ? Further report of an italian affected girl and her mother.

M. P. Natale[1], F. Papadia[1], S. Pesce[1], M. Masciopinto[1], M. Gentile[2], F. Nicastro[1], V. Lillo[1], **R. Fischetto**[1];
[1]U.O.C. Malattie Metaboliche e Genetica Medica P.O. Giovanni XXIII, A.O.U. Policlinico Consorziale B, Bari, Italy, [2]UO Genetica medica Ospedale "Di Venere", Bari, Italy.

Trichorhinophalangeal syndrome is an autosomal dominant condition characterized by craniofacial and skeletal anomalies and three different clinical subtypes: type I, carrying mutations in TRPS1 gene, type II, a 8q23 microdeletion syndrome with additional features such as mental retardation and exostoses, type III, with mutations in TRPSI gene and severe short stature, short metacarpals and normal intelligence. We report on clinical evaluation in a 10 year old girl presenting with disharmonious short stature, facial dysmorphisms (sparse hair, bulbous tip of the nose, long upper lip), severe metacarpophalangeal shortening and normal intelligence. Hormonal and meta-

bolic screening evaluation (including mucopolysaccaridosis disease) did not reveal pathologic patterns. Since few months she suffered from pelvic pain: an X-ray of the hip revealed left coxa vara and a round area of osteoporosis in the femural external side ,sclerosis of femural nucleus and of the overlying acetabular roof. Spine X-ray brought out convex scoliosis and marked left iliac crest dysmetria, with an overcoming external subluxation of the right hip. The CT scan confirmed these data and an orthopedic follow up started. The peculiar face with short stature, brachidactyly, scoliosis, hip dislocation led us to consider in differential diagnosis Trichorhinophalangeal syndrome type 3: molecular analysis of TRPS 1 gene proved a new missense mutation (exon 7 H1233P), that was also carried by her mother, who presented a minimum clinical phenotype (face anomalies, short metacarpals,not severe short stature). Our study could be a further clinical contribute to the delineation of the Thricorhinophalangeal subtype III syndrome.

P03.45-S
Renal and urinary system malformations in girls with Turner syndrome

S. Turyk, *M. Sakurai, M. Ciaccio, S. Bonsergent;*
Hospital Britanico de Buenos Aires, Buenos Aires, Argentina.

Turner Syndrome (TS), in which there is a loss of all or part of one X chromosome, occurs in 1 in 2500 born femals. Renal and urinary system malformations with their posterior complications such as urinary tract infections or proteinuria have been recognized to increase in patients with TS. In this retrospective study we report a detailed clinical history and analyzed renal and urinary system pathology in 32 girls with TS observed between 2000-2010. All 32 TS patients were evaluated by renal and collecting system utrasonography and if structural renal or urinary malformations were found, cystourethrography and centellography (DMSA or DTPA) was used. Patients mean age at renal and urological studies was 9,8 years (2-18 years). The cytogenetic findings in 32 patients with TS were: classic : 45,X in 18 patients (56,25%), mosaic and structural aberrations of X chromosome: in 14 patients (43,75%). The prevalence of renal and urinary system pathology was 43,75% (14 patients) . The most frequent findings were urinary system malformations 21,87% (7 patients) , associated with renal malformations 9,38% (3 patients), while 4 patients (12,5%) had renal malformations alone. Horseshoe kidney, malrotation or other position abnormalities, duplication of the collecting system, and different ureterovesicular obstruccion were found. Conclusion: The early diagnosis of renal and urinary system malformations in TS and their follow-up is crucial to reduce the morbility in these patients. There appears to be no correlation between karyotype and the presence or type of renal or urinary system malformations.

P03.46-M
Does summation of alleles account for genetic risk and genotype-phenotype association in Type 2 Diabetes Mellitus?

N. P. Pace, *A. E. Felice, J. Vassallo;*
University of Malta, Msida, Malta.

Introduction: Type 2 diabetes (T2DM) and metabolic syndrome are common complex disorders with a high prevalence in the Maltese population. The aim of this study is to further define the genetic interplay between cognate genes from metabolic and inflammatory pathways on the likelihood of developing T2DM in adulthood and to relate the association of certain genetic profiles with defined biological and clinical endpoints. **Method**: Eight hundred carefully characterised T2DM cases were recruited. Anthropometric and biochemical parameters, including serum high-sensitivity C-Reactive protein (hsCRP) levels were determined, and genotyping of 43 cognate genes carried out. Neonatal cord blood samples were used as the control reference population in this study. **Results**: Ten polymorphisms in metabolic/inflammatory pathways showed significant association with T2DM. Three loci showed significant association with lipid profile, body weight and hsCRP levels. hsCRP levels demonstrated a strong positive correlation with body mass index. Genetic score analysis showed that combining multiple genetic markers results in higher relative risks. The functional significance of these polymorphisms is being further evaluated using targeted siRNA-mediated silencing in cultured monocytes. **Conclusion**: A panel of ten candidate genes has consistently demonstrated significant association with type 2 diabetes and metabolic syndrome in the Maltese population. These gene variants serve functional roles in inflammation and adipose tissue function. A recruited cohort of untreated newly-diagnosed T2DM serves to identify and explore genotype-phenotype association. The strong effect sizes of these alleles could be used to develop personal genetic susceptibility profiles for T2DM leading to personalization of care and prevention of chronic complications.

P03.47-S
XX male sex reversal in an azoospermic proband

J. Nevado[1], *M. Alvarez-Blanco*[2], *M. Mori*[1], *B. Garcia*[2], *M. Palomares*[1], *L. Varela*[3], *L. Fernandez*[1], *M. De Torres*[1];
[1]*Ingemm-Idipaz, Madrid, Spain,* [2]*Hospital Universitario De Alcala De Henares, Madrid, Spain,* [3]*Hospital Universitario De Alcala De Henares, Madrid, Spain.*

The basis of conception of genetic sex determination was initially, at least in mammals, limited to a form of chromosomal currency. However, the presence of an entire Y chromosome is not essential for the development of the male phenotype and transfer of the SRY-gene alone could be a sufficient condition. Critically, mutations in the *SRY* gene are linked with XY-female sex reversal in mice and humans indicating that *SRY* is essential for male development. It appears that the only role of SRY is to upregulate the SRY-related HMG box containing gene 9 (SOX9) bipotential gonads, which results in Sertoli cell differentiation and, ultimately, in testes differentiation. XX male sex reversal is rare and in most cases is the result of translocation of the SRY gene to the X-chromosome during male meiosis. However, a recent report by Cox et al. [2011] described a family, two brothers and an uncle, with 46, XX male sex reversal who lacked the SRY gene and had a 600 kb duplication upstream of *SOX9*. We report on a case of a 38 infertile male (sent by the fertility unit) with azoospemia and hypergonadotrophic hypogonadism a 46 XX male sex reversal (without SRY). A 244K aCGH in the proband showed a novel and apparently, de novo duplication within *SOX3* gene (at Xq27.1 chromosomal region) in a complex genomic rearrangement. These data provide additional evidence that *SOX3* gain-of-function in the XX bipotential gonad causes XX male sex reversal.

P03.49-S
Identification of 65 novel mutations and genotype-phenotype correlations in patients with Alport syndrome (ATS) and thin basement membrane nephropathy (TBMN)

K. Straßer[1], *S. Weber*[1], *A. Kittke*[2], *S. Rath*[2], *P. F. Hoyer*[1], *M. Alberer*[3], *B. Lange-Sperandio*[4], *L. T. Weber*[5], *H. Klein*[2], **J. Hoefele**[2];
[1]*Pediatric Nephrology, Pediatrics II, University of Duisburg-Essen, Essen, Germany,* [2]*Center for Human Genetics and Laboratory Diagnostics Dr. Klein, Dr. Rost and Colleagues, Martinsried, Germany,* [3]*Department of Infectious Diseases and Tropical Medicine, Ludwig-Maximilians University, Munich, Germany,* [4]*University Children's Hospital, Pediatric Nephrology, Ludwig-Maximilians University, Munich, Germany,* [5]*University Children's Hospital, Pediatric Nephrology, Cologne, Germany.*

ATS is characterized by hematuria, proteinuria with progression to end-stage renal disease (ESRD), eye abnormalities and sensorineural deafness. Mutations in COL4A3/COL4A4 (autosomal recessive/dominant), and COL4A5 (X-linked) have been identified as underlying cause. Compared to ATS, autosomal dominant TBMN is characterized by hematuria, minimal proteinuria and preserved renal function. Dominant mutations have been identified in COL4A3 and COL4A4.
A cohort of 167 patients and 49 relatives were genetically tested and clinically evaluated. In 145 patients mutations were identified, 65 of them were novel. 54% resp. 88% of the ATS patients showed only one mutation in COL4A3 or COL4A4. Three TBMN and eight ATS patients (COL4A3 or COL4A4) had hearing loss, but only two of the ATS patients carried two mutations. An ATS patient with one mutation in COL4A4 showed no hematuria, but proteinuria, ESRD, and hearing loss. Two patients (COL4A5) showed isolated proteinuria. 26% of the ATS patients (COL4A5) had hearing loss and 43% of these presented the mutation at the 5' end of the gene.
This study comprises one of the largest genotype-phenotype correlation in European ATS and TBMN patients. A large number of novel mutations were detected. Many patients had only one heterozygous mutation in COL4A3/COL4A4. This might be explained either by an autosomal dominant inheritance, the possibility of missed mutations, its function as a modifier additionally to so far unidentified causative mutations, or a combination of these possibilities. Interestingly, ATS/TBMN patients can also be affected by isolated proteinuria and TBMN patients rarely develop hearing loss.

P04.01-S
Screening of 1200 FDA-approved molecules to identify pharmacological modulators of expression of ACVR1, the gene mutated in Fibrodysplasia Ossificans Progressiva.

S. Cappato[1], *F. Giacopelli*[1], *L. Tonachini*[1], *L. Galietta*[2], *R. Ravazzolo*[1,2], *R. Bocciardi*[1,2];
[1]*University of Genova and CEBR, Genoa, Italy,* [2]*Medical Genetics Unit, G. Gaslini Institute, Genoa, Italy.*

ACVR1/ALK-2 encodes for a type I BMP receptor and is mutated in Fibrodysplasia Ossificans Progressiva (FOP, OMIM135100). FOP is a rare and severe disease of heterotopic ossification, with a progressive and episodic course. No treatment is available to the progression of the disease and great effort is devoted to better understand the pathogenic mechanisms underlying the dysregulated BMP pathway associated with FOP that may be targeted by in-

novative therapeutic approaches.
The characterization of the ACVR1 promoter region provide us with the molecular tools to generate a cell-based system exploitable for High-Throughput Screening (HTS) of chemical compounds with potential pharmacological effect on the ACVR1 expression at the transcriptional level. The cell system has been generated in ATDC cells by stable transfection of the Luciferase reporter gene under the control of the ACVR1 promoter.
We describe here in detail the HTS procedure we developed and report the results obtained with the screening of 1200 FDA-approved compounds (Prestwick Chemical Library). We identified 18 compounds, showing an inhibitory effect ≥ 60%, and 8 molecules with activating properties on the ACVR1 transcription. Identified hits belong to different pharmacological classes among which corticosteroids, PDE inhibitors, FANS. We are currently performing experimental validation of selected molecules with different assays.
In conclusion, we present a cell-based system suitable for HTS of small chemical compounds to target the ACVR1 transcriptional activity, thereby modulating the downstream pathway. Screening of compounds approved for clinical purposes, may provide candidates for a drug repositioning approach.

P04.02-M
Autosomal-recessive Adams-Oliver syndrome caused by homozygous mutation in EOGT, encoding an EGF domain-specific O-GlcNAc transferase

I. Cohen[1], *E. Silberstein*[2], *Y. Perez*[1], *D. Landau*[3], *K. Elbedour*[4], *Y. Langer*[1,4], *R. Kadir*[1], *M. Volodarsky*[1], *S. Sivan*[1], *G. Narkis*[1], *O. S. Birk*[1,4];
[1]*The Morris Kahn Laboratory of Human Genetics at the National Institute for Biotechnology in the Negev (NIBN) and Faculty of Health Sciences, Ben-Gurion University, Beer-Sheva, Israel,* [2]*Department of Plastic and Reconstructive Surgery, Soroka Medical Center, Beer-Sheva, Israel,* [3]*Division of Pediatrics, Soroka Medical Center, Beer-Sheva, Israel,* [4]*The Genetics Institute, Soroka Medical Center, Beer-Sheva, Israel.*

Autosomal recessive Adams-Oliver syndrome was diagnosed in three remotely related Bedouin consanguineous families. Genome wide linkage analysis ruled out association with known Adams-Oliver syndrome genes, identifying a single homozygosity ~1.8 Mb novel locus common to affected individuals (LOD score 3.37). Whole exome sequencing followed by Sanger sequencing identified only a single mutation within this locus, shared by all affected individuals and found in patients from five additional apparently unrelated Bedouin families: a 1bp deletion mutation in a predicted alternative splice variant of EOGT, leading to a putative truncated protein. RT-PCR demonstrated that the EOGT predicted alternative splice variant is ubiquitously expressed. EOGT encodes EGF-domain-specific O-linked N-acetylglucosamine transferase, responsible for extracellular O-GlcNAcylation of epidermal growth factor-like domain containing proteins, and essential for epithelial cell-matrix interactions. F-actin staining in diseased fibroblasts showed apparently intact cell cytoskeleton and morphology, suggesting the EOGT mutation acts not through perturbation of cytoskeleton, but through other mechanisms yet to be elucidated.

P04.03-S
Immunomodulation in Atopic Dermatitis: Inherited, Environmental and Behavioral Risk Factors, and Evaluation of Biomarkers

T. M. Luukkonen[1,2], *S. Reitamo*[3], *V. Kiiski*[3], *J. Mandelin*[3], *H. Virtanen*[3], *M. Ahola*[3], *M. Pöyhönen*[4,5], *E. Salminen*[5], *A. Remitz*[3];
[1]*Institute for Molecular Medicine Finland FIMM, Helsinki, Finland,* [2]*National Institute for Health and Welfare, Helsinki, Finland,* [3]*Skin and Allergy Hospital, University of Helsinki, Helsinki, Finland,* [4]*Dept. of Medical Genetics, Haartman Institute, University of Helsinki, Helsinki, Finland,* [5]*Dept. of Clinical Genetics, Helsinki University Central Hospital, Helsinki, Finland.*

The barrier function of the skin is essentially maintained by the epidermal differentiation complex protein filaggrin, which is located in the stratum corneum of the epidermis. Loss-of-function (LoF) mutations of the filaggrin gene (*FLG*) lead to an increased risk of atopic dermatitis (AD), allergic sensitization, as well as asthma in the presence of AD. Patients with active AD, or clinically dry skin show a reduction of the epidermal filaggrin protein levels even in the absence of *FLG* LoF mutations.
Here we investigate the disease modification in AD with principal focus on *FLG* risk variants and their influence on disease severity. To identify additional susceptibility loci we analyze *CLDN1, CLDN4, CLDN23, OCLN, IVL, SPINK5, IVL, IL31, TLR2, CLDN20, SELP,* and *FLG2* variants possibly involved in AD. Altogether 80 variants are genotyped from 500 Finnish patients with a detailed AD history, and from 1000 population cohort controls.
The tight junction proteins claudin-1, claudin-4, claudin -23, occludin and involucrin are essential for proper barrier function. However the LoF state of the encoding genes remains largely unknown. Here we suggest that LoF variation of these genes may be detected especially in patients with very severe disease and a poor treatment response, such as the AD patient cohort with extreme IgE levels (>10 000). Three candidate genes (*CLDN20, SELP* and *FLG2*) are drawn from a systematic survey of LoF variants in human protein-coding genes, that identified rare and likely deleterious LoF alleles markedly enriched in the Finnish population at greater than 1% frequency.

P04.04-M
The benign joint hypermobility syndrome: guidelines for diagnosis and management.

M. Vreeburg[1], *M. Schouten*[2], *J. de Vos-Houben*[1], *A. Maugeri*[3], *Y. Detisch*[1], *M. van Eijsden-Besseling*[1], *D. Marcus-Soekarman*[4];
[1]*Maastricht University Medical Center, Maastricht, Netherlands,* [2]*Radboud University Medical Center, Nijmegen, Netherlands,* [3]*VU University Medical Center, Amsterdam, Netherlands,* [4]*Hamad General Hospital, Doha, Qatar.*

Introduction The hypermobility syndrome (HMS) or benign joint hypermobility syndrome (BJHS) is a frequent condition affecting many females, interfering with their normal activities of daily life. Hypermobility is associated with an increased risk to develop a chronic pain syndrome. Patients often seek medical help in later stages of this condition for therapy-resistant complaints. We designed a protocol to improve the referral and management strategy for this particular patient group. **Methods** We report data on patients (n=167) referred to the department of clinical genetics to exclude rare genetic connective tissue disorders such as the Ehlers Danlos syndrome. **Results** Based on the data of medical history, clinical examination and if indicated, DNA-investigations, the likelihood of an underlying hereditary disorder in the 167 counsellees was estimated. Further DNA-investigation was performed in 83 cases, revealing an underlying monogenetic disorder in two cases. **Conclusions** Based on our experience we provide tools to distinguish between the majority of patients with BJHS and those with a hereditary connective tissue disorder. For the referring physician, the modified scoring list according to Beighton is essential to decide whether to refer or not. Individuals with the BJHS (Beighton scoring (BS) 4-6) should be referred to a rehabilitation specialist for treatment. In case of a BS of 7 or more, or 6 or less with unusual features (f.e. male gender, age over 50, and/or a positive family history) referral to a clinical geneticist is recommended for further evaluation.

P04.05-S
A mutation in the LRP4 gene is associated with bone mineral density in Maltese postmenopausal women

M. Formosa, *J. Borg, S. Bezzina-Wettinger, R. Farrugia, A. Xuereb Anastasi;*
Department of Applied Biomedical Science, Faculty of Health Sciences, University of Malta, Msida, Malta.

Background: Osteoporosis is a hereditary multifactorial skeletal disease characterised by low bone mass and increased fracture susceptibility. The low-density lipoprotein receptor-related protein 4 (LRP4) controls the actions of sclerostin which is a known inhibitor of the Wingless (Wnt)/Beta (β) catenin pathway involved in bone formation.
Objective: To evaluate the effect of two non-synonymous coding polymorphisms rs6485702 (A>G) and rs2306033 (C>T) in relation to Bone Mineral Density (BMD) and different low-trauma fractures in Maltese postmenopausal women.
Methods: Research subjects were 1045 women subdivided in three BMD groups if without history of fragility fracture: normal, osteopenic or osteoporotic. Women with a fracture history were classified as cases. Genotyping was performed by polymerase chain reaction and restriction fragment length polymorphism. Associations with BMD and fracture were analysed using odds ratios (OR) determined by logistic regression and adjusted for age.
Results: Homozygosity for the rs6485702 A allele was associated with a lower BMD at the lumbar spine, LS (OR=2.2 [95% confidence interval 1.1-4.4] p=0.03) relative to research subjects with a normal BMD. Heterozygotes for this allele had a lower BMD at the femoral neck, FN (OR=1.5 [1.1-2.2] p=0.02). The G-C haplotype was strongly associated with LS BMD (p=0.004) and to a lower extent FN BMD (p=0.04). No association with fracture risk was seen (p>0.05).**Conclusion:** The LRP4 rs6485702 variant plays a role in BMD regulation in Maltese postmenopausal women. This polymorphism is located in the β-propeller domain which is thought to interfere with the binding of sclerostin and hence will not affect Wnt signalling.

P04.06-M
A novel mutation in BMPR1B gene(R486L)in a Polish family with brachydactyly A2/C with symphalangism

M. Badura-Stronka[1,2], *D. Mróz*[3], *K. Kozlowski*[4], *K. Wicher*[1], *A. Latos-Bieleńska*[1,2];
[1]*Chair and Department of Medical Genetics, Poznan University of Medical Sciences, Poznań, Poland,* [2]*NZOZ Center for Medical Genetics GENESIS, Poznań, Poland,* [3]*Central Laboratory, Obstetric and Gynecology Clinic Hospital, Poznań, Poland,* [4]*Department of*

Medical Imaging, The Children's Hospital at Westmead, Sydney, Australia.

Two different substitutions at position 486 of the BMPR1B gene result in a phenotype of brachydactyly A2 or brachydactyly C with symphalangism. Here we report a Polish family presenting this rare phenotype.
On X-ray images in the 47 year old female the metacarpals are shortened and the proximal phalanges of the second fingers are hypoplastic. The left finger shows a transverse radiolucent defect consistent with pseudoarthrosis. The middle phalanges of the 2nd fingers are absent. The middle phalanges of the 3rd and 5th fingers are hypoplastic/dysplastic. In the feet there is hypoplasia of the 1st metatarsals with hypoplasia/dysplasia of the proximal phalanges. There is sclerosis of the second metatarsals.
In her 23 year old son the metacarpal of the first right finger is hypoplastic and that of the first left finger is hypoplastic/dysplastic. The proximal phalanges of both the 2nd fingers are hypoplastic and the middle phalanges are present as small bony remnants. In the left 2nd finger there is radial subluxation of the distal phalanx. There is also hypoplasia of the 1st metatarsals with hypoplasia/dysplasia of the proximal phalanges. The second metatarsals are of increased density. Clinical and radiological analysis of skeletal abnormalities suggested alteration of the BMPR1B gene. A novel mutation: c.1457G>T(R486L)segregates with brachydactyly in this family. Our data extends mutational and radiological spectrum associated with mutations in BMPR1B gene and confirms existence of a universal hotspot in the BMPR1B gene for this complex phenotype, that is clearly distinguishable on radiological basis.

P04.07-S
Targeted DNA sequencing of chromosome 8q22 identifies rare variants in *DCSTAMP* in patients with Paget's disease of bone

O. M. E. Albagha, *S. Wani, S. H. Ralston;*
University of Edinburgh, Edinburgh, United Kingdom.

Paget's disease of bone (PDB) is a common bone disease with strong genetic component. We previously identified a PDB-susceptibility locus on chromosome 8q22 tagged by a common SNP located within the *DCSTAMP* gene (Albagha *et al, Nat Genet* 2011). To identify functional susceptibility variants, we investigated this locus using a targeted DNA sequencing approach. A 700kb region containing four genes (*RIMS2*, *DCSTAMP, DPYS,* and *LRP12*) was captured using the Haloplex target enrichment kit followed by DNA sequencing using the Illumina Hiseq2000 platform. A total of 244 samples were sequenced (143 unrelated cases without *SQSTM1* mutation, 40 controls, 48 familial cases and 13 controls). Variants passing quality control were subjected to multiple filters to include missense variant, those in the 5' or 3'UTR or those predicted as functional by the ENCODE database. In *DCSTAMP*, we detected two novel variants (1 missense and 1 in 3'UTR) that were not present in our controls or publicly available databases including 1000 genomes. The novel missense mutation was detected in 3 cases and showed transmission in familial cases. Two other missense mutations were only found in cases (n= 7) but they are present in 1000Genome database with MAF<0.03. No disease-specific mutations were detected in *RIMS2, DPYS* or *LRP12*). *DCSTAMP*, which encodes a dendritic-cell-specific transmembrane protein, is a strong functional candidate gene for PDB because it is required for the fusion of osteoclast precursors to form mature osteoclasts. Our data suggest that rare variants within this gene could influence PDB-susceptibility.

P04.08-M
Identification of mutations in *DYNC2LI1*, a member of the mammalian cytoplasmic dynein 2 complex, expands the clinical spectrum of Jeune/ATD ciliopathies

K. Kessler[1], *N. N. Hauer*[1], *I. J. Wunderlich*[1], *M. Fröhlich*[1], *A. Giessl*[2], *H. Sticht*[3], *N. S. Falk*[2], *J. H. Brandstätter*[2], *A. B. Ekici*[1], *S. Uebe*[1], *E. Seemanová*[4], *A. Reis*[1], *C. T. Thiel*[1];
[1]*Institute of Human Genetics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany,* [2]*Animal Physiology, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany,* [3]*Institute of Biochemistry, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany,* [4]*Department of Clinical Genetics, Institute of Biology and Medical Genetics, 2nd Medical School, Charles University, Prague, Czech Republic.*

Disorders of brain malformations, polydactyly, kidney cysts, and skeletal abnormalities belong to the ciliopathy spectrum caused by defects in formation, maintenance and function of the primary cilium. This phenotypic spectrum is present among patients with short rib-polydactyly syndromes (SRPS), the asphyxiating thoracic dystrophy (ATD/Jeune) and Ellis-van Creveld syndromes (EVC). Underlying genes affect the dynein motor, intraflagellar transport complexes, or the basal body.
After excluding known causative genes we performed exome sequencing in a patient of non-consanguineous parents presenting an intermediate phenotype between ATD/Jeune and EVC. We selected variants based on potential ciliary function as identified in a yeast two-hybrid screen with NEK1, a basal body protein involved in SRPS II. This identified compound heterozygous nonsense (p.R208X) and missense (p.T221I) mutations in *DYNC2LI1* segregating in the family. *DYNC2LI1* is ubiquitously expressed and interacts with DYNC2H1 to form the dynein 2 complex important for retrograde intraflagellar transport. The hypothetical protein caused by the nonsense mutation lacks the coiled-coil domain involved in protein interaction and dimerization. The mutation p.T221I affects a highly conserved nucleoside triphosphate hydrolase domain responsible for GTPase driven dynein protein localization.
Mutations in both DYNC2LI1 interacting partners DYNC2H1 and NEK1 are associated with Jeune/ATD/SRP III and SRPS II/ATD, respectively. The intermediate phenotype in the patient can be explained by its dimerization with DYNC2H1 and the suggested interaction between DYNC2LI1 and the basal body protein NEK1. This is the first report of mutations in the light intermediate chain of the dynein 2 complex further expanding the clinical spectrum of ciliopathies.

P04.09-S
Exome sequencing in patients with Circumferential skin creases Kunze type: Evidence for locus heterogeneity

M. Isrie[1], *M. Breuss*[2], *A. Sifrim*[3], *L. Dehaspe*[1], *G. Peeters*[1], *C. M. Rodriguez Rodriguez*[4], *E. P. Dapena*[4], *K. Doonanco*[5], *F. Tinsa*[6], *S. Moortgat*[7], *V. Congenital circumferential skin creases are extremely rare and children born with this feature are referred to as 'Michelin tyre babies' based on the similarity with the mascot of the French tyre manufacturer. Some of these children have additional abnormalities including typical facial dysmorphism, cleft palate, short stature and intellectual disability. For this syndrome, our group proposed the term 'Circumferential skin creases Kunze type' (Wouters *et al.*, 2011). So far, less than 10 cases have been described in the literature and all occurrences are sporadic. In an international collaboration we collected DNA samples from 8 patients with Circumferential skin creases Kunze type. Exome sequencing was performed on the HiSeq2000 platform for two case-parent trios as well as two additional patients with this syndrome. Data analysis revealed the presence of pathogenic mutations in either one of two interacting genes, providing evidence for genetic heterogeneity. Three additional patients with the same phenotype have also been found to carry a mutation in one of these genes. While some patients carry a heterozygous *de novo* mutation, others present with homozygous mutations. Accurate genotype-phenotype correlations are being investigated. In addition, we are performing functional analyses at the protein level to elucidate the pathogenic mechanism of the mutations.

P04.10-M
The type II collagenopathies: a spectrum of disorders in 194 Italian families

S. Bargiacchi[1], *E. Andreucci*[2], *S. Giglio*[1,2];
[1]*Medical Genetics Unit, Department of Clinical Experimental and Biomedical Sciences, University of Florence, Firenze, Italy,* [2]*Medical Genetics Unit, Meyer Children's University Hospital, Firenze, Italy.*

Mutations in the type 2 collagen gene (*COL2A1*) have been described in a group of dominant skeletal dysplasias with a wide degree of phenotypic severity ranging from perinatally lethal to mild conditions manifesting only in late adolescence or adulthood. In the past 6 years we performed molecular analysis of *COL2A1* in 194 Italian probands and we identified 78 different mutations: 25 known and 53 never described in the literature. The phenotype was quite variable among our patients, ranging from Stickler syndrome (STL), due mainly to nonsense and splice-site mutations, to more severe bone dysplasia phenotypes, usually due to a dominant negative effect (SED, SMED, SPD, ACG2). In 9 of our cases with a diagnosis of STL who were negative at *COL2A1* analysis we found mutations in *COL11A1*. Considering the broad spectrum of phenotypes, the absence of mutational hot spots and the large size of the genes implicated in "type II-collagenopathies", mutational analysis by standard techniques (DHPLC, HRM and/or direct Sanger sequencing), represent a very expensive and exhausting test. We therefore switched to a method coupling amplicon based gene capture to continue both the *COL2A1/ COL11A1* analysis and we are now extending the study

to less frequently mutated genes (*COL11A2*, *COL9A1-2*): this innovation has improved our analysis' reliability and turnaround times.

P04.11-S
About skeletal dysplasia patients carrying two Col2a1 mutations

M. Barat-Houari[1], *B. Dumont*[1], *A. Fabre*[1], *P. Blanchet*[1], *G. Baujat*[2], *V. Cormier-Daire*[3], *M. Le Merrer*[3], *D. Genevieve*[1], *I. Touitou*[1];
[1]*CHRU, Montpellier, Montpellier, France,* [2]*Hôpital Necker-Enfants, Paris, France,* [3]*INSERM U781, Paris, France.*

Background and objectives: Skeletal dysplasia are usually dominant disorders due to heterozygous mutations in COL2A1 mutations. To report on four cases carrying two COL2A1 mutations.
Methods: Bidirectional Sanger sequencing of the whole COL2A1 gene.
Results: Four patients carrying two different mutations were identified in a series of 136 skeletal dysplasia.
Patient 11 carried a p.Thr1439>Met paternal allele and a de novo c.1267-2A>G. This latter may explain that she presented with a more severe form of Kniest dysplasia than her affected father. The p.Ala145Val, predicted as benign, might not be contributive, as the p.Gly405Asp alone was shown associated with SEDC (Meredith SP, 2007). The association of p.Arg137His and p.Gly213Val seems to induce a different phenotype than previously observed in a patient carrying a heterozygous p.Gly213Val (Kannu M, 2011).
Conclusion: We report here the first cases of COL2A1 skeletal dysplasia with either compound heterozygous (recessive) or complex alleles. Recessive forms of type 2 Stickler syndrome were previously associated with COL11A1 (Richards AJ, 2013). Parents' samples from families 41, 47, and 49 are under evaluation to phase the mutations and define whether they are de novo.

Congenital myopathy disorders (CMDs) are heterogeneous inherited diseases of muscle characterized by a range of distinctive histologic abnormalities. We have studied a consanguineous family with a non progressive congenital myopathy. In order to pursue a molecular diagnosis in this family, we performed genotyping on four patients, their parents and a healthy sibling using the Affymetrix GeneChip Human SNP5 array. We determined the genotype calls by using Affymetrix GeneChip Genotyping Analysis Software (GTYPE) and KinSNP software. Based on the consanguinity in the family, we hypothesized homozygosity by descent of a recessive mutation as the likely cause of the disorder. Therefore, we searched for homozygous regions consistent with linkage. Three homozygous blocks (on chromosomes 6, 10 and 14) shared by the three affected individuals, heterozygous in the parents, and not homozygous in the unaffected sib were identified. Exome sequencing revealed a highly suggestive mutation in a gene not previously reported to be associated with myopathy in humans. The variation segregated as expected in the family, it did not appear in dbSNP, evs or the 1000 genome project, nor was it found in 134 Bedouin control individuals.

Diagnostics of connective tissue disorders: NGS gets the target when clinics wanders around

A. Maugeri, *D. van Beek, M. Smit, I. Bakker, J. Egthuijsen, Y. Waterham de Vries, R. Straver, G. Pals, E. A. Sistermans, Q. Waisfisz, M. M. Weiss;*
VU University Medical Center, Amsterdam, Netherlands.

Introduction Next-generation sequencing (NGS) offers a valuable tool for the diagnostics of connective tissue disorders (CTDs), in view of the large size of most of the genes involved and the complex spectrum of, often overlapping, phenotypes, which makes differential diagnosis difficult. Recently, we designed a platform for the targeted analysis of CTDs, including Marfan syndrome, Ehlers-Danlos syndrome, Osteogenesis imperfecta, Stickler syndrome and related disorders. In total, 42 genes were included. Based on the associated phenotypes, six gene panels were defined. **Material and methods** A solution-based target enrichment kit was designed to capture all exons and flanking splice sites of 42 genes. Data were analysed using an in-house pipeline (based on freely available software) and Cartagenia. In total, 309 gene panels were analysed on 290 patients referred to our Diagnostics. The aortic/arterial aneurysms/dissections and the Ehlers-Danlos syndromes were the most requested gene panels (90%). **Results** (Likely) pathogenic mutations were identified in 14.5% of the patients. In most of these patients DNA findings confirmed the clinical diagnosis or were in line with the proposed differential diagnosis. Altogether, NGS strongly facilitated pinpointing the correct diagnosis. Importantly, in a few cases NGS led to a different diagnosis, which had not been considered based on clinical presentation. **Conclusions** The CTDs-NGS platform offers advantages in terms of time-efficiency, in view of the complex spectrum of phenotypes and the difficult differential diagnosis. This methodology helps preventing misdiagnosis, especially in young patient with incomplete phenotypic expression. The clinical phenotype of certain CTDs will possibly expand in the future.

Functional role of the Bardet Biedl Syndrome-associated gene 9 in the pathogenesis of nonsyndromic craniosynostosis: disrupted primary cilium in craniofacial ossification

M. Barba[1], *C. Cicione*[1], *M. C. Geloso*[1], *F. Pignotti*[2], *L. Massimi*[2], *F. Michetti*[1,3], *G. Tamburrini*[2], *M. Caldarelli*[2], *C. Di Rocco*[2], *C. Bernardini*[1], **W. Lattanzi**[1,3];

Sagittal craniosynostosis (sNSC) is a highly prevalent craniofacial malformation, with a widely unclear etiopathogenesis. A possible involvement of the BBS9 gene, encoding a protein located in the transition zone of the primary cilium, has been proposed as a result of the first GWAS carried out in 2012. Through microarray genome-wide expression profiling we have shown an altered expression of cilium-associated genes, including BBS9, in calvarial tissues and cells of sNSC patients. We aimed at investigating the role of BBS9 in the aberrant osteogenic phenotype of calvarial cells isolated from sNSC patients, through gene expression analysis, immunofluorescence, gene silencing, and differentiation assays. BBS9 expression was significantly upregulated in cells isolated from fused sutures (syn-cells) compared to cells isolated from matched patent sutures (control cells), and increased upon 5 days of osteogenic induction. Confocal microscopy showed that: syn-cells produced less primary cilia compared to control cells; BBS9 expression was spread throughout the cytoplasm in syn-cells, while appeared organized in polarized structures surrounding the cilium basal body in control cells. Upon BBS9 silencing in syn-cells, the expression of osteo-specific transcription factors (RUNX2 and OSX), and of SMO (key molecule of the hedgehog pathway), were significantly down-regulated. The osteogenic potential of BBS9-silenced syn-cells decreased and reverted to the physiological behaviour observed in controls. Our results suggest a functional involvement of BBS9 and primary cilium signalling, in the aberrant osteogenic signalling occurring at the site of premature suture closure in sNSC, proving a possible novel role of this molecular machinery in osteogenesis and craniofacial malformations.

Cuore, Rome, Italy,* [4]*Azienda Ospedaliero-Universitaria Policlinico di Bari - Inst. Genetica Medica, Bari, Italy.*

Craniosynostosis (CRS) represent the most prevalent craniofacial malformation, occurring in 1 out of 2500 livebirths, either as an isolated feature

(nonsyndromic CRS) or in complex phenotypes. A genetic basis can be found in 20-30% cases of complex CRS, with extremely high heterogeneity. The aim of this study is to describe the inventory of structural chromosomal aberrations identified through cytogenetic and molecular cytogenetic testing (as a part of the diagnostic algorithm) in a sample of complex CRS patients. The possible role of the genes involved in the genomic rearrangements in CRS etiopathogenesis have been investigated in vitro, using gene expression analysis, immunofluorescence and gene silencing assays, on calvarial stem cells isolated from CRS patients.
In our center we have enrolled 253 patients affected by CRS, including 13 cases with complex phenotypes that did not resemble any clear known syndrome. In 9 out of 13 cases, standard cytogenetics and array CGH allowed evidencing a chromosomal structural mutation, encompassing. multiple alternative genomic loci (2p, 9q, 2q, 22q, 8q, 9, 10, 5, 17, and 7p, among others). Genes involved in craniofacial development have been mapped to those loci enabling a biological interpretation of the abnormalities. In particular, the role of developmental genes involved in the structure and function of the primary cilium has been demonstrated in selected cases.

P04.16-M
The prostaglandinE2-pathway as a key player in the pathogenesis of non-syndromic craniosynostosis

C. Cicione[1], M. Barba[1], L. Massimi[2], G. Tamburrini[2], G. Di Taranto[1], F. Michetti[1,3], M. Caldarelli[2], C. Di Rocco[2], **C. Bernardini**[1], *W. Lattanzi[1,3];*

The etiopathogenesis of midline nonsyndromic craniosynostosis remains still largely unclear. We attempted to clarify this issue using microarray comparative gene expression profiling. Among the differentially expressed genes, we focused particularly on the hydroxyprostaglandin dehydrogenase (HPGD) gene, which encodes the prostaglandin E-2 (PGE2) catabolizing enzyme, whose pathway is known to be involved in osteogenic differentiation. Mutations in this gene result in primary autosomal recessive hypertrophic osteoarthropathy and craniosteoarthropathy. Total RNA and calvarial cells were isolated from calvarial specimens of both sutures and synostoses of NSC patients, collected during surgery. RNA was used for exon-level microarray analysis; gene expression and alternative splicing events were confirmed using real time PCR and RT-PCR. For functional validation, calvarial cells isolated in primary culture were treated with scalar concentrations of PGE2; after 10 days of treatment cells were alternatively lysed to extract RNA or stained with Alizarin Red to analyze osteogenic differentiation. Gene expression profiling allowed the identification of 114 significantly modulated genes and 150 alternatively spliced genes, including HPGD. Exon level analysis of HPGD revealed that the gene encoding the active isoform of the enzyme was significantly downregulated in synostosis-derived tissues. Upon PGE2 treatment, cells isolated from synostoses displayed a higher amount of osteogenic differentiation compared to patent suture-derived cells, as a result of the reduced HPGD levels. The results of this study may provide the original description of an impairment in the PGE2-signaling pathway in the pathogenesis of premature suture fusion in NSC patients. Translational implications may further derive from these data.

P04.17-S
Single-gene testing and Next Generation Sequencing in a Dutch cohort of syndromic craniosynostosis patients

J. A. C. Goos, *S. M. A. Swagemakers, A. J. M. Hoogeboom, A. M. W. van den Ouweland, M. F. van Dooren, P. J. van der Spek, I. M. J. Mathijssen;*
Erasmus MC, University Medical Center, Rotterdam, Netherlands.

Introduction According to literature, the genetic cause of craniosynostosis can be identified in approximately 24% of the patients. Often, mutations are found in *FGFR2*, *FGFR3* and *TWIST1*. But mutations are also identified in many other genes (like *IL11RA*, *TCF12* and *ERF*). Those genes can be sequenced all in parallel by Next Generation Sequencing (NGS), leading to more complete diagnostics. **Methods** Syndromic craniosynostosis was defined as multisuture or unicoronal synostosis, familial craniosynostosis, or as craniosynostosis in combination with other congenital malformations and/or mental retardation. According to protocol, these syndromic craniosynostosis patients were tested by single-gene testing for mutations in *FGFR2*, *FGFR3*, and *TWIST1*. If these genes tested negative, other genes were analyzed if applicable. In addition, a subgroup of 8 families (15 patients, 11 clinically unaffected relatives) and 8 isolated patients were sequenced by NGS and checked for mutations in known craniosynostosis genes. **Results** Of our patient cohort, 705 patients were tested by single-gene testing. Mutations were found in 280 patients. By NGS, mutations were identified in *TCF12* (1 patient, 1 unaffected carrier, 1 relative), *IL11RA* (1 patient, 2 relatives), *ZIC1* (three patients, 1 relative) and in *IDS* (1 isolated patient). **Conclusion** By single-gene testing, mutations were identified in only 15% of the syndromic craniosynostosis patients. Possibly, because the group of tested patients was defined differently, but also because only a subset of genes was tested. By NGS of a small cohort, mutations were identified in additional genes in 6/23 patients, illustrating the power of parallel sequencing.

P04.18-M
CYLD and Brooke-Spiegler syndrome: mutations in Hungarian patients, a review of published variants and a database update

N. Nagy[1], *K. Farkas[2], K. Tripolszki[1], A. Sulák[1], L. Kemény[3], M. Széll[1];*
[1]University of Szeged, Dept of Medical Genetics, Szeged, Hungary, [2]University of szeged, Dermatological Research Group of the Hungarian Academy of Sciences, Szeged, Hungary, [3]University of Szeged, Dept of Dermatology and Allergology, Szeged, Hungary.

Brooke-Spiegler syndrome (BSS; OMIM 605041) is an autosomal dominant condition characterized by skin appendageal neoplasms including cylindromas, trichoepitheliomas, and/or spiradenomas. In 2000, the gene locus for BSS was mapped to 16q12-13, and, in the same year, variants of the cylindromatosis gene (CYLD) were identified in BSS, familial cylindromatosis (FC; OMIM 132700) and/or multiple familial trichoepithelioma type 1 (MFT1; OMIM 601606). The gene codes for an enzyme with deubiquitinase activity. To date, a total of 81 different disease-causing mutations have been published for the CYLD gene. A summary of recurrent mutations identified in Hungarian patients and a review of published mutations is presented in this update. Comparison of clinical features in affected families with the same mutation strongly confirms that identical mutations of the CYLD gene can give rise to different phenotypes, making genotype-phenotype correlations difficult. Variable expression of the phenotype associated with the same CYLD mutation may reflect the influence of other genetic and/or environmental factors. Most mutations are frameshift (43%), nonsense (24%), splicing (16%) and missense ones (12%), but there are some reported rare variants as well (5%). The vast majority of the mutations (99%) are located between exon 9-20, which encodes the 3rd Cap-Glycin and the ubiquitin-specific protease domains of the CYLD protein, suggesting that these domains are important for CYLD deubiquitinating activity.
This research was supported by the European Union and the State of Hungary, co-financed by the European Social Fund in the framework of TÁMOP-4.2.4.A/ 2-11/1-2012-0001 'National Excellence Program'.

An atypical form of progressive extreme heterotopic calcification in a patient with a de novo insertional translocation der(X)ins(X;2)(q26.1;p13.3)

E. Flex[1], *E. Giorgio[2], M. Silengo[3], C. Defilippi[4], E. Di Gregorio[5], C. Bracco[2,5], E. Belligni[3], E. Biamino[3], G. B. Ferrero[3], R. C. Hennekam[6], M. Tartaglia[1], A. Brusco[2];*
[1]Dipartimento di Ematologia, Oncologia e Medicina Molecolare, Istituto Superiore di Sanità, Roma, Italy, [2]Dipartimento di Scienze Mediche, Università di Torino, Torino, Italy, [3]Dipartimento di Scienze della Sanità, Pubblica e Pediatriche, Università di Torino, Torino, Italy, [4]Dipartimento di Radiologia, AO Città della Salute e della Scienza, Torino, Italy, [5]A.O. Città della Salute e della Scienza, S.C.D.U. Medical Genetics, Torino, Italy, [6]Department of Pediatrics and Clinical Genetics, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands.

We report on a girl with widespread, rapidly progressive ectopic calcifications detected shortly after birth. Calcifications became present around most joints, involving tendons and ligaments, but no internal organs or skin, and eventually caused almost complete immobility of the child at 2 years. Laboratory evaluation failed to identify autoimmune disorders as well as calcium metabolism or other biochemical abnormalities; molecular studies did not identify any mutation in disease genes known to be involved in ectopic calcifications. Further analysis identified a de novo insertional translocation (IT). Array-CGH analysis showed a 2p13.3 duplication which was validated by qRT-PCR. Fluorescence in situ hybridization (FISH) confirmed the rearrangement, a der(X)ins(X;2)(q26.1;p13.3). The two breakpoints were characterized at nucleotide level by inverse PCR. The duplication on chromosome 2 encompassed nine coding genes, seven completely duplicated and two (ANTXR1 and MXD1) partially duplicated. ANTXR1 is interrupted in IVS10; the MXD1 coding sequence is maintained, but its 3'-UTR is almost completely lost. The chromosome 2p13.3 duplication is inserted into a gene desert on chromosome Xp26.1, between ARHGAP36 and IGSF1 genes. We suggest the phenotype in our patient is due to a likely gain of function mechanism. We hypothesize that the de novo insertional translocation causes a fusion transcript or an altered regulation of a gene by position effect. Further studies are in progress to identify the pathogenic mechanism triggering this unique phenotype.

P04.20-M
An 8-year-old Iranian girl with the FKBP14- related form of the Ehlers-Danlos syndrome with severe myopathy, scoliosis but normal hearing

A. Kariminejad[1], *C. Fauth*[2], *B. Bozorgmehr*[1], *M. Witsch-Baumgartner*[3], *J. Zschocke*[4], *M. H. Kariminejad*[1], *M. Rohrbach*[5], *G. Guinta*[5];
[1]*Kariminejad Najmabadi Pathology and Genetics Center, Tehran, Islamic Republic of Iran,* [2]*Division of Human Genetics, Innsbruck Medical University, Innsbruck, Austria;, Innsbruck, Austria,* [3]*Division of Human Genetics, Innsbruck Medical University,, Innsbruck, Austria,* [4]*Division of Human Genetics, Innsbruck Medical University, Innsbruck, Austria,* [5]*Connective Tissue Unit, Division of Metabolism and Children's Research Centre (CRC), University Children's Hospital, Zurich, Switzerland.*

Recently mutations in *FKBP14* have been identified in patients with a novel variant of Ehlers-Danlos syndrome (EDS) characterized by progressive kyphoscoliosis, myopathy and hearing loss (MIM #614557). This disorder shares many clinical features with the kyphoscoliotic type of EDS (EDS VIA; MIM 225400) such as congenital hypotonia, progressive kyphoscoliosis, hyperelastic skin and hypermobility of joints. However, there are also some distinctive features like myopathy and hearing loss. While an increased ratio of urinary lysyl pyridinoline (LP) to hydroxylysyl pyridinoline (HP) is diagnostic for EDS VIA, measurement is normal in patients with EDS caused by mutations in *FKBP14*.
Here we report on an 8-year-old girl born to first cousin parents, who presented with severe congenital hypotonia, psychomotor retardation, severe muscle weakness, progressive scoliosis, severe joint hypermobility of fingers, wrists and toes, soft skin, easy bruising, bilateral clubfoot, prominent heel and pes planus, normal hearing, nasal speech and dysarthria. Because of a suggestive clinical history by absence of hearing impairment our initial clinical diagnosis was EDS VIA, but normal LP/HP in urine ruled out this condition. Therefore we sequenced *FKBP14* and detected a novel homozygous c.143T>A substitution in exon 1 causing a p.Met48Lys mutation. Hearing loss, was consistently reported in the initial cohort of patients with this novel form of EDS, in whom nonsense mutations were found. It is compelling to hypothesize that absence of hearing impairment in our patient might reflect a partial loss of function of FKBP14 caused by the identified p.Met48Lys missense mutation, thus suggesting a possible genotype-phenotype correlation.

Zebrafish modeling of β3GalT6-deficient Type of Ehlers-Danlos Syndrome Stresses the Importance of Glycosaminoglycans in Development

T. Van Damme[1], *D. Syx*[1], *S. Symoens*[1], *S. Vanhauwaert*[1], *A. Willaert*[1], *S. Fournel-Gigleux*[2], *A. De Paepe*[1], *F. Malfait*[1];
[1]*Center for Medical Genetics Ghent University Hospital, Gent, Belgium,* [2]*UMR 7365 CNRS-Université de Lorraine (IMoPA), MolCelTEG Team, Biopôle UL, Faculté de Médecine, Vandoeuvre-lès-Nancy, France.*

Proteoglycans are important components of cell plasma membranes and extracellular matrices. They are composed of glycosaminoglycan (GAG) chains attached to a core protein through a tetrasaccharide linker region. The addition of the third residue in this linker is catalysed by galactosyltransferase II (β3GalT6), encoded by B3GALT6.
We recently identified bi-allelic mutations in B3GALT6 in several individuals from independent families with a severe autosomal recessive pleiotropic connective tissue disorder characterized by skin fragility, delayed wound healing, joint hypermobility and contractures, muscle hypotonia, intellectual disability and a spondyloepimetaphyseal dysplasia with bone fragility and severe kyphoscoliosis. To characterize the function of β3GalT6 we employed zebrafish as an in vivo model. Whole mount in situ hybridization of zebrafish embryos showed high b3galt6 expression levels in brain, retina, pharyngeal arches and notochord epithelium, corresponding to tissues that are affected in the human patients. A morpholino-based approach was used to characterize the developmental effects of b3galt6 knockdown in zebrafish embryos. Complete knockdown of b3galt6 is lethal, but partial knockdown results in an abnormal pharyngeal cartilage phenotype and a notably reduced head and eye size. These morphological changes were accompanied by a significant reduction in the total amount of sulfated GAG chains.
In conclusion, our results emphasize a crucial role for β3GalT6 in GAG synthesis and development. Ongoing and future experiments aim to extensively analyze the changes in GAG composition as well as to further characterize the way in which these changes impact embryonic development of e.g. cartilage and heart using different fluorescent transgenic reporter lines.

Familial vascular Ehlers-Danlos syndrome caused by a mutation in *COL5A1*

A. F. Baas[1], *G. Monroe*[1], *M. Harakalova*[1], *v. Saskia*[1], *D. Majoor-Krakauer*[2], *A. Bertoli-Avella*[2], *F. Moll*[1], *A. Vink*[1], *D. Dooijes*[1], *A. Maugeri*[3], *G. Pals*[3], *I. Nijman*[1], *E. Cuppen*[1], *N. Knoers*[1], *G. van Haaften*[1];
[1]*UMC Utrecht, Utrecht, Netherlands,* [2]*Erasmus MC, Rotterdam, Netherlands,* [3]*VUMC, Amsterdam, Netherlands.*

Different forms of Ehlers-Danlos Syndrome (EDS) exist, with specific phenotypes and genes associated. Vascular EDS, caused by mutations in *COL3A1*, is characterized by a fragile vasculature with a high risk of catastrophic vascular events at young age. Classic EDS, characterized by fragile, hyperextensible skin and joint laxity, is caused by mutations in *COL5A1* and *COL5A2*. To date, vessel rupture in four unrelated classic EDS patients with a confirmed *COL5A1* mutation was reported.
In the current report, we describe a familial form of clinically vascular EDS, diagnosed in a mother and her two sons, who all three died at an early age from arterial ruptures. Diagnostic Sanger sequencing failed to detect a *COL3A1* mutation in the eldest son, our index case. Next, our probands DNA was analyzed using a next-generation sequencing approach targeting approximately 550 genes (possibly) linked to vascular disease (VASCULOME project). This revealed a heterozygous pathogenic mutation in *COL5A1*, resulting in an essential glycine substitution in the triple helix domain, nearby the C-terminus of the protein (c.4610G>T; p.Gly1537Val). This novel mutation was present in DNA isolated from autopsy material of his brother. No autopsy material was available from the mother, but the mutation was excluded in her parents, siblings and in the father of her sons, suggesting that the *COL5A1* mutation occurred in the mother's genome de novo.
This is the first describtion of familial vascular EDS with a pathogenic mutation in *COL5A1*. We conclude that this mutation can give a similar vascular EDS phenotype as a *COL3A1* mutation.

Dermatan 4-O-sulfotransferase 1 (D4ST1)-deficient Ehlers-Danlos syndrome (DDEDS), caused by recessive loss-of-function mutations in CHST14, is a recently delineated form of EDS [Dündar et al., 2009; Malfait et al., 2010; Miyake et al., 2010; Kosho et al., 2011], characterized by a unique set of clinical features consisting of progressive multisystem fragility-related manifestations (skin hyperextensibilty and fragility, progressive spinal and foot deformities, large subcutaneous hematoma) and various malformations (facial features, congenital multiple contractures). Multisystem connective tissue fragility is caused by impaired assembly of collagen fibrils through loss of dermatan sulfate (DS) replaced by chondroitin sulfate in the decorin glycosaminoglycan sidechains. Complete loss of DS in patients' urine suggests systemic loss of DS to be the basis of the disorder. Because the patients suffer from progressive multisystem fragility-related complications, appropriate disease modeling is indispensable in view of developing etiology-based therapy. In this study, we report phenotypic features of knockout (Chst14-/-) mice. Frozen sperm from Chst14+/- male mice were obtained from the Mutant Mouse Regional Resource Center, Chst14+/- mice were reproduced, and Chst14-/- mice were generated. Complete loss of DS in urine from Chst14-/- mice was demonstrated, suggesting these mice to reflect glycobiological abnormalities in DDEDS. Chst14-/- mice lacked congenital multiple contractures, but showed perinatal lethality, reduced postnatal weight gain, mild facial asymmetricity, thoracic kyphosis, and reduced grip power and skin tenacity, compared with Chst14+/+ or Chst14+/- mice. These features could be therapeutic targets for etiology-based therapy such as AAV vector-mediated gene therapy.

Metacarpal 4-5 fusion (MF4; MIM%309630) is a rare congenital malformation of the hand characterized by the partial or complete fusion of the 4th and 5th metacarpals. The anomaly occurs either as an isolated trait or part of a genetic syndrome. Recently, using whole exome sequencing (WES), we have uncovered the genetic cause of isolated MF4. WES was performed on samples form a single trio of Polish ethnicity, i.e. sporadic male proband presenting with isolated MF4 and his unaffected parents. The study revealed a nonsense mutation (c.C535T; p.R179X) in exon 3 of the FGF16 gene, which maps to chromosome Xq21.1. The result was than confirmed by Sanger sequencing. The link between FGF16 gene mutations and MF4 was further supported by the identification of two other truncating FGF16 mutation in two unrelated male probands. Sanger sequencing showed that one index case carried a nonsense mutation (c.C470A; p.S157X), whereas the other harbored a truncating frameshift variant (c.474_477del; p.E158DfsX25). Two out of three mothers of the probands were available for testing. Upon assessment, they were clinically and radiologically unaffected and both carried FGF16 heterozygous mutations. All of the FGF16 disease-causing variants identified by us were located in the last exon (exon 3) of the gene, therefore they are unlikely to result in a nonsense mediated decay. Our study shows that truncating mutations of FGF16 are associated with X-linked recessive metacarpal 4-5 fusion and provides evidence for the involvement of FGF16 in the fine patterning of the human skeleton of the hand.

Giant cell tumor of bone (GCT) is an aggressive bone tumor caused by the uncontrolled proliferation of the spindle-like stromal cells which promote osteoclast-like giant cells formation responsible for the osteolitic lesions. A recent study showed that GCT is due to recurrent somatic mutations in *H3F3A* gene in the stromal cells. We analysed a cohort of giant cell tumor of bone for the presence of H3F3A mutations identifying somatic mutations in 38 out of 44 cases (86%). In contrast, the analysis of patients with Paget's disease of bone (PDB) associated with giant cell tumor did not show any mutation in *H3F3A* gene, at both somatic and germline level, suggesting a different genetic background. We recently reported an extended Italian family in which 4 out of 14 PDB affected members developed multiple GCTs at pagetic skeletal sites. Clinically, all affected members had polyostotic PDB, but subjects developing giant cell tumors showed an increased disease severity with a reduced clinical response to bisphosphonate treatment and an increased prevalence of bone pain, deformities, and fractures. Whole exome sequencing, in this family identifies a missense mutation in a novel uncharacterized gene. Additional genetic analysis in 7 independent affected patients with the same clinical phenotype, discloses the same mutation in all patients, strongly suggesting that this clinical phenotype is due to a founder effect. Therefore, we conclude that the GCT phenotypes associated or not with PDB are due to mutations in different genes, suggesting that different molecular signatures are responsible for these two phenotypes.

Nonsyndromic cleft lip with or without cleft palate (nsCL/P) is one of the most common congenital malformations worldwide and considered to be of multifactorial etiology. NsCL/P shows considerable phenotypic variability and can be subdivided into nonsyndromic cleft lip only (nsCLO) and nonsyndromic cleft lip and palate (nsCLP).

Genome-wide and replication studies have recently led to the identification of 15 nsCL/P susceptibility loci. However, a number of additional genetic risk factors still await elucidation. Here we used data from a recent genome-wide meta-analysis (Ludwig et al. 2012, Nature Genetics) and combined these with results from an independent European trio cohort (n=793). Integration of subgroup-information on nsCLO or nsCLP revealed rs1258763 on chr. 15q13 as a novel genome-wide significant locus associated with nsCLP (P=1.04×10-08). The associated region maps in intergenically, between the Gremlin-1 (GREM1) and Formin-1 (FMN1) genes. GREM1 is a known antagonist in bone-morphogenetic-protein pathways which are relevant to craniofacial genesis. Sequencing the entire GREM1 coding region in 196 patients and 196 controls did not reveal a causal variant, however, a significant overrepresentation of rare variants within patients was observed (P=0.02). Analyses of murine Grem1 expression during embryonic craniofacial development might suggest a functional role of Grem1 in lip and secondary palate formation. Notably, the top variant rs1258763 has previously been shown to influence variation in facial morphology (Boehringer et al. 2011, EJHG, Liu et al. 2012, PloS Genetics).

Our results demonstrate that increasing sample sizes and precise phenotypic information might help identifying further risk loci for genetically complex traits.

P04.27-S

Study of clinical and mutational findings in 45 Russian families with ectodermal hypohidrotic dysplasia

T. B. Milovidova, *A. V. Polyakov;*

Research centre for medical genetics, Moscow, Russian Federation.

Ectodermal dysplasia is a group of syndromes involving abnormalities of the ectodermal structures and is comprised of more than 150 different forms. This work is devoted to hypohidrotic ectodermal dysplasia (HED). Main causes of HED are mutations in three genes: EDA, a ligand that belongs to the tumor necrosis factor (TNF)-α family, EDAR, a receptor related to the TNFα receptors, and EDARADD, a specific adaptor.

The study cohort consisted of 45 Russian patients with HED was performed by us, using direct sequencing of coding region EDA gene and MRC-Holland MLPA kit for search of large deletion in EDA, EDAR and EDARADD genes.

In result EDA gene mutations were found in 76% (34 patients) of cases. Twenty new allelic variants of HED were described by us. Repeating mutations are revealed, but the analysis of the polymorphic markers linked to EDA gene showed absence of the founder effect. Large deletion in EDAR and EDARADD genes aren't found. No correlations were revealed between clinical features and specific mutations within a EDA gene.

We present the first in Russia large hypohidrotic ectodermal dysplasia cohort focusing on clinical manifestations in combination with mutational analysis.

Different genetic defects in four females with characteristic features of Incontinentia Pigmenti

C. W. Ockeloen[1], *K. Dreesen*[2], *R. Pfundt*[1], *K. Devriendt*[3], *A. H. Van der Hout*[4], *T. Kleefstra*[5], *C. E. M. Carels*[6];

[1]*Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands,* [2]*Department of Oral Health Sciences and Orthodontics, University Hospitals KU Leuven, Leuven, Belgium,* [3]*Centre of Human Genetics, University Hospitals Leuven, Leuven, Belgium,* [4]*Department of Genetics, University Medical Center Groningen, Groningen, Netherlands,* [5]*Radboud University Medical Center, Nijmegen, Netherlands,* [6]*epartment of Orthodontics and Craniofacial Biology, Radboud University Medical Center, Nijmegen, Netherlands.*

Introduction *IKBKG/NEMO* gene mutations are a well-known cause of Incontinentia Pigmenti (IP), an X-linked dominant neuroectodermal disorder (OMIM #308300). IP is characterized by characteristic skin lesions and ectodermal, ocular and central nervous system features. We collected four female patients with a clinical IP phenotype to study their molecular and phenotypical features.

Methods Direct genomic PCR using primers in the *NEMO* gene was used

to test for the classical exon 4-10 deletion. Sequence analysis of *NEMO* was performed using standard Sanger sequencing. X-inactivation was measured using a methylation-sensitive restriction enzyme. An Affymetrix Cytoscan HD array was used to detect copy number variations (CNVs) according to the manufacturer's protocol.

Results The classical *NEMO* exon 4-10 deletion was detected in one patient and her mother. In another patient, a 130 kb interstitial gain in chromosome 17q25.3 was identified, containing five genes (*CD7, SECTM1, GPR14, TEX19* and *OGFOD3)*. There was no skewed X-inactivation. The fourth patient was not molecularly investigated.

Discussion We show four female patients with a clinical IP phenotype and different genetic defects. *NEMO* deletions impair NF-kB activation, causing IP cells to be highly sensitive to apoptosis. Interestingly, a novel 130 kb gain of chromosome 17q25.3 was identified in another patient, including *SECTM1*. *SECTM1* is shown to induce IFN-γ production *in vitro*; IFN-γ stimulates apoptosis. We hypothesize that a dosis effect, caused by the *SECTM1* duplication, induces cell death and thereby causes IP. This finding suggests heterogeneity of IP and supports the role of apoptotic pathway CNVs in this disorder.

Infantile Systemic hyalinosis (ISH) is a severe rare autosomal recessive inheritance disease characterized by accumulation of amorphous, hyaline material in skin and other organs. It leads to skin lesions, gingival hypertrophy, flexion contractures of the joints, digestive tract and lymph node impairment with severe phenotypes in newborns. Beginning within the first few months of life, it is characterized by painful joints, generalized skin thickening, papules, periorificial nodes, hyperpigmentation over the joints, osseous nodes, failure to thrive. This disorder is progressive and usually leads to death, due to recurrent chest infections and diarrhea, before two years of age. The diagnosis is made by histology on skin biopsy showing hyaline deposits. Deleterious mutations have been reported in Capillary Morphogenesis Gene-2 (*CMG2*) alias Anthrax Toxin Receptor 2 (*ANTRX2*). *CMG2/ANTRX2* (4q21) is composed of 16 exons and the mutations reported in several families with ISH mostly concern exons 13 to 15. We report the causal mutations in 9 families found using Sanger sequencing. Mutations were found in 6 affected newborns, 22 relatives, among them 6 foetus with 6 homozygote mutations, 1 composite heterozygote and 1 associated to a supposed deletion. The 8 different mutations found will be described. 5 of them are non-sens mutations and 3 are 1-2 base(s) deletions or duplications leading to frameshift, Half of them are unknown in literature with 3 mutations in exon 1 and 10 and 1 between intron 8 and exon 9 affecting splicing. There is no treatment for this severe disease and the prenatal diagnosis is available.

P04.30-M

Whole-exome sequencing identifies a TTN mutation in a multiplex family with inguinal hernia

E. Mihailov[1], *T. Nikopensius*[1], *A. Reigo*[1], *C. Nikkolo*[2], *M. Kals*[1], *K. Aruaas*[3], *L. Milani*[1], *H. Seepter*[2], *A. Metspalu*[1,3];

[1]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [2]*Surgery Clinic, Tartu University Hospital, Tartu, Estonia,* [3]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia.*

Inguinal hernia repair is one of the most frequently performed gastrointestinal surgical procedures. Over 700,000 groin hernias are repaired annually both in the United States and Europe. Males are seven times more likely than females to develop a hernia and have a 27% lifetime risk of developing an inguinal hernia. Risk factors that have been associated with developing inguinal hernias include male gender, aging, pulmonary disease with chronic cough, and other conditions that cause constant increase of intra-abdominal pressure. Connective tissue disorders, such as Ehlers-Danlos and Marfan syndromes, and systemic collagen subtype imbalances have also been associated with increased risk of hernia. Furthermore, several studies have demonstrated that a positive family history is an important risk factor for the development of primary inguinal hernia.

The aim of this study was to investigate a multiplex Estonian family with inguinal hernia in four generations. Whole-exome sequencing was carried out in three affected family members and subsequent mutation screening using Sanger sequencing was performed in 8 family members (five affected and three unaffected). A heterozygous missense mutation p. Lys29627Thr was identified in the highly conserved A-band of the titin gene (*TTN*). The mutation co-segregated with the disease in the family, and was not present in 875 ethnically matched control subjects.

Sibs with microdeletion in maternal 14q32.2 and phenotype congruent to paternal isodisomy 14

I. M. van der Werf[1], *E. Reyniers*[2], *M. Mattheij*[2], *P. Vanhaesebrouck*[3], *P. Govaert*[4], *J. Martin*[1], *J. G. Leroy*[5], *F. Kooy*[1], **G. R. Mortier**[2];

[1]*University of Antwerp, Antwerp, Belgium,* [2]*University of Antwerp and Antwerp University Hospital, Antwerp, Belgium,* [3]*Ghent University and Hospital, Ghent, Belgium,* [4]*ZNA Queen Paola Childrens' Hospital, Antwerp, Belgium,* [5]*Ghent University, Ghent, Belgium.*

A girl born to healthy non-consanguineous parents and her three-year-younger brother showed at birth moderate to severe respiratory insufficiency which required long-term tracheostomy in the boy. Both neonates were large with plump facial features, narrow thoracic cage with radiographic bell-shaped configuration. Diastasis of the abdominal wall musculature and signs of distal arthrogryposis were mild in the girl and pronounced in the boy. Neuromotor development was delayed with independent walking achieved at 18 months and at 5½ years respectively. The mild intellectual disability in the boy, who has persisting contractures at the wrists and ankles, may be correlated with bouts of therapy-resistant hypoxia during the NICU admission of six months duration. At night he still needs mechanical support with airflow.

The clinical and radiographic pattern in both sibs was compatible with paternal UPD 14. However, an imprinting defect was ruled out using microsatellite marker analysis. Recently, the lady's complaints about long lasting respiratory infections and physical tiredness prompted reexamination of this family. SNP array analysis using an Illumina Cyto-SNP 12v2.1 chip detected a microdeletion on chromosome band 14q32.2 in both sibs. The deletion with a minimal size of 64 kb encompasses the lncRNA genes MEG3 and MEG8 and several miRNAs. Each of these genes is subject to maternal imprinting. The mother is mosaic for the same microdeletion. Molecular analysis regarding exact size, gene content and degree of methylation is ongoing and bound to contribute to more insights into the disease mechanisms involved in this imprinted region.

P04.32-M

Increased frequency of F5 and F2 thrombophilia predisposing variants in families with unilateral limb reduction defects - a pilot study

A. Jamsheer[1,2], **M. Socha**[1], *E. Olech*[1], *A. Sowińska-Seidler*[1], *A. Latos-Bieleńska*[1,2];

[1]*Department of Medical Genetics, Poznan University of Medical Sciences, Poznan, Poland,* [2]*NZOZ Center for Medical Genetics GENESIS, Poznan, Poland.*

Limb reduction defects (LRDs) are usually unilateral and affect 8 newborns per 10000 livebirths. Several authors hypothesized that vascular accidents may account for a substantial proportion of LRDs, however the basis of such events in the fetus remains unknown. Over the past two decades, a number of genetic thrombophilia risk factors (TRFs) have been identified and associated with the increased risk of peri/postnatal occlusive disease and with a higher rate of pregnancy loss. Mutations c.G1691A(p.R506Q) in F5 and c.*97G>A in F2 genes represent one of the most commonly tested genetic TRFs. In this study, a cohort of 45 proband-mother pairs, in which the child manifested unilateral LRDs, was recruited for the analyses. The patients were clinically evaluated and blood of the probands and their mothers was subjected to both F5 and F2 testing. We found either F2 or F5 heterozygous variant (or both) in 6 mothers (13.3%) and in 4 probands (8.9%). At least one individual carried a single (or both) mutation(s) in seven proband-mother pairs (15.6%). Within this group one proband and one mother carried both mutations. F5 and F2 are identified in a control population with the frequency of about 1-2%. Based on our findings, we hypothesize that there is an excess of genetic TRFs in probands affected by unilateral LRDs and in their healthy mothers in comparison with control population. This may contribute to the higher risk of antenatal vascular accidents and consequently to LRDs. Further studies based on bigger samples are needed to support our findings.

Homozygous Ala529Val LMNA Mutation in Patients with Mandibuloacral Dysplasia in a Turkish family

L. Özer[1], *E. Ünsal*[2], *V. Baltaci*[3], *S. Aktuna*[1], *Ö. Ayvaz*[3], *F. Akyiğit*[4], *P. Çelikkol*[4], *A. Şen*[5], *S. Balcı*[6];

[1]*Mikrogen Genetic Diagnosis Center, Ankara, Turkey,* [2]*İstanbul Bilim University*

Medical School, Department of Histology and Embryology, İstanbul, Turkey, [3]İstanbul Bilim University Medical School, Department of Medical Biology and Genetics, İstanbul, Turkey, [4]Genart IVF Center, Ankara, Turkey, [5]Ufuk University Medical School, Department of Medical Biology and Genetics, Ankara, Turkey, [6]Hacettepe University Medical School, Department of Pediatric Genetics, Ankara, Turkey.

Mandibuloacral dysplasia is a rare autosomal recessive disorder characterized by acroosteolysis, hyperpigmentation, mandibular and clavicular hypoplasia, bird-like facies with beaked nose and prominent eyes, delayed closures of the cranial sutures and joint contractures. Homozygous Arg527His and Ala529Val mutationS in LMNA gene are previously reported in MAD patients with type A lipodystrophy. Ala529Val (c.1586 C>T) missense mutation resulting in substition of alanin with valine may distrupt the formation of salt bridge between arginine 527 and glutamate 537. Mutant lamin A and C proteins alters the nuclear envelope, chromatin organisation and effects the cellular processes.

Here we report a Turkish family with MAD. The proband was 36 years old male and the first child of consanginous parents who have 3 children. He had acroosteolysis, hyperpigmentation, mandibular and clavicular hypoplasia, beaked nose,joint contractures .Aunt of the proband has also detected as MAD with consangineous parents. LMNA gene Exon 9 sequencing revealed homozygous Ala529Val LMNA mutation in affected persons of this family. Proband's parents are also detected as carrier for Ala529Val LMNA mutation and the other family members were detected with normal genotype.

Previously homozygous Ala529Val mutation in patients with MAD was first reported by Garg et al. Up to date our study was the second report about patients with homozygous Ala529Val mutation. Molecular studies of MAD patients will help to determine the genotype-phenotype correlation, variability of phenotypic expressivity of mutations and molecular basis of disease.

P04.34-M

A combined workflow for FBN1 mutation detection using next generation and Sanger sequencing methods

K. Koczok, *L. Madar, É. Oláh, G. P. Szabó, K. Szakszon, G. Pfliegler, I. Balogh; University of Debrecen, Debrecen, Hungary.*

Marfan syndrome is an autosomal dominant disorder of connective tissue with skeletal, ocular and cardiovascular system involvement. Sequencing of the fibrillin-1 (FBN1) gene has a 70-90% mutation detection rate in patients with Marfan syndrome. The goal of this study was to establish a diagnostic workflow for rapid and reliable mutation detection in the FBN1 gene.

Exons and flanking regions of the FBN1 gene were amplified in 65 amplicons using published and newly designed primers. Our workflow was based on the followings: 1) exons containing homopolymer regions (n=16) were tested by Sanger sequencing method because of the well known high error rate of pyrosequencing-based next-generation sequencing (NGS) in such regions, 2) all other amplicons were sequenced using NGS (Roche GS Junior), where coverage criterion was above 40x. Pathogenic mutations detected by NGS method were confirmed by Sanger sequencing.

Eleven families (15 patients) were tested with a mutation detection rate of 8/11 unrelated patients. 7 missense (6 of them affecting cystein residues) were found and one base pair deletion causing frameshift. 5 novel mutations were detected.

By combining NGS and Sanger sequencing methods reliable diagnostic workflow could be established for Marfan syndrome.

P04.35-S

Melorheostosis and *LEMD3* related sclerosing bone diseases: clinical, radiological and molecular characterization of an Italian series

M. Gnoli[1], *E. Pedrini[1], L. Campanacci[2], M. F. Bedeschi[3], A. Wischmeijer[4], G. Tortora[4], F. Gurrieri[5], A. Percesepe[6], M. Tremosini[1], L. Sangiorgi[1];*

[1]Department of Medical Genetics and Skeletal Rare Diseases, Rizzoli Orthopaedic Institute, Bologna, Italy, [2]Department of Muscular-Skeletal Oncology, Rizzoli Orthopedic Institute, Bologna, Italy, [3]Medical Genetics Unit,Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy, [4]Department of Medical Genetics, Policlinico Sant'Orsola-Malpighi, University of Bologna, Bologna, Italy, [5]Medical Genetics Institute, Università Cattolica del Sacro Cuore, Rome, Italy, [6]Medical Genetics Unit, Modena University, Modena, Italy.

Melorheostosis is an uncommon, relatively benign, sclerosing bone disease, characterized by long bones hyperostosis, resembling flowing of candle wax. Skin and subcutaneous tissue can be involved. The disease may be asyntomatic (incidental X-ray diagnosis, finding of the typical hyperostosis pattern) or cause pain, joint stiffness or deformity. Melorheostosis is sporadic and pathogenesis is largely unknown. Occasionally in the same family we observe individuals with melorheostosis and osteopoikilosis, disease characterized by multiple round foci of increased bone density. *LEMD3* gene mutations have been revealed in osteopoikilosis and Buschke-Ollendorff Syndrome (BOS), an association of skin lesions, as connective tissue naevi, and osteopoikilosis or melorheostosis. Sporadically *LEMD3* mutations have been identified in Melorheostosis. Recently it has been suggested that *LEMD3* mutation somatic mosaicism cause Melorheostosis. Most reports describe single cases or are focused on orthopedic management; only few and small series have been reported in medical literature and molecular analysis data are available only for few patients. We present clinical and radiological information of 23 patients with Melorheostosis (14), BOS (2), osteopoikilosis (3) or with findings of similar disease (4). Among patients with isolated melorheostosis until now analyzed, none has *LEMD3* germline mutation. Instead, we identified mutations in all BOS patients and in 2/3 patients with osteopoikilosis. No mutation has been identified in cases with unclear diagnosis. These results confirm literature data, indicating that *LEMD3* germline mutations are not a major cause of isolated melorheostosis and are mainly associated to BOS or osteopoikilosis. Further studies are needed to understand molecular bases of Melorheostosis.

P04.36-M

Intragenic deletion of the FBN1 gene in a child with mildly dilated aortic sinus: a retrotransposal event

M. S. Brett, *G. Korovesis, A. Lai, E. Lim, B. Cham, E. Tan; KK Women's & Children's Hospital, Singapore, Singapore.*

Marfan syndrome (MFS), an autosomal dominant connective tissue disorder, is mainly due to fibrillin 1 (*FBN1*) gene mutations. MFS primarily affects the skeletal, ocular and cardiovascular systems. The vast majority of MFS cases are caused by point mutations in *FBN1* with only 1-2% due to large deletions. Transposons are abundant in the human genome and retrotransposons have been reported to cause disease by inserting into genes. We describe the detection of an intragenic *FBN1* deletion by chromosomal microarray analysis (CMA) in a child with mildly dilated aortic sinus. Breakpoint sequencing showed that the deletion was due to a SVA retrotransposition. The child was first seen at 4 years of age. Echocardiogram showed a mildly dilated aortic sinus. He had a history of muscular VSD (closed spontaneously) and trivial mitral regurgitation. Phenotypes include frontal bossing, anteverted ears, pink striae and joint hyperlaxity. He also had a learning disability and attention deficit. CMA with an Agilent 1M array detected a 36 kb deletion at 15q21.1 which is predicted to result in a deletion of exons 7-9 of the *FBN1* gene. Long range PCR confirmed the deletion of exons 7-9 of the *FBN1* gene and the insertion of a MAST2 SVA transposon. CMA confirmed a diagnosis of MFS in a child who had a few MFS clinical symptoms but who did not fulfil the Ghent criteria. This diagnosis will enable appropriate surveillance, patient management and genetic counselling. To the best of our knowledge, this is the first report of MFS caused by retrotransposition.

P04.37-S

Panel-based Next Generation Sequencing - a powerful diagnostic tool for patients with genetic skin diseases

K. Reicherter[1], *A. C. Russ[1], T. Scheurenbrand[1], A. Sprecher[1], F. Battke[1], N. Günther[1], P. Itin[2], K. Kernland-Lang[3], K. Hoertnagel[1], J. Lemke[4], S. Biskup[1];*

[1]CeGaT GmbH, Tübingen, Germany, [2]Department of Dermatology, University Hospital Basel, Basel, Switzerland, [3]Department of Dermatology, University Hospital, Inselspital, Bern, Switzerland, [4]Division of Human Genetics, University Children's Hospital, Inselspital, Bern, Switzerland.

Purpose: Genetic skin diseases (genodermatoses) represent a broad and heterogeneous spectrum of mainly rare conditions. Overlapping phenotypes additionally often hamper clear clinical diagnosis and straightforward genetic testing. As a precise genetic diagnosis is crucial for counseling of patients regarding the course of the disease, prognosis, recurrence risk, and therapeutic approach, we have developed a diagnostic panel based on Next Generation Sequencing (NGS).

Method: 241 genes were selected from the OMIM database and literature. After customized target enrichment, NGS was performed using the HiSeq 2500 platform (Illumina), followed by bioinformatics analysis. Variants with minor allele frequencies < 5 % were selected for further investigation. Validation of relevant variants was performed using Sanger sequencing.

Results: We subdivided the genodermatoses panel according to the most relevant phenotypes, e.g., ichthyosis, epidermolysis bullosa, ectodermal dysplasia, connective tissue defects, dyskeratosis congenita, albinism, and skin disorders associated with malignancy. In a pilot study we have identified clear pathogenic mutations within the genes *ALOX12B*, *TP63*, *PLOD1*, and *ABCC6*. The preliminary data indicate high detection rates: in 22 % of the cases we identified clearly pathogenic mutations, in 33 % likely pathogenic variants were detected, and 44 % remained unsolved. **Conclusion:** We have developed a comprehensive panel based diagnostic NGS tool for diagnosing genetic skin diseases. This highly reliable and very cost-efficient diagnostic panel enables us to molecularly diagnose patients with clinically heterogeneous and also very rare skin diseases. Furthermore, it contributes to a better understanding of genotype-phenotype correlations.

P04.38-M
Neurofibromatosis type 1 and Legius syndrome: differential molecular diagnosis in children

C. Santoro[1], *T. Giugliano*[2], *S. Strianese*[1], *C. Pisano*[2], *M. D'Arco*[1], *F. Del Vecchio Blanco*[2], *S. Perrotta*[1], *V. Nigro*[2], *G. Piluso*[3];
[1]*Dipartimento della Donna, del Bambino e di Chirurgia Generale e Specialistica, Seconda Universita' degli Studi di Napoli, Napoli, Italy,* [2]*Dipartimento di Biochimica, Biofisica e Patologia Generale, Seconda Universita' degli Studi di Napoli, Napoli, Italy,* [3]*Dipartimento di Biochimica Biofisica e Patologia Generale, Seconda Universita' degli Studi di Napoli, Napoli, Italy.*

Neurofibromatosis type 1 (NF1) and Legius syndrome (LS) are autosomal dominant disorders caused by germline mutations in *NF1* or *SPRED1* gene respectively. The NF1 phenotype partially overlaps the most benign of LS that can be just molecularly distinguished. Appearance of typical NF1-features, like neurofibromas and Lisch nodules, is age-related thus pigmentary manifestations (cafè-au-lait macules and/or freckling) can be the only clinical sign of NF1 in early childhood, making difficult to distinguish NF1 and LS. The occurrence of serious NF1-complications (i.e. MPNST, brain gliomas) emphasizes the usefulness of an early differential diagnosis. To address a proper diagnosis, we applied a specific clinical workflow and a comprehensive genetic test in a cohort of 149 children. Pigmentary manifestations were considered as the main sign combined with presence of typical NF1 features and/or affected first-degree, and with the age at medical examination. 128 (85.9%) had a clinical diagnosis of NF1. For 17 (11.4%) NF1 vs LS was undistinguishable and 4 (2.7%) had a diagnosis of familiar occurrence of pigmentary manifestations. A causative mutation was found in 122/128 patients (95.3%) confirming NF1 clinical diagnosis. 11 patients with ambiguous diagnosis carried *NF1* mutations (64.7%), 2 carried *SPRED1* mutations (11.8%). Among those thought to be LS, 3 had mutation in *SPRED1* (75.0%), one in *NF1* (25.0%). Children with just NF1 pigmentary manifestations would be clinically followed for long time waiting the age-related appearance of most typical features. Thus an early molecular diagnosis might be very useful, considering that the milder LS phenotype require a less intensive follow-up.

P04.39-S
Clinical description of NF1 patients and motivations to perform the genetic test

S. Miccoli, *A. Wischmeijer, M. Gnoli, M. Seri, D. Turchetti;*
U.O. Genetica Medica, Policlinico Sant'Orsola-Malpighi, Bologna, Bologna, Italy.

Diagnosis of Neurofibromatosis I (NF1) is typically based on clinical criteria, with genetic testing being performed only in a fraction of cases. We reviewed the records of NF1 patients referred to our clinic to explore what factors may have conditioned the choice to undertake genetic testing.
Among 100 consultants attending for a family/personal history of NF1 in the period December 2002 to December 2013, clinical data were available for 94 patients: 68 patients satisfied the criteria for the clinical diagnosis of NF1 and in 44 of these (65%) NF1 gene analysis were performed, leading to mutation detection in 26 cases (60%). Tested patients differed from untested patients by median age at diagnosis (12 versus 23 years) and number of criteria satisfied (≥3 in 75% of tested and 30% of untested), while the rate of familial cases did not differ between the two groups (27% among tested, 26% of non-tested). Moreover, the rate of patients tested has increased in the years, from the 33-50% in the period 2003-2005 to the 50-100% of patients tested in the period 2006-2013. In conclusion, genetic testing was more likely to be undertaken in patients diagnosed in childhood and in those with a more severe phenotype, especially in recent years. Indeed NF1 analysis is demanding but has been improved across the years, which makes genetic test now more accessible.

P04.40-M
Tyrosinase gene mutations in Chinese Han population with OCA1

K. Xiang-dong, *L. Ning, S. Hui-rong, W. Qing-hua;*
the First Affiliated Hospital of Zhengzhou University, Zhengzhou, China.

Background/Aims: Oculocutaneous albinism (OCA) is a heterogeneous autosomal recessive genetic disorder which affects melanin synthesis. OCA results in reduced or absence of pigmentation in the hair, skin, and eyes. Type 1 OCA (OCA1) results from tyrosinase (*TYR*) gene mutation and is a severe disease type. This study investigated *TYR* mutations in a Chinese cohort with OCA1. **Methods:** This study included two parts: patient genetic study and prenatal genetic diagnosis. Thirty OCA1 patients were subjected to analyze *TYR* gene mutation. Ten pedigrees were included for prenatal genetic diagnosis. One hundred unrelated healthy Chinese individuals were characterized for controls. The coding sequence and the intron/exon junctions of *TYR* were analyzed by bidirectional DNA sequencing. **Results:** Twenty mutations were identified, four of which were novel. In these thirty OCA1 patients, twenty-five patients were *TYR* compound heterozygosity; two patients carried homozygous *TYR* mutations and three were heterozygous. Among the ten prenatal diagnostic fetuses, three fetuses carried compound heterogeneous mutations; seven carried no mutation or only one allele mutation in *TYR* and appeared normal at birth. **Conclusion:** We identified four novel *TYR* mutations and showed that molecular based prenatal screening to detect *TYR* mutation in a fetus at risk for OCA1 provided essential information for genetic counseling of at risk couples.

P04.41-S
Oligodontia segregating with a 7p21.2p21.1 ~1 Mb duplication in an Italian family with three affected siblings

E. Di Gregorio[1,2], *E. Grosso*[1], *M. C. Amione*[1], *G. D'Alessandro*[1], *A. Carbone*[1], *M. C. Paradiso*[1], *T. Scopacasa*[1], *P. Pappi*[1], *F. Talarico*[1], *A. Brusco*[1,2], *C. Bracco*[1,2];
[1]*S.C.D.U. Medical Genetics, Città della Salute e della Scienza, Turin, Italy,* [2]*Department of Medical Sciences, University of Turin, Turin, Italy.*

We report on a 60 yrs. patient with short stature (< 2nd centile), spontaneous eruption of 7 teeth only, fusion of C1 to C4 vertebrae with partial occipito-atlantal fusion. Two of her seven siblings presented oligodontia. Standard chromosome analysis in the proband showed a mosaic karyotype 45,X[3]/46,XX[27], which may relate with the short stature. Array-CGH (60K, Agilent Technologies) showed a ~1 Mb duplication encompassing chromosome 7p spanning eight genes (*ISPD, SOSTDC1*, *LRRC72*, *ANKMY*, *TSPAN13*, *AGR2* and *AGR3*): (arr[hg19] 7p21.2p21.1(15,926,980x2,15,99 4,233-17,074,396x3,17,222,770x2). Real-time PCR on available members showed the duplication segregated in the two siblings with oligodontia, but it was absent in one healthy sister. We hypothesize that oligodontia is associated with the duplication of *SOSTDC1* (OMIM* 609675), which is a member of the sclerostin family. The protein acts as a bone morphogenetic protein (BMP) antagonist. Mice overexpressing Sostdc1 have a reduced number of teeth, whereas *Sostdc1*$^{-/-}$ show an increased number of teeth number and anomalies in teeth morphology. The gene has been demonstrated to antagonize Wnt signaling in mice. Interestingly, *WNT10A* mutations have been associated with oligodontia in humans. In conclusion, we speculate that the duplication of *SOSTDC1* at chromosome 7p21.2p21.1 may increase its protein level leading to oligodontia in our family. *SOSTDC1* could be a new candidate gene to be screened in isolated oligodontia.

P04.42-M
Identification of a novel regulatory variant in *OPTN* in familial cases of Paget's disease of bone

S. Wani, *S. H. Ralston, O. M. E. Albagha;*
University of Edinburgh, Edinburgh, United Kingdom.

Paget's disease of bone (PDB) is a common bone disease with strong genetic component. Previous studies have identified a PDB-susceptibility locus on chr10p13 tagged by rs1561570 which is located within the *OPTN* gene (Albagha *et al, Nat Genet* 2011). *OPTN* encodes a protein that plays a role in multiple cellular processes including autophagy and NF-KB signalling but its role in bone metabolism is yet unclear. Here we investigated the 10p13 locus by targeted DNA sequencing of a 650kb region surrounding the rs1561570 which includes seven genes. A total of 260 samples were sequenced including unrelated cases and controls, 60 familial cases and controls. All cases were negative for *SQSTM1* mutations. Target capture was performed using Haloplex kit followed by DNA sequencing using the illumina Hiseq2000 platform. Variants passing quality control measures were filtered to include only rare coding (MAF<0.01 in 1000Genome) or regulatory variants (as predicted by ENCODE). No disease-specific missense mutations were detected in any of the seven genes located in this region including *OPTN*. However, we identified a novel rare variant located in the *OPTN* promoter which was found to alter NF-KB transcription factor binding site. This novel variant had a high call quality (Q>4200, read depth >150) and was not present in the public databases including 1000 genomes and showed transmission from an affected father to an affected daughter and the unaffected mother did not carry this mutation. In conclusion our data suggest that rare regulatory variants within OPTN influence PDB susceptibility.

Evaluating susceptibility loci for nonsyndromic cleft lip with or without cleft palate in the Arabic population: Analysis of 15 risk loci in a new case-control sample recruited in Yemen

E. Mangold[1], *A. Böhmer*[1,2], *K. Aldhorae*[3], *A. Esmail*[4], *N. Al-Hebshi*[5], *B. Lippke*[1,2], *L. Gölz*[6], *M. Nöthen*[1,2], *N. Daratsianos*[6], *M. Knapp*[7], *A. Jäger*[6], *K. Ludwig*[1,2];
[1]*Institute of Human Genetics, University of Bonn, Bonn, Germany,* [2]*Department of Genomics, Life and Brain Center, University of Bonn, Bonn, Germany,* [3]*Orthodontic of Department, College of Dentistry, Thamar University, Thamar, Yemen,* [4]*Cleft Lip and Palate Center, College of Dentistry, University of Aden, Aden, Yemen,* [5]*Molecular Research Laboratory, Faculty of Medical Sciences, University of Science and Technology, Sana'a, Yemen,* [6]*Department of Orthodontics, University of Bonn, Bonn, Germany,* [7]*Institute of*

Medical Biometry, Informatics and Epidemiology, University of Bonn, Bonn, Germany.

Nonsyndromic cleft lip with or without cleft palate (nsCL/P) has a genetically complex etiology. In recent years, several genome-wide significant susceptibility loci for nsCL/P were identified, most of them by genome wide association studies. However, most studies have been performed in populations from Europe and Asia, and few data are available concerning genetic susceptibility to nsCL/P in Arabic populations. The present study investigated a newly recruited nsCL/P sample from Yemen. Twenty-four single nucleotide polymorphisms (SNPs) representing all 15 currently known nsCL/P risk loci were genotyped in 242 nsCL/P cases and 420 healthy controls. Single marker association analysis revealed significant associations for four loci (8q24, 9q22, 10q25, 13q31). The strongest association was for the European high risk locus at 8q24 ($P_{corrected}$ = 5.09x10^{-4}; heterozygous odds ratio (OR_{het}) = 1.74, 95% confidence interval (CI 95% CI) = 1.22-2.47, homozygous odds ratio (OR_{hom}) = 2.47, CI 95% = 1.55 - 3.93). Five additional loci (1q32.2, 3q12, 8q21, 17q22, 20q12) showed nominal significance that did not withstand correction for multiple testing. Two loci (1p36, 2p21) failed to reach nominal significance but displayed a trend towards association with $P < 0.1$. Although the four remaining loci (1p22, 3p11, 15q22, 17p13) failed to reach nominal significance, the risk alleles were in the same direction as in the discovery studies. Our results suggest that four of the 15 analyzed nsCL/P risk loci which were identified in European and Asian ethnicities significantly confer risk for nsCL/P in Arab populations.

P04.44-M

Defective proteolytic processing of fibrillar procollagens and other extracellular matrix proteins due to mutations in *BMP1* results in a severe form of Osteogenesis Imperfecta

D. Syx[1], *S. Symoens*[1], *A. Medeira*[2], *A. B. Sousa*[2], *T. Hermanns-Lê*[3], *P. Coucke*[1], *A. De Paepe*[1], *F. Malfait*[1];

[1]*Center for Medical Genetics, Ghent, Belgium,* [2]*Serviço de Genética, Hospital de Santa Maria, Lisboa, Portugal,* [3]*Department of Dermatopathology, University Medical Center of Liège, Liège, Belgium.*

Bone morphogenetic protein 1 (BMP1) is an astacin metalloprotease with manifold roles in morphogenesis and diverse substrates. Besides its role as procollagen C-proteinase for the major fibrillar collagens (types I, II and III) and its participation in N-propeptide removal of the minor fibrillar collagens (types V and XI), BMP1 is involved in the proteolytic trimming of multiple other substrates including a.o. small leucine-rich proteoglycans (e.g. decorin). Mutations in *BMP1* have recently been identified in three families with a severe, autosomal recessive form of osteogenesis imperfecta (OI). We report novel, bi-allelic mutations in two unrelated adult patients with severe OI, characterized by severe osteoporosis with numerous fractures, short stature with limb deformities and severe kyphoscoliosis. Biochemical analysis of secreted (pro)collagens showed defective type I procollagen C-propeptide processing. Immunofluorescent staining of type I and V collagen secreted by the patients' dermal fibroblast cultures showed a reduced and abnormal collagen deposition in the extracellular matrix (ECM). In addition, the reduced BMP1-activity was shown to result in deficient proteolytic trimming of decorin, an important regulator of collagen fibril organisation, leading to the retention of its propeptide. Ultrastructural analysis showed marked variability in collagen fibril diameter and uneven interfibrillar spaces. Overall, this indicates that BMP1 defects result in disturbed collagen deposition in the ECM. Besides the defective procollagen processing, it is likely that deficient cleavage of other BMP1 substrates contributes to abnormal ECM assembly and signalling, and as such to the phenotypic severity.

P04.45-S

Genotype-phenotype correlation in patients with dominant Osteogenesis Imperfecta

M. Maioli[1], *M. Gnoli*[1], *M. Celli*[2], *L. Sangiorgi*[1];

[1]*Istituto Ortopedico Rizzoli, Bologna, Italy,* [2]*Policlinico Umberto I, Roma, Italy.*

Osteogenesis Imperfecta (OI) is a rare genetic disorder of connective tissue that occurs in approximately one in 15000-20000 new born with mostly autosomal dominant inheritance caused by mutations in the type I collagen genes, COL1A1 and COL1A2. The clinical spectrum is strongly heterogeneous with a wide intrafamilial and interfamilial variability; a continuum ranging from nearly asymptomatic individuals with occasional fractures, normal stature and lifespan, to lethal phenotypes characterized by severe skeletal fragility, deformity and growth deficiency. Affected patients may also show blue sclerae, hearing deficit, dentinogenesis imperfecta, cardiac lesions and joint hyperlaxity.

Actually more than 1100 COL1A1/A2 distinct variants associated with dominant OI have been identified without hot spot regions; most of the mutations are glycine substitutions followed by splice site alterations and nonsense mutations. Despite the identification of many mutations, few genotype-phenotype correlation studies have been performed and there are no unambiguous and clear indications.

To evaluate whether the severity and specific clinical manifestations of disease are linked with a specific genetic background we performed a genotype-phenotype correlation study analyzing an Italian case study of 300 patients. All patients have a clinical and radiographic diagnosis of OI from mild to lethal perinatal forms, according with Sillence clinical classification. The presence of mutations in COL1A1/COL1A2 genes has been investigated using a molecular screening protocol with High Resolution Melting (HRM) and multiplex ligation-dependent probe amplification to detect either point mutations and big deletions-insertions.

P04.46-M

Osteogenesis imperfecta - a dominant mutation of COL1A2 gene c.964G>A causes in homozygote status more serious phenotype

J. Behunova, *F. Laccone, O. Brandau, H. Rehder;*

Institute of Medical Genetics, Medical University of Vienna, Vienna, Austria.

Osteogenesis imperfecta (OI) is a heterogeneous group of connective tissue disorders characterized by a predisposition to fractures and variable extraskeletal symptoms. Original classification distinguishes OI regarding clinical and RTG findings to OI types I-IV. Clinical manifestation of OI can result from mutations of minimal 12 various genes and in the most of OI cases (~90%) the mutations are identified in COL1A1- or COL1A2-gene. The mutations of these genes affect collagen type I synthesis (chains A1 and A2) and the vast majority of the mutations in these two genes follows AD pattern of inheritance.

We refer on a child from a consanguineous family (the parents are the first cousins) with clinical findings of OI type III-IV and molecular finding of homozygote pG322S mutation (c.964G>A). This mutation has been described only in heterozygote form, causing a mild form of OI - type I. The clinical features of 4,5 year-old boy represented a very low stature (18 cm below 3.Percentile), history of both femurs and upper arm fractures in early infancy, slight skeletal deformities and disproportions, inability to stand or walk without support, slightly blue scleras and dentinogenesis imperfecta. Mental status was age-appropriate.

Although the parents initially denied any health problems (both were 160 cm tall and healthy), after repeated questioning they admitted a history of possible femur and arm fractures in young age (the mother) and one fracture after fall (the father). The analysis confirmed heterozygosity for pG322S mutation in both parents.

P04.47-S

A novel mutation in IFITM5, encoding BRIL, impairs osteoblast production of PEDF and causes atypical type VI osteogenesis imperfecta

A. Reich[1], *C. R. Farber*[2], *A. M. Barnes*[1], *P. Becerra*[3], *F. Rauch*[4], *W. A. Cabral*[1], *A. Bae*[1], *F. H. Glorieux*[4], *T. L. Clemens*[5], **J. C. Marini**[1];

[1]*Bone and Extracellular Matrix Branch, NICHD, HIN, Bethesda, MD, United States,* [2]*Center for Public Health Genomics, Depts Public Health Sciences, Biochemistry & Mol Genet, UVA, Charlottesville, VA, United States,* [3]*Section on Protein Structure and Function, LRCMB, NEI, NIH, Bethesda, MD, United States,* [4]*Shriners Hosp for Children and McGill Univ, Montreal, QC, Canada,* [5]*Dept Orthopaedic Surgery, Johns Hopkins Sch Med, Baltimore, MD, United States.*

Osteogenesis imperfecta (OI) type V is caused by a recurrent dominant mutation (c.-14C>T) in *IFITM5*, which encodes BRIL, a transmembrane ifitm-like protein strongly expressed in osteoblasts, while type VI OI is caused by recessive null mutations in *SERPINF1*, encoding pigment epithelium-derived factor (PEDF). We identified a 25-year-old woman with severe OI, with normal serum PEDF but absent PEDF secretion by cultured osteoblasts. Her *SERPINF1* sequences were normal despite bone histomorphometry typical of type VI OI. Whole exome sequencing of the proband, parents and an unaffected sibling revealed a *de novo IFITM5* mutation in one allele of the proband, causing a p.S40L substitution in the BRIL intracellular domain. *IFITM5* expression was normal in proband fibroblasts and osteoblasts, as was BRIL protein level in proband osteoblasts on western blot and in permeabilized proband osteoblasts by microscopy. Notably, *SERPINF1* expression was decreased in proband osteoblasts and PEDF was barely detectable in conditioned media of proband cells. Expression and secretion of type I collagen was similarly decreased in proband osteoblasts, confirming this OI as collagen-related. Osteoblasts with the S40L mutation also had decreased expression of ALP and osteocalcin, as seen in primary PEDF defects. In contrast, osteoblasts from classical type V OI have increased *SERPINF1* expression and PEDF secretion during differentiation. These data suggest (1) that the type V OI and p.S40L BRIL are gain- and loss-of-function mutations, respectively, and (2) that BRIL and PEDF have a relationship that connects the genes for types V and VI OI and their roles in bone mineralization.

P04.48-M

A novel deletion mutation involving TMEM38B associated with autosomal recessive osteogenesis imperfecta.

E. Rubinato[1], *A. Morgan*[1], *A. D'Eustacchio*[2], *M. La Bianca*[2], *V. Pecile*[2], *G. Gortani*[2], *P. Gasparini*[1,2], *F. Faletra*[2];
[1]*University of Trieste, Trieste, Italy,* [2]*Institute for Maternal and Child Health - IRCCS "Burlo Garofolo", Trieste, Italy.*

Osteogenesis imperfecta (OI) is and hereditary bone disease characterized by decreased bone density and multiple fractures, usually inherited in an autosomal dominant manner. Recently several genes encoding proteins related to collagen metabolism have been described in some cases of autosomal recessive (AR) OI (like *CRTAP, LEPRE1, PPIB, FKBP65, SERPINF1, BMP1)*. More recently, *TMEM38B*, a gene involved in releasing of calcium from intracellular stores and in cell differentiation, has been associated with AR OI. We describe the second new deletion-mutation involving the *TMEM38B* gene in a 11 year-old Albanian female, born of apparently non consanguineous parents from the same small village, showing an OI clinical phenotype. Since molecular analysis of *COL1A1* and *COL1A2* genes were negative for the presence of causative mutations, a SNP array analysis was performed using the Illumina Infinium SNP genotyping platform (HumanOmniExpress - 12 chips and BeadStation Scanner) in order to detect regions of homozygosity encompassing genes known to be involved in AR OI. The analysis revealed one homozygous region larger than 2 Mb (chr9:107,793,426 - 109,935,841) overlapping with the *TMEM38B* locus and characterized by a 35 Kb homozygous deletion spanning from marker rs1567368 to rs9408800 and involving exons 1 and 2 of *TMEM38B* gene. A long PCR amplification confirmed this finding. Eventually, we postulated that the deletion was promoted by the presence of repeated sequences in the segments before and after the breaking points. Our finding contributes to expand the role of *TMEM38B*, thus supporting the role of deletions in generating this type of AR OI.

P04.49-S

High spontaneous osteoclastogenesis in pediatric osteogenesis imperfecta patients receiving and not receiving intravenous neridronate

M. F. Faienza[1], *R. Fischetto*[1], *A. Tummolo*[1], *L. Piacente*[1], *A. Ventura*[2], *L. Cavallo*[3], *F. Papadia*[4], *G. Brunetti*[5];
[1]*A.O.U.Policlinico Consorziale P.O.Giovanni XXIII, Bari, Italy,* [2]*Dipartimento di Scienze mediche di Base, Neuroscienze ed organi di senso, Sezione di Anatomia ed Istologia, Università di Bari, Bari, Italy,* [3]*Dipartimento di Pediatria; Ospedale Pediatrico Giovanni XXIII-Policlinico; Università di Bari, Bari, Italy,* [4]*U.O. Malattie Metaboliche e Genetica Medica; A.O.U.Policlinico Consorziale , Bari, Bari, Italy,* [5]*Dipartimento di Scienze Mediche di Base, Neuroscienze ed organi di senso, Sezione di Anatomia ed Istologia, Università di Bari, Bari, Italy.*

Background. Osteogenesis Imperfecta (OI) is a heritable disease of connective tissue characterized by abnormal bone mineralization and skeletal deformities. Objective. This study investigate the osteoclastogenic potential of unfractioned peripheral blood mononuclear cells (PBMCs) from OI patients (mean age 10,44+/- 3,48) who received cyclical neridronate infusions for at least 1 year, untreated OI patients and control subjects. **Methods.** PBMCs from 6 patients and 6 controls were cultured in presence/absence of M-CSF and RANKL. At the end of the culture period, mature multinucleated osteoclasts (Ocs) were identified as TRAP+ cells. By real time PCR we studied gene expression in freshly isolated PBMC. By flow cytometry we characterized the presence of OC precursors (CD14+/CD16+) and TNF-α expression. **Results.** Spontaneous OC formation, without adding M-CSF and RANKL, occurred in PBMC cultures from treated and untreated OI patients. In these patients, the percentage of circulating OC precursors, increased respect to the controls (12,5% vs 0,1%, p< 0,01). By real time PCR, we found high levels of RANKL, TNF-α and MSCF receptor, as well as decreased OPG levels, thus leading to the increase of RANKL/OPG ratio. High TNF-α levels were also found on monocytes through flow citometry. **Conclusion.** We showed for the first time the high osteoclastogenic potential of PBMCs from OI patients, treated and untreated with biphosphonate, which could be due to the high percentage of circulating OC precursors, to the elevated TNF-α levels as well as to the increased RANKL/OPG ratio. This condition could contribute to bone disease affecting these patients.

P04.50-M

Study of ATG2B and ATG16L1 polymorphisms in Spanish patients with Paget's disease of bone

V. Rivero[1,2], *R. Usategui*[3,2], *J. Del Pino*[4], *R. González*[2,1];
[1]*Centro de investigación del Cáncer, Salamanca, Spain,* [2]*Institute of Biomedicine Research (IBSAL), Salamanca, Spain,* [3]*Unidad de Medicina Molecular. Facultad de Medicina, Salamanca, Spain,* [4]*Department of Reumatology, Virgen Vega Hospital, Salamanca, Salamanca, Spain.*

Paget's disease of bone (PDB) it's a chronic skeletal disorder, that is characterized by abnormal resorption associated with inadequate remodeling, that leads to deformity of the bone. It's the second most common metabolic bone disease after osteoporosis and affects approximately 3% of the population over 40 years old and approximately 10% of those over the age of 85 years.

Missense and truncating mutations have been reported within the SQSTM1 gene (25–50% of familial and 5–10% of sporadic PDB patients) encoding the p62 protein. This protein has a crucial role as an assembly factor for autophagy, important for cell survival. Recent investigations showed that Microtubule-associated protein 1A/1B-light chain 3 (LC3) directly interacts with p62 via a newly identified LC3-interacting region (LIR), located between its ZZ and ubiquitin-associated UBA domains.

We studied the potential association of the two variants of autophagy-related gene (ATG), ATG2B (rs3759601) and ATG16L1 (rs2241880), in 292 patients with PDB and 192 controls, using the TaqMan® Pre-designed SNP-Genotyping Assay(Applied Biosystems).

We detected a significant association between genotype GG and PDB in the ATG2B polymorphism rs3759601 (p=0.004, OR=0.434; 95% CI=0.246-0.769). Moreover, we found a statistical significance between the T allele variant in ATG16L1 polymorphism rs2241880 (TT: p=0.000 OR=5,102 CI=2.853-9.123; CT: P=0.030 OR=2.821 CI=1.850-4.300)

In conclusion, these findings suggest that allele G of ATG2B polymorphism might contribute to increase risk in Paget's disease development and allele T of ATG16LB1 polymorphism may play a protective role in Paget's disease of bone in Spanish patients.

P04.51-S

Common variants at 20q11 influence skin color in Europeans

F. Liu[1], *M. Visser*[1], *D. Duffy*[2], *P. G. Hysi*[3], *L. Jacobs*[4], *O. Lao*[1], *K. Zhong*[1], *S. Walsh*[1], *V. L. C. Subramanyam Reddy*[1], *A. F. Ralf*[1], *G. Zhu*[2], *A. Hofman*[5], *A. G. Uitterlinden*[6], *R. T. S. Palstra*[1], *T. D. Spector*[3], *N. G. Martin*[2], *T. E. C. Nijsten*[4], *M. Kayser*[1];
[1]*Department of Forensic Molecular Biology, Erasmus University Medical Center Rotterdam, Rotterdam, Netherlands,* [2]*Queensland Institute of Medical Research, Brisbane, Australia,* [3]*Department of Twin Research and Genetic Epidemiology, King's College London, London, United Kingdom,* [4]*Department of Dermatology, Erasmus University Medical Center Rotterdam, Rotterdam, Netherlands,* [5]*Department of Epidemiology, Erasmus University Medical Center Rotterdam, Rotterdam, Netherlands,* [6]*Department of Internal Medicine, Erasmus University Medical Center Rotterdam, Rotterdam, Netherlands.*

We carried out a genome-wide association study (GWAS) on skin color in 6,000 Dutch Europeans followed by successful replications in thousands of Europeans from Australia and UK. We identified a total of five distinct genomic regions showing genome-wide significant association with continuous or categorical skin color phenotypes - all including known pigmentation genes: 5p13.2 SLC45A2; 6p25.3 IRF4; 15q13.1 OCA2 and HERC2; 16q24.3 MC1R; and 20q11.22 ASIP. The role of 20q11.22 in skin coloration has been much less clear than other genes/regions. In this large region (spanning ~ 1.5Mb), the top-associated DNA variant was rs6059655 (P=4.2e-13) in RALY. All other associated SNPs in this region were all in linkage disequilibrium with rs6059655 (r2>0.4). Among these are rs1885120 in MYH7B and rs910873 in PIGU that have been previously associated with risk of melanoma. Additional transcriptional analysis of 20 genes from 20q11.2 in 29 human skin epidermis samples highlighted RALY as well as other regional genes such as EIF2S2, ITCH and GSS with significant (P<0.01) expression differences between light and dark pigmented skin samples. A multivariate analysis highlighted 9 pigmentation genes (i.e. OCA2-HERC2, IRF4, SLC45A2, MC1R, RALY/ASIP, TYR, BNC2, SLC24A4, and SLC24A5 in a descending order) jointly explaining 16.3% phenotypic variance of perceived skin darkness in Europeans. The weighted allele sums showed a spatial pattern that is clearly correlated with latitude in Europe, but much less so in the rest of the world, suggesting that variants responsible for skin color variation between Asians and Africans are not included here.

P04.52-M

A spectrum of disorders are associated with somatic mutations in *PIK3CA*, encoding the p110α catalytic subunit of phosphatidylinositol-4,5-bisphosphate 3-kinase

V. E. R. Parker[1], *A. Luchetti*[1], *H. Martin*[1], *I. Isaac*[1], *M. J. Lindhurst*[2], *J. Sapp*[2], *K. Keppler-Noreuil*[2], *L. G. Biesecker*[2], *E. R. Maher*[1], *R. K. Semple*[1];
[1]*Cambridge University Hospitals NHS Trust, Cambridge, United Kingdom,* [2]*National Human Genome Research Institute (NHGRI)/NIH, Bethesda, MD, United States.*

Aim: Somatic activating mutations in *PIK3CA,* encoded by the p110α catalytic subunit of phosphatidylinositol-3-kinase (PI3K), have been identified in several different disorders of segmental overgrowth. PI3K is a critical mediator of cellular growth, survival and metabolism, and is frequently mutated in cancers. We assessed the prevalence of *PIK3CA* mutations in 40 patients with variable forms of mosaic overgrowth.

Methods: Screening of DNA derived from affected tissue was undertaken using a PCR-based target enrichment with the Ion AmpliSeq™ Cancer Hotspot Panel v2™, and sequenced on an Ion PGM platform. Exons 2,5,7,8,10,14,19 and 21 were screened, and the detection level was 5% at 1500x depth.
Results: We identified 20 patients with somatic variants in exons 8, 10 and 21 of *PIK3CA* exhibiting a range of clinical phenotypes. There were no reported cases of cancer or metabolic disturbance, and 1/3 of adult patients had minimally progressive disease from the third decade.
Discussion: Somatic activation of *PIK3CA* causes a diverse spectrum of disease, ranging from isolated digit enlargement to more extensive overgrowth of the limbs, abdomen, brain or blood vessels. The rate of malignancy appears to be low, although this will need to be substantiated in larger studies. In the future, identification of biomarkers to predict disease progression will provide critical prognostic information, whilst the possibility of therapy with inhibitors of the PI3K-AKT pathway warrants evaluation in clinical trials.

PRINS, the psoriasis susceptibility related non-coding RNA contributes to various aspects of cellular stress response

M. Szél[1], *A. Göblös*[2], *S. Bacsa*[2], *K. Szegedi*[2], *M. Antal*[3], *J. Danis*[2], *A. Dobozy*[2], *Z. Bata-Csörgő*[2], *L. Kemény*[2];
[1]*University of Szeged, Dept of Medical Genetics, Szeged, Hungary,* [2]*University of Szeged, Dept of Dermatology and Allergology, Szeged, Hungary,* [3]*Institute of Plant Biology, Biological Research Center of the Hungarian Academy of Sciences, Hungary, Szeged, Hungary.*

We identified PRINS (Psoriasis susceptibility Related non-coding RNA Induced by Stress) and showed that it is highest expressed in the psoriatic uninvolved epidermis. According to the results of in vitro experiments PRINS expression is induced by various stessors such as UVB, translation inhibition and microbial agents. It has been previously demonstarted by us and by others that keratinocytes of the psoriatic uninvolved epidermis possess an abnormal response to various stressors and respond with hyperproliferation. Therefore we aimed to understand how the altered expression of PRINS in the uninvolved epidermis contributes to the aberrant stress response of the keratinocytes thus to disease susceptibility. To this end we identified a chaperon protein, nucleophosmin (NPM) as a direct interacting partner of PRINS. We could demonstrate that UV-B irradiation induced the shuttling of NPM from the nucleolus to the nucleoplasm and silencing of the PRINS non-coding RNA in the UV-B-irradiated keratinocytes resulted in the retention of NPM in the nucleolus. These results suggest that PRINS is physically and functionally linked to NPM, thus it plays a role in the NPM-mediated cellular stress response. In an other set of experiments we have demonstrated that PRINS signals independently from the NF-kappaB signal trasduction pathway, however its expression was induced when the keratinocytes were treated with the inflammasome-activating poly(dA:dT).
Our results indicate that the PRINS non-coding RNA is part of a ribonucleo-complex. Its altered expression in psoriatic uninvolved epidermis could contribute to the well-established aberrant stress response of psoriatic keratinocytes and as a consequence to psoriasis susceptibility.

We describe a 40 years old man from Albania with clinically evident hematuria and proteinuria; renal function was normal. The peculiar renal CT findings were: small multiple calcifications at the cortical junction bilaterally. The pedigree analysis revealed two sisters affected by an unspecified skin disease; no consanguinity was reported in the family. The clinical genetic examination showed yellowish papules of the skin on the neck. The association of renal calcifications in a young patient with skin lesions and the recurrence of a skin disease in the family led us to take into account Pseudoxanthoma elasticum (PXE). Therefore an ocular examination looking for signs of the disease was performed and angioid streaks radiating from the peripapillary area without subretinal neovascularization signs were detected. Pseudoxanthoma elasticum (PXE), is a rare multisystem disease characterized by degeneration and calcification of elastic fibres and blood vessels. The causative gene is ABCC6, mapped on chromosome 16p13.1, which encodes an ABC transporter protein (ABCC6) expressed primarily in liver and the kidneys. Patients typically develop cutaneous, ocular, cardiovascular and gastrointestinal manifestations. The molecular analysis of the ABCC6 gene detected a homozygous deletion of exons 23-29 (del23_29); this is the most common deletion described in literature associated to PXE, resulting in a premature stop codon with loss of 505 amino acids of MRP6 protein. Although this renal pattern cannot be considered specific for the diagnosis of PXE, we recommend to test PXE when both renal and skin abnormalities are present in a patient.

P04.56-M
KIF3A is associated to arthopaty envolvement in psoriatic patients

R. Cascella[1], *M. Ragazzo*[1], *S. Zampatti*[1], *F. Diano*[1], *E. Galli*[2], *C. Strafella*[1], *C. Germani*[1], *F. Sangiuolo*[1], *G. Novelli*[1], *E. Giardina*[1,3];
[1]*Department of Biomedicine and Prevention, School of Medicine, University of Rome "Tor Vergata", Rome, Italy,* [2]*S. Pietro Fatebenefratelli Hospital, Rome, Italy, Rome, Italy,* [3]*Laboratorio di Genetica Molecolare UILDM, Fondazione Santa Lucia, Rome, Italy.*

Psoriatic arthritis (PsA, OMIM #607507) is a chronic inflammatory disorder presenting a highly heterogeneous phenotype and clinical course. PsA is a multifactorial disease associated with psoriasis, affecting the 30% of patients with psoriasis vulgaris (PsV).
Some genetic risk factors are specific for the arthropaty, other are shared with PsV (HLA-Cw*06:02, LCE, TNFα and TRAF3IP2). On this subject, different European studies have recently found several susceptibility genes, which are involved in the inflammatory and immunologic pathways of the disease.
To date, no associations between PsA and genes involved in bone metabolism have been observed. Thus we decided to screen a list of genes involved in bone metabolism and/or osteogenesis. We have carried out this screening in 429 PsA patients and 417 health, 380 PsV cases and 389 controls. A single nucleotide polymorphism rs2897442 (A/G) showed a significant association in PsA cases (p = 0.006; OR = 0.73, 95% CI 0.59-0.92). Interestingly , it is not associated to PsV but only in PsA. The rs2897442 is located in the 8th intron of KIF3A gene (5q21), which encodes for a kinesin II complex subunit required for the assembly of primary ciclia and involved in bone formation and in keratinocyte differentiation. Full resequencing of coding and regulatory regions failed to reveal evidence of further association. LD pattern does not reveal significant haplotypes associated to PsA. Immunohistochemistry analyses, as well as replication in an independent data set of patients, are expected to clarify the functional role of KIF3A in the pathogenesis and development of PsA.

P04.57-S
Spectrum of phenotypic anomalies in four families with deletion of the SHOX enhancer region

C. Palka[1], *V. Gatta*[2,3], *V. Chiavaroli*[1], *S. Franchi*[2], *S. Sperduti*[2,4], *L. D'Onofrio*[2,4], *M. D'Aurora*[2,4], *F. Chiarelli*[1], *A. Mohn*[1], *G. Palka*[1,5], *L. Stuppia*[2,3];
[1]*Department of Paediatrics, "G. d'Annunzio" University, Chieti, Italy,* [2]*Functional Genetics Unit, Center of Excellence on Aging, (Ce.S.I.), Chieti, Italy,* [3]*Department of Psychological, Humanities and Territorial Sciences, School of Medicine and Health Sciences, "G. d'Annunzio" University, Chieti, Italy,* [4]*Department of Neuroscience and Imaging, "G. d'Annunzio" University, Chieti, Italy,* [5]*Department of Oral Health and Biotechnological Sciences, School of Medicine and Health Sciences, "G. d'Annunzio" University, Chieti, Italy.*

SHOX alterations have been reported in 67% of patients affected by Léri-Weill dyschondrosteosis (LWD), with a larger prevalence of gene deletions than point mutations. It has been recently demonstrated that these deletions can involve the SHOX enhancer region, rather that the coding region, with variable phenotype of the affected patients.
Here, we report a SHOX gene analysis carried out by MLPA in LWD patients from 4 families with variable phenotype. All patients presented a SHOX enhancer deletion. In particular, a patient with a severe bilateral Madelung deformity without short stature showed a homozygous alteration identical to the recently described 47.5 kb PAR1 deletion. Moreover, we identified,

for the first time, in three related patients with a severe bilateral Madelung deformity, a smaller deletion than the 47.5 kb PAR1 deletion encompassing the same enhancer region (ECR1/CNE7).
Data reported in this study provide new information about the spectrum of phenotypic alterations showed by LWD patients with different deletions of the SHOX enhancer region.

P04.58-M
Sjögren-Larsson syndrome: molecular characterization of the first reported Cypriot families

G. Tanteles[1], *M. Nicolaou[1], N. Patsia[1], E. Leonidou[2], E. Spanou[1], T. Delikurt[1], T. Kyriakides[2], V. Christophidou-Anastasiadou[1,3];*
[1]The Cyprus Institute of Neurology & Genetics; Clinical Genetics Clinic, Nicosia, Cyprus, [2]The Cyprus Institute of Neurology & Genetics; Neurology Clinics, Nicosia, Cyprus, [3]MMC, Nicosia, Cyprus.

Sjögren-Larsson syndrome (SLS; MIM #270200) is a rare autosomal recessive disorder caused by deficient fatty aldehyde dehydrogenase (FALDH) activity. This reduction in enzymatic activity is secondary to bi-allelic mutations in the ALDH3A2 gene and results in impaired fatty alcohol oxidation and accumulation of fatty alcohols and related lipid products. SLS is typically characterized by pruritic ichthyosis, spasticity, intellectual disability and seizures. In the present study we report, for the first time in the Cypriot population, three apparently unrelated SLS patients. All three were homozygous for a CCC deletion at nucleotide 941 to 943 coupled with a 21 nucleotide 5'-GGGCTAAAAGTACTGTTGGGG-3' insertion (c.941-942delins21-bp). This genetic alteration, identified previously in two Caucasian patients, leads to the substitution of Ala314 and Pro315 to Gly and Ala, respectively, accompanied by the addition of six amino acids, Ala-Lys-Ser-Thr-Val-Gly (p.Pro315AsnfsX7).

P04.59-S
Next step in collagenopathies and osteodysplasies diagnosis: NGS Targeted re-sequencing

D. M. Valero-Hervás, *A. Romera-López, C. Camprubí, D. Cantalapiedra, L. Pérez-Cabornero, V. Felipe, G. Hernández, D. Diego, C. Buades, C. Collado, R. Rodríguez de Pablos, M. García-Ruíz, Ó. Rodríguez, S. Zúñiga-Trejos, J. Triviño, S. Santillán; Sistemas Genómicos S.L., Paterna, Valencia, Spain.*

Collagenopathies and osteodysplasies constitute a genetically heterogeneous group of diseases with low incidence, representing however an important health problem because patients require continuous specialized care, due to their deteriorating quality of life. The molecular diagnosis is essential to confirm clinical suspicion, but is not straightforward due to the high number of candidate genes. NGS targeted re-sequencing is a fast and cost-effective alternative to Sanger sequencing, as it can sequence all the genes involved in disease development.
We designed a NGS targeted re-sequencing panel for 229 genes associated with skeletal dysplasias, which spans 1.5Mb comprising coding exons, splice sites and 5' and 3' untranslated regions. Once panel was validated for diagnostic use testing HapMap cell lines, these regions were sequenced in 40 patients with clinical suspicion of these pathologies. Target regions were enriched and captured using the Enrichment SureSelect system (Agilent) and sequenced either with a SOLiD 5500 (Life Technologies) or MiSeq (Illumina) platform. Results were confirmed by Sanger sequencing.
The analysis identified 47 variants in 24 patients, of which 8 were classified as disease-causing and 4 as probably pathogenic. Both types of variants were either truncating mutations or glycine substitutions in collagen genes (essential for collagen structure). The identification of these mutations allowed the molecular diagnosis and an appropriate genetic counseling in affected families. Targeted re-sequencing is especially suited to highly heterogeneous diseases such as skeletal dysplasias, because it allows the identification of mutations in genes whose study by traditional sequencing would be difficult and expensive, increasing diagnostic time.

P04.60-M
Mutations in DNASE1L3 and familial SLE/Hypocomplementemic Urticarial Vasculitis Syndrome: the first italian case

G. Mancàno[1], *A. Carbonella[2], E. Gremese[2], G. Ferraccioli[2], F. S. Alkuraya[3], N. Patel[3], F. Gurrieri[1];*
[1]Università Cattolica del Sacro Cuore, Istituto di Genetica Medica, Rome, Italy, [2]Università Cattolica del Sacro Cuore, U.O. Reumatologia, Rome, Italy, [3]King Faisal Specialist Hospital and Research Center, Developmental Genetics Unit, Riyadh, Saudi Arabia.

Systemic lupus erythematosus (SLE) is a complex autoimmune disease that causes substantial morbidity. Much of the heritability of SLE remains unknown. Here we present the case of a patient who showed typical sign of an autoimmune disorder (recurrent febrile episodes, arthritis, skin lesions) at age 17. The clinical phenotype has worsened with age as many other symptoms appeared (asthenia, severe anemia, C3 and C4 decrease; urticarial dermatitis; microscopic hematuria, petechiae; glomerulonephritis; splenic strokes; interstitial pneumopathy, pulmonary hypertension; mesenteric ischemia). Interestingly, we also observed joint hyperlaxity with a peculiar apparent contractions of interphalangeal joints (manually extendable without difficulties). Familial history revealed parents' consanguinity; moreover, two other siblings were reported to show signs of an autoimmune disorder. Molecular analysis of *DNASE1L3* revealed the homozygous mutation c.289_290delAC (Thr97Ilefs*2), previously reported in three sisters, born from consanguineous parents and affected with HUVS (Hypocomplementemic Urticarial Vasculitis Syndrome). This is the first italian reported case of autosomic recessive SLE/HUVS caused by a mutation in *DNASE1L3* gene.

P04.61-S
Spondyloenchondrodysplasia in Brazilian patients with intrafamilial variability and a pattern of pseudo-dominance

D. P. Cavalcanti[1], *C. A. Moreno[1], T. Y. Kanazawa[1], C. O. Barbosa-Buck[1], C. Silveira[1], A. Superti-Furga[2], E. Lausch[3], S. Unger[2];*
[1]UNICAMP, Campinas, Brazil, [2]University of Lausanne, Lausanne, Switzerland, [3]Freiburg University, Freiburg, Germany.

Spondyloenchondrodysplasia (SPENCD) is an AR spondylometaphyseal dysplasia characterized by radiolucent spondylar and metaphyseal lesions, whose patients can also present neurological and immunological changes. It is caused by mutations in ACP5, a gene encoding the tartrate-resistant acid phophatase. Considering that just 24 individuals with mutations on this gene were described so far, and the great clinical heterogeneity of this condition, the unusual pattern of a new family prompted us to present these Brazilian patients. The proband is the third child of non-consanguineous parents. At birth he presented mild hydrocephalus, esophageal atresia without fistula, and absence of right kidney. None radiological evidence of skeletal dysplasia was present. At the age of 6 it was observed short stature (-3SD), mental retardation and skeletal changes compatible with SPENCD. Complementary investigations showed normal CGHa and sequencing of the TRPV4, no calcification in the CNS, and autoimmune hypothyroidism. The radiological evaluation of his sister (19 yo) and his maternal uncle (34 yo) due to mild disproportionate short stature showed similar aspect of the spine without, however, other skeletal involvement. The proband´s mother has vitiligo without skeletal changes. By direct sequencing of the ACP5 a homozygous mutation (c.791T>A) was identified in the proband, his sister and his maternal uncle. The parents were heterozygous. We conclude that the proband has a pattern of malformation not associated with the SPENCD diagnosis; unlike the metaphyseal, spine involvement seem to be permanent; the homozygosity strongly suggest a high inbreeding in this family, and the mother´s vitiligo could suggest a heterozygous manifestation.

P04.62-M
Identification of copy-number variations (CNVs) in patients affected by split hand/foot malformation (SHFM)

A. Sowińska-Seidler[1], *A. Jamsheer[1,2], A. Latos-Bieleńska[1,2];*
[1]Department of Medical Genetics, University of Medical Sciences, Poznań, Poland, [2]Center for Medical Genetics GENESIS, Poznań, Poland.

Split-hand/foot malformation (SHFM) refers to the group of congenital limb malformations characterized by the absence or hypoplasia of the central rays of the autopod, especially the digits but also the metacarpals and/or metatarsals. The malformation is clinically and etiologically heterogeneous. It often shows reduced penetrance and variable expressivity. SHFM occurs either as an isolated trait or part of a multiple congenital anomaly syndrome. The genetic origin of approximately 50% cases is still unknown. The main objective of this study was to identify submicroscopic genomic rearrangements in a group of 30 probands affected by isolated or syndromic SHFM with use of high-resolution array based comparative genomic hybridization (aCGH). All probands were previously screened for the most common SHFM-related genetic lesions (i.e. 10q24.32 and 17p13.3 duplications, TP63 mutations). Results of aCGH in one family with isolated SHFM showed a pathogenic deletion in SHFM1 (7q21.3) locus, much smaller than typical causative changes identified in this region. In another proband with syndromic SHFM, we identified a novel duplication likely being responsible for the patient's phenotype. In four other probands we detected previously unreported copy number variations of unclear clinical significance.

P04.63-S
The impairment of MAGMAS function in human is responsible for a severe skeletal dysplasia

C. Mehawej;
Medical Genetics Unit- USJ, Beirut, Lebanon.

Impairment of the tightly regulated ossification process leads to a wide ran-

ge of skeletal dysplasias and deciphering their molecular bases has contributed to the understanding of this complex process. Here, we report a homozygous mutation in the mitochondria-associated granulocyte macrophage colony stimulating factor-signaling gene (*MAGMAS*) in a novel and severe spondylodysplastic dysplasia. MAGMAS, also referred to as PAM16 (presequence translocase-associated motor 16), is a mitochondria-associated protein involved in preprotein translocation into the matrix. We show that *MAGMAS* is specifically expressed in trabecular bone and cartilage at early developmental stages and that the mutation leads to an instability of the protein. We further demonstrate that the mutation described here confers to yeast strains a temperature-sensitive phenotype, impairs the import of mitochondrial matrix pre-proteins and induces cell death. The finding of deleterious *MAGMAS* mutations in an early lethal skeletal dysplasia supports a key role for this mitochondrial protein in the ossification process.

P04.64-M
A novel missense mutation in ST14 in a patient with ichthyosis, follicular atrophoderma and hypotrichosis

S. Baldassari[1], *G. Tortora*[1], *R. Balestri*[2], *I. Neri*[2], *M. Seri*[1];
[1]U.O. Genetica Medica, Dipartimento Scienze Mediche e Chirurgiche, Università di Bologna, Bologna, Italy, [2]U.O. Dermatologia, Policlinico Sant'Orsola-Malpighi, Università di Bologna, Bologna, Italy.

Congenital ichthyoses are a clinically and genetically heterogeneous group of genodermatoses characterized by disorders of cornification. Mutations in *ST14* are causative of two syndromes: Ichthyosis, Follicular Atrophoderma and Hypotrichosis (IFAH, OMIM 602400) and Autosomal Recessive Ichthyosis and Hypotrichosis (ARIH, OMIM 610765). These two syndromes are caused by different types of mutations in the gene: loss of function mutations (splice site or deletion) have been found in 2 IFAH families, while missense mutations have been found in 2 ARIH probands. We report on the identification of a new homozygous disease-causing mutation in *ST14* in a girl with diffuse ichthyosiform scaling of the trunk and arms, follicular atrophoderma of both forearms and sparse hair. The screening of *ST14* by Sanger sequencing revealed a homozygous missense mutation, p.Glu519Gln, inherited by healthy parents, both carriers of the variation described. The mutation is not present in 1000Genomes nor in ESP databases, involves a highly conserved aminoacid and is predicted to be pathogenic by Polyphen2 and SIFT. *ST14* encodes the matriptase, a type II transmembrane serine protease, expressed predominantly in the epithelial cells of the surface-lining epithelium. Our result supports the role of matriptase alterations in IFAH, but the finding of a missense mutation points out the need of other experiments to better define the functional role of different mutations in the pathogenesis of IFAH and ARIH.

P04.65-S
De Novo Mutation of the Latency-Associated Peptide Domain of TGFB3 in a Patient with Clinical Features of Loeys-Dietz Syndrome

G. Matyas[1], *P. Naef*[1], **K. Oexle**[2];
[1]Zentrum fuer Kardiovaskuläre Genetik und Gendiagnostik, Schlieren-Zürich, Switzerland, [2]Institut für Humangenetik, Technische Universität München, München, Germany.

We report the first case of a patient with a disease-causing mutation in the LAP domain of TGFB3 [c.899G>A, p.Arg300Gln; no mutation detected in FBN1, TGFBR1, TGFBR2, TGFB2, and SMAD3]. Previously, TGFB mutation has been described in one patient only (Rienhoff et al. 2013, Am J Med Genet A 161A:2040-6). That mutation was hypomorphic while we cannot exclude that mutations of the LAP domain result in constitutive activation of TGFB3 as in case of LAP mutations of TGFB1 [Saito et al., 2001, J Biol Chem 276:11469-72]. There were phenotypic similarities between our patient and the patient reported by Rienhoff et al. (2013) such as low muscle mass, hypertelorism, cleft soft palate, pectus excavatum, and arachnodactyly, but also considerable differences such as overgrowth and generalized hyperextensibility of joints instead of growth retardation and digital contractures, respectively. Both the previous case and our present case emphasize the inclusion of TGFB3 in the comprehensive genetic testing of (Marfanoid) patients with LDS clinical features, such as bifid uvula and hypertelorism. Further studies are needed to clarify the phenotypic spectrum of TGFB3 mutations including the risk for vascular disease.

P04.66-M
Modelling Poikiloderma with Neutropenia in zebrafish: a start point to elucidate disease pathogenesis

E. A. Colombo, *S. Carra, L. Fontana, E. Bresciani, F. Cotelli, L. Larizza;*
Università degli Studi di Milano, Milano, Italy.

Poikiloderma with Neutropenia (PN; OMIM#604173) is a rare autosomal recessive genodermatosis characterized by early onset poikiloderma, hyperkeratosis, pachyonychia, bone alterations, craniofacial dysmorphisms and non-cyclic neutropenia, which accounts for recurrent infections in infancy and susceptibility to myelodysplastic syndrome and solid tumours.
C16orf57, disclosed in 2010 as the causative gene of PN, has been recently renamed USB1 (U six biogenesis 1) as its protein is a RNA exonuclease involved in the 3' end processing and stability of U6 snRNA, a core component of the active spliceosome. However, no evidence for splicing defects could be achieved in PN patients cells unlike in Usb1 defective yeast. As no multicellular organism has been modeled for PN, we enrolled zebrafish, a vertebrate model increasingly important for the study of human genetic diseases and haematological malignancies, to gain insights into the consequences of USB1 disruption during early embryogenesis.
The zebrafish genome harbours only one copy of the USB1 orthologue (NM_001003460.1) ubiquitously expressed and with a high degree of conservation in genomic structure and aminoacid sequence (73% similarity and 46% identity).
Loss-of-function experiments, performed injecting three different specific antisense, morpholinos in embryos at one cell stage, allowed to obtain embryos with an overall phenotype that recapitulates the major traits of PN.
Usb1 depletion causes the development of embryos with decreased skin pigmentation, small head with defects in early cartilages of pharyngeal arches, oedema in the pericardial area, defects in blood circulation with a reduction of myeloid and erythroid cells as highlighted by in-situ hybridization and real-time experiments.

P04.67-S
Whole-exome sequencing identifies polymorphic variants in a large Arab family with split-hand/foot malformation with long-bone deficiency

U. Radhakrishna[1], *U. Ratnamala*[1], *M. Naveed*[2], *M. T. Al-Ali*[2], *S. K. Nath*[3];
[1]Green Cross Pathology & Molecular Laboratory, Paldi, Ahmedabad, India, Ahmedabad, India, [2]Center for Arab Genomic Studies (CAGS), Dubai, United Arab Emirates, [3]Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK, United States.

Split-hand/foot malformation with long-bone deficiency (SHFLD) is a rare, severe limb deformity**.** This is characterized by tibia aplasia with or without split-hand/split-foot deformity. Using DNA microarray analysis and employing various statistical methods, we have mapped the SHFLD1 and SHFLD2 phenotypes to chromosomes 1q42.2-q43 and 6q14.1 regions respectively. Additionally, we have identified six suggestive loci with evidence of linkage on chromosomes 1p36.13, 1q31.1, 1q42.3, 4q34.3, and 6q14.1 and 17p13.1 regions in a large multigenerational Arab family (Am. J. Hum. Genet.2007; 80:105-111). Subsequently, we have reported microduplications on chromosome 17p13.3, suggesting the association of BHLHA9 gene within the duplication in the pathogenesis of SHFLD development (J Med Genet.2012 Feb;49:119-25). Our recently performed exome sequencing using the SOLiD™ system at x200 coverage followed by prioritized mutation search within the linkage region between SNP markers rs1124110/rs535043, and rs623155/rs1547251 in selected SHFLD subjects showed polymorphic variants within the coding regions of *FILIP1* gene on 6q14.1 regions. A heterozygous nucleotide substitution G>A (c.3476G>A) resulting in a change from arginine and histidine Arg1159His (R/H) was observed in heterozygous condition in selected affecteds. However the data on chromosome 1q31.1 region is yet to be analyzed. Our present analysis provides the understanding the pathophysiology of the SHFLD disease and also provides ultimate genetic diagnosis of the condition. Additionally, the data can also help us in developing non-invasive methods of screening for the disorder in at-risk family members, in order to reassure those are not carrying the mutation and to plan prophylactic measures for those who are/will be affected.

P04.68-M
Biomarkers and early stage drug development in ectodermal dysplasias

K. M. Huttner[1], *O. F. Gaide*[2], *S. Chang*[1], *P. Schneider*[3];
[1]Edimer Pharmaceuticals, Inc., Cambridge, MA, United States, [2]Service de Dermatologie, CHUV, Lausanne, Switzerland, [3]Dept of Biochemistry, University of Lausanne, Lausanne, Switzerland.

EDI200 is a recombinant ectodysplasin currently in clinical trials for the correction of abnormal ectoderm development in neonates affected by X-linked hypohidrotic ectodermal dysplasia (XLHED). For early drug trials, there is a premium placed on identifying molecular markers of drug response likely to predict long-term clinical benefit, especially when endpoints in XLHED such as teeth, hair and sweat function may take months to years to ascertain. The ectodysplasin-deficient Tabby mouse model for XLHED demonstrates a consistent and sustained phenotype response to EDI200. Through a combined approach of qPCR and RNA-seq we have begun to map the Tabby ectodysplasin-responsive biological pathways. EDI200 at 2 mg/kg (or vehicle alone)

was administered by intraperitoneal injection to newborn Tabby mice, with tail, back and footpad tissues harvested at time points ranging from two hours to one month post-injection. Isolated RNA was subjected to analysis by qPCR for eight genes known to contribute to the development/structure of ectodermal placodes and appendages. Levels of expression for the ectodysplasin receptor EDAR and the downstream regulator sonic hedgehog (Shh) were upregulated specifically at 24 hrs post-injection in all tissues. RNA-seq analysis with DAVID bioinformatics software confirmed these results for EDAR and Shh and extended the gene set analysis to identify novel and unexpected response pathways including those for fat metabolism and solute transporters. This combined approach for biomarker validation and delineation of system response biology will provide an invaluable tool set in identifying pathways for drug targeting as well as in optimizing drug dosing in ectodermal dysplasias.

P04.69-S
A new col5a1 genomic variant identified in an italian patient with ehlers danlos syndrome classic type

F. Cortini[1,2], *L. Costantino*[1], *M. Seia*[1], *A. Biffignandi*[1], *L. Porcaro*[1], *B. Marinelli*[2], *P. A. Bertazzi*[2], *A. Bassotti*[3];
[1]*Medical Genetics Laboratory, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy,* [2]*Center of Molecular and Genetic Epidemiology, Department of Environmental and Occupational Health, Università di Milano, Fondazione Cà Granda, IRCCS Ospedale Maggiore Policlinico, Milan, Italy,* [3]*Ehlers-Danlos disease regional center, Department of Enviromental and Occupational Health, Università di Milano, Fondazione Cà Granda, IRCCS Ospedale Maggiore Policlinico, Milan, Italy.*

Ehlers Danlos syndrome (EDS) is a group of heterogeneous connective tissue disorders. The clinical classification recognizes six subtypes and the Classic type is the most frequent. Classic EDS is an autosomal dominant disorder, characterized by skin hyperextensibility, abnormal wound healing and joint hypermobility. It is estimated that approximately 50% of patients with classic EDS phenotype harbor mutations in COL5A1 and COL5A2 gene. We report a case of 43 Italian patient, presented to Ospedale Maggiore Policlinico (Milan) for clinical and genetic counselling. He showed: soft and hyperextensibility skin specially at the neck, face and hands, atrophic scars and joint hypermobility. The cDNA sequencing revealed a new single base variation in COL5A1 gene. The mutation was a change of C for T in exon63 and established an amminoacid substitution Leucine by Valine at the c.1656. This mutation was located on higly conservated domain of the protein. Sequencing of COL5A2 gene and study of the null allele of COL5A1 gene didn't showed any differences. CGH-Array platform, characterized by a higher density of probes in those chromosomal regions that are thought to be related to EDS, didn't revealed any variations. Bioinformatics analysis identified that this nucleotide sequence is extremely conserved in different species, indeed, up to date, no mutation or polymorphism have been described for this region. The identification of new genomic variant represent the first step towards the understanding of symptom causes. Moreover, further studies on protein structure could be necessary to understand the real properties of this mutation.

P04.70-M
Further phenotypic delineation of metatropic dysplasia

M. Lopes-de-Almeida[1], *C. Reis*[1], *P. Cardoso*[2], *J. Sá*[1], *J. M. Saraiva*[1,3], *A. Beleza-Meireles*[1];
[1]*Medical Genetics Unit, Hospital Pediátrico de Coimbra, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal,* [2]*Orthopedics Unit, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal,* [3]*Faculty of Medicine, University of Coimbra, Coimbra, Portugal.*

Dominant mutations in *TRPV4* are responsible for a family of rare skeletal dysplasias that encompasses, in decreasing severity, metatropic dysplasia (MD), parastremmatic dysplasia, spondyloepiphyseal dysplasia Maroteaux type, spondylometaphyseal dysplasia Kozlowski type, autosomal dominant brachyolmia, and familial digital arthropathy with brachydactyly. Here, we present the case of two monozygotic twins, daughters of healthy, non consanguineous parents. They were referred to our clinic at age 5 months because of suspected skeletal dysplasia. They presented unspecific craniofacial dysmorphism, including congenital torcicolis associated to a C1-C2 subluxation, long narrow trunk and short extremities. Radiologically they presented marked platyspondyly, flared metaphyses, a halberd shaped pelvis and no carpal ossification. Now, aged 24 months, they show an inversion of the proportions due to progressive and severe kyphoscoliosis. *TRPV4* sequencing analysis revealed a c.2396C>T (p.Pro799Leu) heterozygous *de novo* mutation, conforming the diagnosis. This *TRPV4* mutations, that affects the cytoplasmic domain of the protein is one of the most common MTD mutation and usually associated with a moderate phenotype. In conclusion, MD is diagnosed by its characteristic clinical and radiographic features. Genetic testing can help confirm a diagnosis and to provide specific molecular prenatal genetic testing to couples at risk, as germline mutations has already been reported. Being a rare disorder with few reports in the medical literature, consultation with an experienced clinical geneticist may be required before a diagnosis is made. An early diagnosis is beneficial for early referral of the patients to the appropriate follow-up. These patients are best managed by a multidisciplinary team.

P04.71-S
A review of Molecular Genetic diagnosis of Epidermolysis bullosa cases from Southwest Iran

G. Shariati[1,2], *H. Galehdari*[3], *A. Saberi*[1], *M. Hamid*[4];
[1]*Genetics Department, Medical School of Sciences, Ahvaz Jundishapur University, Ahvaz, Islamic Republic of Iran,* [2]*Narges Genetic diagnosis & PND Lab, Ahvaz, Islamic Republic of Iran,* [3]*Department of Genetics, Shahid Chamran University, Ahvaz, Islamic Republic of Iran,* [4]*Department of Biotechnology, Pasteur Institue, Tehran, Islamic Republic of Iran.*

Epidermolysis bullosa (EB) is a skin disorder that is divided regarding involved skin area into three main forms: Junctional epidermolysis bullosa (JEB), dystrophic epidermolysis bullosa (DEB), and epidermolysis bullosa simplex (EBS). EB ranges from mild to very severe forms with the age of onset form infancy to childhood. The landscape of EB is extensive blistering and scarring. Other signs include fused fingers and toes, joint deformities and alopecia. EB is a rare disorder with autosomal recessive and dominant genetic pattern. This disease is very rare in southwest Iran. From last decade to date, 12 individuals were diagnosed for DEB. But, more clinical differential diagnosis was not possible for patients. Mutations in 4 genes COL17A1, LAMA3, LAMB3, and LAMC2 cause the JEB disease, whereby the LAMB3 gene mutations are responsible for more than 70% of all JEB cases. In contract, mutation in the COL7A1 gene causes all three forms of DEB including autosomal recessive HS -RDEB, non HS-RDEB, and autosomal dominant DDEB. Mutations within exons 70-75 of the COL7A1 gene very frequent in the DEB patients. However, three patients from southwest Iran with DEB as preliminary diagnosis showed frame shift mutations within exons 73-74, and another individual was positive for a novel nonsense mutation in the LAMB3 gene. He was also affected by JEB, and not DEB. We were not able to detect any mutation in other 8 individuals with EB. Exom sequencing or next generation sequencing might be helpful to resolve their puzzle.

Perturbation of Specific Pro-mineralizing Signalling Pathways in Human and Murine Pseudoxanthoma Elasticum

O. M. Vanakker[1], **M. J. Hosen**[1], *P. J. Coucke*[1], *O. LeSaux*[2], *A. De Paepe*[1];
[1]*Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium,* [2]*Department of Cell and Molecular Biology, John A. Burns School of Medicine, Honolulu, HI, United States.*

Pseudoxanthoma elasticum (PXE) is characterized by skin, ocular and cardiovascular manifestations, due to calcification and fragmentation of elastic fibres. Caused by mutations in the ABCC6 gene, the mechanisms underlying this disease remain unknown. The knowledge on the molecular background of soft tissue mineralization largely comes from insights in vascular calcification, with involvement of the osteo-inductive Transforming Growth Factor beta (TGFβ) family (TGFβ1-3 and Bone Morphogenetic Proteins [BMP]), together with ectonucleotides (ENPP1), Wnt signalling and a variety of local and systemic calcification inhibitors. In this study, we have investigated the relevance of these signalling pathways as well as apoptosis and ER stress using immunohistochemistry and mRNA expression profiling in dermal tissues and fibroblasts of PXE patients, and the eyes and whiskers of the PXE knock-out mouse. Apoptosis was evaluated by TUNEL staining. We demonstrate upregulation of the BMP2-SMADs-RUNX2 and TGFβ-2-SMAD2/3 pathway, co-localizing with the mineralization sites, and the involvement of MSX2-canonical Wnt signalling. Further, involvement of apoptosis is shown with activation of Caspases and BCL-2. In contrast to vascular calcification, neither the other BMPs and TGFβs nor endoplasmic reticulum stress pathways were perturbed in PXE. Our study shows that we cannot extrapolate knowledge on cell signalling in vascular calcification to a multisystemic mineralization disease as PXE. Contrary, we demonstrate a specific set of perturbed signalling pathways in PXE patients and the mouse model, and propose a preliminary cell model of ECM calcification in PXE.

Neonatal case of thumb duplication: case report and review

I. Caliendo[1], *I. Franzese*[2], *V. Franzese*[3], *S. Amoroso*[4], *C. Fabbricatore*[1], *M. Ergoli*[1], *C. Di Stefano*[2];
[1]*U.O.C. Oncoematologia, P.O. „A.Tortora", Pagani (Salerno), Italy,* [2]*Terapia Intensiva Neonatale, P.O."Umberto I", Nocera Inferiore (Salerno), Italy,* [3]*U.O.C. Ortopedia Università „Federico II", NAPOLI, Italy,* [4]*Dip. Tutela Salute Donna, Bambino, Adolescente, Università Cattolica del Sacro Cuore, Roma, Italy.*

Introduction. The preaxial polydactyly represents a complete or partial duplication of the thumb, usually is unilateral. The thumb duplication is

the most common anomaly of the hand. This congenital anomaly may be isolated and sporadic or expressed with a syndrome's phenotype. Within the Oberg, Manske, Tonkin (OMT) classification thumb duplications are a failure of formation and/or differentiation affecting the radial/ulnar axis of the hand plate. The primary signal centre involved is the zone of polarising activity (ZPA) in the posterior part of the developing limb bud. Sonic Hedgehog protein, which is expressed in the ZPA, plays a major role in determining radial-ulnar characteristics. Other morphogens are involved in the development of thumb duplications. Instead for an approach of management the Wassel description is used. Case report. We describe a case of a female newborn with a isolated hand left preaxial polydactyly. The weight at birth was 2050g, 45 cm of lenght and head circumference 33 cm, physical examination revealed preaxial hexadactyly with thumb duplication. Extra digit was mild hypoplasic and the patient was unable to move it independently. Radiographs showed extra thumb containing two proximal phalanges (type IV polydactyly, according to the Wassel's Classification). Conclusion. In this condition are recommended to value radiographs of the affected limb to show whether the rudimentary digit contains skeletal elements, and any associated non-hand anomalies. Surgical reconstruction of the radial polydactyly is indicated, not only for the obvious cosmetic improvement, but also to obtain a stable, mobile thumb of adequate size and appropriate shape.

The gene variants in 3' end of prothrombin gene in patients with idiopathic thrombophilia in Serbian population

M. Aradjanski[1], V. Djordjevic[1], I. Pruner[1], B. Tomic[1], M. Gvozdenov[1], M. Kovac[2,3], **D. Radojkovic**[1];

[1]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia, [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [3]Blood Transfusion Institute of Serbia, Hemostasis Department, Belgrade, Serbia.

Background: Thrombophilia is a multifactorial disorder which arises from the interaction of acquired and genetic risk factors. Despite the significant effort made to understand the etiology of this disease, there are still a certain number of patients suffering from idiopathic thrombophilia.
Objectives: The aim of this study was to screen 3' end of prothrombin gene, which is susceptible for gain-of-function mutations due to its non-canonical sequence elements, in patients with idiopathic thrombophilia and to determine its eventual role in the pathogenesis of thrombophilia.
Material and Methods: This study was carried out in100 patients with idiopathic thrombophilia and 100 healthy controls DNA variants in the 715bp long region of the 3'end of the prothrombin gene were identified by sequencing.
Results: In our study, we detected two variants: A19911G and C20068T. The frequency of A19911G gene variant was slightly increased in the group of patients compared to controls. Heterozygous carriers of FII C20068T were four times more frequent in the patients (4%) than in controls (1%), but this difference did not reach statistical significance.
Conclusions: Our findings suggest that variant A19911G is not a significant risk factor (OR=1.05; 95%CI 0.57-1.93), while C20068T may represent a potential risk factor for idiopathic thrombophilia (OR=4.12; 95%CI 0.57-1.93). To confirm our results, further studies should be conducted in a larger cohort of patients.

P05.02-M

Molecular analysis of aneurysm genes in familial and sporadic abdominal aortic aneurysm

K. M. van de Luitgaarden[1,2], H. T. Bruggenwirth[3], A. Maugeri[4], J. M. Weiss[5], **D. F. Majoor-Krakauer**[3];

[1]Department of Vascular Surgery, Erasmus University Medical Center, Rotterdam, Netherlands, [2]Department of Anesthesiology, Erasmus University Medical Center, Rotterdam, Netherlands, [3]Department of Clinical Genetics, Erasmus University Medical Center, Rotterdam, Netherlands, [4]Department of Clinical Genetics, VU Medical Center, Amsterdam, Netherlands, [5]Department of Clinical Genetics, VU Medical Center, Amsterdam, Netherlands.

The role of aortic aneurysm syndromes genes in abdominal aorta aneurysms (AAA) was investigated by analysing the TGF-β pathway genes *TGFBR1*, *TGFBR2*, *SMAD3*, *FBN1, EFEMP2,* smooth muscle cells genes *MYH11*, *MYLK* and *ACTA2* and the vascular Ehlers-Danlos gene *COL3A1* in a large group of familial and sporadic AAA patients.
Sanger sequencing was performed of all coding exons and exon-intron boundaries of the aneurysm genes in AAA patients diagnosed. Patients with at least one affected first-degree relative with an aortic aneurysm were classified as familial AAA (fAAA). *In silico* analysis was used for assessment of the clinical significance of the variants.
We found 38 different variants of unknown clinical significance (VUS) in this study population of 72 AAA patients including 56 fAAA patients (78%) and 16 patients (22%) with sporadic AAA. In fAAA one null mutation in *COL3A1* and 48 VUS were observed in 26 (46%) patients. In sporadic AAA one *de novo TGFBR2* mutation and 11 VUS were observed in 8 (50%) patients. Four VUS (11%) were possibly pathogenic; *TGFBR2* c.1234G>A (Val412Met), *MYH11* c.760C>T (Arg254Cys), *MYH11* c.5697G>C (Glu1899Asp), and *MYLK* c.3403G>A (Gly1135Arg). Fifteen patients (13 familial and 2 two sporadic) had complex genotypes, including seven *in cis* variants. Altogether 3% of the AAA patients had a pathogenic mutation and 24 (47%) one or more VUS.
The results endorse the genetic heterogeneity of AAA, showing a modest contribution of *TGFBR2* and *COL3A1* in AAA. In addition a high prevalence of rare VUS suggests involvement of other aneurysm genes in AAA.

P05.03-S

Longer GT repeats and rs2071746T allele in the heme oxygenase-1 gene promoter are associated with abdominal aortic aneurysm

E. Strauss[1], *K. Waliszewski[2], A. Miklaszewska[3], R. Staniszewski[2], G. Oszkinis[2], R. Słomski[1,3];*

[1]Institute of Human Genetics of the Polish Academy of Sciences in Poznan, Poznan, Poland, [2]Department of General and Vascular Surgery of the Poznan University of Medical Sciences, Poznan, Poland, [3]Department of Biochemistry and Biotechnology of the Poznan University of Life Sciences, Poznan, Poland.

Abdominal aortic aneurysm (AAA) is multi-factorial disease with life-threatening complications due to mainly asymptomatic course of development. Vascular inflammation induced by oxidative stress contribute to pathogenesis. Inter-individual differences in response to oxidative stress are partially under genetic control. In this study the associations between the functional SNPs and (GT)n repeat length polymorphisms in genes involved in the vascular response to hypoxia/ischemia: HIF1A (hypoxia inducible factor-1α) and HMOX1 (heme oxygenase-1) and the development of AAA were examined.
The study encompassed a series of 518 AAA patients, 345 patients with atherosclerotic aortoiliac occlusive disease (AOID) and 498 controls. The HIF1A rs11549465C>T, rs11549467G>A and HMOX1 rs2071746A>T SNP genotyping was performed by using predesigned TaqMan SNP-genotyping assays. For simultaneous assessment of the HIF1A and HMOX1 (GT)n polymorphisms, the method based on multiplex-PCR with fluorescent-labeled sense primers and fragment size analysis using DNA sequencer has been developed.
We found, that carriers of the HMOX1 (GT)n repeat long allele (n>27) had increased risk of developing AAA (OR=1.46 for dominant model, P=.034). The frequency of carriers of both HMOX1 risk alleles: rs2071746T and/or long (GT)n repeat in AAAs (58,5%) was higher as compared to AIOD (49,0%, P=.007). On the other hand, the frequency of noncarriers in AAAs was 0.0%, as compared to 1.3% in controls (P=.010) and 0.9% in AIOD (P=.066).
In conclusion, HMOX1 gene promoter long (GT)n repeat allele and rs2071746T, allele related to decreased anti-inflammatory and antioxidant capacity of heme oxygenase-1, are associated with abdominal aortic aneurysm. Supported by Polish Ministry of Sciences grant NN403_250440.

P05.04-M

Age- and sex-specific causal effects of adiposity on cardiovascular risk factors

T. Fall[1], *S. Hägg[1,2], A. Ploner[2], R. Mägi[3,4], K. Fischer[3], I. Prokopenko[4,5], N. L. Pedersen[2], M. McCarthy[4,6], E. Ingelsson[1];*

[1]Uppsala University, UPPSALA, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Estonian Genome Center, University of Tartu, Tartu, Estonia, [4]University of Oxford, Oxford, United Kingdom, [5]Imperial College London, London, United Kingdom, [6]Oxford National Institute for Health Research Biomedical Research Centre, Oxford, Sweden.

Observational studies have reported different effects of adiposity on cardiovascular risk factors between men and women and among different age groups, but these aspects have not been investigated with regards to causality.
We estimated the causal effect of adiposity on blood pressure, lipid concentrations, glycemic indices, and markers of inflammation and liver disease in up to 67,553 individuals using a non-weighted genetic score constituting of 32 genetic variants associated with body mass index (BMI) within a Mendelian randomization framework. All analyses were stratified by age (cut-off, 55 years) and sex.
We found similar effects of the genetic instrument on BMI in different strata. Each additional allele of the genetic score was associated with an increase in BMI of 0.03 SD (95% CI, 0.028-0.033; P=3x10^{-107}). We found evidence of a causal effect of adiposity in non-stratified analysis on blood pressure (systolic and diastolic), circulating lipids (high-density-lipoprotein cholesterol, triglycerides), glucose homeostasis (HbA1c, fasting insulin), and markers of inflammation (C-reactive protein, interleukin-6), and liver damage (alanine aminotransferase and gamma-glutamyl transferase) (all P<0.05). We observed significantly larger causal estimates in younger individuals than in older for low-density-lipoprotein cholesterol and total cholesterol (P_{diff}=0.04 and

0.02 respectively). For fasting insulin, in secondary analysis, we found a larger effect of adiposity in males than in females (P_{diff}=0.01 using *FTO* variant as a genetic instrument).
We provide evidence for a causal effect of adiposity on many cardiovascular risk factors, and observe differential estimates across age and sex for insulin and circulating lipids.

Background: Long QT Syndrome (LQTS) is an inherited arrhytmogenic disease characterized by a prolonged QT interval in association with life-threatening arrhythmias. The LQTS can be congenital (cLQTS) or acquired (aLQTS) as an adverse response to drugs, hypokalemia or bradycardia. Mutations in 13 genes have been associated with cLQTS, while the genetic background of aLQTS remains unclear. The aim was therefore to evaluate if a genetic substrate may contribute to aLQTS. Methods: Through a multicentre study, 211 aLQTS probands were collected from Japan, Italy and France. They were clinically evaluated and divided into 3 groups according to the baseline QTc interval: "true-aLQTS" (females QTc<460ms, males QTc<450ms, n=112), "unmasked-LQTS" (females QTc ≥ 460ms, males QTc ≥ 450ms, n=74), and "unclassified-LQTS" (without ECG, n=25). Genetic screening of the 5 major cLQTS genes was performed and mutations were compared to those of 875 genotyped cLQTS families. Results: Genetic analysis led to the identification of mutations in LQTS-susceptibility genes in 27% of aLQTS probands (57/211). In the "true-aLQTS" and "unmasked-LQTS", a mutation was detected in 23% and 38% of cases, respectively (p=0.04). Interestingly, KCNH2 was the most mutated gene (62% vs 15% of KCNQ1), while the frequency of mutations in the cLQTS population were 39% and 48%, respectively. Conclusions: Genes implicated in cLQTS play an important role also in aLQTS. The likely underlying mechanism would be a critical loss in repolarization reserve even in the presence of just a modest QT interval prolongation. KCNH2 mutations seem to have a prominent role.

+11525 C/A Polymorphism in MicroRNA Binding Site of Angiotensinogen is Associated with Occurrence of Restenosis in Patients After Myocardial Infarction

J. Novak[1], *R. Hezova*[2], *F. Zlamal*[1], *J. Machal*[1], *J. Vinklarek*[1], *I. Necesanek*[1], *O. Hlinomaz*[3], *L. Groch*[3], *J. Vitovec*[3], *O. Slaby*[2], *J. Bienertova-Vasku*[1];
[1]*Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic,* [2]*Molecular Oncology II, Central-European Technological Institute (CEITEC), Brno, Czech Republic,* [3]*International Clinical Research Center – Department of Cardiovascular Diseases, St. Anne's University Hospital Brno, Brno, Czech Republic.*

Introduction:
Angiotensinogen (AGT) is a key component of the renin-angiotensin-aldosterone system that plays a crucial role in blood pressure (BP) regulation. Increased BP is a well-known risc factor for various cardiovascular diseases. With the discovery of microRNAs, polymorphisms in 3´-untranslated regions (3´-UTR) of known genes became of interest. The aim of our study was to investigate the possible association of rs7079 in 3´-UTR of AGT gene with the outcomes in patients after myocardial infarction (MI).
Methods:
Total of 652 patients (men) presenting at the emergency room with chest pain with suspicious MI underwent selective coronarography. Diagnosis of MI was confirmed in 571 patients. Peripheral blood for DNA isolation was sampled during hospitalization and the genotypes were determined using TaqMan Genotyping Assay.
Results:
Statistically significant differences in age at onset of the first MI were observed among the genotypes of investigated polymorphism, the homozygote genotypes preseting with MI at younger age (AA/CC vs. AC; 58.3±9.7 years vs. 59.91±9.62 years, p = 0.04). Furthermore, statistically significant association was found between the occurrence of restenosis and AGT genotypes (p = 0.008). The logistic regression model revealed that the CC and AA homozygotes were at the higher risk of restenosis before 45 years of age compared to AC heterozygotes.
Conclusion:
Our study shows that rs7079 homozygotes present with MI at younger age and that the risk of restenosis is higher in these patients. This may be partially explained by altered miR-30 and miR-584 binding to 3´UTR region of AGT, as shown previously.

P05.07-S
Targeted next generation sequencing in heritable aortopathies uncovers unexpected findings

K. Mayer, *I. Vogl, T. Slupova, S. Datter, H. Klein;*
Center for Human Genetics and Laboratory Diagnostics, Martinsried, Germany.

Aortopathies are characterized by aneurysms, dissections, dilation, and tortuosity of predominantly the thoracic aorta (TAA) but also the abdominal aorta. Inherited forms comprising both syndromic and non-syndromic entities are genetically heterogeneous and phenotypically overlapping. Currently, mutations in at least 15 genes are known to cause familial thoracic aortic aneurysms (AAT3-AAT8), as well as dominant and recessive syndromic aortopathies. Molecular testing is impeded by similar phenotypes caused by mutations in different genes and mutations in the same gene leading to a wide clinical variability. In this setting NGS of an aortopathy gene panel offers an efficient alternative to conventional gene-by-gene Sanger sequencing.
We developed a NGS aortopathy multigene panel encompassing 15 genes (ACTA2, COL3A1, EFEMP2, ELN, FBN1, FLNA, MYH11, MYLK, NOTCH1, PRKG1, SLC2A10, SMAD3, TGFB2, TGFBR1 and TGFBR2). Coding and adjacent intronic regions were analyzed using Nextera Rapid Capture Custom Enrichment and 2x150 bp paired-end sequencing on a MiSeq instrument (Illumina). So far, the analysis of 20 patients with both syndromic and non-syndromic aortic disease identified eight disease causing mutations in seven patients in the genes COL3A1, EFEMP2 (compound heterozygous), FBN1 (2x), SMAD3, TGFB2 and TGFBR2, representing a diagnostic sensitivity of 35%. Additionally, two rare variants of unknown clinical significance were identified in the MYH11 and TGFB2 gene. Surprisingly, two patients with FBN1 and TGFB2 mutations were clinically diagnosed with vascular Ehlers-Danlos syndrome supported by ultrastructural findings of a skin biopsy. In conclusion, patients with aortopathies will benefit from a parallel testing approach enabling efficient and appropriate surveillance and intervention measures.

Apolipoprotein E (ApoE) plays a role in the regulation of lipid metabolism in humans. The objective of this work was to examine the association between ApoE gene polymorphisms and the risk of coronary heart disease (CHD) in Bulgarians. The case-control study was carried out on a total of 725 samples including 104 patients with angiographically verified coronary artery disease,151 patients with myocardial infarction and 470 population controls without data for cardiovascular complications. ApoE gene polymorphisms were genotyped by High Resolution Melting Analysis. The differences in allele frequency between the CHD patients and controls were evaluated with chi-square test. The frequencies of ApoE alleles in the CHD subjects were 0.81 for E3, 0.14 for E4 and 0.06 for E2, and in the control group were 0.84 for E3, 0.09 for E4 and 0.07 for E2. The ApoE4 allele frequency was significantly higher in the CHD patients than in the control group (OR=1.68, p=0.002). The carriers of E4 containing genotypes (E2/E4, E3/E4 and E4/E4) had a higher risk to develop CHD than carriers of E2 and E3 containing genotypes (OR=1.72, p=0.004). There were no significant differences in patients between the mean of total cholesterol, triglycerides, low density lipoproteins and high density lipoproteins levels among different ApoE ge-

notypes. The current study data suggest that ApoE4 allele is a significant risk factor for CHD in Bulgarian population. Targeted next generation sequencing of 51 genes involved in primary electrical disease

D. Proost[1], *G. Vandeweyer*[1], *A. Rotthier*[2], *J. Saenen*[3], *G. Mortier*[1], *C. Vrints*[3], *J. Del-Favero*[2], *B. Loeys*[1], *L. Van Laer*[1];
[1]*Center of Medical Genetics, Faculty of Medicine and Health Science, University of Antwerp, Antwerp, Belgium,* [2]*Multiplicom, Niel, Belgium, Antwerp, Belgium,* [3]*Department of Cardiology, Faculty of Medicine and Health Science, University of Antwerp, Antwerp, Belgium.*

Primary electrical disease (PED) encompasses a diversity of syndromes including the Short QT Syndrome, Long QT Syndrome, Brugada Syndrome, Early Repolarization Syndrome, and Catecholaminergic Polymorphic Ventricular Tachycardia. Each of these disorders predisposes to ventricular arrhythmias (i.e. polymorphic ventricular tachycardia, Torsade de Pointes, bidirectional ventricular tachycardia) that can degenerate into ventricular fibrillation which often results in sudden cardiac death. These disorders are all genetically heterogeneous and a significant phenotypic and genetic overlap exists. This overlap might be a source of misdiagnosis resulting in negative genetic testing. Therefore we suggest to test these patients for all genes involved in these disorders.
We developed and optimized a MASTR (Multiplex Amplification of Specific Target for Resequencing) assay comprising 51 genes involved in PED. The MASTR protocol consists of a multiplex PCR whereby a first PCR is performed to amplify all target regions followed by a secondary PCR in which patient specific barcodes and sequencing adaptors are incorporated. The PED assay consists of 951 amplicons distributed over 11 multiplexes. Following the MASTR assay, 2x250bp sequencing is performed on MiSeq v2. Next, data-analysis and -interpretation is performed using our local Galaxy-instance and our in-house developed variant database. For validation purposes, 20 CEPH samples (variants present in 1000G) and 20 positive controls were analysed, and we have achieved 100% sensitivity. Currently, we are in the process of screening 100 PED patients with unknown genetic defect. The results of this analysis will be presented. Subsequently, this panel will be implemented in a genetic diagnostic setting.

Homozygous founder mutation in desmocollin-2 gene causes arrhythmogenic cardiomyopathy

A. Lorenzon[1], *B. Bauce*[2], *I. Rigato*[2], *K. Pilichou*[2], *M. De Bortoli*[1], *M. Calore*[1], *G. Poloni*[1], *E. Lazzarini*[2], *E. Mazzotti*[2], *C. Basso*[2], *L. Daliento*[2], *D. Corrado*[2], *G. Thiene*[2], **A. Rampazzo**[1];
[1]*Department of Biology, Padua, Italy,* [2]*Department of Cardiac, Thoracic and Vascular Sciences, Padua, Italy.*

Dominant mutations in genes encoding desmosomal proteins are reported to cause arrhythmogenic cardiomyopathy (AC), an inherited heart muscle disease characterized by lethal ventricular arrhythmias and heart failure, accounting for 15 to 25% of cases of sudden cardiac death in patients <35 years. Recessive mutations are infrequent and most of them cause cardiocutaneous syndromes.
We report here the identification of the first founder homozygous desmocollin-2 (DSC2) mutation in the Italian population, segregating in 4 AC families showing a cardiac-restricted phenotype.
We performed an exon-by-exon analysis of the DSC2 gene on 80 unrelated Italian index patients diagnosed affected with AC according to revised 2010 Task Force criteria. We identified the p.D179G homozygous mutation in DSC2 gene in 4 (5%) of them, all originating from the same north-eastern Italian region. One of them resulted to carry an additional plakophilin-2 frameshift mutation. Haplotype analysis revealed a conserved haplotype among the DSC2 mutation carriers, strongly indicating a common founder. A severe form of biventricular cardiomyopathy with typical electrical features of AC was diagnosed in all homozygous mutation carriers, whereas heterozygous family members were clinically asymptomatic. In vitro functional studies on HL-1 cells showed that mutated DSC2 protein correctly localizes at the intercalated discs.
In conclusion, this is the first founder homozygous mutation in DSC2 gene invariably associated with a severe AC phenotype in the Italian population. This finding could have important implications for mutation screening strategy and risk stratification.

Added Diagnostic Value of Multiplex Ligation-Dependent Probe Amplification of plakophilin-2 in Arrhythmogenic Cardiomyopathy

E. Lazzarini[1], *I. Rigato*[1], *J. Jongbloed*[2], *M. Cason*[1], *R. Celeghin*[1], *E. Carturan*[1], *G. Thiene*[1], *C. Basso*[1], *K. Pilichou*[1], *P. van Tintelen*[2];
[1]*University of Padua, Padua, Italy,* [2]*University of Gronigen, University Medical Center Groningen, Groningen, Netherlands.*

Background: Arrhythmogenic Cardiomyopathy (ACM) is an inherited cardiomyopathy characterized pathologically by fibro-fatty infiltration and clinically by ventricular arrhythmias and an increased risk of sudden death. Genetic testing is limited to genes encoding desmosomal components resulting in a diagnostic yield of about 50%.
Aim: The aim of this study is to search copy number variations (CNVs) in the plakophilin-2 gene (*PKP2*) in order to increase the mutational detection in ACM.
Methods: Genetic screening for all 5 desmosomal-encoding genes was carried out in 60 unrelated patients with a clinical diagnosis of ACM by Sanger sequencing on a ABI-PRISM 3730 (Life Technologies). Genotype-negative probands underwent Multiplex Ligation-dependent Probe Amplification (MLPA) using SALSA MLPA kit P168 ARVC-PKP2 (MRC-Holland) and quantitative Real-Time PCR (qPCR) on a Light Cycler 480 (Roche Applied Science) in search of large deletions/duplications in *PKP2.*
Results: 60% of ACM patients (n=36) resulted positive on direct sequencing, showing 5 mutations in Desmoglein-2 gene (8%), 14 in Desmoplakin (23%), 7 in PKP2 (12%), 2 in Desmocollin-2 (3%), 2 in Plakoglobin (3%) and 6 patients (10%) carried multiple mutations. Additional screening by MLPA in patients without mutations in ACM-genes successfully identified a large heterozygous *PKP2* deletion, further confirmed by qPCR showing a *PKP2* copy number reduction when compared to control samples.
Conclusions: This study improved the diagnostic genetic yield in our population by nearly 2% for one gene, highlighting the usefulness of performing additional analysis for CNVs in ACM patients.

P05.12-M
Molecular and clinical analysis of digenic inheritance in a family with left dominant Arrhythmogenic Cardiomyopathy

K. Pilichou[1], *P. Sarto*[2], *E. Carturan*[1], *M. Cason*[1], *E. Lazzarini*[1], *R. Celeghin*[1], *M. Perazzolo Marra*[1], *C. Furioso*[2], *D. Corrado*[1], *G. Thiene*[1], *C. Basso*[1];

Background. Compound/digenic heterozygosity has been identified as one of the most important determinants of malignant arrhythmic outcome in arrhythmogenic cardiomyopathy (AC). The impact of two single nucleotide variations (SNV) in the AC phenotype expression in a small family was assessed.
Methods. Autopsy identified a concealed left dominant AC in a 40- years old competitive athlete. Conventional genetic screening for all desmosomal-related AC genes and parallel exome sequencing was carried out. SNV segregation and disease penetrance was further assessed in the family members.
Results. By exome and conventional sequencing two SNVs in different desmosomal genes were identified in the proband: one in exon 14 of DSG2, c.2137 G>A (rs79241126, E713K), previously reported in AC cases as an 'uncertain' variant with minor allele frequency (MAF) equals to 0.037; and the other SNV in exon 16 of DSC2, c.2603 C>T (rs141873745, S868F), considered a variant 'likely to be pathogenic' since can alter the functional properties of the protein, has no available reported MAF and in silico analysis predicted a malignant outcome (Polyphen-2: malignant, SIFT: probably deleterious).
Cascade genetic screening showed that all relatives were carriers for only one of the two SNVs. The brother and the sister, SNV carriers, showed a less severe AC phenotype with septal and LV late-enhancement at cardiac magnetic resonance.
Conclusions. The data herein reported confirm that digenic heterozygosity predicts a more severe phenotype and arrhythmic outcome in AC. However, the risk conferred by SNV in family members needs to be evaluated further by follow-up studies.

P05.13-S
Desmoglein-2 propeptide cleavage-site mutations in Arrhythmogenic Right Ventricular Cardiomyopathy

E. Gandjbakhch[1], *A. Vite*[2], *T. Hery*[2], *V. Fressart*[3], *F. Gary*[2], *G. Dilanian*[2], *F. Hidden-Lucet*[1], *P. Charron*[4], *E. Villard*[2];
[1]*APHP, Hôpital Universitaire Pitié Salpêtrière, Institut de Cardiologie, Paris, France,* [2]*ICAN, INSERM UMRS 1166, Paris, France,* [3]*APHP, Hôpital Universitaire Pitié Salpêtrière, Département de Biochimie Métabolique, Paris, France,* [4]*APHP, Hôpital Universitaire Pitié Salpêtrière, Département de Génétique, Paris, France.*

Purpose
Mutations in Desmoglein-2 (DSG2), a heart specific cadherin, are common

causes of Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC). A hot spot of DSG2 missense mutations targets the consensus cleavage-site of DSG2 pro-peptide (Arg-X-Arg/Lys-Arg) by Kex2-like proprotein-convertases. These mutations are responsible for severe phenotype associating frequent severe right ventricular dysfunction and left ventricular involvement. In the present work, we aim to explore the pathophysiological mechanisms of these mutations.

Methods and Results

We performed ex vivo analysis on heart samples from two mutation carriers, and in vitro analysis by expressing wild-type (WT) or mutants pro-DSG2-GFP fusion proteins in cellular models. First, we demonstrated that all mutations prevented N-terminal propeptide cleavage. Using Biacore technology, we demonstrated that the presence of propeptide led to the loss of interactions between EC1 domains of cadherins, known to interact to structure desmosomes. Uncleaved pro-DSG2 mutants were correctly addressed to the intercellular junctions (cellular models) or at the intercalated disks (human tissue). However, we observed at low calcium concentration a mis-incorporation of pro-DSG2 mutants into desmosomes associated with an EGFR-dependant internalization of pro-DSG2 mutants and of desmosomal partners (Plakophillin-2 and Plakoglobin) suggesting increased turn-over of the unprocessed pro-DSG2. Mutants mis-incorporation in desmosomes was further confirmed by western-blot in cells submitted to cyclic mechanical stress showing an increase in mutant pro-DSG2 in the desmosome-independent soluble fraction as compared to DSG2-WT.

Conclusion

Our results strongly suggest a loss in desmosomal adhesiveness due to mis-incorporation of uncleaved pro-DSG2 mutant into desmosomes that might play a central role in ARVC pathophysiology.

P05.14-M

Human Genetic Evidence that Common Variants near PIK3CG are Associated with Atherosclerotic Plaque Hemorrhage and Vessel Density

S. W. van der Laan[1], *L. Folkersen*[2], *J. van Setten*[1], *A. H. Schoneveld*[1], *S. M. van de Weg*[1], *F. W. Asselbergs*[1], *D. P. V. de Kleijn*[3,4], *R. Malik*[5], *M. Dichgans*[5], *A. Gabrielsen*[2], *P. I. W. de Bakker*[1,6], *G. Pasterkamp*[1];

[1]*UMC Utrecht, Utrecht, Netherlands,* [2]*Karolinska Institute, Stockholm, Sweden,* [3]*Interuniversity Cardiology Institute of the Netherlands, Utrecht, Netherlands,* [4]*National University of Singapore, Singapore, Singapore,* [5]*Institute for Stroke and Dementia Research, München, Germany,* [6]*Program in Medical and Population Genetics, Broad Institute, Cambridge, MA, United States.*

Aim: Atherosclerotic plaques may vary among individuals, in part due to heritable factors. However, the genetic architecture of plaque phenotypes is largely unknown. A common variant near PIK3CG on 7q22.3 has previously been associated with carotid plaque presence. Animal models suggest that PIK3CG may play a role in plaque formation through neovascularization. We hypothesized that the PIK3CG variant is associated with intraplaque hemorrhage (IPH) and vessel density in human plaques. Secondarily we focused on characterizing the functional role of genetic variants near PIK3CG in advanced human atherosclerosis.

Methods: We collected 571 Athero-Express Biobank Study patients, and genotyped them using Affymetrix SNP 5.0. After quality control we tested rs17398575 for association to immunohistochemically scored IPH and vessel density, correcting for age, gender and 10 principal components. We used the BiKE cohort to assess the effect of PIK3CG variants on PIK3CG expression in circulating monocytes (n=95) and in carotid plaques (n=126).

Results: The reported PIK3CG variant, rs17398575 (risk allele A, frequency=0.72), was associated with IPH (OR=1.40 [1.10-1.69 95% CI], p=0.0271) and vessel density (β=0.095 [0.0415 s.e.m.], p=0.0221).

The SNP dependent PIK3CG expression demonstrated a differential effect in the vascular wall (p=0.783 for rs17398575) compared to monocytes (p=0.0261 for rs17398575).

Conclusion: To our knowledge this is the first report involving the association of genetic variants to histological plaque phenotypes in humans. Further research should focus on replicating these results and elucidating the etiology of plaque vessel formation and intraplaque hemorrhage, as epidemiological studies demonstrated these associate with cardiovascular disease.

P05.15-S

Assessment of genetic risk for cardiovascular disease in Azores and mainland Portugal: a healthy population-based study

C. C. Branco[1,2,3], *A. Capocci*[1], *J. González*[1], *J. Duarte*[1], *A. M. Vicente*[4,2,3], *L. Mota-Vieira*[1,2,3];

[1]*Hospital of Divino Espirito Santo of Ponta Delgada, EPE, Ponta Delgada, São Miguel Island, Portugal,* [2]*Instituto Gulbenkian de Ciência, Oeiras, Portugal,* [3]*Center for Biodiversity, Functional & Integrative Genomics (BioFIG), Lisbon, Portugal,* [4]*Departamento Promoção da Saúde e Doenças Crónicas, Instituto Nacional de Saúde Dr. Ricardo Jorge (INSA), Lisbon, Portugal.*

Cardiovascular diseases (CVD) are a major source of morbidity and mortality worldwide, including the Azores archipelago where CVD have a higher mortality rate when compared to mainland Portugal. In order to investigate this question, we characterized 15 SNPs in 4 genes and 1 genomic region associated with CVD risk: 4 in PCSK9 (rs11591147, rs11206510, rs562556, rs505151), 4 in APOE (rs405509, rs429358, rs7412, rs439401), 4 in LDLR (rs2228671, rs5927, rs1433099, rs2738466), 1 in USF1 (rs10908821) and 2 in 9p21 (rs10757274, rs1333049). Genotyping was performed by real time PCR using TaqMan Assays in a sample of 170 Azorean and 108 mainland Portuguese healthy individuals. Results demonstrate that allele frequencies were similar in both populations; however, there were statistically significant differences for two SNPs: rs10757274 (9p21) and rs405509 (APOE; $\chi 2$, $p<0.05$). Genotype evaluation of rs1333049 (9p21), the most replicated risk SNP for CVD, showed that 19.4% and 18.5% of Azoreans and mainland Portuguese, respectively, present homozygosity for this risk allele. Moreover, it is possible to observe that, although there is no statistical significance, Azoreans (9.1%) carry a higher frequency of APOE4 allele compared to mainland (8.8%). Overall, the results are suggestive of an increased risk for CVDs in Azoreans compared to mainland; however, the joint analysis of all variants is being carried out. Finally, the results validate the need to study regional differences in Portugal, information that should integrate the Portuguese National Health Plan, in order to achieve a more direct and accurate strategy in terms of prevention and community health.

Matteo, Department of Cardiology, Pavia, Italy,* [4]*IRCCS Istituto Auxologico Italiano, Center for Cardiac Arrhythmias of Genetic Origin, Milano, Italy,* [5]*Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany,* [6]*IRCCS Istituto Auxologico Italiano, Center for Cardiac Arrhythmias of Genetic Origin and Laboratory of Cardiovascular Genetics, Milano, Italy.*

Background: Brugada syndrome (BrS) is a cardiac channelopathy characterized by a coved-type ST-segment elevation in the right precordial leads. The controversy about the value of high intercostal spaces (ICSs) and the number of diagnostic leads has been settled by a recent consensus statement. We have tested the validity of the new ECG diagnostic criteria through a multidisciplinary approach, including the molecular one. Methods: We analyzed 114 BrS patients with a spontaneous or drug-induced type 1 pattern recorded in one or more right precordial leads in 4th, 3rd and 2nd ICSs. The right ventricular outflow tract (RVOT) was localized by echocardiography. Molecular screening of SCN5A was performed through DHPLC and direct sequencing. Results: In total, 23 patients (21%) were carriers of a disease-causing mutation. The percentage of mutation carriers (MCs) and the cardiac event rate were similar irrespective of the diagnostic ICS (4th vs high ICSs: MCs,23% vs 19%; cardiac event rate 22% vs 28%) and the number of diagnostic leads (1 vs ≥ 2: MCs 20% vs 22%; cardiac event rate 22% vs 27%) used. The concordance between RVOT anatomical location and the diagnostic ICSs was 86%. Conclusion: The percentage of SCN5A-MCs and the cardiac event rate are similar regardless of the diagnostic criteria used. The site where the diagnostic pattern is recorded is mainly due to the anatomical location of the RVOT. This study supports the robustness of BrS diagnosis as achieved through the new diagnostic criteria.

P05.17-S

Mutational analysis of mitochondrial DNA in Brugada Syndrome patients

L. Stocchi[1,2], *E. Polidori*[3], *L. Potenza*[3], *M. Rocchi*[3], *C. Calcabrini*[3], *P. Busacca*[4], *M. Capalbo*[5], *D. Potenza*[6], *F. Amati*[2], *R. Mango*[7], *F. Romeo*[7,8], *V. Stocchi*[9];

Brugada syndrome (BrS) is a cardiac disorder characterized by typical ECG alterations and a high risk for sudden death due to ventricular fibrillation. This pathology has nuclear heterogeneous genetic basis and at present molecular diagnostic tests on nuclear DNA cover only 25-30% of BrS pa-

tients. The aim of this study was to assess a possible involvement of mitochondrial (mt) DNA variants in Brugada syndrome since their etiological role has been already described in several cardiomyopathies.
To reach this goal, mitochondrial genome of BrS patients was sequenced and analyzed. A specific mtDNA mutation responsible for Brugada syndrome can be excluded. However the most severe spontaneous ECG type 1 symptomatic patients show a high substitution rate in their mitochondrial genome. These patients also share a combination of four mt single nucleotide polymorphisms (SNPs: T4216C, A11251G, C15452A and T16126C), not found in asymptomatic subjects (either spontaneous ECG type 1 or induced) with a low number on mtDNA SNPs.
Our evidences suggest that the detected mtDNA allelic combination and a high number of mtDNA SNPs could represent an important cofactor in manifestation of BrS phenotype and seem to be associated to a higher risk for a more severe clinical state of Brugada syndrome.

P05.18-M
SCN5A mutation analysis in 147 Brugada syndrome probands

S. J. Van Dooren[1,2,3], *U. Peeters[2], D. Daneels[2], P. Brugada[4], G. Pappaert[4], M. Meuwissen[1], S. Van Malderen[4], L. Peirsman[1], I. Timmermans[1], M. Biervliet[1], D. Raimundi[3], M. Bonduelle[1,2];*
[1]Centre for Medical Genetics, Universitair Ziekenhuis Brussel, Vrije Universiteit Brussel (VUB), Brussels, Belgium, [2]Centre for Medical Genetics, Research Group Reproduction and Genetics, Vrije Universiteit Brussel (VUB), Brussels, Belgium, [3]Interuniversity Institute of Bioinformatics in Brussels, Vrije Universiteit Brussel (VUB)- Université libre de Bruxelles (ULB), Brussels, Belgium, [4]Heart Rhythm Management Center, Cardiovascular Division, Universitair Ziekenhuis Brussel, Vrije Universiteit Brussel (VUB), Brussels, Belgium.

SCN5A mutation analysis in 147 Brugada syndrome (BrS) probands identified 27 variants possibly associated with cardiac channelopathies, which resulted in a genetic diagnostic yield of 17,4%. 18 (66,7%) SCN5A variants have already been associated with BrS, 4 (14,8%) with other cardiac arrhythmias and 5 (18,5%) are novel undescribed variants. When only taking into account the patients with a baseline BrS type I ECG (8,2%) the genetic diagnostic yield increased to 41.6%. Interestingly, this was not observed in patients with a BrS type II ECG (11,6%), in which SCN5A
variants seem to be either novel or associated with other arrhythmias. We also identified a substantial number of described SCN5A mutations (> 9%) in BrS patients clinically diagnosed by ajmaline positive testing and a family history of BrS and/or sudden cardiac death (80,2%), demonstrating the added value of sodium channel blocker-induced ECG testing.
Segregation analysis was performed in available families of the identified SCN5A positive BrS probands to determine genotype-phenotype correlations. In more than 66% of tested families there was an incomplete segregation of the discovered variant. Revision of all ECG data revealed that some ajmaline or baseline ECG negative BrS patients with SCN5A mutations did not meet the stringent diagnostic criteria but demonstrated conduction disease. These results also urge for the need to revise the clinical diagnostic criteria for BrS, in order to stratify BrS patient groups based on more detailed phenotypic data necessary to discover novel major disease associated genes.

P05.19-S
Identification of candidate genes for Brugada Syndrome by targeted next generation sequencing

S. Benedetti[1], *C. Di Resta[2], A. Pietrelli[3], S. Sala[4], P. Della Bella[4], G. De Bellis[3], M. Ferrari[2,5], R. Bordoni[3];*
[1]Laboratory of Clinica Molecular Biology, Diagnostica e Ricerca San Raffaele, Milano, Italy, [2]Vita-Salute San Raffaele University, Milano, Italy, [3]Institute of biomedical technologies, National Council of Resarch (ITB-CNR), Milano, Italy, [4]Department of Arrhythmology, San Raffaele Hospital, Milano, Italy, [5]Genomic Unit for the Diagnosis of Human Pathologies, Center for Translational Genomics and Bioinformatics, San Raffaele Scientific Institute, Milano, Italy.

Recent developments of next generation sequencing (NGS) represent a great opportunity to identify new candidate genes in genetically heterogeneous pathologies such as Brugada Syndrome (BrS), an inherited cardiac arrhythmogenic disorder with a prevalence of 1:5000 in Western countries leading to sudden cardiac arrest in young asymptomatic adults. Until now BrS genetic background remained elusive, since mutations in known genes cover approximately 30% of patients. We thus aimed at identifying new candidate genes performing targeted NGS in a cohort of 91 BrS patients. The coding regions of 158 genes were sequenced using the Illumina GAIIx platform, yielding a mean target coverage of 99.16% and a mean sequencing depth of 327.22x among the samples. Excluding all common polymorphisms and considering only protein-coding variations, we overall identified 98 novel variants in 71 subjects in a total of 70 genes, including missense, nonsense, splice-site and INDELs, and 33 clinical rs annotated in dbSNP137. To select more promising BS candidate genes, we then compared the mutational rate of each gene to that observed in repeated random sampling of healthy controls from 1000 genomes project data. Besides confirming an important role for sodium, potassium and calcium ion channels, our results identified new candidate BrS genes previously associated with other forms of inherited cardiopathies, such as ANK2, RYR2, DSG2, LMNA, suggesting an overlap between different disorders; however, many patients still remained genetically uncharacterized, prompting more extensive studies and suggesting a possible multigenic aetiology.

P05.20-S
A protein network of common susceptibility genes provides a link between inflammation and cardiovascular disease

M. Riemenschneider[1], *S. K. Fassl[2], J. Austermann[2], J. Roth[2], M. Stoll[1];*
[1]Genetic Epidemiology, LIFA at the University of Muenster, Muenster, Germany, [2]Institute of Immunology, University of Muenster, Muenster, Germany.

Genome-wide association studies (GWAS) have identified hundreds of susceptibility loci for chronic and inflammatory disease phenotypes in humans. There is increasing evidence that chronic inflammation is a crucial driver in the pathogenesis of cardiovascular diseases (CVD), which may be genetically determined. To understand the genetic architecture underlying chronic inflammation and CVD we performed a systematic analysis of (1) common risk alleles coming from published GWAS, (2) of protein-protein interaction (PPI) networks informed by (3) gene expression data with a defined molecular target involved in the inflammatory processes promoting CVD, myeloid-related protein (MRP) 8. (4) Through analysis of integrated haplotype scores (iHS) and F_{ST} values in HapMap phase 2 data, we investigated whether recent selection pressure acting upon inflammatory genes affected CVD susceptibility loci. Our findings provide significant evidence for a PPI network (P = 0.033), which connects inflammatory and cardiovascular susceptibility genes, and establish a genetic framework of inflammatory CVD. 41.59% of PPI genes are associated with immune functions. 28.3% of integrated genes can be linked to both, an inflammatory and cardiovascular disease phenotype. Interestingly, *CDKN2B*, and *CELSR2/PSRC1/MYBPHL/SORT1*, unequivocally replicated CVD loci, are integrated within this network as are several SNPs located in transcription factor recognition sequences, i.e. NFKB1, STAT3, which are key factors in inflammation. Finally, we observed a significant enrichment of inflammatory variants within CVD loci that are targets of selection (P=2.001e-11 in CEU population), suggesting that recent selective sweeps may have affected the genomic architecture underlying CVD.

P05.21-S
Systematic screening of rare coding variants in genes involved in cardiac arrhythmias

S. Le Scouarnec[1], *M. Karakachoff[1], P. Lindenbaum[1], S. Bonnaud[1], L. Duboscq-Bidot[1], R. Teusan[1], X. Daumy[1], V. Portero[1], F. Simonet[1], L. Bellanger[2], J. Gourraud[3], J. Barc[4], S. Chatel[1], F. Sacher[5], M. Haissaguerre[5], C. Bezzina[4], C. Dina[1], F. Kyndt[6], S. Bézieau[6], J. Schott[1], V. Probst[3], R. Redon[1];*
[1]L'institut du thorax, INSERM UMR1087, Nantes, France, [2]Département de Mathématiques, Laboratoire Jean Leray UMR CNRS 6629, Nantes, France, [3]L'institut du thorax, Nantes University Hospital, Nantes, France, [4]Department of Clinical and Experimental Cardiology, Academic Medical Center, Amsterdam, Netherlands, [5]Bordeaux University Hospital, Bordeaux, France, [6]Nantes University Hospital, Nantes, France.

The development of new strategies based on next-generation sequencing enables the large-scale screening of genes involved in rare diseases. We have developed a custom design based on the HaloPlex™ technology (Agilent Technologies) to sequence the coding regions of 163 candidate genes, including all genes previously linked to cardiac arrhythmias.
In total, 570 individuals were included in this study. To validate our design, we first analysed 42 patients with inherited cardiac arrhythmias. Among the 69 genetic variants previously identified in these patients, 68 were detected automatically after HaloPlex library preparation and Illumina sequencing. The undetected variant is a substitution located in a low-coverage region. Subsequently, 361 additional patients were analysed (178 patients with Brugada syndrome; 89 patients with early repolarization syndrome; 94 cases of progressive cardiac conduction defects). We also analysed 167 controls, over 65 years of age and showing no signs of cardiac rhythm or conduction abnormalities. The mean coverage was 577X and we found 5 rare functional variants per patient on average. Then, burden tests were performed to detect genes significantly associated to cardiac arrhythmias. This approach also identified potential new disease genes, and replication in an independent cohort is in progress.
Our study will lead to a catalogue of mutations in genes linked to hereditary cases of sudden cardiac death. The systematic screening of our cohorts will also guide our future molecular investigations for these diseases and contribute towards improving the prevention of sudden cardiac death.

P05.22-M

Targeted oligonucleotide-selective sequencing of 101 genes from 150 patients with idiopathic dilated cardiomyopathy in Finland.

T. Alastalo[1], *O. Akinrinade*[1], *L. Ollila*[1], *T. H. Ojala*[1], *H. Koillinen*[1], *M. Kaartinen*[2], *J. W. Koskenvuo*[3], *S. Myllykangas*[1], *J. Tallila*[4], *M. Gentile*[4], *T. Heliö*[2];
[1]*University of Helsinki, Helsinki, Finland,* [2]*University Hospital Helsinki, Cardiology, Helsinki, Finland,* [3]*University of Turku, Turku, Finland,* [4]*Blueprint Genetics, Helsinki, Finland.*

The genetic basis of idiopathic dilated cardiomyopathy (DCM) is recognized but still not widely utilized in diagnostics. Hundreds of mutations in >50 genes have been reported to associate with DCM. Comprehensive genetic testing not only improves diagnostics, prognostics and treatment optimization, but also allows effective screening of asymptomatic family members. We adopted the novel oligonucleotide-selective sequencing (OS-Seq) and developed a custom data analysis pipeline to identify pathogenic variants in 101 genes associated with cardiomyopathies. Our sequencing panels covered >99% of the targeted regions with >15x coverage. Validation with reference samples showed >99% sensitivity and >99.9% specificity. The accuracy to detect short INDELs was 100%. We sequenced well-documented 150 DCM patient and identified pathogenic or likely pathogenic variants in >50% of cases. Truncating titin gene mutations were identified in >20% of patients with familial form of DCM. Other major findings were in genes of the nuclear lamina, desmosomal genes and sarcomeric genes. We performed statistical analyses to identify genotype-phenotype correlations and performed family segregation analysis for selected kindreds. This study represents one of the largest multi gene analyses of patients with DCM, to date. The utilized novel technology allows significant cost reduction and rapid turn-around-time from sample to clinical interpretation. These results demonstrate that the high-throughput targeted OS-Seq platform for cardiomyopathies meets the technical criteria of clinical diagnostics and is a cost-efficient tool in clinical research.

P05.23-S

Application of (targeted) next generation sequencing (NGS) in clinical genetic diagnostics of cardiomyopathies

J. D. H. Jongbloed[1], *R. C. Niessen*[1], *A. Pósafalvi*[1], *Y. M. Hoedemaekers*[1], *P. A. van der Zwaag*[1], *I. M. Mulder*[1], *J. Dijkhuis*[1], *D. Q. C. M. Barge-Schaapveld*[2], *S. R. D. Piers*[3], *J. J. van der Smagt*[4], *F. W. Asselbergs*[5], *R. A. de Boer*[6], *M. P. van den Berg*[6], *R. Almomani*[1], *J. P. van Tintelen*[1], *R. J. Sinke*[1];
[1]*Department of Genetics, University of Groningen, University Medical Center Groningen, Groningen, Netherlands,* [2]*Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands,* [3]*Department of Cardiology, Leiden University Medical Center, Leiden, Netherlands,* [4]*Department of Medical Genetics, University Medical Center Utrecht, University of Utrecht, Utrecht, Netherlands,* [5]*Department of Cardiology, University Medical Center Utrecht, Utrecht, Netherlands,* [6]*Department of Cardiology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands.*

The strength of next generation sequencing (NGS) in both research and diagnostics is becoming increasingly evident. It can be successfully applied to find causal mutations and confirm the clinical diagnosis in genetic cardiomyopathies. However, exome sequencing (ES) show incomplete representation and coverage of several exons, leading to clinically relevant mutations being missed. Therefore ES will, at least for now, coexist in clinical genetic diagnostics with other NGS-based strategies, such as targeted resequencing. To this end, using an enrichment kit targeting 48 genes associated with hereditary cardiomyopathies and analysing 90+ patient samples, we demonstrated that the sensitivity, specificity and robustness of targeted NGS are equal to those of Sanger Sequencing (SS). Subsequently, we constructed an improved kit targeting 55 genes and implemented this into routine diagnostics. Using this kit, 700+ patients have been analysed, and additional haplotype and cosegregation analyses were performed to further support pathogenicity of potentially causal mutations. Our results show that: (1) our approach results in significant increase in diagnostic yield, as in up to 50% of patients (potentially) pathogenic mutations were identified; (2) critical evaluation of the clinical diagnoses showed that higher diagnostic yields are achieved for patients fulfilling the respective cardiomyopathy subtype criteria; (3) *TTN* mutations account for a significant part of the yield; (4) in >10% of cases two or more (potentially) pathogenic mutations were identified; (5) further haplotype and cosegregation analyses support the pathogenicity of a significant number of potentially causal mutations. Taken together, our gene-panel based approach largely improved genetic diagnostics in cardiomyopathies.

P05.24-M

The genetic basis of early-onset cardiomyopathies in Finland

C. Vasilescu[1], *C. J. Carroll*[1], *V. Brilhante*[1], *A. Hiippala*[2], *E. Jokinen*[2], *T. A. Tyni*[3], *T. H. Ojala*[2], *A. Suomalainen*[1,4];
[1]*Research Programs Unit, Molecular Neurology, Biomedicum, University of Helsinki, Helsinki, Finland,* [2]*Department of Pediatric Cardiology, Helsinki University Central Hospital, Helsinki, Finland,* [3]*Department of Pediatric Neurology, Helsinki University Central Hospital, Helsinki, Finland,* [4]*Department of Neurology, Helsinki University Central Hospital, Helsinki, Finland.*

Introduction: Cardiomyopathies (CMPs) are a group of severe, genetically heterogeneous heart disorders with more than 100 disease-causing genes reported to date. By enabling comprehensive genetic screening, Next Generation Sequencing (NGS) is an appealing diagnostic approach for CMPs. In this study, we apply NGS to a cohort of genetically undiagnosed patients in order to identify the disease-causing mutations and characterize the molecular background of early-onset CMP in Finland. By detecting robust genotype-phenotype correlations, genetic data can be informative in prioritizing cases to cardiac transplantation.
Materials and methods: Our cohort consists of 57 Finnish early-onset CMP patients. The clinical presentation is diverse, ranging from heart-specific muscle diseases to multiorgan syndromes. Nine of the patients were screened for mutations by whole-exome sequencing (WES) and 48 by targeted sequencing using a custom-designed panel (HaloPlex) of 117 cardiac genes. Variants were prioritized in respect to frequency and pathogenicity prediction. The candidate mutations were further verified to match the disease segregation in the family and to be absent in Finnish controls.
Results: Mutations were confirmed in four of the WES-investigated patients. Among these, screening of family members revealed *de novo* mutations in three sporadic severe cases. For the patients investigated with targeted sequencing, strong candidate mutations were identified in 14 cases.
Conclusions: In the current stage of the study, WES has led to a genetic diagnosis success rate of approximately 45%, while for targeted sequencing a success rate of 30% is expected. *De novo* mutations were found to cause CMPs in the early-onset cohort under study.

Application of the next generation sequencing technology in identification of mitochondrial mutations in patients with congenital heart defects

N. Abaci[1], *M. Arikan*[1], *E. Gok*[2], *A. Cakiris*[1], *S. Sirma Ekmekci*[1], *T. Tansel*[2], *D. Ustek*[1];
[1]*Institute of Experimental Medicine, Istanbul, Turkey,* [2]*Department of Cardiovascular Surgery, Istanbul Medical Faculty, Istanbul, Turkey.*

Introduction: Inherited type of cardiomyopathy is caused by mutations not only in nuclear genes, but also in mitochondrial genes. Mitochondrial DNA mutations are involved in development of cardiomyopathy through disturbing oxidative energy metabolism. It has been shown that various types of cardiomyopathy can be attributed to disturbed mitochondrial oxidative energy metabolism. The goal of our study was to apply next generation sequencing (NGS) technology as a method to detect mtDNA mutations in patients with cardiomyopathy.
Methods: 18 patients were included in this study. The entire mitochondrial DNA was amplified in two overlapping polymerase chain reaction (PCR) fragments from the Cardiac tissue of the patients undergoing cardiac surgery. mtDNA was deep sequenced by NGS technology.
Results: Six newborns and 12 infant patients with cardiomyopathy were studied using NGS technology and bioinformatics analysis of the sequence data allowed determination of new and reported variation for each individual. Both known and unknown mutations were determined from 18 of patients. Eleven novel mtDNA mutations were identified at seven patients. Three of the patients have novel mutations together with reported cardiomyopathy mutations. LHON, Cyclic Vomiting Syndrome with Migraine, Multiple Sclerosis, and Breast cancer risk associated mutations also observed at three patients.
Discussion: In this report, we provide the results of mtDNA analysis for 18 patients with cardiomyopathy. All patients displayed at least one mtDNA mutation. Sixty mutations were found, and 13 of them were unreported. This study represents the most comprehensive mtDNA mutational analysis in congenital cardiac infant patients.

Chromosomal rearrangements of the 22q11.2 region, including the 22q11.2

deletion and microduplication syndromes, are frequently associated with congenital heart diseases (CHDs). The present work aimed to study copy number variants (CNVs) in the 22q11.2 region of 87 CHD patients from São Miguel Island, Azores.
The CNVs were searched in all patients using MLPA, according to MRC-Holland protocol. Results showed that four (4.6%) out of 87 CHD patients presented CNVs, which were confirmed by aCGH in patients 1 and 2, and by FISH in patients 3 and 4. Patients 1 and 3, both affected with a ventricular septal defect, carried a de novo 2.5 Mb deletion of the 22q11.2 region, whereas patient 2, with an atrial septal defect, carried a de novo 2.5 Mb microduplication (2:1). Finally, patient 4 showed a 2.5 Mb triplication (3:1) and presented dysmorphic facial features, cognitive deficit, and aortic stenosis, a clinical feature not reported in the first case described in the literature. Interestingly, the evaluation of this patient's parents revealed that her non-affected father had a 2.5 Mb microduplication (2:1). Now we are investigating by microsatellite analysis the mechanisms responsible for microduplication and triplication.
In summary, the present study allowed the identification of very rare deletion and microduplication syndromes in Azorean CHD patients. Moreover, we report the second patient with a 22q11.2 triplication, whose clinical features increase the symptoms that could be present. This work emphasizes the relevance of biomedical research, since it can help paediatricians and other professionals to better assess health care needs.

Congenital heart malformations represent one of the most common birth defects, affecting about 0.7 or 0.8% of all live births. The association of wide range of conotruncal heart malformations with 22q11.2 microdeletion is well recognized. 22q11.2 microdeletion is the most common deletion in human genome and more than 80 dysmorphism/malformations have been described in patients with 22q11.2 microdeletion syndrome. In this study we investigated the frequency of 22q11 microdeletion among patients with congenital heart defect and clinical features of 22q11.2 deletion syndrome. The study population was 57 individuals who underwent detailed clinical evaluation including assessment of cardiac morphology, facial appearance, lymphocyte immunophenotyping, presence of cleft palate and hypocalcemia/hypoparathyroidism screening. All tested patients have had congenital heart defect. Fluorescence in situ hybridization and multiplex ligation-dependent probe amplification analysis revealed 22q11.2 microdeletion in 42.1% of studied patients. Cardiac malformations observed in patients with 22q11.2 deletion were tetralogy of Fallot, pulmonary artery atresia, common arterial trunk, interrupted aortic arch, ventricular septal defect and mitral stenosis. Echocardiography accompanied by contrast computed tomography scan and magnetic resonance angiography revealed malposition of branch pulmonary arteries in two patients with 22q11.2 microdeletion. In conclusion, with this study we stress the need for multidisciplinary assessment of patients with congenital heart malformations which should include testing for 22q11.2 microdeletion.

P05.28-M
Conotruncal malformations and absent thymus due to a deleterious NKX2-6 mutation

A. Ta-Shma, *N. El-lahham, S. Edvardson, P. Stepensky, A. Nir, Z. Perles, S. Gavri, J. Golender, N. Yaakobi-Simhayoff, A. Shaag, A. Rein, O. Elpeleg;*
Hadassah Hebrew University Medical Center, Jerusalem, Israel.

Background: Truncus arteriosus (TA) accounts for ~1% of all congenital heart defects (CHD) in live birth. The etiology of isolated TA is largely unknown; syndromic TA is mostly associated with chromosome 22q11 deletion. Hadassah Cardiogenetic Project includes a detailed registry and biobank. Within the frame of this Project we now report the results of a study of patients with multiple conotruncal malformations accompanied by athymia. **Methods and Results:** The subjects were patients originating from two unrelated families. Following the exclusion of 22q11 deletion, exome analysis was performed in one patient from each family. A homozygous mutation in chr8: 23560417InsA, p.Lys152fs*0, in the *NKX2-6* gene was identified in patients from both families. The mutation segregated with the disease in the families and was absent from large cohorts of controls. **Conclusions:** *NKX2-6* encodes a homeobox-containing protein which is expressed in mouse caudal pharyngeal arches and outflow tract at E8.0-E9.5. NKX2-6 was previously shown to be regulated by TBX1. The clear phenotype associated with a homozygous deleterious mutation in our patients, falls well within the spectrum of the cardiac defects seen in DiGeorge syndrome, is in agreement with NKX2-6 downstream location in the TBX1 signaling pathway and confirms *NKX2-6* role in human cardiogenesis..

P05.29-S
Is Type 2 diabetes gene ABCC8 coding a subunit of KATP channel associated with coronary artery disease in Turkish people?

H. Arikoglu[1], *D. Erkoc Kaya*[1], **E. Avci**[1], *S. Zeybek*[1], *F. Iscioglu*[2];
[1]*Selcuk University, Faculty of Medicine, Department of Medical Biology, Konya, Turkey,* [2]*Ege University, Science Faculty, Department of Statistics, Izmir, Turkey.*

Coronary artery disease (CAD) is one of the most common cardiovascular diseases and is a major cause of morbidity and mortality worldwide. Classical risk factors for atherosclerosis, such as central obesity, arterial hypertension, and dyslipidemia, frequently coexist with type 2 diabetes and contribute to the increased prevalence of CAD. ATP-sensitive potassium (KATP) channels of pancreatic β-cells, which is assembled from two different subunits; a Kir6.2 and a sulfonylurea receptor 1(SUR1), play a key role in glucose-stimulated insulin secretion mechanism. ABCC8 gene which is located on chromosome 11p15.1 contains 39 exons and encodes SUR1. We performed a study to scan ABCC8 gene variants which we found significantly associated with type 2 diabetes previously, in patients with CAD. 125 individuals with CAD and 123 healthy individuals were included in the study. Genotyping was performed by PCR-RFLP technique for R1273R and exon 16/-3t→c substitutions using BslI and PstI, respectively. Statistical analysis was performed using SPSS18.0 program. p<0.05 was considered significant. Exon 16/-3t→c substitution showed association with disease (OR:17.13 [95% CI:4.84-60.62] p<0.001, under dominant model, while silent substitution R1273R in exon 31 had no effect on disease. According to our results, exon 16/-3t→c substitution accepted as having important role in type 2 diabetes genetic background has also associated with CAD in our population. Because relatively small sample size of our population is a limitation for the study, replicative studies in larger populations are needed.

Genetic evaluation of plakophilin-2 and desmoplakin gene variants in ethnically different populations with dilated cardiomyopathy

E. Zuccolo[1], *R. Insolia*[1,2], *S. Ghio*[3], *L. Scelsi*[3], *C. Raineri*[3], *M. Mbele*[4], *M. Fish*[4], *G. Shaboodien*[4], *K. Sliwa*[4], *G. Castelli*[3], *S. Schirinzi*[3], *S. Lucibello*[3], *L. Crotti*[2,5,6], *B. M. Mayosi*[4], *P. J. Schwartz*[4,5];
[1]*Molecular Cardiology Laboratory, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy,* [2]*Department of Molecular Medicine, University of Pavia, Pavia, Italy,* [3]*Department of Cardiology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy,* [4]*Hatter Institute for Cardiovascular Research in Africa, Department of Medicine, Groote Schuur Hospital and University of Cape Town, Cape Town, South Africa,* [5]*IRCCS Istituto Auxologico Italiano, Center for Cardiac Arrhythmias of Genetic Origin and Laboratory of Cardiovascular Genetics, Milan, Italy,* [6]*Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany.*

Background
Cardiomyopathies are a heterogeneous group of diseases with various etiologies. The potential involvement of genes encoding desmosomal proteins, usually associated with arrhythmogenic right ventricular cardiomyopathy (ARCV), was preliminarily evidenced in Caucasian patients with dilated cardiomyopathy (DCM). Accordingly, we investigated this potential genetic overlap in a large cohort of patients with clear diagnosis of DCM and belonging to different ethnicities.
Methods
DNA from 455 DCM patients, referred to our tertiary centres in Pavia and Cape Town, was collected following complete clinical evaluation. 290 samples (184 Caucasians; 84 black Africans; 5 Indians; 17 mixed ancestries) were screened for the two main ARVC genes: plakophilin-2 (PKP2) and desmoplakin (DSP).
Results
Of the 290 patients tested, 9 (3.1%) were found to carry a most likely pathogenic variant, being absent in the publicly available databases (nearly 20.000 controls) and functionally relevant through 6 bioinformatic tools. Respectively, 3 (3.6%) black Africans (1 in PKP2, 2 in DSP), 5 (2.7%) Caucasians (2 in PKP2, 3 in DSP), and 1 African patient of mixed-ancestry (1 in DSP) were positive. Variants of unknown significance (VUS) were found in 15 patients; interestingly, one Caucasian carried two VUS in DSP, suggesting a potential compound effect.
Conclusion

Our data confirm the presence of potentially damaging mutations in desmosomal protein genes in patients with DCM. The prevalence of these mutations is similar in black Africans and in Caucasians.

P05.31-S
eNOS as hypertension susceptibility gene: example from genome-wide association study to functional and clinical evidences

E. Salvi[1], *T. Kuznetsova*[2], *S. Lupoli*[1], *L. Thijs*[2], *F. D'Avila*[1], *M. Barcella*[1], *P. Benaglio*[3], *F. Frau*[1], *D. Velayutham*[1], *D. Braga*[1], *F. Rizzi*[1], *Hypergenes Consortium, FLEMENGHO study, EPOGH study, J. Staessen*[2], *C. Barlassina*[1], *D. Cusi*[1];
[1]*University of Milan, Milan, Italy,* [2]*University of Leuven, Leuven, Belgium,* [3]*University of Lausanne, Lausanne, Switzerland.*

Genome-wide association studies (GWAS) usually point to genomic regions of interest in relation to a trait, but seldom directly identify the causal or functional variant.
In a two-stage GWAS [Salvi et al, Hypertension 2012, PMID: 22184326], we revealed the association between rs3918226 polymorphism in the promoter of the endothelial nitric oxide synthase (eNOS) gene and hypertension (T allele, odds ratio 1.54; combined p = 2.58·10^-13). We identified *in-silico* a putative binding site for transcription factors of the ETS (E-twenty six) family only one nucleotide away from rs3918226.
We then confirmed our preliminary findings by target sequencing, in-vitro experiments, and a population study [Salvi et al, Hypertension 2013, PMID: 24019403]. Target sequencing and imputing of the eNOS region validated rs3918226 as the polymorphism most closely associated with hypertension. HeLa and HEK293T cells transfected with the eNOS promoter carrying the risk T allele had 20% to 40% (P<0.01) lower transcriptional activity than those carrying the C allele (luciferase reporter assays). In a general population of 2722 randomly recruited Europeans, TT homozygosity enhanced the age-related increase in blood pressure and risk of hypertension. The prevalence of TT homozygosity is low but the attributable risk is 51.0%.
Combined with other genetic markers, the rs3918226 polymorphism might, therefore, contribute to the stratification of cardiovascular risk. Further clinical research should establish whether eNOS might be a target for preventive or therapeutic intervention.

P05.32-M
The analysis of cytokine network gene expression profiles in peripheral blood leukocytes of patients with essential hypertension

Y. Timasheva, *I. A. Tuktarova, V. A. Matveeva, O. E. Mustafina;*
Institute of Biochemistry and Genetics Ufa Science Centre Russian Academy of Sciences, Ufa, Russian Federation.

Essential hypertension (EH) is a multifactorial disease with obscure etiology and pathogenesis. Transcriptome of patients with EH is virtually unexplored. We performed the analysis of gene expression in peripheral blood leukocytes of patients with EH and healthy individuals using microarray technology (RT2ProfilerTM PCR Array, SABiosciences Corporation, Qiagen) with subsequent validation of the obtained results by quantitative real-time RT-PCR. We discovered a group of genes with altered transcriptional activity in hypertensive patients: CCL16, CCL17, CCL18, CCL19, CCL23, CCL8, CCR6, CCR8, CX3CR1, CXCL1, CXCL13, ICEBERG, IL17C, IL1F10, IL1F6, IL1F9, SPP1, CD40LG, XCR1, CCL2. Further quantitative analysis of genes with altered transcriptional activity was performed using cDNA samples of 32 EH patients and 31 control subjects. The results have confirmed significant differences of CCL18, CX3CR1, CXCL1, CXCL13, IL10, IL13, and CCR2 expression level between cases and controls (p=0.001). Relative expression level changes in EH patients were more pronounced for CX3CR1 gene (29.2-fold), CXCL13 (13.8-fold), IL1F6 (12.9-fold), CD40LG (8-fold), CXCL1 (7.2-fold). Functional analysis of differentially expressed genes was performed using Gene Ontology Biological Process and Kyoto Encyclopedia of Genes and Genomes databases. The genes with altered transcriptional activity in EH patients were found to encode for cytokines and cytokine receptors involved in immune response and inflammation, and their action was mediated via cytokine signaling pathway. These findings confirm both the hypothesis of implication of blood cells trancriptome in the pathogenesis of EH and the hypothesis of inflammatory basis of the development of EH. The study was supported by the RFBR grants 13-04-01561_a, 14-04-01169_a.

Application of exome sequencing in differential diagnosis of pediatric hypertrophic cardiomyopathy

L. Pezzoli[1], *C. Lodrini*[1], *M. Sana*[1], *C. Marrone*[2], *D. Marchetti*[1], *A. Lincesso*[1], *K. Migliorati*[1], *M. Iascone*[1];
[1]*Laboratorio Genetica Medica, AO Papa Giovanni XXIII, Bergamo, Italy,* [2]*Cardiologia Pediatrica, AO Papa Giovanni XXIII, Bergamo, Italy.*

Hypertrophic cardiomyopathy (HCM) is the most common monogenic cardiac disorder, usually caused by mutations in sarcomere genes. Little is known on genetic basis of infantile forms, since the etiology of HCM in this population is heterogeneous and includes inborn errors of metabolism, neuromuscular disorders, and malformation syndromes. Timely diagnosis is important for patients' management but it could be difficult at first clinical presentation, since the phenotype may not yet be clearly defined. Here we present the analysis of 8 patients presenting severe HCM at less than 1 month of age and their healthy parents by a panel of 2761 known disease genes (TruSight exome). We obtained 27,457,869 reads/sample, the mean coverage was 265X and 98% of target regions were covered at >20X. In one patient we identified a de novo mutation in a classical HCM-associated sarcomere gene (MYH7). Two infants were diagnosed with glycogen storage diseases, one cytoplasmic and one lysosomal, respectively caused by a de novo PRKAG2 heterozygous mutation and a GAA homozygous mutation, for which a specific enzyme replacement therapy exists. One patient carried a homozygous SLC22A5 mutation associated to carnitine deficiency. In the remaining 4 patients we identified 3 PTPN11 heterozygous missense mutations and one de novo heterozygous RAF1 deletion, suggesting the diagnosis of Noonan syndrome. Our results demonstrate the utility of exome sequencing in clinical practice, especially in infants who may benefit of prompt differential diagnosis for therapeutic management and follow-up planning.

Early recognition of Familial defective apolipoprotein B-100 with identification of common p.Arg3527Glu mutation

G. Klancar[1], *P. Malovrh*[2], *U. Groselj*[1], *N. Bratina*[1], *N. Bratanic*[1], *M. Bozic-Mijovski*[2], *M. Cevc*[2], *T. Battelino*[1,3], *K. Trebusak Podkrajsek*[4];
[1]*UMC Ljubljana, University Children's Hospital, Department of Endocrinology, Diabetes and Metabolic Diseases, SI-1000 Ljubljana, Slovenia,* [2]*UMC Ljubljana, Division of Internal Medicine, Department of Vascular Diseases, SI-1000 Ljubljana, Slovenia,* [3]*University of Ljubljana, Faculty of Medicine, SI-1000 Ljubljana, Slovenia,* [4]*UMC Ljubljana, University Children's Hospital, Unit for Special Laboratory Diagnostics, SI-1000 Ljubljana, Slovenia.*

Background: Familial defective apolipoprotein B-100 (FDB) is a dominant inherited disorder most commonly caused by the substitution of glutamine to arginine at position 3527 in the ApoB-100 gene. The mutant p.Arg3527Glu causes a marked reduction in the affinity of low-density lipoproteins (LDL) for the LDL receptor, which leads to hypercholesterolemia and increased risk for cardiovascular diseases (CVD). The p.Arg3527Glu mutation among Caucasian patients have a wide geographic and population distribution. Its prevalence varies among various European populations ranging from 0.08 % to 1.4 %. To our knowledge, this mutation has not yet been studied in the Slovenian population.
Materials and Methods: Following clinical evaluation, p.Arg3527Glu mutation was analysed in a cohort of 102 paediatric patients recruited through nation-wide hypercholesterolemia screening, and 44 adult patients referred to specialised outpatient clinic due to hypercholesterolemia resulting in CVD.
Results: p.Arg3527Glu mutation gene was identified in 14 out of 102 paediatric and in 6 out of 44 adult patients.
Conclusions: Studied population represents two clinical extremes of the FDB, one with and one without manifestations of CVD. Similar frequencies of the mutation were detected in both studied groups, namely 13.7 % in paediatric and 13.6 % in adult patients. Early definitive identification of FDB through paediatric hypercholesterolemia screening and genetic testing is crucial for CVD prevention.

P05.35-S
Insight into genetic determinants of resting heart rate

S. Ulivi[1], *M. Mezzavilla*[1], *P. Gasparini*[1], *A. Iorio*[2], *G. Sinagra*[2];
[1]*Institute for Maternal and Child Health - IRCCS „Burlo Garofolo", Trieste, Italy,*
[2]*Cardiovascular Department, Ospedali Riuniti and University of Trieste, Trieste, Italy.*

Recent studies suggested that resting heart rate (RHR) might be an independent predictor of cardiovascular mortality and morbidity. Nonetheless, the interrelation between RHR and cardiovascular diseases is not clear. In order to resolve this puzzle, the importance of genetic determinants of RHR has been recently suggested, but it needs to be further investigated.
The aim of this study was to estimate the contribution of common genetic variations on RHR using Genome Wide Association Study.
We performed a Genome Wide Association Study in an isolated population cohort of 1737 individuals, the Italian Network on Genetic Isolates - Friuli Venezia Giulia (INGI-FVG). Moreover, a haplotype analysis was performed. A regression tree analysis was run to highlight the effect of each haplotype combination on the phenotype. A significant level of association (p<5x10-8) was detected for Single Nucleotide Polymorphisms (SNPs) in two genes expressed in the heart: MAML1 and CANX. Founding that the three different variants of the haplotype, which encompass both genes, yielded a phenotypic correlation. Indeed, a haplotype in homozigosity is significantly associated with the lower quartile of RHR (RHR≤58 bpm). Moreover no significant association was found between cardiovascular risk factors and the different

haplotype combinations. Mastermind-like 1 and Calnexin were found to be associated with RHR. We demonstrated a relation between a haplotype and the lower quartile of RHR in our populations. Our findings highlight that genetic determinants of RHR may be implicated in determining cardiovascular diseases and could allow a better risk stratification.

P05.36-M
Different genetic background in the clinical onset of Hypertrophic Cardiomyopathy analyzed by Next-Generation Sequencing

C. Bozzao, *S. D. Rubattu, B. M. Musumeci, M. Piane, C. Savio, M. Rapazzotti Onelli, F. Libi, P. Lulli, E. Pennacchini, E. Pagannone, M. Volpe, C. Autore, L. Chessa;*
Department of Clinical and Molecular Medicine, Sapienza University, Roma, Italy.

More than 20 genes have been correlated with Hypertrophic Cardiomyopathy (HCM), making the molecular diagnostic process time consuming, complex and often inconclusive. To better understand the molecular bases of HCM and to assess the utility of next-generation sequencing (NGS) into clinical laboratory practice we designed a panel to analyze 17 HCM related genes on PGM Ion Torrent. We selected 70 HCM patients, 35 early onset (≤35 years) and 35 late onset (≥65 years), with a well-defined hypertrophic phenotype.
All samples had on average 98% of target regions with coverage higher than 20X, with a mean coverage of 600X. Common variants (MAF>5%) were removed from the analysis, while potential splice variants and novel single nucleotide variants were analysed with bioinformatics pathogenicity prediction programs. We identified 40 different pathogenetic mutations (9 novel) in 9 genes: *MYBPC3* (16/40=40%); *MYH7* (14/40=35%); *TNNT2* (3/40=7.5%); *CAV3* (2/40=5%); and *GLA*, *MYH6, TNNI3*, *MYL2* and *MYL3* (1/40=2.5% each). The mutation detection rate was 9/35 (26%) in the late onset and 29/35 (83%) in the early onset group (p<0.0001). Considering only early onset patients with positive family history the detection rate was >90%.
Our results showed a strong difference in genetic background of HCM patients for age at onset, family history and clinical features of the disease. Genetic testing with NGS was reliable and allowed the molecular diagnosis especially for cases with early onset and positive family history. These results also demonstrated that an appropriate selection is required for molecular testing in patients with HCM.

P05.37-S
HDAC9 gene is overexpressed in stroke patients

S. Ferronato[1], S. Olivato[2], A. Scuro[3], C. Patuzzo[1], S. Mazzucco[2], **M. Gomez Lira**[1];
[1]Department of Life and Reproduction Sciences, Section of Biology and Genetics, University of Verona, Verona, Italy, [2]Department of Neurological, Neuropsychological, Morphological and Movement Sciences, Section of Neurology, University of Verona, Verona, Italy, [3]Department of Vascular Surgery, University of Verona, Verona, Italy.

Aim: HDAC9 is a class IIa histone deacetylase family member and it regulates the epigenetic status of histones and therefore gene expression by catalyzing deacetylation. Risk variant rs11984041 of HDAC9 gene has been demonstrated to be associated with large vessels stroke. HDAC9 expression has been correlated with common carotid intima-media thickness, suggesting an association of HDAC9 gene with the atherosclerotic process, by accelerating atherosclerosis or promoting plaque instability. In this study we investigated the expression of HDAC9 in peripheral blood (PB) of stroke patients (large vessel and cardioembolic) and healthy controls. Aiming to understand the mechanism by which the risk allele is associated with large vessel stroke, we also evaluate the effect of rs11984041 polymorphism on gene expression.
Methods: HDAC9 gene expression analysis was performed on 26 atherothrombotic stroke patients, 26 cardioembolic stroke patients, and 20 healthy controls by Real Time PCR using Sybr Green. Polymorphism rs11984041 was genotyped by PCR-RFLP method.
Results: A significant increase of HDAC9 gene expression was observed in atherothrombotic and cardioembolic stroke patients compared to healthy controls (1.39±0.68 vs 0.61±0.36; p<0.001; 1.58±1.19 vs 0.60±0.36; p<0.001, respectively).
The genotyping of 70 individuals showed no gene expression differences between patients carrying CC and CT genotypes.
Conclusions: The gene HDAC9 is overexpressed in stroke patients compared to controls. This result indicated that this gene, that can regulate other genes implicated in the peripheral inflammatory reaction after stroke can represent a new target for the development of therapeutic agents against ischemic stroke injury.

P05.38-M
Novel mutations in the *ZIC3* gene cause X-linked heterotaxy

A. D. Paulussen[1], *A. Steyls[1], F. van Tienen[1], R. Lutgens[1], I. Krapels[1], S. Chocron[2], L. Boersma[1], C. Velter[1], Referring clinicians from Europe, B. Smeets[1], J. Bakkers[2], A. van den Wijngaard[1];*
[1]Maastricht University Medical Center, Maastricht, Netherlands, [2]Hubrecht Institute for Developmental Biology and Stem Cell Research, Utrecht, Netherlands.

Congenital heart defects (CHD) is one of the most common congenital abnormalities in newborns, affecting almost 1% of the general population and is associated with substantial morbidity and mortality. A small subset (3%) of this patient population fails to correctly establish left-right patterning during embryogenesis, resulting in abnormal lateralization of the abdominal and thoracic organs, a clinical phenotype called heterotaxy. As the heart is the first organ to develop asymmetrically, disturbances in the left-right axis lead to a variety of serious cardiac malformations in heterotaxy. One of the first genes linked to heterotaxy was *ZIC3*, a zinc transcription factor of the GLI superfamily, located on the X-chromosome. The *ZIC3* gene is a transcriptional regulator, based on the ability to activate transcription of target genes and to bind DNA.
Over the last 10 years we collected and diagnostically tested over 300 patients referred to our clinical genetics center with heterotaxy and/or a variety of heart defects for mutations in the *ZIC3* gene. We identified five potentially pathogenic mutations, as well as variations in the N-terminal polyalanine-repeat. The mutations were detected in families with a clear X-linked clinical profile. To support pathogenicity of detected mutations we performed several functional assays. We used confocal imaging to detect subcellular localization of mutated proteins and the *in vivo* zebra fish model to investigate the potential laterality and/or cardiac defects of these mutated proteins.

P05.39-S
Copy Number Polymorphism study in Essential Hypertension

D. Velayutham, **D. Braga**, *D. Cusi, C. Barlassina, on behalf of HYPERGENES Consortium;*
Department of Health Science, University of Milan, Milan, Italy.

Essential Hypertension is a complex trait influenced by multiple susceptibility genes interacting with environmental factors. We used 2044 hypertensive cases and 1872 normotensive controls recruited over many years across European regions within Hypergenes project and genotyped with Illumina-1M arrays.
Cases and controls were genotyped together to avoid the batch effect for chips and time periods. The Log R ratio of the samples for each SNP was obtained from Genome Studio and the Copy Number (CN) call was performed in Golden Helix after quality controls. CN was estimated in each sample as a mere signal intensity interval measured at a particular locus. Thorough quality control to refine the signal intensity was essential before CN call. Approximately 9% of the samples uniformly distributed between cases and controls were removed for signal to noise ratio and waviness. The PCA analysis on wave corrected data doesn't show demarcation on sex/phenotype, whereas the distinguishable genotyping batches were corrected. Among the 824 segments identified and discretized into 3 state CN, 13 segments were significantly associated with the phenotype.
Odds ratio for these segments were calculated and we identified a top common variant around 1kb in 1st intron of LEPREL1 gene with an odds ratio of 1.7 for hypertension (95% CI 1.3-1.9, p-value = 3.01×10^{-12}). This result suggested that carriers of that CNP had a 1.7 times higher risk for hypertension than non-carriers. Further studies are needed to confirm the association of this CNP with hypertension in other dataset.

P05.40-M
Whole exome sequencing concentrating on the metabolome in familiar hypertrophic- and dilated cardiomyopathy: a pilot collaborative Czech study

N. Ptákova[1], *V. Stránecký[2,1], M. Kubánek[3], A. Krebsová[3], L. Piherová[2], H. Hartmannová[2,1], K. Hodaňová[2,1], J. Kautzner[3], M. Macek Jr[1], M. Macek Sr[1];*
[1]Department of Biology and Medical Genetics, Charles University in Prague-2nd Faculty of Medicine and University Hospital in Motol, Prague, Czech Republic, [2]Institute of Inherited Metabolic Disorders, Charles University Prague -1st Faculty of Medicine and General Hospital, Prague, Czech Republic, [3]Department of Cardiology, Institute for Clinical and Experimental Medicine, Prague, Czech Republic.

Hypertrophic- (HCM) or dilated (DCM) cardiomyopathies are associated with the risk of heart failure and sudden cardiac death. Molecular genetic diagnosis contributes to risk stratification in relatives and may allow for personalized therapy. Altogether, 35 Czech cases from 13 families (7 HCM / 6 DCM) with three or more affected individuals were analyzed by whole exome next generation sequencing (NGS) concentrated on the metabolome and utilizing TruSight Exome Gen Set on HiSeq1500 (Illumina). Potentially pathogenic gene variants were found in 11/13 families and comprised 17 genes that have been associated with all forms of CM, familiar arryth-

mogenic disease or myopathies (TTN, RYR2, CALR3, MYH 7, TPM1, JPH2, DSP, ACTC1, KCNH2, FLNC, SYNE2, CASQ2, VCL, PKP2). Three variants were detected in MYO1C, JAG1, SYNE1 that have not been associated with CM, thus far. Only 12/17 identified genes are included in the currently available targeted TruSight assay. In 3/11 families the potential causative variant was found only in one gene. The combination of two to three pathogenic variants in CM-associated genes were found in 8/11 families. Pathogenic potential of the identified variants must be substantiated by segregation and/or RNA/protein analyses. The failure to detect variants in two large families underscores the limitations of NGS. Nevertheless, our preliminary data suggest, that the use of metabolome NGS in complex families may have higher diagnostic yield than targeted approaches in CM.Supported by conceptual research of FNM 64203, CZ.2.16/3.1.00/24022 and IGA NT13770.

Mexicans have a higher prevalence of dyslipidemia than Europeans which causes a serious health problem due to the increased risk for cardiovascular disease. However, complex population substructure in this admixed population leads to a decrease in statistical power hindering genetic research. Consequently, Mexicans are substantially underrepresented in genomic studies despite their high susceptibility to dyslipidemias. We hypothesized that part of the increased predisposition is explained by population-specific variants. To test our hypothesis, we performed a two-stage cross-population genome-wide association study (GWAS) of hypertriglyceridemia using 19,273 subjects of European and Mexican origin to screen for Mexican-specific variants. First, we compared the Mexican population with its European ancestry population represented by Finns, utilizing Mexican low triglyceride (TG) controls and Finnish low TG controls to screen for variants that differ in frequency between the two populations. Subsequently, we included only these variants in a Mexican TG case-control GWAS to identify Mexican-specific variants. Four Mexican-specific variants were discovered and replicated in an independent Mexican cohort (n=6,159), including signals near the lipoprotein lipase (LPL) and apolipoprotein A5 (APOA5) genes, suggesting that regulation of the two key TG genes, APOA5 and LPL, play a crucial role in elevated TGs in Mexicans. We validated the cross-population GWAS results with local ancestry analysis, and all replicated variants reside in highly Amerindian-ancestry enriched regions in Mexicans with high TGs, indicating that cross-population GWAS can effectively screen for population-specific variants. In summary, we present a novel approach, cross-population GWAS, which can be adapted for other admixed populations and different diseases.

P05.42-M
Whole gene deletion of MYBPC3 in Hypertrophic Cardiomyopathy

N. Carson[1], *J. McGowan-Jordan[1], S. Goobie[2], S. Conacher[2], D. McCarty[3], O. Jarinova[1];*
[1]Eastern Ontario Regional Genetics Program, Ottawa, ON, Canada, [2]Medical Genetics Program of Southwestern Ontario, London, ON, Canada, [3]Department of Cardiology, London Health Sciences Centre, London, ON, Canada.

Hypertrophic Cardiomyopathy (HCM) is characterized by left ventricular hypertrophy in the absence of a predisposing cardiovascular condition. Pathogenic variants in 12 genes that encode proteins of the sarcomere have been implicated in HCM. Most of the pathogenic variants act in a dominant negative fashion. However loss of function (haploinsufficiency) is the most common disease mechanism for pathogenic variants in MYBPC3 suggesting that large deletions of the MYBPC3 gene may play a role in HCM pathogenesis. Here, we describe an individual affected with HCM who carries a deletion of the entire MYBPC3 gene.
The patient was diagnosed with non-obstructive hypertrophic cardiomyopathy in his mid forties when undergoing assessment for palpitations and hypertension. Echocardiogram revealed moderately dilated left and right atria with mild mitral regurgitation. There was severe asymmetric left ventricular hypertrophy with interventricular septal hypertrophy. The left ventricular systolic function was normal with an ejection fraction of 65-70%.
MLPA analysis showed a deletion of all exons of the MYBPC3 gene. Subsequent microarray analysis confirmed this deletion and showed that it extended both 5' and 3' of MYBPC3 and included 3 additional known OMIM morbid genes (DDB2, SLC39A13 and RAPSN). Unlike MYBPC3, these additional genes are implicated in autosomal recessive disorders and therefore deletions of these genes are not expected to have clinical significance in this patient.
Our results suggest that although large copy number variation of HCM-related genes would still be considered rare, patients highly suspected of HCM may benefit from MLPA analysis if other deleterious variants have not been identified.

P05.43-S
The c.912_913delTT mutation in MYBPC3 gene is a founder mutation accounting for one-fifth of the Italian patients affected with hypertrophic cardiomyopathy

M. De Bortoli[1], *C. Calore[2], C. Romualdi[1], A. Lorenzon[1], M. Calore[1], G. Poloni[1], G. Rizzon[2], A. Ortile[2], G. Thiene[2], S. Iliceto[2], P. Melacini[2], A. Rampazzo[1];*
[1]Department of Biology, Padua, Italy, [2]Department of Cardiac, Thoracic and Vascular Sciences, Padua, Italy.

Background - Hypertrophic cardiomyopathy (HCM) is considered the most common cause of sudden cardiac death (SCD) in young people. Over 18 genes have been associated with the disease. The aim of this study was to evaluate the clinical characteristics, penetrance and prognosis of HCM patients carrying a founder mutation in myosin binding protein C (MYBPC3) gene.
Methods and Results - Ninety seven HCM probands were screened for MYBPC3 mutations. The frameshift mutation c.912_913delTT (p.F305PfsX27) was found in 19 (19.5%) patients (14 males and 5 females). Among 81 relatives belonging to 14 apparently unrelated families, 45 (20 males and 25 females) resulted to be mutation carriers and 29 had HCM (17 males and 12 females). The family haplotype analysis confirmed a common founder ancestor.
Disease penetrance was incomplete (64.4%) and greater in males than females (85% versus 48%, p=0.009). Eleven (38%) affected mutation carriers were diagnosed between 30 and 40 years old. Probands carrying this founder mutation showed a worse prognosis for SCD or aborted SCD (p=0.01) compared with patients negative for MYBPC3 mutations.
Conclusions - The founder MYBPC3 mutation carriers have a high probability to develop the disease between 30 and 40 years of age, with an increased risk if they are men. They show a significantly reduced survival after the fourth decade of life when compared to patients without MYBPC3 mutations. These findings are of relevant importance for the genetic counseling and therapy, considering the high frequency and poor prognosis associated with this founder mutation.

P05.44-M
MYH7 and *MYBPC3* genetic characterization in Hypertrophic Cardiomyopathy (HCM)

E. Manfredini[1], *F. Turazza[2], M. Frigerio[2], G. P. Gesu[1], S. Penco[1], P. Primignani[1];*
[1]S.S. Genetica Medica, Dip. di Medicina di Laboratorio A.O. Niguarda Ca' Granda, Milan, Italy, [2]S.C. di Cardiologia 2-Insufficienza Cardiaca e Trapianto, A. De Gasperis, A.O. Niguarda Ca' Granda, Milan, Italy.

Hypertrophic cardiomyopathy (HCM) is a common disorder of the heart characterized by cardiac hypertrophy of variable degree, myocyte disarray and fibrosis and can cause severe disorders as angina, arrhythmias and heart failure. HCM affects approximately 1/500 subjects and is an autosomal dominant hereditary disease associated with mutations in genes encoding proteins of the contractile apparatus. As other inherited cardiomyopathies, HCM shows marked phenotypic variability, even within families. Mutations of *MYH7* and *MYBPC3* genes cover about 50% of cases. The *MYH7* gene (14q11.2), encoding the heavy chain of β-myosin protein, was the first gene whose mutations have been associated with hypertrophic cardiomyopathy and is responsible for about 25% of all currently known pathogenic variations. The *MYBPC3* gene (11p11.2) consists of 35 exons encoding the myosin binding protein-C, whose cardiac isoform consists of 1274 amino acids.
Here we report the data collected by our Unit since 2012. We tested 52 patients and found *MYBPC3* causative mutations in 11 affected subjects (21% of cases); six mutations are already described in literature while five result novel ones. *MYH7* genetic testing led to the identification of seven different

mutations in 7/34 patients (20,6%), 3 are novel mutations. Search for causative mutations is an integral part of the HCM diagnosis. The finding of a causative mutation in a patient, permits the identification of family members who may have the disease in an asymptomatic way or who may develop disorders in the future and may in turn transmit the mutation to their offspring.

P05.45-S
Semiconductor (Ion Torrent) massive parallel sequencing of the main Hypertrophic Cardiomyopathy genes based on two tubes multiplex amplification of DNA pools

J. Gómez, *J. Rodríguez-Reguero, C. Morís, E. Coto;*
Hospital Universitario Central De Asturias, Oviedo, Spain.

At least 30 different genes have been linked to Hypertrophic Cardiomyopathy (HCM), with MYBPC3 and MYH7 accounting for most of the mutations. Due to the large size of these genes, Sanger-sequencing of single amplicons is labor-intensive and expensive. Next generation sequencing (NGS) could facilitate the genetic screening of the HCM-genes in large cohorts. Our purpose was to designate and validate a procedure for sequencing the 9 most commonly mutated genes in HCM (*MYH7*, *MYBPC3*, *TNNT2*, *TNNI3*, *ACTC1*, *TNNC1*, *MYL2*, *MYL3*, and *TPM1*), based on two-tubes multiplex amplification of DNA-pools (*Ampliseq;* 176 primer-pairs covering 15,690 bp, 98,62% of the target coding sequence) followed by semiconductor array sequencing with the *Ion Torrent* Personal Genome Machine (PGM; Life Technologies). We created a pool with DNA from 13 patients previously Sanger-sequenced for the coding exons plus at least 5 intronic flanking nucleotides of the nine genes. Each patient was heterozygous for a unique rare variant (including a small deletion); each unique allele (control variant) was thus diluted 1/26 inside the pool. We sequenced the DNA-pool in a medium capacity Ion chip 316 (semiconductor 100 Mb) array, and the data was analyzed with the *Torrent Suite* software optimized to detect insertion/deletion nucleotide changes. We successfully identified all the 13 control variants (including the indels). In conclusion, we developed a NGS protocol for the main HCM genes. The multiplex amplification of DNA pools would reduce the time and cost of screening these genes at a population scale.

Introduction: In approximately 5%-10% of the survivors of sudden cardiac death no underlying cardiac disease is identified and consequently the event is classified as idiopathic ventricular fibrillation (IVF). The genetic etiology of IVF remains mostly obscure and current consensus statements recommend the genetic screening only in presence of clear clinical indications. Methods: Using whole-exome sequencing (Illumina HiSeq 2000) we molecularly investigated 2 Italian unrelated infants with IVF together with the unaffected parents and 3 affected members of a German family with history of sudden unexpected deaths below age 40. Results: In one infant (2 yo) we identified a de novo missense variant in RYR2, the main gene responsible for cathecholaminergic polymorphic ventricular tachycardia (CPVT). The available clinical data were not sufficient to make the diagnosis, as the stress test, the leading clinical tool in CPVT diagnostic process, is not feasible in infancy. In the second infant (4 months), we detected a de novo missense variant in the PARN gene and the biological plausibility of this result is currently under investigation. In the German family we detected in all affected members a novel frameshift mutation in the desmoplakin gene, associated with ARVC with LV involvement (left-dominant arrhythmogenic cardiomyopathy, LDAC). As a matter of fact this finding allowed a better management and follow-up of affected members. Conclusion: Our approach suggests that a target screening for channelopathy and cardiomyopathy genes could be indicated in those IVF cases in which a complete clinical and familial evaluation is not feasible.

P05.47-S
FBN1 deep intronic mutations: Can they explain the molecularly unresolved Marfan cases?

E. Gillis[1], *M. Kempers*[2], *S. Salemink*[2], *J. Timmermans*[3], *E. C. Cheriex*[4], *S. C. A. M. Bekkers*[4], *E. Fransen*[1], *C. E. M. De Die-Smulders*[5], *B. L. Loeys*[1,2], *L. Van Laer*[1];
[1]*Center for Medical Genetics, Faculty of Medicine and Health Sciences, University of Antwerp, Edegem, Belgium,* [2]*Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [3]*Department of Cardiology, Radboud University Medical Center, Nijmegen, Netherlands,* [4]*Department of Cardiology, Maastricht University Medical Center, Maastricht, Netherlands,* [5]*Department of Clinical Genetics, Maastricht University Medical Center, Maastricht, Netherlands.*

Marfan syndrome (MFS) is a multi-systemic autosomal dominant connective tissue disorder caused by mutations in the FBN1 (fibrillin-1) gene, but approximately 10% of MFS cases remain genetically unsolved. Here, we report a new FBN1 mutation in an MFS family that had remained negative after extensive molecular genomic DNA FBN1 testing, including denaturing high performance liquid chromatography (DHPLC), Sanger sequencing, multiplex ligation-dependent probe amplification (MLPA) and micro-array analysis for copy number variation. In addition, four other aneurysm-linked genes were screened for mutations by Sanger sequencing, TGFBR1, TGFBR2, SMAD3 and ACTA2, without any result. Linkage analysis in the family revealed a large linked region on chromosome 15 which was confirmed by microsatellite analysis. Cultured proband fibroblasts and subsequent cDNA sequencing revealed a double peak pattern at the junction of exon 56 and 57. Sanger sequencing of intron 56 revealed a deep intronic point mutation generating a new splice donor site (c.6872-961A>G; ENST00000316623). Together with an existing cryptic splice acceptor site, this mutation results in the integration of a 90 bp pseudo-exon between exons 56 and 57 containing a stop codon and causing nonsense-mediated mRNA decay. Although more than 90% of FBN1 mutations can be identified with regular molecular testing at the genomic level, deep intronic mutations will be missed and require cDNA sequencing or whole genome sequencing.

P05.48-M
Compound-heterozygous Marfan syndrome?

D. Haziri, *L. Risom, M. Dunø, B. Rode Diness;*
Department of Clinical Genetics, Copenhagen University Hospital, Copenhagen, Denmark.

Introduction
Marfan syndrome is an autosomal-dominant condition often caused by mutations in the fibrilllin-1 (*FBN1*) gene. Here we report a family where the proband is compound-heterozygous for two mutations in *FBN1*.
Case
The proband (II:1) was on suspicion of Marfan syndrome at 21 years of age. An aortic dilation was found at age 17, during clinical investigation for rheumatoid arthritis. Family history was ambiguous: His father was operated for an aortic aneurism at age 30, allegedly caused by endocarditis. Sequencing using an NGS panel for Marfan and Marfan-like syndromes was undertaken. Two mutations were found in *FBN1;* one previously reported as causative for Marfan syndrome, the other novel. Results of family investigation and clinical findings are reported in table 1.
Interpretation
Compound heterozygousity has previously been reported in Marfan syndrome. Neither of the two mutations found are present in ESP, nor found among 2000 Danish exomes. In the present case we find it more likely that the previously reported supposed pathogenic mutation found in I:2 is of no/little phenotypical consequence. It was originally found in an isolated case of aortic dissection where no further details were given. The involved amino acid is not evolutionary conserved. Individual I:2 is without clinical symptoms of Marfan syndrome at age 55. The novel c.7694G>A mutation is *in silico* predicted to be likely pathogenic and segregates with the clinical phenotype.

Individual	Number	Mutation ***FBN1***	Clinical features	Medical history	Diagnosis
Father	I:1	c.7694G>A; p.Cys2565Tyr (novel)	Marfanoid face, wrist sign, arm-span to height ratio 1,05	Aortic dissection at age 36 Childhood surgery for pectus carinatum.	Marfan syndrome according to revised Ghent criteria
Mother	I:2	c.4727T>C; p.Met1576Thr (previously reported)	Normal		Healthy
Proband	II:1	c.7694G>A; p.Cys2565Tyr c.4727T>C; p.Met1576Thr	Marfanoid face, wrist sign, asymmetric chest, pes planus, myopia (-7,5 bilaterally), striae Height 200 cm	Aortic dilation	Marfan syndrome according to revised Ghent criteria

P05.49-S

Several loci enriched in lower frequency variants are associated to risk factor for metabolism and cardiovascular diseases in 4,000 Italian isolated individuals

M. Traglia[1], *M. Cocca*[2], *J. Huang*[3], *Y. Memari*[3], *C. F. Sala*[1], *C. Masciullo*[1], *C. Barbieri*[1], *P. D'Adamo*[2], *P. Gasparini*[2], *N. Soranzo*[3], *D. Toniolo*[1];
[1]Division of Genetics and Cell Biology, San Raffaele Research Institute, Milano, Italy, [2]Institute for Maternal and Child Health–IRCCS Burlo Garofolo, Trieste, Italy, [3]Wellcome Trust Sanger Institute, Genome Campus, Hinxton, United Kingdom.

The main strength of genetic isolated populations is the enrichment in low frequency variants in respect to the general population. To date they have been used in large meta-analyses to highlight genetic association of common variants with several complex traits. Thanks to next-generation sequencing approaches we are now able to map population-specific low-frequency variants.
The Italian Network of Genetics Isolates (INGI) collects > 4,000 genotyped individuals from several isolated populations along Italy sampled for a large set of obesity and cardiovascular related traits. The whole Italian cohort has been imputed to UK10k sequenced reference set to highlight rare variants associations for ~ 30 traits in common that affect metabolism: several population-specific associated LOCI were enriched in rare variants, 33 suggestive LOCI were shared in 2 or more cohorts and most of UK10k outcomes were replicated by Italian cohorts.
A first random subset of 110 Italian isolated individuals was sequenced by a low-coverage approach: 39% were rare variants, 22% were private SNPs and 14% were population-specific variants. Most of lower-frequency SNPs match with 1000GP and UK10k called variants but many are population specific. To further enrich in lower frequency variants and design a Southern Europe reference panel with, ~ 1,000 samples were randomly selected from each isolated cohort and are being typed by low-coverage whole-genome sequencing and high-coverage exome-sequencing. The preliminary results will be presented.

P05.50-M
Differentially expressed miRNAs in the hepatic acute phase response

S. W. Lukowski, *R. J. Fish, M. Neerman-Arbez;
University of Geneva, Geneva, Switzerland.*

Understanding gene regulation in the cardiovascular system provides a source of potential cardiovascular disease (CVD) mediators and therapeutic targets. It may also give functional evidence for associations between genetic variants and CVD. The link between inflammation and CVD is well established and Acute Phase Proteins (APPs) of the innate immune system are recognized CVD markers. Changes in the expression of APPs are primarily due to altered hepatic expression in response to circulating inflammatory cytokines such as interleukin-6 (IL-6). Whereas cytokines are rapidly cleared following induction of the Acute Phase Response (APR), the expression of APPs is maintained for several days and is diagnostically useful. MicroRNAs (miRNAs) also show potential as CVD biomarkers since many are stable in the circulation and their expression is altered in acute myocardial infarction and cancer.
To determine whether miRNAs are involved in modulating the expression of specific APPs in the APR, we performed RNAseq on small RNAs in HepG2 cells, and human and mouse primary hepatocytes stimulated with IL-6 for 0, 6 and 24h. Our data revealed 21 differentially expressed miRNAs upon IL-6 stimulation across all samples (10 up-regulated, 11 down-regulated), 13 of which are known circulating miRNAs. Interestingly, although no differentially expressed miRNAs were shared between the three hepatic cell types, groups of functionally related target genes (SOCS, ADAMTS, MMP, interleukins) are common to all three and are involved in cytokine signaling, coagulation, hypoxia and angiogenesis. Identifying new APR markers may provide important diagnostic tools and enhance our understanding of this complex system.

[1]de Duve Institute (Université catholique de Louvain, Brussels, Belgium, [2]Center for Human Genetics Katholieke Universiteit Leuven, Leuven, Belgium, [3]Department of Ophthalmology, St Rafael University Hospitals, Leuven, Belgium, [4]Department of Clinical Genetics, University Hospitals of Leicester, Leicester, United Kingdom, [5]Department of Clinical Genetics, Lund University Hospital, Lund, Sweden, [6]Hospital General de Niños „Pedro de Elizalde", Buenos Aires, Argentina, [7]Pediatrics and Medical Genetics, Barzilai Medical Center, Ashkelon, Israel, [8]Division of Human Genetics, University of Cape Town, Cape Town, South Africa, [9]Medical Genetics, Kaiser Permanente, Sacramento, CA, United States, [10]Center for Medical Genetics, Ghent University Hospital, Ghent, Belgium, [11]Department of Ophthalmology, Queen Fabiola Children's University Hospital, Brussels, Belgium, [12]Servicio de Pediatría, Hospital San Pedro de Alcántara, Cáceres, Spain, [13]Center for Vascular Anomalies, Cliniques Universitaires St-Luc, Brussels, Belgium, [14]Walloon Excellence in Lifesciences and Biotechnology (WELBIO), Brussels, Belgium.

Microcephaly with or without chorioretinopathy, lymphedema, or mental retardation syndrome (MCLMR, OMIM 152950) is a rare autosomal dominant disorder with variable expressivity. It is characterized by mild-to-severe microcephaly, often associated with developmental delay, ocular defects and lymphedema, usually on the dorsum of the feet. It can be sporadic or inherited. So far, 25 families (46 patients) have been described to carry a mutation in KIF11. This gene encodes a homotetrameric motor kinesin, EG5. Members of this protein family are involved in the establishment of a bipolar spindle during cell mitosis, in chromosome positioning and in centrosome separation. EG5 inhibition impairs endothelial cell proliferation and migration, and angiogenesis. We tested a series of 23 unreported MCLMR index patients for KIF11 and found 14 mutations, 12 of which are novel. We detected a mutation in all 7 familial cases and 7 of the 16 sporadic patients. The inherited mutations were found in an additional 12 family members. We subsequently reviewed the clinical phenotypes of all the patients with a KIF11 mutation, including those already published (n=46+26=72). Microcephaly in frequency was present in at least 94%, eye anomalies in 69%, mental retardation in 68% and lymphedema in 53% of patients. Three mutation carriers are unaffected. We observed 14 de novo cases within 39 index patients (36%). As the remaining sporadic patients may be mosaic, KIF11 mutations likely cause the majority, if not all, of MCLMR.

P05.52-M
Next-generation sequencing as a diagnostic tool in sudden unexplained death victims and patients with a cardiac disease

C. L. Hertz[1], *S. L. Christiansen*[1], *L. Ferrero-Miliani*[1], *S. L. Fordyce*[1], *A. G. Holst*[2], *R. Frank-Hansen*[1], *H. Bundgaard*[2], *N. Morling*[1];
[1]Section of Forensic Genetics, Department of Forensic Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, [2]The Unit for Inherited Cardiac Diseases, The Heart Centre, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark.

Objective
Sudden cardiac death (SCD) is responsible for a large proportion of deaths in young individuals. After routine post-mortem investigations, many cases are still unexplained. Implementation of genetic investigations in forensic medicine may increase the diagnostic rate – not least in sudden unexplained death (SUD). With next generation sequencing (NGS), genetic analysis has become faster and more efficient, enhancing the outcome. The purpose of the study was to explore the yield of genetic analysis using NGS in forensic pathology and to compare the genetic findings to routinely diagnosed patients.
Methods and results
Genetic investigation was performed in 44 unrelated individuals; 15 forensic SUD cases and 29 unrelated patients diagnosed with channelopathies. In-solution targeted sequencing capture probes were custom designed by Roche NimbleGen, including all exons of 31 genes, and sequenced on the Illumina MiSeq. Larger deletions and insertions in five genes were investigated with multiplex ligation-dependent probe amplification. Of the SUD cases, 21% were found to have a probably pathogenic variant. The corresponding hit-ratio in the patient cohort was 37%. Two patients (7%) had large deletions.
Conclusion
By NGS, it was possible to detect a probably pathogenic single nucleotide variant in one fifth of the SUD cases, disposing to a cardiac disease. In contrast, almost half of the patients were found to carry a probably pathogenic variant or larger deletion. Genetic investigation with NGS can be used as a diagnostic tool in both a forensic and clinical setting.

P05.53-S
PRDM16 and MIB1 mutations are rarely identified in nonsyndromic left ventricular noncompaction cardiomyopathy

Y. M. Hoedemaekers, *L. G. Boven, M. P. van den Berg, R. A. de Boer, J. D. H. Jongbloed, P. J. van Tintelen;
UMCG, Groningen, Netherlands.*

Background Left ventricular noncompaction cardiomyopathy (LVNC) is a subtype of cardiomyopathy characterised by an excessively thickened endocardial layer with deep intertrabecular recesses. It is familial in the majority of cases, with involvement of mainly sarcomeric genes. Recently mutations in MIB1 were associated with LVNC while the LVNC in 1p36 deletion syndrome was attributed to the PRDM16 gene. The MIB1 gene is involved in the NOTCH pathway, regulating endocytosis of Notch ligands. PRDM16 regulates leukamogenesis, palatogenesis, neurogenesis and brown fat development and is expressed in both embryonic and adult left ventricular myocardium. **Methods and results** To establish the contribution of PRDM16 and

MIB1 mutations to nonsyndromic LVNC we analysed the coding regions of PRDM16 and MIB1 in a cohort of 41 nonsyndromic LVNC patients (39 adults and 2 children). In PRDM16, we identified 5 synonymous variants, and five missense variants. Two of these missense variants were found in 40 and 14 patients respectively and are considered single nucleotide polymorphisms (SNPs). Two variants are considered likely pathogenic (c.89C>T; p.A30V and c.1882G>A; p.D628N) and one was classified as a variant of unknown significance (VOUS: c.2290G>A; p.V764M). We did not find any mutations in the MIB1 gene. **Conclusions** We identified two likely pathogenic variants and one VOUS in the PRDM16 gene, supporting previous evidence of mutations in the PRDM16 gene as a rare cause for LVNC. The MIB1 gene did not contribute to LVNC in our cohort.

[1]*Erasmus Medical Center, Rotterdam, Netherlands,* [2]*University of Groningen, Groningen, Netherlands,* [3]*University Medical Center Utrecht, Utrecht, Netherlands,* [4]*Sint Anna Hospital, Geldrop, Netherlands,* [5]*Academic Medical Center, Amsterdam, Netherlands.*

Background: Bicuspid aortic valve (BAV), congenital aortic valve stenosis (AVS), coarctation of the aorta (COA) and hypoplastic left heart syndrome (HLHS) are part of the spectrum of left-sided ventricular outflow tract obstructions (LVOTO) and are highly heritable congenital heart malformations. Mutations in *NOTCH1* are associated with LVOTO, but since its discovery in 2006 only eight new *NOTCH1* mutations have been identified, mostly in sporadic LVOTO patients. **Patients and methods:** In 427 LVOTO probands (204 BAV/AVS, 135 COA, 75 HLHS, 13 other) *NOTCH1* mutation analysis was performed. Also family members of probands with *NOTCH1* mutations were screened for the mutation. We report on the clinical characteristics and natural history of *NOTCH1* mutation carriers. **Results**: Thirteen pathogenic *NOTCH1* mutations were detected in 427 (3%) LVOTO probands (8% of familial cases and 1% of sporadic cases). In total 52 *NOTCH1* (obligate) mutation carriers were identified. The phenotype included not only LVOTO, but a wide variety of cardiovascular malformations (CVM) including conotruncal heart malformations (12%), septal defects (8%), and thoracic aortic aneurysms (8%). The disease seems highly penetrant at adult age. **Conclusion**: *NOTCH1* mutations are present in 8% of familial LVOTO. The phenotypic spectrum is expanded and includes a wide variety of heart malformations, indicating an effect of these mutations on neural crest derived cells and epithelial to mesenchymal transition. The high penetrance at adult age highlights the importance of genetic testing of *NOTCH1* for early diagnosis, not only in LVOTO families but in a variety of familial congenital CVM.

Rationale: The genetic basis of idiopathic pulmonary arterial hypertension (iPAH) is well recognized but still rarely utilized in diagnostic setting. Hundreds of mutations in coding exons and introns of, at least, seven genes have been reported to associate with idiopathic and familial forms of PAH. Comprehensive genetic testing can improve diagnostics, prognostics and treatment optimization of the index patient but it also allows effective screening of asymptomatic family members, which is a basis for well-informed genetic counseling. Methods: We adopted the novel oligonucleotide-selective sequencing (OS-Seq) and developed a custom data analysis and interpretation pipeline to identify pathogenic base substitutions and insertions and deletions in seven genes associated with PAH: BMPR2, BMPR1B, ACVRL1, ENG, SMAD9, CAV1 and KCNK3. Our sequencing panels covered >99% of the targeted regions with >15x coverage. We validated our diagnostic panels using reference HapMap samples with known genomes and mutations. Results: The sensitivity of OS-Seq to detect base substitutions was >99% and specificity was >99.9%. The accuracy to detect short INDELs was 100%. We then analyzed 22 iPAH patient samples to identify known and novel variants potentially associating with the disease. We confirmed all candidate variants using direct sequencing. The utilized novel technology allows significant cost reduction and rapid turnaround time from sample to clinical interpretation. Conclusion: These results demonstrate that the developed high-throughput targeted OS-Seq platform for PAH meets the technical criteria of clinical diagnostics and is a cost-efficient tool in clinical research.

Introduction: Noonan Syndrome-Multiple Lentigines (NS-ML) is a rare autosomal dominant disorder, and one of the conditions known as RASopathies. PTPN11, RAF1, and BRAF are the genes known to be associated with NS-ML. Sequence analysis of coding exons 7, 12, and 13 of PTPN11 detects missense mutations in about 90% of individuals tested.
Objective: The aim of this study was to characterize the clinical and molecular features of Chilean patients with NS-ML. Methods: collaborative and descriptive study. Results: thirteen patients have been confirmed molecularly. This includes two familial cases. The age at diagnosis ranged from 20 days to 33 years old. In six patients including one of the family cases, the recurrent mutation p.Tyr279Cys in exon 7 was identified. They showed interfamilial and intrafamiliar variable expressivity. Four patients have mutations in exon 12, three with the recurrent mutation p.Thr468Met and one with an infrecuently reported one, p.Ala461Thr. Two different mutations were identified in exon 13, in three patients. The uncommon mutation p.Gln510Glu, was found in two patients, both with prenatal cardiac manifestations, and a Hypertrophic cardiomyopathy (HCM) rapidly progressive. The other mutation at codon 510 is a Gln510Pro. Discussion: The diagnosis of this condition may be challenging because clinical features overlap with other RASopathies. Although NS-ML seems to be rare, we have diagnosed a considerable number of patients. We developed a high index of suspicion particularly in patients with HCM. Eventually specific mutations could be predictor of adverse cardiac events.

Shprintzen-Goldberg syndrome (SGS) is a rare, systemic connective tissue disorder characterized by craniofacial, skeletal and cardiovascular manifestations that show significant overlap with the features observed in the Marfan (MFS) and Loeys-Dietz syndrome (LDS). A distinguishing observation in SGS patients is the presence of intellectual disability, although not all patients in this series present this finding. Recently, SGS was shown to

be due to mutations in the SKI gene, encoding the oncoprotein SKI, a repressor of TGFβ activity. Here we report eight recurrent and three novel SKI mutations in eleven SGS patients. All were heterozygous missense mutations located in the R-SMAD binding domain, except for one novel in-frame deletion affecting the DHD domain. Adding our new findings to the existing data clearly reveals a mutational hotspot, with 74% (23 out of 31) of the hitherto described unrelated patients having mutations in a stretch of five SKI-residues (from p.(Ser31) to p.(Pro35)). This implicates that the initial molecular testing could be focused on mutation analysis of the first half of exon 1 of SKI. As the majority of the known mutations are located in the R-SMAD binding domain of SKI, our study further emphasizes the importance of TGFβ signaling in the pathogenesis of SGS.

P05.58-M

Mutations in the *TSPYL1* gene are not associated with sudden infant death syndrome in a Swiss cohort of deceased infants

S. Schubert[1], *C. Haas*[2], *C. Bartsch*[2], *M. Mirshekarnejad*[1], *S. Kohrs*[1], *I. Röttinger*[1], *M. Stuhrmann*[1], *C. Scholz*[1], *J. Schmidtke*[1];
[1]*Institute for Human Genetics, Hannover Medical School, Hannover, Germany,* [2]*Institute of Legal Medicine, University of Zurich, Zurich, Switzerland.*

Background: Sudden infant death syndrome (SIDS) is currently the major cause of an unexpected and unexplained death of infants in the first year of lifetime in industrialized countries. Besides environmental factors also genetic factors are supposed as risk factors for SIDS. Notably, a frameshift mutation (c.457dupG, p.Glu153Glyfs*17) in the *TSPYL1* gene has been reported as disease causing for an autosomal recessive sudden infant death with dysgenesis of the testes syndrome (SIDDT) in an Old Order Amish community in Pennsylvania. Because the Amish community was originally founded in the German speaking part of Switzerland, including people from Alsace and Palatinate, a mutation analysis of the entire *TSPYL1* gene was performed in a cohort of 166 SIDS cases originating from the Swiss population around Zurich in comparison to 163 controls.
Eight known SNP variants (rs61746509, rs3828743, rs3749895, rs61746508, rs56100880, rs3749894, rs45490498 and rs9400897) were detected in the analyzed SIDS cohort, none of which was significantly associated with SIDS. In this context we also found two potentially disease causing amino acid substitutions in three deceased girls. One SIDS affected girl was heterozygous for the novel *TSPYL1* variant c.106C>G (p.Leu36Val) and two affected girls were heterozygous for the rare known *TSPYL1* substitution rs140756663 (c.1098C>A, p.Phe366Leu). *In silico* analyses predicted rather non-pathogenic effects for pPhe366Leu and p.Leu36Val, although protein features might be affected. The founder nonsense mutation c.457dupG (p.Glu153Glyfs*17) was not detected in our analyzed SIDS cohort of Swiss origin.
Conclusions: Mutations in the *TSPYL1* gene are not associated with SIDS in Swiss infants.

P05.59-S

SMAD3-related aortic aneurysms & dissections: A new physical finding in a large affected family

W. S. Meschino[1,2], *L. Collins*[3], *K. L. Boycott*[4], *C. F. Morel*[5], *J. So*[5,6];
[1]*North York General Hospital, Toronto, ON, Canada,* [2]*University of Toronto, Toronto, ON, Canada,* [3]*Porcupine Health Unit, Timmins, ON, Canada,* [4]*Childrens Hospital of Eastern Ontario, Ottawa, ON, Canada,* [5]*University Health Network, Toronto, ON, Canada,* [6]*Lakeridge Health, Oshawa, ON, Canada.*

Objective: To expand the phenotype of *SMAD3*-related aortic aneurysm and dissections by investigation of a large family. **Methods**: Genetic testing of *SMAD3* was undertaken. Physical features of two male first cousins presenting to a Genetics Clinic with thoracic aortic aneurysm/dissection were compared followed by testing and clinical characterization of the extended family. **Results**: Molecular testing confirmed that the proband and his cousin were heterozygous carriers of a deletion of exons 4-12 in *SMAD3*. Each had several features typically seen in Marfan syndrome or Loeys-Dietz syndrome (marfanoid habitus, ocular hypertelorism in one case and mild marfanoid craniofacial features and excessive striae in the other). One feature not reported in either condition was the presence of multiple small, punctate, palmar keratoses. Additional members of the kindred were examined and tested. Eight more mutation carriers were identified. Of the adults 39 years or older who carried the mutation, all 5 had multiple punctate palmar keratoses. For the 5 carriers aged 13-22 years, one had definite palmar keratoses. None of the mutation-negative patients had palmar keratoses. There was considerable variability in age at onset for aneurysm/dissection and presence of non-vascular features. A summary of features will be presented. **Conclusions**: We conclude that punctate palmar keratoses may be a previously unreported feature of some families with *SMAD3*-related aortic aneurysms and dissections, and a useful sign in distinguishing SMAD3-related cases from other genes associated with aortic aneurysm/dissection.

P05.60-M

Are ALOX5AP SNPs a risk or protective factor for Stroke?

A. Papapostolou, K. Spengos, E. Fylaktou, M. Poulou, S. Kitsiou-Tzeli, E. Kanavakis, **M. Tzetis**;
Dept of Medical Genetics, Athens, Greece.

ALOX5AP (5-lipoxygenase) has been recognized as a susceptibility gene for stroke. Using a case-control design, we sequenced the whole coding and adjoining intronic regions of *ALOX5AP* to study the role of SNPs and their interplay with other risk factors in Greek patients with stroke. 277 patients were included and classified by the Trial of Org 10172 in Acute Stroke Treatment (TOAST): large vessel disease (63), intracerebral hemorrhage (33), cardioembolic origin (14), undetermined (38), other causes (12) and lacunes (117). The mean age of patients was 58.9±14.64, comprising 191 males. A control group of 210 subjects, ethnicity, sex and age matched, with no stroke history were also genotyped. Risk factors (hyperlipidemia, hypertension, atrial fibrillation, migraine, CAD, diabetes, smoking and alcohol consumption) were assessed as confounding factors. SNPs rs4769055, rs3803277 and rs202068154 showed significantly different ($p<0.01$) frequencies between patients and controls. More specifically the genotype frequencies of AA (minor allele) of rs4769055, of genotype CA (A minor allele) of rs3803277 and of AC genotype (C minor allele) of rs202068154 were significantly higher ($p<0.01$) in controls than in patients. All the above SNPs are located in intronic regions of the gene and according to *in silico* programs EX_SKIP and HSF they affect splicing of exons 1 and 2 of *ALOX5AP*. The results were indicative of a protective role of the three SNPs either in homozygosity or heterozygosity for MAF. However, confounding factors as mentioned above have a strong impact on stroke occurrence and outweighed the protective role of the above SNPs.

P05.61-S

Postmortem genetic testing in a series of 36 young patients after sudden cardiac death

I. Marey[1], *V. Fressart*[1], *C. Rambaud*[2], *E. Gandjbakhch*[1], *A. Mallet*[1], *E. Le Boette*[1], *C. Bordet*[1], *G. Lorin de la Grandmaison*[2], *P. Richard*[1], *P. Charron*[1];
[1]*Centre de référence pour les maladies cardiaques héréditaires, Groupe Hospitalier Pitié Salpétrière, Paris, France,* [2]*Service d'anatomie pathologique, CHU Raymond Poincaré, Garches, France.*

The incidence of sudden cardiac death (SCD) increases with age in parallel with coronary's diseases' prevalence. In young persons and athletes, SCD occurs in half of the cases, in the setting of genetically transmitted disorders such as cardiomyopathies. Molecular testing performed after necropsy may help management of families but experience in this area appears very limited. The aim is to report our experience of post mortem molecular testing after SCD and necropsy. We studied 36 patients <40 years who died suddenly with a suspected diagnosis of cardiomyopathy, established either after autopsy or known before death , with 6 dilated cardiomyopathy (DCM), 12 hypertrophic (HCM), 2 HCM/DCM , 1 restrictive (CMR), 14 arrhythmogenic right ventricular cardiomyopathy (ARVC), 1 HMC and left ventricular noncompaction. Fifteen mutations have been identified in sarcomeric or desmosomal or lamin genes. The identification of these mutations had significant impact: assessing right diagnosis in a doubtful case (HCM without LVH), modifying the appropriate diagnosis in another case (HCM and not DCM), providing guidance for genetic counselling and predictive genetic testing in relatives in all situations. Technical, ethical and legal issues may however be encountered and will be discussed. This study is one of the first series of post-mortem molecular testing after SCD which suggests the feasibility, efficiency and the benefit of the approach to improve the management of families. Postmortem molecular testing must take its place in the strategy of family care after SCD, even if a cardiomyopathy is suspected at necropsy, since genetic findings provide additional information.

P05.62-M

Mutation detection rate and -characteristics in thoracic aortic aneurysm (TAA) related disorders: results from next generation sequencing (NGS) panel testing

L. Campens[1], *L. Muino Mosquera*[1], *B. Callewaert*[1], *M. Baetens*[1], *M. Renard*[1], *A. De Paepe*[1], *J. De Backer*[1,2], *P. J. Coucke*[1], **F. Malfait**[3];
[1]*Center for Medical Genetics Gent, Gent, Belgium,* [2]*Cardiology Department, University Hospital Gent, Gent, Belgium,* [3]*University Hospital Gent, Gent, Belgium.*

Background: Targeted gene testing for Heritable Thoracic Aneurysms and Dissections (H-TAD) is compromised due to overlapping clinical features and the identification of mutations in non-syndromic patients. Therefore panel testing of multiple genes has now emerged as the preferred approach. So far, no data on mutation detection rate with this technique have been reported. **Methods:** We implemented NGS based screening after targeted

PCR enrichment of the 7 most common H-TAD-associated genes (*FBN1*, *TGFBR1/2*, *SMAD3*, *TGFβ2*, *ACTA2* and *COL3A1)*. Between November 2012 and December 2013, 141 samples from unrelated probands presenting either TAD (N=119), arterial aneurysm/dissection outside the aorta (N=10) or syndromic features with a positive family history for TAD (N=12), were sequenced on an Illumina MiSeq sequencer. **Results:** The median age of the cohort was 41.7 years (IQR 29.3 - 52.7y). We found a causal mutation in 22 patients (16%). Clinical and genetic findings are summarized in the table below.

	FBN1	TGFBR1	TGFBR2	TGFB2	SMAD3	COL3A1	ACTA2
Total	10	1	2	3	2	3	1
Clinic	9MFS 1NS-HTAD	1LDS	1LDS 1NS-HTAD	2S-HTAD 1MFS	1S-HTAD 1MFS	1vEDS 2NS- HTAD	1NS-HTAD

MFS: Marfan Syndrome; LDS: Loeys-Dietz Syndrome; (N)S-HTAD: (Non) Syndromic HTAD; vEDS: vascular Ehlers Danlos Syndrome.

Conclusion: NGS based gene panel testing in patients with H-TAD efficiently reveals a mutation in 16% of patients. Causal mutations in patients not presenting clinical manifestations of syndromal H-TAD, as well as mutations in genes -other than *FBN1*- in patients meeting the diagnostic criteria for specific syndromes including Marfan syndrome are identified, justifying a widespread application of this technique.

P05.63-S

A new COL3A1 transgenic mouse model recapitulates the clinical features of vascular Ehlers-Danlos Syndrome

S. D'hondt[1], *B. Guillemyn[1], M. Bertrand[2], S. Janssens[2], W. Toussaint[2], L. Vanhoutte[2], R. De Rijcke[2], B. Lambrecht[2], P. Coucke[1], S. Symoens[1], P. Seghers[3], F. Malfait[1], A. De Paepe[1];* *[1]Center for Medical Genetics - UGent, Ghent, Belgium, [2]Inflammation Research Center - VIB, UGent, Ghent, Belgium, [3]bioMMeda - UGent, Ghent, Belgium.*

Vascular Ehlers-Danlos Syndrome (vEDS) is a severe, life-threatening heritable connective tissue disorder, characterized by translucent skin, easy bruising, and propensity to rupture of arteries and hollow organs. The molecular basis of vEDS has been well-studied, showing a wide range of mutations in COL3A1, encoding type III procollagen. Most mutations result in a glycine substitutions, pivotal for correct folding of the triple helical domain. The mechanisms by which mutant type III collagen cause vascular fragility are not well understood, but factors, other than mechanical failure, are believed to contribute to the phenotype. A Col3a1 knock-out mouse model shows early lethality and is therefore not suitable for functional studies.
We generated a transgenic vEDS mouse model with a Col3a1 missense mutation. With a BAC transgenic approach, the Col3a1 c.547G>A (p.Gly183Ser) mutation, a typical helical glycine substitution, was introduced into the C57BL/6 mouse genome. Spontaneous development of open skin wounds was observed in all transgenic males, but not in females. Expression analysis on dermal fibroblasts revealed substantial higher expression of type III collagen in transgenic males compared to transgenic females. Biomechanical testing of both transgenic males and females showed significantly reduced tensile strength of the skin, aorta and colon. Transmission electron microscopy of skin and aortic tissues showed severely abnormal collagen fibrils, intracellular spaces between smooth muscle cells and dilation of the endoplasmic reticulum (ER) , indicating excessive protein load and ER-stress. This novel animal model provides new opportunities for in-depth analyses of the pathogenic basis of vEDS and for possible therapeutic interventions.

P05.64-M

Genetic tests in the diagnosis of congenital vascular malformations

A. Bruson[1], *R. E. Mattassi[2], A. Porcella[3], S. Benedetti[1], S. Cecchin[1], M. Bertelli[1];* *[1]MAGI Human Genetics Institute, Rovereto (TN), Italy, [2]Director, Center for Vascular Malformations „Stefan Belov"; Clinical Institute Humanitas „Mater Domini", Castellanza (Va), Italy, [3]Director, Laboratory of clinical Analysis; Clinical Institute Humanitas, Castellanza (Va), Italy.*

Vascular anomalies are a heterogeneous group of congenital malformations of the circulatory system characterized by morpho-structural and/or functional defects of various nature, severity and extent in any type of vessel (arteries, capillaries, veins and lymphatic vessels) and in any part of the body. Although most vascular malformations are sporadic (simple or combined), syndromic and familial forms also exist. Diagnosis may be complicated even for experienced specialists, because there is substantial clinical overlap between lesions and each can mimic the others. To our knowledge, there are currently 15 known genetic forms of Mendelian vascular malformation and mutations with autosomal recessive, autosomal dominant or paradominant inheritance have been identified in 25 genes. Sporadic cases with de novo mutations in causative genes of familial forms have also been described. In this study, we investigated all 25 known genes in 108 patients with sporadic congenital vascular anomalies by next-generation sequencing. We identified 24 variations (22%). To estimate their pathogenicity, each variation was looked up in dbSNP137, its frequency was compared using data from the Exome Variant Server, the effect of amino acid substitution on the protein was evaluated using *in silico* analysis, and where possible, it was investigated in the family. Our results confirm the utility and efficacy of genetic testing, even in sporadic cases. Identification of causative genes will be decisive for: determining genotype-phenotype relationships; determining transmission risk; organizing personalized follow-ups; characterizing new drug targets for experimental gene-specific therapies.

P05.65-S

Association of VAV2 and VAV3 polymorphisms with cardiovascular risk factors in hypertensive and diabetic patients

N. Perretta-Tejedor[1,2,3], *J. Fernández Mateos[3,2,4], L. García-Ortiz[2,5], M. Gómez-Marcos[2,5], J. Recio-Rodriguez[2,5], R. González-Sarmiento[2,6,4], J. López-Novoa[1,2], C. Martínez-Salgado[1,2,3];* *[1]Unidad de Fisiopatología Renal y Cardiovascular, Instituto Reina Sofía de Investigación Nefrológica, Universidad de Salamanca, Salamanca, Spain, [2]IBSAL, Hospital Universitario de Salamanca, Salamanca, Spain, [3]IESCYL, Unidad de investigación, Hospital Universitario de Salamanca, Salamanca, Spain, [4]Centro de Investigación del Cáncer,Universidad de Salamanca, Salamanca, Spain, [5]Unidad de Investigación,Centro de Salud La Alamedilla, Salamanca, Spain, [6]Unidad de Medicina Molecular, Departamento de Medicina, Universidad de Salamanca, Salamanca, Spain.*

Hypertension, diabetes and hypercholesterolemia are risk factors for the development of cardiovascular disease, one of the leading causes of death in the world. There are few data on the influence of genetic polymorphisms in these diseases. The guanine nucleotide exchange factors VAV2 and VAV3 play an important role in vascular homeostasis in vivo. Therefore, we evaluated the association of VAV2 (rs 602990) and VAV3 (rs7528153) polymorphisms with susceptibility to hypertension and diabetes-induced cardiovascular risk and cardiovascular damage. We extracted DNA from peripheral blood of 384 patients (152 hypertensive, 66 diabetic and 166 non-diabetic non-hypertensive). Polymorphisms were detected by qPCR with TaqMan® probes. We analyzed systolic, diastolic and pulse blood pressure, basal glycaemia, endothelial dysfunction (by measurement of pulse wave velocity), retinopathy, left ventricular hypertrophy and cardiovascular risk. VAV2 Val584Met polymorphism is associated with family history of hypercholesterolemia in non hypertensive patients carrying the TT genotype (p=0.034, OR=2.706, 1.205-6.321) and the CT genotype (p=0.034, OR=2.194, 1.059-4.545), with elevated pulse pressure in smoker patients carriers of the TT allele (p=0.016, OR=5.538, 1.022-30.019) and with reduced risk of developing metabolic syndrome in non-smokers patients carriers of the TT allele (p=0.05, OR=0,408, 0.180-0.927). VAV3 Sher298Thr heterozygous polymorphism is associated with patients with lower incidence of family history of diabetes (p=0.018, OR=0.470, 0.279-0.793) and with increased fasting glucose in non-smoking non-diabetic patients carrying the TT allele (p=0.043, OR=3.700, 1.266-10.815). Our results suggest that polymorphic variants of VAV2 and VAV3 genes may be involved as risk factors associated with cardiovascular disease in hypertensive and diabetic patients.

P05.66-M

Association of Cytochrome P450 2C9 (CYP2C9) and VKORC1 polymorphisms and warfarin dosage in Iranian patients refer to Shahid Rajaie Heart Center

R. Kameli[1,2], M. Babanejad[1], M. Imeni[1,3], M. Soveizi[1], M. Afshari[4], **S. H. Jamaldini**[1]*;* *[1]Cardiogenetics Research Center , Shahid Rajaie Cardiovascular Medical & Research Center, Tehran Un, Tehran, Islamic Republic of Iran, [2]Biology Department of Islamic Azad University of pharmaceutical sciences, Tehran, Islamic Republic of Iran, [3]Biology Department of Islamic Azad University of pharmaceutical sciences, Tehran, Islamic Republic of Iran, [4]Zabol university of medical science, Zabol, Islamic Republic of Iran.*

Background: Warfarin is a commonly prescribed oral anticoagulant for the treatment and prevention of thrombotic diseases. Warfarin dose has a large interindividual variation. An insufficient dose may fail to prevent thromboembolism, while an overdose increases the risk of bleeding. Patients with CYP2C9*2 and/or CYP2C9*3 polymorphisms need lower dose than wild-type patients. VKORC1 (vitamin K epoxide reductase complex 1) is another gene affecting warfarin metabolism. VKORC1 variants have been reported to be associated with a need for lower doses of warfarin compared with wild-type variants during long-term therapy.
Objective: This study was conducted to identify the associations between demographic characteristics (sex, height, weight, age, ethnicity), and genetic polymorphisms of CYP2C9 and VKORC1 (-1639G>A) with warfarin dose among Iranian patients.
Materials and Methods: Our study concluded 200 patients that reached to a stable dose of warfarin. By PCR-RFLP method CYP2C9*2 and CYP2C9*3 polymorphisms of CYP2C9 gene and VKORC1 (-1639G>A) was genotyped.
Results and Conclusion: Our study showed that CYP2C9 polymorphisms had significant influence on Iranian daily warfarin dose(P=). Our results

suggested that patients with AA genotype in VKORC1 (-1639G>A) require lower doses of warfarin than those with AG or GG genotype. Height and weight did not have a significant correlation with the warfarin maintenance dose. In addition there was no significant relationship between sex and ethnicity with the maintenance dose of warfarin (p< 0.05).

P05.67-S
Analysis of c.1166A>C polymorphism in 3´UTR region of AGTR1 gene in patients with Pulmonary Arterial Hypertension

G. Pousada[1,2], *A. Baloira*[3], *D. Valverde*[1,2];
[1]*Dep. Biochemistry, Genetics and Immunology. Universidad de Vigo, Vigo, Spain,* [2]*Instituto de Investigación Biomédica de Vigo (IBIV), Vigo, Spain,* [3]*Servicio de Neumología del Complejo Hospitalario de Pontevedra, Pontevedra, Spain.*

Pulmonary arterial hypertension (PAH; OMIM 178600) is a progressive vascular disorder characterized by pulmonary vascular resistance increase, vascular remodelling and right heart failure. Angiotensin II is both a potent vasopressor hormone and a primary regulator of aldosterone secretion. It is an important factor that controls blood pressure and volume in the cardiovascular system. AGTR1 gene plays an integral role in blood pressure control, and is involved in the pathogenesis of hypertension. In this study, we demonstrated the association between c.1166A>C polymorphism and PAH. We included 55 PAH patients and 52 controls. Using specifically designed primers we amplified and sequenced the 3´-untraslated region of AGTR1.
We analyzed the c.1166A>C polymorphism located on 3´UTR of AGTR1 gene. By comparing genotype frequencies of controls and patients with PAH, we obtained statistically significant differences for this SNP between the two groups (p>0.001). The RR of developing PAH in patients with this SNP is 20.3; IC 95%; p<0.001. The statistical analysis of clinical and hemodynamics parameters between patients with or without this SNP showed significant differences in systolic pulmonary pressure (p=0.037), cardiac index (p=0.012) and PAH subtypes (IPAH vs APAH) (p=0.028). This SNP is present in 72.4% of IPAH patients and in 67.8% of APAH patients, producing a more severe phenotype. This SNP only appears in 25% of control cohort.
In conclusion, this polymorphism in AGTR1 gene is more frequent in IPAH than in APAH patients and predispose individuals to an increased risk of developing PAH associated with a more severe phenotype.

Alkaptonuria (AKU, “black bone disease”) is caused by mutations in homogentisate-1,2-dioxygenase (*HGD*) gene leading to deficiency of HGD enzyme activity. Clinically it leads mainly to homogentisic aciduria, ochronosis and painful and disabling ochronotic arthritis. AKU was described by Sir Archibald Garrod as the first inborn error of metabolism in 1902, and now, more than 110 years later, we test nitisinone as the first possible treatment of this disorder. We analysed for *HGD* mutations 40 AKU patients enrolled for the first part of this 7FP-supported project DevelopAKUre run in two study centres in Piestany (Slovakia) and Liverpool (UK). In this cohort we observed 20 different pathogenic variants, two of which were novel. The first mutation (R53Q c.158G>A) was present in homozygous state in one patient of Indian origin. The second one (T167I,c.500C>T) was identified in one copy in Slovak AKU patient, further confirming the genetic heterogeneity of AKU in this small country with increased incidence of AKU, where now already 13 mutations are reported. Eight additional novel *HGD* mutations were found in AKU patients sent to our laboratory for a routine molecular diagnostics within a frame of different collaborations. The novel R53Q mutation identified in DevelopAKUre was found also in one Italian patient. One mutation was identified in a patient from Brasil (M186K, c.557T>A), in patient from India (ivs7+6T>C,c.469+6T>C), from France (F147S,c.440T>C), and five in cases from Italy (K248E,c.742A>G// G205D,c.614G>A// K353Q,c.1056A>G// G251D,c.752G>A// Y40S,c.119A>C)). The total number of different AKU-causing mutations as published in our *HGD* mutation database is now 126.

P06.02-M
Intrafamilial gene rearrangements in Barth syndrome leading to different TAZ mutations in siblings

L. Ferri[1,2], *M. A. Donati*[3], *S. Funghini*[2], *L. Spaccini*[4], *F. Natacci*[5], *S. Gasperini*[6], *D. N. Cooper*[7], *R. Guerrini*[1,2], *A. Morrone*[1,2];
[1]*Dept. of NEUROFARBA, University of Florence, Florence, Italy,* [2]*Paediatric Neurology Unit and Laboratories, Meyer Children's Hospital, Florence, Italy,* [3]*Metabolic and Muscular Unit, Meyer Childrens' Hospital, Florence, Italy,* [4]*Ambulatorio Genetica Medica, Ospedale „ Vittore Buzzi „, Milan, Italy,* [5]*Medical Genetics Unit, Ca' Granda IRCCS Foundation, Ospedale Maggiore Policlinico, Milan, Italy,* [6]*Metabolic Unit, San Gerardo Hospital, Milan, Italy,* [7]*Institute of Medical Genetics, School of Medicine, Cardiff University, Cardiff, United Kingdom.*

The X-linked infantile-onset Barth syndrome (BTHS; OMIM #302060) is caused by mutations in the *TAZ* gene and generally manifests in hemizygous males. The major clinical manifestations are cardiomyopathy with or without left ventricular noncompaction, skeletal myopathy, hypotonia, growth delay and neutropenia. Confirmatory tests are provided by mutational analysis of the *TAZ* gene and/or the biochemical dosage of the monolysocardiolipin/ tetralinoleoyl cardiolipin ratio. Heterozygous females do not normally manifest clinically but may undergo molecular prenatal diagnosis during pregnancy.
Here we report the unusual case of a family in whom the male proband and his mother carry different *TAZ* mutations. The ten year-old proband harboured a novel g.4552364_4562302del9937ins705 complex rearrangement which serves to remove *TAZ* exons 1-5. However, during a subsequent maternal pregnancy, molecular prenatal diagnosis of the male fetus revealed that he carried a different *TAZ* gene lesion, g.4558047_4558278del232. The mother was subsequently confirmed to be heterozygous for this novel g.4558047_4558278del232 deletion (which removes only *TAZ* exon 1) but negative for the g.4552364_4562302del9937ins705. The g.4552364_4562302del9937ins705 mutation must therefore have occurred *de novo* in the male proband. The g.4558047_4558278del232 must have occurred *de novo* in the mother since it was not detected in either her mother or grandmother. Sequencing of the breakpoint junctions revealed microhomologies which could have prompted both rearrangements by serial replication slippage.
In conclusion, a mother carrying a gross *TAZ* gene deletion can undergo further germline gene rearrangement and generate children with a different mutation. Such a situation can complicate the pre- and post-natal molecular diagnosis of BTHS.

P06.03-S
Diagnosis of GM1-gangliosidosis or galactosialidosis by enzymology and molecular genetic testing from a single dried blood spot

D. Cregeen, *E. Davidson, O. Chiu, E. P. Green, M. Jackson;*
GSTS Pathology, London, United Kingdom.

GM1-gangliosidosis and galactosialidosis are rare autosomal recessive lysosomal disorders associated with defects in the same protein complex. GM1 gangliosidosis is caused by a deficiency of β-galactosidase, whilst galactosialidosis is associated with deficiencies of both β-galactosidase and α-neuraminidase activity secondary to a defect in the protective protein cathepsin A. We have developed a dried blood spot enzyme assay for β-galactosidase and have added a reference enzyme (α-galactosidase) which is measured simultaneously as a measure of sample integrity. A panel of 300 unaffected individuals were tested to establish a normal reference range; all 5 affected GM1-gangliosidosis patients tested showed clear enzyme deficiency. α-neuraminidase is an unstable enzyme which is therefore unsuitable for dried blood spot analysis and difficult to interpret in leucocyte samples. Differential diagnosis of GM1-gangliosidosis and galactosialidosis has traditionally been carried out by measurement of α-neuraminidase in cultured fibroblasts; however skin biopsy and cell culture can take many weeks. Nested PCR and Sanger sequencing analysis of the GLB1 and CTSA genes can be carried out at this centre from the same dried blood spot sample as enzyme testing, providing a rapid diagnosis from a single convenient sample.

P06.04-M
Unraveling Boucher-Neuhauser syndrome: the multifaceted consequences of PNPLA6 gene mutations

C. M. Lourenco[1], *M. Gonzalez*[2], *F. Speziani*[2], *W. Marques Junior*[1], *S. Zuchner*[2];
[1]*University of Sao Paulo, Ribeirao Preto, Brazil,* [2]*John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, United States.*

Boucher-Neuhauser syndrome (BNS) is a rare genetic entity belonging to the group of hereditary cerebellar ataxias with hypogonadism. The combination of chorioretinal dystrophy, hypogonadotropic hypogonadism and progressive spinocerebellar ataxia are the hallmarks of the disease. Here we report a new phospholipid disorder in a Brazilian BNS family caused by mutations in the PNPLA6 gene (Patatin-like phospholipase domain con-

taining 6) and its role in the metabolism of lysophospholipids. Biochemical and molecular investigations were undertook in a Brazilian kindred affected by a complex neurological disorder, presenting mainly as a spinocerebellar ataxia with hypogonadism and early vision loss. After molecular analysis of genes associated with spinocerebellar ataxia and exclusion of other inborn errors of metabolism (IEMs) associated with cerebellar disease, whole exome sequencing (WES) was performed. Mutations in the PNPLA6 gene were identified in all affected patients. They presented with very early onset visual loss (chorioretinal dystrophy) accompanied by progressive cerebellar ataxia and primary hypogonadism. Brain MRI showed cerebellar and pons atrophy. Peripheral neuropathy (motor axonal neuropathy) was identified in all of them. Mutant mice with mutations in PNPLA6 gene have shown a relentless neurological disease. PNPLA6 codifies a neuropathy target esterase (NTE) hydrolase, an integral membrane protein located on the endoplasmic reticulum. It shows phospholipase activity, being involved in the hydrolysis of lysophosphatidylcholine to yield glycerophosphocholine. Boucher-Neuhauser syndrome is a clear example of the profound biological consequences of mutations in such gene in the central and peripheral nervous system.

P06.05-S

Dissecting the genetic architecture of loci with established effects on multiple cardiometabolic phenotypes

L. Marullo[1], *T. O. Kilpeläinen*[2], *B. K. Cornes*[3], *J. Dupuis*[4], *C. Scapoli*[1], *R. J. F. Loos*[5], *J. B. Meigs*[3], *A. P. Morris*[6], *I. Prokopenko*[7], *on behalf of the XC-Pleiotropy Group;*
[1]The Department of Life Sciences and Biotechnologies, University of Ferrara, Ferrara, Italy, [2]The Novo Nordisk Foundation Center for Basic Metabolic Research, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, [3]General Medicine Division, Massachusetts General Hospital, Boston, MA, United States, [4]Department of Biostatistics, Boston University School of Public Health, Boston, MA, United States, [5]The Icahn School of Medicine at Mount Sinai, New York, NY, United States, [6]Department of Biostatistics, University of Liverpool, Liverpool, United Kingdom, [7]Department of Genomics of Common Disease, Imperial College London, London, United Kingdom.

Genome-wide association studies (GWAS) have identified hundreds of loci associated with cardiometabolic phenotypes, many of which overlap or lie in close proximity. Variants associated with multiple phenotypes, such as at *IRS1*, can provide insight into biology of correlated cardiometabolic traits. However, the genetic architecture of these loci is frequently complex and needs further investigation. To disentangle association patterns of 630 associated SNPs (Dec 2012) from GWAS meta-analyses in Europeans for 19 quantitative phenotypes and two cardiometabolic diseases, we defined sets of adjacent variants located less than 500kb apart and harboring 446 associated SNPs within 151 genomic regions (range=2-8 SNPs/region). We examined, whether associations with multiple phenotypes within each region could be explained by LD through approximate conditional analysis (ApCA) using the GCTA tool.
Across the 151 regions, we observed 14 (10%) loci in which the same SNP was associated with multiple phenotypes. Associations in 11 of these 14 loci were with epidemiologically highly correlated traits. Through ApCA, we identified 41 (27%) regions with multiple associated variants that underlie the same association signals, thus suggesting multi-phenotype effects. Within 45 (30%) regions, multiple signals were explained by independent variants. Thirty-two (21%) regions showed complex architecture, and for the remaining 19 (13%), the association with one phenotype partially explained the effect on another.
Overall, a substantial number (87 or 57.62%) of cardiometabolic loci shows potential pleiotropic effects on multiple phenotypes, which might contribute to their shared biology. Within other regions, distinct genetic effects or more complex architecture could underlie independent regulatory mechanisms.

P06.06-M

Severe thrombocytopenia in CDG1a

S. Goobie[1,2], *P. Atkison*[1,2], *S. Zelcer*[1,2], *C. Prasad*[1,2];
[1]London Health Sciences Centre, London, ON, Canada, [2]Western University, London, ON, Canada.

Congenital disorders of glycosylation type 1a (CGD1a), caused by mutations in the PMM2 gene, is a multi-systemic disorder characterized by the abnormal glycosylation of serum glycoproteins. There is a variable disease course, with the mildest form being virtually asymptomatic, to the most severe form presenting as lethal hydrops fetalis. The classical presentation is that of failure to thrive, abnormal fat distribution, and inverted nipples, with developmental delay, seizures and ataxia. Other systemic features can include protein-losing enteropathy, hepatomegaly, cardiomyopathy, renal cysts, and coagulopathy. Aside from coagulopathy, there are few case reports of hematologic abnormalities in CDG1a. We report a three and a half year old girl with CDG1a diagnosed at 4 months of age. She presented with feeding difficulties and typical physical features. At 6 months she developed progressive hepatosplenomegaly, liver cirrhosis, and ascites. After a life-threatening deterioration, she responded to aggressive management with diuretics, albumin infusions, and repeated paracentesis. She was noted to have pancytopenia with marked thrombocytopenia at 2 years of age, with platelet counts in the range of 10-20x10^9/liter. She did not improve with IVIG or steroids. She had a normocellular marrow with mild decrease of megakaryocytes and granulocytes, which suggested a primary consumptive thrombocytopenia, with some component of reduced megakaryopoesis. As she had become refractory to transfusion, splenectomy was performed in this medically fragile child and resulted in a moderate recovery of platelet levels. This is the second reported case of severe thrombocytopenia in CDG1a, and the only reported case of splenectomy with this disorder.

P06.07-S

Citrin deficiency caused by a novel mutation in the SLC25A13 gene - clinical, biochemical and genetic characterization of new Caucasian case

M. B. Ivanova[1], *D. Avdjieva-Tzavella*[2], *T. Todorov*[3], *A. Todorova*[3], *E. Panteleeva*[4], *E. Lazarova*[5], *H. Kathom*[2], *P. Yaneva*[4], *R. Tincheva*[2];
[1]National Genetic Laboratory, University Hospital of Obstetrics and Gynecology, Sofia, Bulgaria, [2]Department of Clinical Genetics, University Pediatric Hospital, Medical University, Sofia, Bulgaria, [3]Department of Medical Chemistry and Biochemistry, Medical University, Sofia, Bulgaria, [4]Department of Gastroenterology and Hepatology, University Pediatric Hospital, Medical University, Sofia, Bulgaria, [5]Department of Pediatrics, Tokuda Hospital, Sofia, Bulgaria.

Citrin deficiency is an autosomal recessive disorder caused by mutation in the SLC25A13 gene and has three different age-dependent clinical phenotypes: neonatal intrahepatic cholestasis caused by citrin deficiency (NICCD) in newborn, failure to thrive and dyslipidemia caused by citrin deficiency (FTTDCD) in older children, and recurrent hyperammonemia with neuropsychiatric symptoms in citrullinemia type II (CTLN2) in adults. To date almost all reported patients were from East Asia and only few cases from Caucasian origin have been described.
We report the first Bulgarian case of NICCD - a male infant with a mild neonatal jaundice which resolved spontaneously. The patient became jaundice again at 40 days old.
Initial investigations revealed conjugated hyperbilirubinemia and evidence of liver dysfunction, hypoproteinemia, mild hypoglycemia and mild anemia. Metabolic evaluation showed lactate acidemia, galactosemia and significant elevation of citrulline, methionine and arginine.
Mutation study of the SLC25A13 gene showed the compound heterozygote, c.1081C>T (p.R361X) and c.74C>A (p. A25E), which confirmed the diagnosis of NICCD. c.1081C>T (p.R361X) is previously unreported nonsense mutation.
After galactose restriction and supplementation with fat-soluble vitamins liver functions were normalized and cath-up growth was achieved before 8 months of age.
In conclusion, we presented a new genetically confirmed case of NICCD patient from non-Asian origin. We detected a previously undescribed nonsense mutation in SLC25A13 which further expanded the genotypic spectrum and genotype-phenotype correlations of citrin deficiency.
NICCD has been underdiagnosed and should be considered in infants with intrahepatic cholestasis, especially when associated with elevated plasma galactose and citrulline, regardless of ethnicity.

P06.08-M

Mmachc is required for pre-implantation in the mouse

M. A. Moreno-Garcia, **M. Pupavac**, *D. S. Rosenblatt, M. Tremblay, L. A. Jerome-Majewska; McGill University, Montreal, QC, Canada.*

Mutations in *MMACHC* cause the most common inborn error of vitamin B_{12} (cobalamin) metabolism - *cblC.* Patients with this disease are unable to convert cobalamin into the two active forms, methylcobalamin and adenosylcobalamin; consequently, they have elevated homocysteine and methylmalonic acid levels in blood and urine. Some *cblC* patients also have structural abnormalities, including congenital heart defects. In the mouse, *Mmachc* has tissue and stage-specific expression during organogenesis (Pupavac, M. *et al. Mol Genet Metab.* **103**, 401-405 (2011)). We generated mice with a gene-trap insertion in intron 1 of the *Mmachc* gene, (*Mmachc*$^{Gt(AZ0348)Wtsi}$). Mice heterozygous for this gene-trap allele were viable and fertile, but showed a 50% reduction in Mmachc protein compared to wild-type littermates. The *Mmachc*^{Gt} allele was inherited with a transmission ratio distortion in a subset of matings. Homozygous *Mmachc*^{Gt} embryos were not found after embryonic day 3.5. These studies indicate that the *Mmachc* gene product is essential for early mouse development.

P06.09-S
POLG mutations in Polish patients with mitochondrial disease of unknown etiology - preliminary data

D. Piekutowska-Abramczuk[1], *J. Trubicka[1], M. Kaliszewska[2], K. Tońska[2], P. Kowalski[1], S. Łuczak[1], E. Ciara[1], D. Jurkiewicz[1], M. Borucka-Mankiewicz[1], M. Pelc[1], J. Taybert[1], E. Bartnik[2], M. Krajewska-Walasek[1], E. Pronicka[1];*
[1]Children's Memorial Health Institute, Warsaw, Poland, [2]Institute of Genetics and Biotechnology, Faculty of Biology, University of Warsaw,, Warsaw, Poland.

POLG mutations are considered as a major cause of mitochondrial diseases (MD) including AHS, MCHC, MEMSA, MIRAS, SCAE, SANDO, PEO, LS, MNGIE, MERRF, MELAS, and SMA-like phenotypes. Epidemiological data point the widespread occurrence of recurrent c.1399G>A (p.A467T), c.2243G>C (p.W748S), and c.2542G>A (p.G848S) mutations in European populations and emphasize significant differences depending on carriers' ethnicity.
A large group of 210 Polish patients with clinical suspicion of MD, and excluded common point mtDNA mutations, large-scale mtDNA rearrangements, and nuclear encoded *SURF1* and *SCO2* mutations, was recruited for *POLG* screening. DNA samples isolated from blood, saliva, urine, muscle and liver biopsies were genotyped for the presence of three common mutations by Real-time PCR with specific TaqMan allele discrimination assays (Light Cycler 480 II, Roche), and were then verified using ABI PRISM dye terminator cycle sequencing kits (Applied Biosystems).
The only mutation identified in the studied group was p.W748S; one case - in homozygous, and seven cases in heterozygous form. Six patients presented with AHS, one adult demonstrated sensory motor neuropathy, and one child psychomotor retardation and stroke-like episodes. In three children despite sequencing the whole gene we did not confirm the presence of the second mutation. Significant predominance of p.W748S mutation indicates similarity to the genotype identified in Nordic patients, that is not frequent in another parts of the world.
Evaluation of the carrier frequency of the common *POLG* mutations among MD patients are being continued.
The study was financed by NCN projects 2012/05/B/NZ2/01627 and 2857/B/P01/2010/39, CMHI projects S126/12 and S217/12.

P06.10-M
A targeted resequencing approach for diagnostics of Congenital Disorders of Glycosylation

E. Souche[1], *L. Keldermans[1], D. Rymen[1,2], G. Matthijs[1], V. Race[1];*
[1]Center for Human Genetics, Leuven, Belgium, [2]Center for Metabolic Diseases, University Hospital Gasthuisberg, Leuven, Belgium.

Congenital Disorders of Glycosylation (CDG) are a genetically heterogeneous group of disorders caused by the alteration in synthesis and structure of protein and lipid glycosylation. To date, more than 60 different causes of CDG have been defined genetically. CDG is also characterised by extremely variable phenotypes with manifestations ranging from severe developmental delay and hypotonia beginning in infancy, to hypoglycemia and protein-losing enteropathy with normal development. Till recently, finding the causative mutation of CDG patients has been impaired by this extreme genetic heterogeneity: it was virtually impossible to Sanger sequence all candidate genes. Instead, one or few genes were tentatively selected based on a combination of biochemical, cell biological and glycobiological investigations. In order to obtain a better diagnostic yield, we designed a capture assay for a panel of 79 genes associated with CDG type I, CDG type II and congenital muscular dystrophy-dystroglycanopathy. To evaluate the assay, targeted sequencing was performed for 16 CDG type I and 15 CDG type II patients. The mean coverage in the target region was about 600x and a genotype was called for more than 97% of the targeted bases. A diagnosis was confirmed in 8 cases. Interestingly, mutations could also be detected (and confirmed) in the gene ALG1 that could not be assayed by genomic Sanger sequencing due to the abundance of pseudogenes. After our targeted assay enabled an increased diagnostic yield, the the most interesting, unsolved cases will be subjected to exome sequencing for gene discovery.

P06.11-S
A patient with congenital disorders of glycosylation type 1q due to mutation in SRD5A3

B. Tüysüz[1], *D. Pehlivan[2], J. Lupski[2], J. Jaeken[3];*
[1]İstanbul University, Cerrahpasa Medical Faculty, İstanbul, Turkey, [2]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States, [3]Centre for Metabolic Diseases, University Hospital, Leuven, Belgium.

Congenital disorders of glycosylation type I (CDG1) are inherited metabolic diseases with an extremely broad spectrum of clinical presentations caused by defective glycosylation of glycoproteins and glycolipids. Recently, mutations in the SRD5A3 gene was found in patients with cerebellar ataxia, and eye malformations. Serum transferrin isoelectric focusing (IEF) demonstrated a type 1 glycosylation defect, thus this disorder was classified as CDG1q. We present here a 4 month old male with coarse face, hypertrichosis and developmental delay. The baby was the fourth child of first-cousin parents. He had narrow forehead, depressed nasal bridge, proptotic eyes, large fontanelle (6x8cm), long philtrum, thin lips, loose skin, hepatosplenomegaly and bilateral inguinal hernia. He also had iris coloboma, glaucoma, nystagmus, corneal clouding and elevated serum transaminases. He was followed up until 27 months of age. He had severe hypotonia and no head control at this age. Dark pigmentation of dorsum of feet was developed. His cranial MR imaging revealed cerebellar hypoplasia, enlargement of lateral ventricules and frontal atrophy. Serum transferring IEF showed a type 1 pattern. Serum IGF1 and antithrombin level also were decreased. Using homozygosity mapping followed by whole-exome genotyping, we described a homozygous missense mutation (c.320G>A; p.Trp107X) in the SRD5A3 gene in the patient. This mutation was reported previously in a Turkish patient with hypotonia and similar eye and cranial findings.

P06.12-M
Congenital Hyperinsulinism of Infancy (CHI): hunt for new genes

C. Battaglia[1,2], *C. Cosentino[1], M. C. Proverbio[3], E. Mangano[2], A. Pietrelli[2], R. Bordoni[2], C. Perego[4], E. S. Di Cairano[4], A. Magi[5], T. Lorenzo[5], G. De Bellis[2];*
[1]Dipartimento di Biotecnologie Mediche e Medicina Traslazionale (BIOMETRA), Dottorato di Medicina Molecolare e traslazionale, Università degli Studi di Milano, Segrate, Italy, [2]Institute for Biomedical Technologies, National Research Council (ITB-CNR), Segrate, Italy, [3]Dipartimento di Fisiopatologia Medico-Chirurgica e dei Trapianti, Università degli Studi di Milano, Segrate, Italy, [4]Dipartimento di Scienze Farmacologiche e Biomolecolari, Università degli Studi di Milano, Milan, Italy, [5]Department of Clinical and Experimental Medicine, University of Florence, Florence, Italy.

Congenital Hyperinsulinism of Infancy (CHI) is a rare disorder, characterized by heterogeneity in clinical and genetic features. An inappropriate insulin secretion is responsible of hypoglycaemia, which can result in serious neurological damage and life-long handicap. The genetic causes of CHI have been found in genes regulating insulin secretion from pancreatic beta-cells but in about 50 % of CHI patients the molecular defect remain unknown. Hunting for novel CHI-causing genes we performed whole-exome sequencing (WES) on 10 CHI patients [Proverbio MC et al, 2013; doi:10.1371/journal.pone.0068740]. To pinpoint the causal mutation in a small number of samples and to select the most promising candidate genes, we implemented a computational strategy including: 1) a bionformatics pipeline to identify a high quality single nucleotide variants (SNV); 2) an exome homozygosity mapping using a novel algorithm H3M2 [Pippucci T el al, 2011; doi: 10.1159/000330164] and 3) a prioritization analysis using the list of rare and novel coding variants by mean of web tools such as ToppGene suite, Endeavour and Gene Distiller. Our approach resulted in a selection of small number of genes that significantly correlate with human phenotype and molecular pathways associated to congenital hyperinsulinism and insulin signalling. Among them we selected missense mutations affecting CDKAL1 and PIK3R1 for further investigations either at the level of protein structure (in silico protein modelling) and in respect to their role in beta cell using INS1-E cellular model and human pancreatic islets.

P06.13-S
Whole-exome sequencing for genetic diagnosis in congenital hypothyroidism

E. G. Serra[1,2], *N. Schoenmakers[3], K. Chatterjee[3], C. A. Anderson[1];*
[1]Wellcome Trust Sanger Institute, Hinxton, United Kingdom, [2]University of Cambridge, Cambridge, United Kingdom, [3]University of Cambridge Metabolic Research Laboratories, Cambridge, United Kingdom.

Congenital hypothyroidism (CH) is the most common endocrine disorder among newborns but its genetic aetiology is still largely unknown, with genetic defects identified in less than 20% of the cases. Mutations in genes for thyroid hormone synthesis (TG, TPO, DUOX2, IYD, SLC5A5, SLC26A4) have been implicated in dyshormonogenesis, while defects in thyroid transcription factors (PAX8, Nkx2.1, Nkx2.5 and FOXE1) and in the TSH receptor have been linked to thyroid dysgenesis. To identify novel mutations in CH, 42 patients and 21 unaffected relatives (25 families) were whole-exome sequenced (WES) as part of the UK10K project. A further 29 patients and 10 unaffected relatives (24 families) were sequenced across a customized panel of genes. We searched for functional de novo or inherited variants that were rare in affected individuals, using 1000 Genomes, NHLBI ESP and UK10K as control datasets. A total of 15 mutations in known causative genes were identified in 10 dyshormonogenesis families. Ten of these variants were novel and predicted to be damaging (TG: 509X, C707Y, W1031L, C1474Y, W2666L, 140X, Q1625E, T1397RfsX30, G638+5; DUOX2: Q570L) and the remaining five were previously reported in CH cases (TG: R277X; DUOX2: Q686X, R354W; TPO: R665Q, R491H).
Our initial findings highlight the potential of WES as a diagnostic tool: five

families harbouring known TG/TPO/DUOX2 mutations have a conclusive genetic diagnosis and novel recessive nonsense mutations here identified are also likely causative. Wider pedigree-genotype correlation is needed to confirm the pathogenicity of the remaining recessive missense mutations here identified.

Danon disease (DD) is a X-chromosome-linked disorder that manifests by cognitive deficit, myopathy and cardiomyopathy in males. The phenotype in females is variable and mitigated as a likely consequence of tissue-specific X-chromosome inactivation (XCI) ratios. DD is caused by mutations in the lysosomal-associated membrane protein 2 (*LAMP2*) gene. Majority of the mutations abolish the protein expression due to truncation of LAMP2 open reading frame. 10-15% of the mutations are exon-copy number variations (eCNV) stemming primarily from recombination events in *LAMP2* intron 3. DD laboratory testing relies on identification of the absence of the protein and characterization of the mutation within the *LAMP2* gene. Importantly, the diagnostic protocol must reflect the following: (i) gender of the proband/patient, (ii) expression patterns of LAMP2 protein, (iii) alternative splicing of *LAMP2* pre-mRNA, (iii) mosaic *LAMP2* expression determined by XCI in female patients, (iv) germinal/somatic mosaicism phenomena. LAMP2 protein testing should be performed by flow cytometry in peripheral white blood cells as this approach offers both minimal invasiveness and detection sensitivity down to 0.008% of deficient granulocytes. The latter is of critical importance in samples from suspect XCI mosaic female patients and/or family members who are potentially germinal/somatic mosaics. Molecular genetics methods should universally assess full-length *LAMP2* mRNA isoforms (2B, A and C) and consequently compare the abnormal findings to gDNA changes. This integrative approach has major advantages in genetic setups when qualitative PCR based methods failed to identify the mutation. Model examples of such situations will be provided in families affected by *LAMP2* eCNVs.

Disorders of postsqualene cholesterol biosynthesis (DCB) are a group of inborn errors of metabolism characterized by multiple congenital abnormalities, including significant skeletal involvement. The most frequent and best characterized example is the Smith-Lemli-Opitz syndrome (SLOS). Nine other disorders are known to date, namely autosomal recessive Antley-Bixler syndrome, Greenberg dysplasia, X-linked dominant chondrodysplasia punctata, X-linked recessive male emopamil-binding protein (EBP) deficiency, congenital hemidysplasia with ichthyosiform erythroderma and limb defects (CHILD) syndrome, CK syndrome, SC4MOL deficiency and the SLOS-like desmosterolosis and lathosterolosis. This study provides an overview of the skeletal radiology of DCB: we report the radiological features of 14 previously unreported patients and review the literature. Our study shows that the DCB have a common pattern of limb abnormalities including polydactyly, which is typically postaxial and rarely interdigital and can involve all four limbs, and syndactyly of the toes. Chondrodysplasia punctata (CDP) is specifically associated with a subgroup of DCB (Greenberg dysplasia, CHILD syndrome, X-linked dominant chondrodysplasia punctata, male EBP deficiency); the possible occurrence of epiphyseal stippling in SLOS, initially reported, does not appear to be confirmed. CDP is also associated with other congenital disorders such as chromosomal abnormalities, brachytelephalangic CDP (X-linked recessive CDP, disruption of vitamin K metabolism, maternal autoimmune diseases), peroxisomal disorders (rhizomelic CDP) and lysosomal storage disorders. In the differential diagnosis of epiphyseal stippling, a moth-eaten appearance of bones, asymmetry or the presence of the common pattern of limb abnormalities are further indicators of DCB. In conclusion, the specific differentiating radiological features of DCB are highlighted.

P06.16-M
Regional reference range lysosomal storage diseases in the Kazakhstan

M. Bayanova, *B. Kamaliyeva, D. Samatkyzy, G. Abildinova;*
National Research Center Maternal and Child Health, Astana, Kazakhstan.

Objective of the study was investigating the criteria's of enzyme activity of alpha-L-iduronidase, iduronate-2-sulfatase, N-acetylgalactosamine-6-sulfatase, β-galactosidase, arylsulfatase B and providing diagnostics of patients with mucopolysaccharidosis from Kazakhstan.
The materials used for the study were dry blood spots of 2500 healthy newborns to study the enzyme activity of lysosomal storage diseases (LSD) by tandem mass spectrometry and fluorimetry. Reference ranges of enzymes activity were the following: alpha-L-iduronidase was 450-2614 nmol / spot* 20 h., iduronate-2-sulfatase was 0.02-0. 25 nmol / spot* 21 h., arylsulfatase B was 0.14-0.7 nmol / spot* 21 h., β-galactosidase was 35-126 nmol/h/ml., N-acetylgalactosamine-6-sulfatase was 5.7-33 nmol/24h/ml.
13 out of 2500 patients had lysosomal enzyme below the reference range. Two patients were defined with alpha-L-iduronidase activity which were below the reference range and constituted 33.06-187. 26 nmol / spot* 20 h. Activity iduronate-2-sulfatase was determined in 6 patients with suspected MPS type II. Decrease in enzyme activity was observed in all cases and was 0 nmol / spot* 21 h. In 2 cases, a decrease activity of to β-galactosidase 25-30 nmol/h/ml, the 1 patient had a decreased activity of N-acetylgalactosamine-6-sulfatase to 2.2 nmol/24h/ml. Arylsulfatase B activity was determined in 3 patients, a decrease of enzyme activity was observed 5-20 times, and was 0.03-0.07 nmol / spot* 21 h. The reference ranges of enzyme activity of LSD were calculated.

P06.17-S
Massive parallel sequencing in suspected familial hypercholesterolemia patients of Latvia

I. Radovica, *R. Berzins, D. Silava, D. Fridmanis, J. Klovins;*
Latvian Biomedical Research and Study Centre, Riga, Latvia.

Familial hypercholesterolemia (FH) is one of the most common single gene disorder mostly inherited as autosomal dominant trait. The physical sign of FH is elevated low density lipoprotein cholesterol (LDL-C), elevated total cholesterol (TC) levels and tendon xantomas. Identification and early treatment of affected individuals is desirable and in lack of physical symptoms DNA based diagnosis provides confirmations of diagnosis and enables early patient management.
Majority of FH cases are caused by mutations in four genes (APOB, LADLR, PCSK9 and LDLRAP1). There are commercial kits available for testing of most common FH causing mutations, but the spectrum of disease causing mutations is quite diverse in various populations.
Here we report mutations found in 64 patients with suspected FH in a sample from the Genome Database of Latvian population. We used targeted next generation sequencing approach in order to determine the full spectrum of mutations in coding regions of LDLR, APOB, PCSK9 and LDLRAP1. In total we found 28 missense one nucleotide mutations from which two rs5742904 (Arg3527Gln) in APOB gene and rs147509697 (Gly20Arg) in LDLR gene has been previously described as FH causing mutation confirming the FH in three patients (4.6 %). Possible FH causing mutations however were identified in majority of patients.
Conclusion: most commonly employed commercial mutation panel is not sufficient for diagnosis of FH patients and NGS can help to identify FH causing mutations in Latvian population. Our results also provide an example that DNA testing can identify FH patients before they develop serious physical symptoms.

P06.18-M
Development of a cell-based reporter assay suited for small-molecule drug discovery in FGF23-inducible HEK293 cells stably expressing Klotho

S. Diener[1], *K. Schorpp*[2], *B. Lorenz-Depiereux*[1], *K. Hadian*[2], *T. M. Strom*[1,3];
[1]Helmholtz Zentrum München, German Research Center for Environmental Health,Institute of Human Genetics, Neuherberg, Germany, [2]Helmholtz Zentrum München, German Research Center for Environmental Health,Institute of Molecular Toxicology and Pharmacology, Neuherberg, Germany, [3]Klinikum Rechts der Isar der Technischen Universität München, Institute of Human Genetics, Munich, Germany.

Fibroblast growth factor 23 (FGF23) is a key regulator of phosphate homeostasis. It is of crucial importance in hereditary and acquired hypo- and hyperphosphatemic disorders. Moreover, FGF23 has emerged as a promising biomarker for the prediction of adverse clinical outcomes in patients with chronic kidney disease (CKD), as it might be related to mortality, cardiovascular abnormalities and disease progression. FGF23 is a bone-derived endocrine factor, which inhibits renal tubular phosphate reabsorption by activating receptor complexes composed of FGF receptor (FGFR) 1c and the co-receptor Klotho. As a major signalling pathway mitogen-activated protein kinase (MAPK) pathway is employed. For the investigation of FGF23 in an in vitro model we established FGF23-inducible HEK293 cells that stably express Klotho (HEK293-KL). The induction of HEK293-KL cells by FGF23 was shown by detecting the activation of MAPK pathway, which could be reduced by the use of two known small-molecule inhibitors of MAPK pathway: SU5402 and U0126. To identify novel small-molecule compounds that modulate FGF23/FGFR1c/Klotho signalling, we developed a cell-based reporter assay that is suited for high-throughput screening (HTS). The assay is based on the AlphaScreen SureFire platform of Perkin Elmer to monitor the phosphorylation of endogenous extracellular signal-regulated kinase 1 and 2 (ERK1/2) in cellular lysates of HEK293-KL after the induction with FGF23 in the presence of small-molecule compounds. Since increased plasma concentrations of FGF23 are the main cause of many phosphatemic disorders, a modulation of its effect could be a potential strategy for drug discovery and new therapeutic approaches in disorders affecting phosphate homeostasis.

P06.19-S
Gaucher disease and Langerhans cell histiocytosis

M. Sabbadini[1], *A. Alhariri*[1], *C. Lee*[1], *E. Muller*[2], *D. Oglesbee*[3], *S. Segal*[1], *S. Packman*[1];
[1]UCSF, San Francisco, CA, United States, [2]California Pacific Medical Center, San Francisco, California, San Francisco, CA, United States, [3]Mayo Clinic, Rochester, MN, United States.

Gaucher disease [GD] is an autosomal recessive lysosomal storage disease, with deficient glucocerebrosidase activity caused by mutations in the *GBA* gene. Patients are often categorized as manifesting three distinct phenotypes: non-neuronopathic [type 1]; severe, infantile neurologic [type 2]; and chronic, progressive neurologic [type 3]. We describe a male infant with neurologic GD as well as concomitant Langerhans cell histiocytosis [LCH]. The child presented at age 9 months with weight loss, hematochezia, pallor, and irritability. He had hepatosplenomegaly, anemia, thrombocytopenia, as well as a right upper lobe nodule. Excisional biopsy of the nodule led to a histologic diagnosis of LCH. Bone marrow and rectal biopsies did not reveal findings of LCH, but the presence of macrophages concerning for a storage disease. Enzyme assay confirmed a diagnosis of GD and gene testing revealed apparent homozygosity for a novel mutation in *GBA*, c.488C>T [p.A163V]. His presentation was intermediate between 'classical' type 2 and type 3 GD. Upon physical examination, he demonstrated opisthotonic posturing, hypotonia, horizontal oculomotor apraxia, and swallowing difficulties but was also able to sit with support, was attentive to environmental stimuli, and had not lost previously gained developmental skills. To our knowledge, this is the first GD patient reported with concomitant LCH. Even though the simultaneous occurrence of GD and LCH could be coincidental, it is also possible that LCH is secondary to the specific *GBA* mutation identified in the patient and thus LCH should be added to the list of lymphoreticular neoplasms associated with GD.

Glucocerebrosidase enhancement in selected Gaucher disease fibroblasts by a series of DIX compounds

J. Serra-Vinardell[1], *L. Díaz*[2], *J. Casas*[2], *L. Vilageliu*[1], *H. Michelakakis*[3], *I. Mavridou*[3], *J. M. F. G. Aerts*[4], *C. Decroocq*[5], *P. Compain*[5], *A. Delgado*[2], *D. Grinberg*[1];
[1]Dept. Genetics, Universitat de Barcelona, CIEBER, IBUB, Barcelona, Spain, [2]RUBAM, Dept. Quimica Biomèdica, IQAC-CSIC, Barcelona, Spain, [3]Dept. Enzymology and Cellular Function, Institute of Child Health, Athens, Greece, [4]Department of Medicinal Biochemistry, Academic Medical Center, Meibergdreef, Amsterdam, Netherlands, [5]Laboratorie de Synthèse Organique te Melécules Bioactives, Univetsité de Strasbourg, Strasbourg, France.

Gaucher disease (GD) is a lysosomal storage disorder due to an inherited deficiency of the lysososmal enzyme glucocerebrosidase (GBA1). It produces the accumulation of glucosylceramide in cells of the reticuloentothelial system and causes multisystemic manifestations. The limited efficacy of the current treatments has led to the development of new strategies, including the use of pharmacological chaperones. These are small molecules, generally competitive inhibitors of the target enzyme, which at sub-inhibitory concentrations may induce the proper folding and trafficking of the mutated enzyme resulting in a concomitant increase in the residual activity. The aim of this work is to report on the ability of seven compounds to increase the residual GBA1 activity on fibroblasts from six Gaucher patients bearing different genotypes. This series of compounds, named DIX, has been designed by combination of the iminoxylitol scaffold of parent **1C9DIX** with triazolylalkyl side chains as GBA1 enhancers as potential pharmacological chaperones in GD. Most of the **DIX** compounds showed a preferential GBA1 enhancement towards genotypes bearing the G202R mutation, responsible for a neuronopathic phenotype of the disease. In particular, DIX-28 was the one with the best activity enhancement, reaching a 4-5 fold increase at100 nM. Moreover this compound showed also a remarkable effect, around 2-fold increase, on the N370S/N370S genotype at the same concentration. Finally, immunofluorescence staining and confocal microscopy imaging were used to confirm that **DIX28** increases the trafficking of the G202R mutant enzyme to the lysosome.

P06.21-S
Two New Cases of Myopathy with Cataracts and Combined Respiratory Chain Deficiency caused by Mutations in GFER gene

D. Gavrilov, *A. Studinski;*
Departments of Medical Genetics, and Laboratory Medicine and Pathology, Biochemical Genetics Laboratory, Mayo Clinic School of Medicine, Rochester, MN, United States.

Myopathy with cataracts and combined respiratory chain deficiency (MPMCHD, OMIM#613076) is caused by mutations in GFER gene and has been described in a single consanguineous family (Di Fonzo et al, AJHG 2009, 84:594). We report two additional cases of MPMCHD in a non-consanguineous Caucasian family: one patient presented at 6 months with cataracts, mild developmental delays (DD) and hypotonia and at 16 months suffered severe episodes of hypoglycemia and lactic acidosis. Despite intermittent periods of relative metabolic stability, the condition is progressing. At 13 years he is wheel-chair bound, has failure to thrive (requiring tube feeding), global DD, autistic features, central hypotonia, and dystonia. Urine organic acid analyses reveal persistent 3-methylglutaconic aciduria. Muscle biopsy showed ragged red fibers and decreased staining for cytochrom C oxidase. Muscle analysis demonstrated reduced respiratory chain complex IV activity and increased mtDNA content in the absence of mutations or deletions. This patient's sister has clinical presentation characterized by later onset and milder, but similar clinical course which includes congenital cataracts, global DD and autistic features. Bouts of lethargy associated with lactic acidosis are frequent and require hospital admissions. Whole exome sequencing [done at Baylor College of Medicine] revealed two mutations in GFER gene: c.581G>A (p.R194H, previously reported) and c.215delG (p.A73Pfs*73).
These cases further describe the phenotype associated with GFER gene mutations. Although both patients have features similar to the other 3 reported patients with MPMCHD, the clinical course in our patients is more severe and includes prominent lactic acidosis and 3-methylglutaconic aciduria but not deafness.

P06.22-M
Digenic Glycogen Storage Disease type I?

E. L. Mendes, *M. B. Baptista, D. Z. Scherrer, C. E. Steiner;*
State University of Campinas, Campinas, Brazil.

We report a patient referred to our service due to a clinical diagnosis of Glycogen Storage Disease type 1. She is the only child of a healthy and non consanguineous couple, seen at the age of six months when hepatomegaly was detected during a routine pediatric evaluation. Laboratorial investigation revealed glycemia after 4-hour fasting ranging from 33 to 60 mg/dl, hypertriglyceridemia (252 mg/dl), and abnormal values of aspartate aminotransferase (132 mg/dl) and alanine transaminase (98 mg/dl). Gamma-GT, urea, creatinine, uric acid, total cholesterol, coagulation tests, blood gases, and CBC resulted normal. After starting treatment with frequent meals, cornstarch, and dietary restriction of lipids and sugars, she normalized neuromotor and somatic development but still presents with hepatomegaly. Genomic DNA was extracted from peripheral blood leukocytes of the patient and both parents by using the standard phenol/chloroform method. Exons of G6PC and SLC37A4 genes and their flanking intron/exon junctions were amplified by PCR using previously described primers. The fragments were directly sequenced using a MegaBACE1000® DYEnamic ET (Amersham Biosciences) apparatus, twice on both strands, and the obtained sequences were compa-

red with the sequences available in the Ensembl genome browser. Mutation analysis revealed that the patient is a double heterozygote for the previously known nonsense mutation p.Arg415Ter (rs121908979; c.1243C>T) in SLC37A4, inherited from the mother, and an undescribed missense mutation p.Gly222Glu (c.665G>A) in G6PC, inherited from the father. The molecular analysis of the two genes suggests that the clinical picture of this patient could be caused by digenic inheritance of GSDI.

P06.23-S
High frequency of the c. 3980 G>A (p.W1327X) mutation in AGL gene of Tunisian patients with hepatic presentation of glycogen storage disease type III syndrome

A. Mili[1], *W. Manoubi*[1], *A. Ayadi*[2], *A. Saad*[1], *M. Gribaa*[1];
[1]*Laboratoire de Cytogénétique, de Génétique Moléculaire et de Biologie de la Reproduction Humaines, Sousse, Tunisia,* [2]*Service of Pediatry, hopital Tahar Sfar Mahdia- Tunisia, Mahdia, Tunisia.*

BACKGROUND: Glycogen storage disease type III (GSD-III) is an inborn error of glycogen metabolism caused by a deficiency of the glycogen debranching enzyme (AGL) .Some of the mutations appear to be population specific, whereas others are found in probands from a variety of different ethnic backgrounds. The recurrent mutation W1327X in exon 31 was identified in the Tunisian population, suggesting a founder effect. In this present study, we report a phenotype-genotype correlation of this frequent mutation. METHODS: Seven unrelated Tunisian families (from MAHDIA); including 10GSD type III patients were presented with hepatomegaly, progressive severe myopathy and cardiomyopathy. The routine laboratory findings showed an elevated serum aspartate aminotransferase, alanine aminotransferase, creatine kinase and triglyceride levels. The blood lactate and uric acid levels were within normal limits. RESULTS: The biochemical results of ten patients indicated a striking elevation of glycogen content in the erythrocytes after several hours fasting favours type III GSD and completely decrease of debranching enzyme activity was measured in leucocytes. Mutational analysis of the AGL gene showed a homozygous p.W1327X mutation. Study of genotyping method, in 30 families, using four polymorphic microsatellite markers on chromosome arm 1p21, we identified a common haplotype for all patients originated from MAHDIA.
CONCLUSIONS: p.W1327X is the most characteristic mutation for Tunisian patients with GSD IIIa. A common haplotype which shows the existence of a specific effect founder of this population confirmation of GSD-IIIa in Tunisisan (from MAHDIA) patients by clinical and genetic findings.

A yeast model to evaluate the pathogenicity of missense mutations causing HHH Syndrome

M. Doimo[1,2], *F. M. Santorelli*[3], *L. Salviati*[1,2];
[1]*Department of Woman and Child Health, University of Padova, Padova, Italy,* [2]*I.R.P.-Pediatric Research Institute „Città della Speranza", Padova, Italy,* [3]*Molecular Medicine and Neurodegenerative Diseases, IRCCS Stella Maris, Pisa, Italy.*

Hyperornithinemia-hyperammonemia-homocitrullinuria (HHH) syndrome is an autosomal recessive multisystemic disorder characterized by mental retardation and myoclonic seizures. It is caused by mutations in ORNT1 encoding the mitochondrial ornithine transporter. In placentate mammals there is a second gene, ORNT2, that originated from a retro-transposition event, whose precise function has not been clarified. In yeast the major function of this transporter (encoded by ARG11) is to shuttle ornithine from the mitochondrial matrix to the cytosol.
We employed a yeast model to study the function of human ORNT2 and to test the pathogenicity of mutations found in HHH patients. The two human Ornithine transporters were expressed into the ΔARG11 strain. We found that ORNT1 but not ORNT2 complements the deletion of the yeast gene. Three ORNT1 residues, conserved from yeast to humans, are not conserved in ORNT2. We could recover ORNT2 activity by replacing these three residues with those found in ORNT1. This result suggests that, despite the high level of homology between the two transporters, their function is not overlapping. We used our yeast model to test the effect of missense mutations carried by patients with HHH syndrome. All missense mutations tested have a detrimental effect on the function of the human gene indicating that yeast is a simple and effective system to validate missense mutations occurring in patients with HHH.

P06.25-S
A case of siblings with Leigh-like disease caused by 3-hydroxyisobutyryl-CoA hydrolase deficiency

K. Yamada[1], *M. Naiki*[2], *S. Hoshino*[3], *Y. Kitaura*[4], *Y. Kondo*[4], *N. Nomura*[1], *R. Kimura*[1], *D. Fukushi*[1], *Y. Yamada*[1], *Y. Shimomura*[4], *K. Miura*[5], *N. Wakamatsu*[1];
[1]*Department of Genetics, Institute for Developmental Research, Aichi Human Service Center, Kasugai, Japan,* [2]*Department of Pediatrics, Nagoya University Graduate School of Medicine, Nagoya, Japan,* [3]*Department of Pediatrics, Kasugai Municipal Hospital, Kasugai, Japan,* [4]*Department of Applied Molecular Biosciences, Graduate School of Bioagricultural Sciences, Nagoya University, Nagoya, Japan,* [5]*Department of developmental disability medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

3-Hydroxyisobutyryl-CoA hydrolase (HIBCH) is an enzyme specific for removing CoA in the catabolic pathway for valine. So far, only 4 cases of HIBCH deficiency have been reported. In 1 case, a homozygous null mutation in *HIBCH* caused congenital anomalies including a characteristic facial appearance, congenital heart disease, and multiple vertebral anomalies and led to death in infancy. The 3 other cases, which harbored missense or splice mutations, presented with hypotonia, neurological regression, developmental delay in infancy, episodes of ketoacidosis, and abnormal MRI findings in the basal ganglia. Here, we describe a case of Leigh-like disease in Japanese siblings with HIBCH deficiency who presented with developmental delay in infancy, abnormal MRI findings in the globus pallidus, and remarkable ketoacidosis without highly increased levels of pyruvate and lactate in the CNS during infections. The patients died before the age of 5. A new homozygous missense mutation was identified at the substrate binging site in these patients, and their parents were found to be heterozygous for this mutation. The levels of HIBCH activity in patient lymphoblastoid cells and HEK293 cells transiently expressing a mutant HIBCH confirmed that the patients had HIBCH deficiency. HIBCH deficiency leads to the accumulation of the HIBCH substrate 3-hydroxyisobutyryl-CoA and subsequently an increase in the amount of methacrylyl-CoA in the mitochondrial matrix. The methacrylyl-CoA then strongly binds to thiol compounds (cysteamine, cysteine, glutathione) and reduces the activity of mitochondrial enzymes by binding to their SH residues, thus leading to a dramatically decreased reduction state and reduced ATP production.

P06.26-M
Deleterious mutations in mitochondrial NADH dehydrogenase subunit 4 and ATPase subunit 6 in two siblings of Leigh Syndrome with progressive motor retardation and loss of visual function

M. Urfali, **O. Ozdemir**, *D. Kankaya, A. Uludag, S. Yalcintepe, F. Silan;*
Department of Medical Genetics, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey.

We report a mitochondrial NADH dehydrogenase subunit 4 and ATPase subunit 6 mutations in two siblings from first degree relative couple with Leigh Syndrome. Peripheral blood-EDTA samples were used for DNA isolation and target mitochondrial genes were analysed by MLPA technique (MRC-Holland). A girl of 16 years old presented with a episode of progressive mental and motor reardation. Until seven year she had normal apperance but at the age of 7 year, she had developed neurological and imaging features such as; loss of visual function, walking and speech impairment and epilepsy complaints that compatible with Leigh syndrome. We also present a 12-year-old boy with muscle weakness, severe neurological problems, hyperactivity, developmental retardation and complete visual loss. Screening of both siblings, based on their clinical phenotype revealed the homoplasmic deleterious mutation in the mitochondrial DNA MT-ATP6(ligation site of probe 12068-12069) and heteroplasmic deletion in NADH subunit 4(ligation site of probe 8993-8992R). The maternal mtDNA screening for target deletorious genes is still going on. These findings are consistent with infantile Leigh syndrome for the presented siblings.

P06.27-S
Lysosomal Storage Disorders (LSDs): Clinical and Genetic Spectrum: Local Experience at The Eastern Province of Saudi Arabia

N. A. Al-Sanna'a[1], *H. Y. Al-Abdulwahed*[1], *P. M. Mathew*[2], *P. M. Mathew*[2];
[1]*Johns Hopkins Aramco Healthcare, Dhahran, Saudi Arabia,* [2]*Vanderbilt Children's Hospital, Nashville, TN, United States.*

Lysosomal Storage Disorders (LSDs) are clinically and genetically heterogeneous a group of more than 50 inherited disorders, each one is caused by a deficiency of a particular lysosomal enzyme resulting in a progressive accumulation of specific macromolecules within the lysosomes. This eventually leads to an irreversible cell damage, and multi-organs dysfunction. The majority of LSDs are inherited in an autosomal recessive manner, with the exception of Fabry disease and Mucopolysaccharidosis type II which follow the X-Linked mode of inheritance. The majority of LSDs are pan-ethnic, but some are more prevalent in specific ethnic groups.
Here, we report our local experience of LSDs at Johns Hopkins Healthcare Main Hospital, Dhahran, The Eastern Province of Saudi Arabia from January, 1st, 1984 to December, 31st, 2013. A total of 86 patients were diagnosed with different LSDs within this time period. ucopolysaccharidosis type VI was found to be the most common disorder (18 %), followed by juvenile Neuronal Lipfuscinosis (13 %). The patients are distributed according to

the geographic location or their tribe origin where particular disorders and specific genotypes were identified. This information had been utilized for asymptomatic carrier testing for those selective disorders among the high risk population. However, this valued data could be further utilized for establishing the newborn screening of LSDs in Saudi Arabia.

Lysinuric protein intolerance (LPI; MIM222700) is a rare autosomal recessive disorder caused by a defect of cationic amino acid transport in the small intestine and kidney tubules. All the Finnish patients share the same homozygous mutation c.1181-2A□T in the SLC7A7 gene which encodes the y+LAT1 amino acid transporter. LPI can be considered a multisystem disease which can be life-threatening. The main symptoms of LPI include protein aversion, failure to thrive, osteoporosis and hepatosplenomegaly. However, despite the homogenous mutation in the Finnish LPI patients, symptoms may vary markedly even within one family and may include severe complications, such as alveolar proteinosis and end-stage renal disease. Some LPI patients also suffer from combined hyperlipidemia.
Our recent microarray study revealed that also other amino acid transporter genes than SLC7A7, including non-cationic amino acid transporters, have changes in their expression levels in LPI patients compared to the controls. Therefore, LPI patients seem to have wide and persistent changes in their amino acid balance. This finding together with the fact that patients have combined hyperlipidemia let us hypothesize that there may be hitherto uncharacterized systemic metabolic and lipid alterations in LPI. We studied these alterations in the whole blood plasma samples of 26 Finnish LPI patients and 19 gender and age-matched controls. Global metabolomic and lipidomic analyses were performed with GCxGC-TOF and Q-TOF mass spectrometry, respectively, combined with ultra-performance liquid chromatography (UPLC). Taken together, this study will reveal the nature of system-wide dysregulation of metabolites and lipids associated with the Finnish founder mutation of LPI.

Establishment of Zbtb16 role in metabolic syndrome by means of single-gene congenic rat strain derivation

B. Chylikova[1], *M. Krupkova*[1], *F. Liska*[1], *L. Sedova*[1], *D. Krenova*[1], *L. Kazdova*[2], *V. Kren*[1,3], *O. Seda*[1];
[1]*Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Praha, Czech Republic,* [2]*Institute of Clinical and Experimental Medicine, Praha, Czech Republic,* [3]*Institute of Physiology, Academy of Sciences of the Czech Republic, Praha, Czech Republic.*

In the process of positional cloning of apparently pleiotropic locus on rat chromosome 8 affecting major features of metabolic syndrome we have derived the congenic SHR.PD-(D8Rat42-D8Arb23)/Cub (SHR-Lx) strain carrying only 7 genes of polydactylous rat strain (PD) origin on spontaneously hypertensive rat (SHR) genetic background. In this study, we have derived 2 new minimal congenic sublines in order to determine the role of candidate *Zbtb16* gene of PD/Cub origin carrying 2.9kbp deletion in intron 2.
Adult male rats of SHR.PD(*Zbtb16*) and SHR.PD(*Htr3*) strains were fed standard diet (STD) and subsequently treated with dexamethasone in drinking water (0.026 mg/ml) for 3 days. We contrasted morphometric and metabolic profiles between the two strains.
The differential segment of SHR.PD(*Zbtb16*) subline containing only *Zbtb16* gene spans 254kb, while the one in SHR.PD(Htr3) subline spans 563kb and contains 6 genes: *Htr3a*, *Htr3b*, *Usp28*, *Zw10*, *Tmprss5*, and *Drd2*. SHR.PD(*Zbtb16*) were slightly heavier and showed significantly higher fasting levels of glucose and triacylglycerides, increased area under the glycemic curve during oral glucose tolerance test in comparison to SHR.PD(*Htr3*). The insulin sensitivity of visceral adipose tissue was comparable in the two strains, however, both basal and insulin-stimulated glycogenesis was substantially impaired in SHR.PD(*Zbtb16*) skeletal muscle in comparison to SHR.PD(*Htr3*).
The metabolic disturbances including dyslipidemia, impaired glucose tolerance and insulin resistance of skeletal muscle observed in the original SHR-Lx strain are present in the single-gene congenic SHR.PD(*Zbtb16*) strain, establishing the *Zbtb16* as a pleiotropic hub of metabolic syndrome features.

DNA diagnostics of MIDD and MELAS syndromes in Slovakia

D. Gasperikova[1], *M. Skopkova*[1], *I. Masindova*[1], *L. Valentinova*[1], *J. Stanik*[1,2], *L. Varga*[1,3], *M. Huckova*[1], *D. Danis*[1], *Slovak group for MIDD/MELAS study, M. Profant*[3], *I. Klimes*[1];
[1]*Diabgene & Diabetes Laboratory, Institute of Experimental Endocrinology SAS, Bratislava, Slovakia,* [2]*First Department of Pediatrics, School of Medicine, Comenius University, Bratislava, Slovakia,* [3]*First Department of Otorhinolaryngology, School of Medicine, Comenius University, Bratislava, Slovakia.*

The two syndromes, MIDD (Maternally Inherited Diabetes and Deafness) and MELAS (Mitochondrial Encephalopathy, Lactic Acidosis and Stroke-like episodes) arise on a common genetic cause - a mutation in mtDNA, most often m.3243A>G in the gene for tRNALeu. This mutation leads to different clinical symptoms according to heteroplasmy levels in different tissues. Usually, the first presentation of the MIDD syndrome is a progressive bilateral sensorineural hearing loss emerging in adolescence. Diabetes develops mostly in 30 - 40 years of life with clinical picture resembling type 2 diabetes. The MELAS syndrome has a more severe progression with further neurological and metabolic symptoms.
We tested 317 patients from 257 families with suspected MIDD or MELAS syndromes fulfilling criteria of matrilineal inheritance, conjoint diabetes and hearing impairment, diabetes development after 25th year of life, or progressive hearing loss. Patients´ DNA was extracted from peripheral blood and/or buccal mucosa and analysed for presence of m.3243A>G variant using RFLP and/or Real-Time PCR.
The m.3243A>G mutation was found in 18 patients from 8 families. The heteroplasmy was higher in DNA samples from buccal swabs compared to blood DNA samples. In one case, the heteroplasmy was detected in the buccal DNA only, while the DNA sample gave negative results repeatedly. Patients´ phenotypes varied from diabetes as the sole symptom to a complex picture of the MELAS syndrome.
DNA testing helped to determine the diagnosis, thus permiting correct patient management and intensified surveillance of yet healthy mutation cariers.

The monogenic forms of obesity have so far been demonstrated in only about 3-5% of the severely obese subjects. No systematic study has been carried out to assess the genetic spectrum of early onset extreme obesity in a single population. The present on-going study was undertaken to identify genetic variants in a cohort of 46 unrelated children with early onset severe obesity. All subjects were first screened for mutations in the leptin (LEP) and melanocortin 4 receptor (MC4R) genes by direct sequencing. Subjects found negative for these two genes, were subsequently screened using microdroplet PCR-enrichment (RainDance) combined with NGS. Of the 46 severely obese subjects, we identified 14 subjects carrying loss of function homozygous mutations in three genes that are directly involved in leptin-melancortin signaling. Of these, 9 subjects carried mutations in LEP, 3 in LEPR and 2 in MC4R. The genetic variants identified here included a novel LEP and LEPR mutation. All mutants had a BMI SDS for age > 3 and were extremely hyperphagic. However, the phenotypic features of MC4R mutants were less severe compared to those carrying LEP and LEPR mutations. These results together with the findings reported by us previously for the same consanguineous population, add up to 28 (25%) of a total of 110 severely obese children, with known or novel homozygous mutations in the 3 genes. Novel genetic findings leading to severe obesity in the remaining probands through screening by whole exome sequencing, is to be anticipated.

Mitochondrial (mt) DNA disorders are a large group of multisystem con-

ditions with a very heterogeneous clinical presentation, initiated by a maternally inherited pathogenic aberration residing in the mtDNA. Over 400 mtDNA alterations (including point mutations and deletions) implicated in a deleterious OXPHOS are already identified, with tRNA leucine and lysine genes being hot spot mutation regions (www.mitomap.org, updated 15th November 2013). A UK study for the occurrence of 10 frequent point mutations in cordial blood of newborns, revealed an unexpected carrier frequency of 1 in 200. Usually, mtDNA aberrations are heteroplasmic, a term referring to the co-existence of both wild type and variant mtDNA molecules within the same cell of an individual and opposite to homoplasmy. We present here the case of a young male patient with a cerebral-vascular accident, but also suffering from migraine, epilepsy and transient lactic acidosis and renal insufficiency. This clinical picture was compatible with a respiratory chain disease caused by a mtDNA mutation. First line analysis of his tRNA leucine and lysine genes identified both the common MELAS (Mitochondrial Encephalomyopathy, Lactic Acidosis and Stroke like episodes) and MERRF (Myoclonic Epilepsy with Ragged Red Fibers) mutations, in our patient's blood. This is a rather unique and unusual situation. To our knowledge, the presence of both pathogenic mtDNA mutations, at clinical relevant levels, within the same patient has never been reported before. Further molecular investigation with sequencing technologies of the leukocytes, urine epithelial cells and other tissues of the patient and maternal relatives is in progress.

A unique combination of mitochondrial ribosomal RNA variants responsible for a form of mitochondriopathy with respiratory complex I deficit and hypoacusia

I. Kurelac[1], *M. A. Calvaruso*[2], *R. Zuntini*[1], *F. G. Specchia*[3], *M. Seri*[1], *A. Pession*[3], *S. Ferrari*[1], *A. M. Porcelli*[2], *G. Gasparre*[1];
[1]*UO Medical Genetics, Bologna, Italy,* [2]*FABIT, University of Bologna, Bologna, Italy,* [3]*DIMEC, Bologna, Italy.*

Mitochondrial DNA mutations are known to cause highly heterogeneous phenotypes and their functional effects are often difficult to assess. Here we present a novel pathogenicity mechanism for two mtDNA variants found in ribosomal RNA genes. The whole mtDNA was screened in a patient who displayed clinical indications of mitochondriopathy, including hypoacusia and 37% deficit of mitochondrial complex I activity in muscle. No protein-coding mutations were identified, albeit two rare variants in ribosomal RNA genes, namely m.1452T>C/RNR1 and m.2397C>T/RNR2, both homoplasmic and present in the proband mother, who also displayed hypoacusia. Low population frequency was revealed for both variants by using the HmtDB database, which collects nearly 16,000 human mitochondrial genomes. Although the two variants were present in tips of the haplogroups tree, they were never found to co-occur in the same individual, implicating a potential mutual exclusivity. Therefore, it was hypothesized that their co-existence might lead to perturbations in mitochondrial ribosomal assembly. To this aim, since the patient's fibroblasts displayed a normal basal respiration and complex I function, mitochondrial proteins translation kinetics was analyzed in cybrids derived from patient and control fibroblasts. Patient-derived cybrids showed reduced synthesis of mitochondrial proteins and less efficient recovery of complex I activity after treatment with mitochondrial translation inhibitors. These results imply that the combination of the two variants might lead to mitochondrial translation defects, mainly affecting complex I function, especially in cells with a high energy demand.

P06.34-M
A new heterozygous compound mutation of the Galns Gene as a cause of mucopolysaccharidosis type IV in two brothers of the south-west of Colombia

H. Pachajoa, *F. Ruíz, M. F. Hernandez-Amaris;*
Universidad Icesi, Cali, Colombia.

Mucopolysaccharidosis type IVA (MPS IVA), or Morquio syndrome type A is an autosomal recessive disease caused by deficiency of the lysosomal enzyme N-acetylgalactosamine-6-sulfatase (GALNS).
clinical, biochemical and molecular two brothers with MPS IVA was characterized.
Decreased enzymatic activity was found to GALNS, and molecular study, we found a mutation in exon 3 (c.280C> T p.R94C) and not reported a new mutation in exon 9 (c.998G> A p. G333D). Pending outcome of parents and brother.
Was analyzed with Polyphen-2 (2.2.2) software and this variant is predicted as probably harmful.
Two different heterozygous mutations were found to cause the MPS IVA patient presented a new mutation was found and another had been previously described by Ogawa in 1995.

Mucopolysaccharidosis IVA (Morquio A syndrome) is an autosomal recessive lysosomal storage disorder, caused by the deficiency of the enzyme N-Acetylgalactosamine-6 sulfate sulfatase (GALNS). The disease, albeit multisystemic, is characterized by prevalent skeletal involvement, short stature, and cardiorespiratory complications. Here we report two new large genetic rearrangements detected at the heterozygous level in two patients (Pt1 and Pt2) affected by Morquio A. The deletions include part of the PIEZO1 gene (piezo-type mechanosensitive ion channel component 1) whose mutations were found in the dehydrated hereditary stomatocitosis, a dominant autosomal recessive syndrome. This syndrome is typically associated with silent to mild hemolysis, perinatal edema, splenomegaly, elevated bilirubin levels and iron overload. Pt1 was found to be seemingly homozygous for the c.1485C>G (p.Asn495Lys) missense mutation in the exon 14 of the GALNS gene. Parents' genetic analysis, haplotyping some loci in exon 14 of the GALNS gene (in the context of a prenatal diagnosis of a patient's relative), and CGH-array revealed that Pt1 has a large deletion encompassing exons 10-14 of the GALNS gene and three upstream genes, including a part of the PIEZO1 gene. In Pt2, heterozygous for the c.346G>A (p.Gly116Ser) missense mutation, a large deletion ablating exons 9-14 of the GALNS gene and exon 1 of the PIEZO1 gene was also identified. The breakpoint regions were characterised in both patients and the eventual contribution of the partial deletion of the PIEZO1 gene on such patients' phenotype was considered at a biochemical and clinical point of view.

Mucopolysaccharidosis II (Hunter syndrome, MPS II) is a rare X-linked recessive disorder caused by a deficiency of the lysosomal enzyme iduronate-2- sulfatase. Major clinical manifestations of the severe form of MPSII include coarse facial features, short stature with joint stiffness, hepatosplenomegaly, cardiomyopathy and mental retardation.
The diagnosis of MPSII based on clinical symptoms and increased excretion of glycosaminoglycans in urine is confirmed by enzymatic assay and mutation analysis. We performed mutation analysis in 24 unrelated male patients and found 21 different mutations: two large and four small deletions, three small insertions, two splicing defects, two nonsense mutations, seven missense mutations and a recombination between *IDS* gene and pseudogene *IDS2*. Eleven of the found mutations are novel.
Even though the MPSII is expected to be found in males, few symptomatic females have been reported. We present a case of four-year-old girl with severe phenotype of MPSII. Molecular analysis of gDNA revealed a missense mutation c.1403G>A (p.R468Q) in heterozygous state, but only the mutant allele was detected at the cDNA level. X-inactivation was nonrandom and silencing preferentially the maternal X-chromosome. The mutation was not found in periferal blood samples of both parents. These findings support the assumption of either a *de novo* mutation in affected girl or a germinal mozaicism in the girl's father.
In spite of extremely rare manifestation of MPSII in females, an unrelated female patient with skewed X-inactivation and p.R468Q inherited from her mother was reported in the literature.

P06.38-M
Rare mutation in a patient with MPSII (Hunter disease)

M. Kocova[1], **E. Sukarova-angelovska**[1], *A. Rolfs*[2];
[1]*Pediatric Clinic, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Center for Mental Health, Rostock, Germany.*

Mucopolysaccharidosis type II (MPS II) is an X-linked recessive multisystem disorder characterized by glycosaminoglycans (GAG) accumulation. Different severity of the disease has been described depending on the mutation in the iduronat sulphatase gene (IDS). Here we present a case, with severe MPS II detected early with an unusual duplication of the exon 7.
The child presented with a delay in reaching milestones of the first year and recurrent febrile episodes. At 11 months he had most of the major features of the MPSII: hoarse and hairy face, significant thoracic kyphosis, large scull, hepatomegaly and neurodevelopmental delay. X rays of the spine were typical for MPSII. Urinary mucopolysacharides were increased as well as the iduronatsulphatase in the urine (80nmol/h/ml).
Genetic analysis confirmed duplication of the exon 7 of the IDS gene in the child and his mother who does not have any signs of the disease.
The patient has been followed for 5 years. His growth during this period was unusual, he had height 4 SDS above the average for the age, head circumpherence was 3SD above the average. Values of growth hormone were normal, as well as the MRI of the pituitary region.
Therapy with Elaprase (Idursulphatase) improved the joint mobility, however, the boy has severe neuro-developmental delay.
Although no significant genotype/phenotype relation has been shown in children with MPSII, it seems that this rare gene change is associated with a severe form of the disease.
Prenatal diagnosis in the mother is planned for the second pregnancy.

The common feature of a group of genetic disorders collectively identified as Neurodegeneration with Brain Iron Accumulation (NBIA) is brain iron overload visualized by radiological and histopathological examinations. The clinical spectrum of NBIA is wide and includes early-onset neurodegeneration, with a fatal outcome, and adult-onset parkinsonisms-dystonia. Pantothenate Kinase Associated Neurodegeneration and Infantile Neuroaxonal Dystrophy are the most frequent forms of the disease due to recessive mutations in PANK2 and PLA2G6. Recently it was shown that NBIA is also caused by mutations in FA2H, ATP13A2 and C19orf12 genes, but still in a large proportion of patients, no genetic alteration can be found. Using exome-sequencing strategy we identified, in a NBIA patient, a homozygous missense mutation in the gene coding for Coenzyme A Synthase (CoASy). By performing traditional Sanger sequencing in a cohort of NBIA cases, we found another mutant patient. CoASy is a mitochondrial enzyme involved in the last step of Coenzyme A biosynthesis, a important molecule for several metabolic pathways. The missense mutation affects a highly conserved aminoacid residue in the catalytic site of the enzyme, a region conserved from yeast to human. Western-blot analysis showed that CoASy protein was absent in patient fibroblasts, whereas RT-PCR revealed that mRNA was reduced only in the patient carrying the non-sense mutation. HPLC analysis demonstrated reduced CoA concentration in mitochondria isolated from mutant yeast and patient fibroblasts. Together with mutations in PANK2, coding for the first enzyme in CoA biosynthesis, mutations in CoA synthase impinge on the same biosynthetic pathway causing NBIA.

Novel mutations in the PNLPA2 gene causing late one-set of neutral lipid storage disease with myopathy in an Italian family

D. Tavian[1], *S. Missaglia*[1], *E. Tasca*[2], *C. Angelini*[2];
[1]*Catholic University, Milan, Italy,* [2]*IRCSS. S CAMILLO, Venice, Italy.*

Neutral Lipid Storage Disease with Myopathy (NLSDM), is a rare autosomal recessive disorder characterized by an abnormal accumulation of triacylglycerol into cytoplasmic lipid droplets (LDs). Mutations in the PNPLA2 gene cause the onset of NLSDM. PNPLA2 codes for adipose triglyceride lipase (ATGL), an enzyme that hydrolyses fatty acids from triacylglycerol. NLSDM patients are mainly affected by progressive myopathy, cardiomyopathy and hepatomegaly. Other clinical symptoms may include diabetes, chronic pancreatitis and short stature. To our best knowledge, twenty six different PNPLA2 mutations have been described in thirty two NLSDM patients. Here we report the clinical and genetic findings of a NLSDM Italian family with different affected members. In our patients we identified two novel PNPLA2 missense mutations (pL56R and pI193F). Since age of 38 years, the oldest brother had weakness and hypotrophy of right upper arm and kyphosis. He is now unable to raise arms in horizontal position (61 years old). The second brother, since 44 years of age, had exercise intolerance, cramps and pain in lower limbs. He currently has a distal amyotrophy. Genetic analysis revealed that also one of the two sisters presents the pL56R and pI193F mutations, but she is still barely symptomatic. Using a functional in vitro assay, we have observed that these mutations caused the production of ATGL proteins with diminish lipase activity, but able to bind to LDs. This is a very interesting family since it shows heterogeneity of clinical presentation from relatively asymptomatic phenotype to full expression of a severe myopathy.

P06.41-S
Producing hiPS cells for disease modeling of NLSD-M

S. Missaglia[1], *M. Castagnetta*[2], *D. Tavian*[1,3], *E. M. Pennisi*[4], **D. Coviello**[2];
[1]*Laboratory of Cellular Biochemistry and Molecular Biology, CRIBENS,Catholic University of the Sacred Heart, Milan, Italy,* [2]*Laboratory of Human Genetics, Galliera Hospital, Genoa, Italy,* [3]*Psychology Department , Catholic University of the Sacred Heart, Milan, Italy,* [4]*UOC Neurologia, A.C.O.San Filippo Neri, Roma, Italy.*

NLSD-M (Neutral Lipid Storage Disease with Myopathy) is a rare autosomal recessive disorder characterized by an abnormal intracellular accumulation of triacylglycerol into cytoplasmic lipid droplets (LDs). In most tissues the lipid droplets (LDs) are cellular organelles for the triacylglycerol storage. LDs metabolic functions are mediated by proteins bound to their surface. In particular, the lipase that catalyzes the removal of the first acyl chain from triacylglycerol is the patatin-like phospholipase domain-containing protein 2 (PNPLA2). This protein is coded by the PNPLA2 gene whose mutations cause the onset of Neutral Lipid Storage Disease with Myopathy. NLSD-M patients are affected by progressive myopathy, cardiomyopathy and hepatomegaly. Other clinical symptoms may include diabetes, chronic pancreatitis and short stature. NLSD-M has, at present, no specific therapy. We have previously reported clinical and genetic findings of some NLSD-M patients obtaining dermal biopsies from them. Here we report the development of hiPSc (human induced pluripotent stem cell) from patients' fibroblasts harboring different PNPLA2 mutations. Initial hiPSc colony selection was based on morphologic evaluation and on detection of pluripotency surface markers (SSEA-4 and TRA-1-81). HiPSc also expressed undifferentiated ES cell markers (NANOG, SOX2 and OCT4). Karyotypic analysis of hiPSc lines indicated a normal complement of chromosomes. Immunohystochemical evaluations of LDs on hiPSc revealed that they recapitulate pathological hallmark of the disease. We propose use of differentiated cells derived from hiPSc to study the pathogenetic mechanisms leading to NLSD-M and as a cellular model for therapeutic evaluation.

Niemann-Pick type C (NPC) disease is a neurodegenerative lysosomal lipid storage disease, with autosomal recessive transmission, characterized by lysosomal/late-endosomal accumulation of endocytosed unesterified cholesterol. The clinical manifestations of NPC are heterogeneous. Most patients have a progressive neurologic disease, but both age at onset, which ranges from early infancy to adulthood, and subsequent course vary.
We present the first three Bulgarian female patients with genetically verified NPC disease. Two of the patients are sisters. All three patients presented neurovisceral involvement with juvenile onset with a mean age of onset varying between 11 and 19 years. Vertical gaze palsy, ataxia, involvement of the upper motor neuron and cognitive decline were prominent features of the whole group, while cataplexy was present in both sibs. Clinical and echographic examinations revealed hepatomegaly in one of them and splenomegaly in all of the affected. Neuroimaging changes encompass cerebellar atrophy and white matter changes. In two of them chitotriozidase was moderately elevated, while in the third patient it had a borderline value. The molecular genetic testing detected missense mutation in the NPC1 gene. The sisters are compound heterozygous carriers of the mutations c.3019C>G, p.Pro1007Ala and c.3718G>A, pGly1240Arg. The third patient is a compound heterozygous carrier of the mutations c.1421C>T, p.(Pro474Leu) and c.2974G>A, p.(Gly992Arg).
In conclusion, the detected mutations in our patients are already known in the literature. All detected mutations were missense and caused the same classical phenotype in Bulgarian patients. These cases are the first genetically confirmed NPC cases in Bulgaria.

Aims:Previous genome wide-association studies(GWAS) have identified over 40 obesity-associated variants; however, these are primarily non-coding common variants and account for &lt3% obesity heritability. We performed an exome-wide association study(EWAS) to identify obesity-associated coding variants using the Illumina HumanExome array.

Methods:192 East-Asian(Singaporean Chinese and Malay) early-onset obese cases(body weight &gt150% of ideal weight for height and onset &lt10 years of age) and normal BMI adult controls (18.5kg/m2 ≤BMI&lt23.0kg/m2) from the Singapore Chinese Eye Study (SCES) were genotyped. Samples-QC procedures were performed(Table 1). SNP-QC excluded SNPs with call-rate below 95%, rare(MAF&lt0.05%) and/or monomorphic SNPs in total samples/cases and SNPs with significant deviations from Hardy-Weinberg equilibrium(p-value&lt0.0001). 47,605 SNPs remained for statistical analysis. Fisher's exact test was performed for rare SNPs(3%&ltMAF≤0.05%) and logistic regression adjusting for population stratification(first 5 principle components) and sex was carried out for common SNPs(MAF≥3%) using PLINK(v1.07). 58 hits with study-wide p-value&lt1.05x10-6 were followed-up using samples at extremes of BMI distribution (cases= BMI&gt27.5kg/m2 and controls= BMI&lt18.5kg/m2) from 2 adult Singaporean Chinese datasets[SCES (321 cases/140 controls)and Singapore Prospective Study Program(SP2, 89cases/94controls)].

Results:A coding SNP (exm1271824) at FANCA showed strong associations in the discovery EWAS [OR=4.69(2.67-8.2895%CI),p-value=4.95x10-7) and was validated in the adult datasets(metap-value=0.0327). The risk allele(G) was enriched in Chinese and Malay early-onset cases(MAF=3.904% and 10.004%) as well as adult cases(mean MAF=2.232%) and was rare among controls(MAF=0.717%).

Conclusion:We identified an obesity-associated coding variant at FANCA in East-Asians.

Table1

Sample	SCES	Early-onset extreme obese children
Total samples	2576	192
Sample with call-rate &lt 0.99	67	0
Samples with extreme heterozygozity (&gt 3 SD)	5	1
1st degree relatedness	38	8
PCA outliers	50	5
Samples remaining	2416	178
Samples with BMI data	2403	NA
Controls (BMI between 18.5kg/m2 and 23.0kg/m2)	1083	NA

P06.44-M

Identification of new missense variations in the SH2B1 gene in obese and lean individuals

E. Aerts[1], *D. Zegers*[1], *J. K. Van Camp*[1], *K. Van Hoorenbeeck*[2], *G. Massa*[3], *A. Verrijken*[4], *I. L. Mertens*[5], *J. Cassauw*[1], *K. Van Ackeren*[1], *R. R. Rooman*[2], *K. N. Desager*[2], *L. F. Van Gaal*[5], *W. Van Hul*[1], *S. Beckers*[1];

[1]*Centre of Medical Genetics, University of Antwerp, Antwerp, Belgium,* [2]*Department of Pediatrics, Antwerp University Hospital, Antwerp, Belgium,* [3]*Department of Pediatrics, Jessa Hospital, Hasselt, Belgium,* [4]*Department of Endocrinology, Diabetology Diseases, Antwerp University Hospital, Antwerp, Belgium,* [5]*Department of Endocrinology, Diabetology and Metabolic Diseases, Antwerp University Hospital, Antwerp, Belgium.*

Genetic evidence coming from animal studies, genome-wide association studies and studies looking for structural variation, has identified the *SH2B1* gene as a novel candidate gene for obesity. Moreover, the SH2B1 protein has been shown to act as a positive regulator of leptin signaling. As such, it seems plausible that rare *SH2B1* variants might exist that influence food intake and weight regulation. Therefore, we have designed an extensive mutation analysis investigating the prevalence of genetic variation in *SH2B1* in both Belgian obese and lean individuals. We have screened 500 obese children and adolescents and 500 healthy, lean individuals for mutations with high-resolution melting curve analysis. Direct sequencing was performed for samples with melting patterns deviating from wild-type. Screening of all coding exons and intron-exon boundaries in *SH2B1* identified thirteen different non-synonymous heterozygous variants in our populations. Several of these were found both in lean and obese subjects, suggesting these are common polymorphisms. However, five private, heterozygous, non-synonymous variations were present in obese children only. Furthermore, we also identified five variants solely in lean individuals. Our mutation analysis has demonstrated that variation in the *SH2B1* gene is frequent in both groups, with distinctive variations being present on either side of the weight spectrum. We therefore speculate that both weight-increasing and weight-decreasing variations exist in *SH2B1* for which different functional effects can be recognized. Further functional testing of the variants identified here will thus be necessary to fully understand the impact of these variants on SH2B1 and the leptin signaling pathway.

P06.45-S

Ornithine transcarbamylase deficiency and a novel OTC mutation in two Bulgarian families

A. Todorova[1,2], *S. Tincheva*[1,2], *D. Avdjieva*[3], *H. Kathom*[3], *R. Tincheva*[3], *T. Todorova*[2], *V. Mitev*[1];

[1]*Department of Medical Chemistry and Biochemistry, Sofia Medical University, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [3]*Department of Clinical Genetics, University Pediatric Hospital, Medical University, Sofia, Bulgaria.*

Disorders caused by affected urea cycle enzymes are characterized by hyperammonemia, encephalopathy, and respiratory alkalosis. Ornithine transcarbamylase (OTC) deficiency is an X-linked inborn error of metabolism of the urea cycle which causes hyperammonemia. The disorder is treatable with supplemental dietary arginine and low protein diet. Here we report two unrelated Bulgarian families with OTC deficiency, subjected for genetic testing. The first patient is a 3 years old female with persisting hyperammonemia, elevated transaminase activity and elevated orotic acid excretion in urine. The girl demonstrated behavioral and sleep disturbances. The genetic test revealed a novel frameshift mutation c.695dupT in exon 7 of the OTC gene. The mutation is de novo, both parents are not carriers. After the genetic verification of the disease, the patient was subjected to low protein diet and ammonaps with a very good outcome. The second patient is a 1 year old boy with abnormal profile of organic acids (organic aciduria), undetectable citruline level and hyperammonemia. The genetic test revealed a missense mutation c.622G>A, p.(Ala208Thr) in exon 6 of the OTC gene. The mutation is available in the literature and inherited from the mother. The carrier mother does not demonstrate any clinical symptoms of the disease. The presented data enlarges the spectrum of OTC gene mutations in patients with persisting hyperammonemia. The genetic testing provides the possibility for adequate genetic counseling and prenatal diagnostics in affected families.

P06.46-M

Biochemical diagnosis of Peroxisomal disorders by GC/MS: Egyptian patients with X-linked adrinoleukodystrophy

M. M. Ibrahim, *E. M. Fateen, A. S. A. Gouda;*
National Research Centre, Cairo, Egypt.

Introduction: Peroxisomes are organelles responsible mainly for metabolism of lipids and peroxides. Lack of peroxisomes or dysfunction in any of their normal functions is the cellular basis for human peroxisomal disorders (PDs).

Aim of the Work: diagnosis of peroxisomal disorders among a high risk group of Egyptian patients using gas chromatography mass spectrometry.

Subjects and Methods: Forty six patients suspected to have peroxisomal disorders were included in this study. Their ages ranged from 2 to 20 years. They were referred to The Biochemical Genetics Department, National Research Centre from all over Egypt. Forty one (89%) were males while five were females (11%). Parental consanguinity was positive in 28 cases (61% out of 46). Very long chain fatty acids were quantified after extraction from plasma of all cases using gas chromatography/mass spectrometry (GC/MS) technique.

Results: The present study included 46 cases suspected clinically to have one of the peroxisomal disorders; four of them (8.7%) proved to have X-linked adrenoleukodystrophy by quantitative determination of the very long chain fatty acids after extraction from their plasma. The other 42 cases showed normal profile for very long chain fatty acids.

Conclusion: X-linked adrenoleukodystrophy is the only type diagnosed among the study group of the suspected Egyptian cases. This study showed that GC/MS analysis for VLCFA discriminates patients from controls, representing a non-invasive, reliable, specific and sensitive method for the diagnosis of peroxisomal disorders.

P06.47-S
X-linked adrenoleukodystrophy from Iran, reporting 8 cases and a novel mutation

Y. -. Shafeghati[1,2], *Z. Hadipour*[1], *F. Hadipour*[1], *S. Shafeghati*[1];
[1]*Med. Genet. Dept., Sarem Women Hospital, Tehran, Islamic Republic of Iran,* [2]*Genetics Research Center, University of Social Welfare Science and Rehabilitation, Tehran, Islamic Republic of Iran.*

X-linked adrenoleukodystrophy (X-ALD) is a rare peroxisomal disorder resulting in progressive cerebral demyelination, axonal dysfunction, and adrenal insufficiency. It is the most common peroxisomal disorder with an estimated birth incidence of about 1 out of every 20,000. There is no ethnic predominance.
X-ALD most severely affects male hemizygotes. The age of onset and morbidity are highly variable and progression is unpredictable. Male hemizygotes may initially present with neurological symptoms in two different forms: (X-ALD) with childhood presentations, and Adrenomyeloneuropathy (AMN) that presents in adulthood.
X-ALD, affects 4 to 8 year old boys. Primary manifestations of X-ALD are moderate cognitive deficits followed by diminished visual acuity, central deafness, cerebellar ataxia, hemiplegia, convulsions and dementia leading to a neurovegetative state or death within several years.
X-ALD is inherited in an X-linked manner. About 93% of index cases have inherited the *ABCD1* mutation from one parent; and 7% of individuals have a *de novo* mutation.
The diagnosis of X-ALD is based on clinical findings. MRI is always abnormal in males with neurologic symptoms and often provides the first diagnostic lead. Plasma concentration of very long chain fatty acids (VLCFA) is abnormal in 99% of males with X-ALD. *ABCD1* is the only gene known to be associated with X-ALD.
Here we report 8 affected boy with X-ALD from Iran. VLCFA was increased strongly, and MRI images were typical in all of them. Molecular analysis of ABCD1 gene confirmed the diagnosis in 4 of the patients and we detected 1 novel mutation in one.

P06.48-M
Rhizomelic chondrodysplasia punctata due to a novel mutation in the *PEX5*

T. Barøy[1], *D. Misceo*[1], *M. S. Ebberink*[2], *S. Ferdinandusse*[2], *A. Holmgren*[1], *B. Woldseth*[3], *T. Hughes*[1], *K. Stadskleiv*[4], *B. Tvedt*[4], *E. Ormerod*[1], *R. J. A. Wanders*[2], *H. R. Waterham*[2], *E. Frengen*[1], *P. Strømme*[4,5];
[1]*Department of Medical Genetics, University of Oslo and Oslo University Hospital, Oslo, Norway,* [2]*Laboratory Genetic Metabolic Diseases, Depts. of Pediatrics and Clinical Chemistry, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands,* [3]*Department of Medical Biochemestry, University of Oslo and Oslo University Hospital, Oslo, Norway,* [4]*Department of Clinical Neurosciences for Children, Oslo University Hospital, Oslo, Norway,* [5]*Faculty of Medicine, University of Oslo, Oslo, Norway.*

Peroxisome biogenesis disorders (PBD) are caused by mutations in one of 13 PEX genes. Based on the clinical and biochemical presentation the patients are divided into: 1) Zellweger spectrum disorders (ZSD) and 2) Rhizomelic chondrodysplasia punctata type 1 (RCDP1). ZSD is characterized by multiple organ defects and elevated levels of very long chain fatty acids (VLCFA). The patients have mutations in one of 12 genes (not *PEX7*). 2) RCDP1 is characterized by congenital cataracts, multiple skeletal abnormalities, normal VLCFA, reduced plasmalogens and elevated phytanic acid levels. Most RCDP1 patients have mutations in *PEX7*, but a RCDP phenotype with slightly different biochemical profile is caused by deficiency of either of the two peroxisomal enzymes DHAPAT and ADHAPS involved in plasmalogen biosynthesis.
We identified a homozygous frame shift mutation in *PEX5* in three siblings with congenital cataracts, multiple skeletal abnormalities, moderate to severe intellectual disability, epilepsy, demyelinating neuropathy, normal VLCFA and high phytanic acid levels. This clinical and biochemical profile is in agreement with RCDP1. *PEX5* encodes two isoforms, PEX5S and PEX5L, and the mutation in our patients is located in a sequence only present in PEX5L and required for interaction with PEX7, which is important for peroxisomal import of three enzymes (ADHAPS, PHYH and thiolase 1), carrying a peroxisomal targeting signal 2 (PTS2). We believe that disruption of the interaction between PEX5L and PEX7 causes the RCDP-like phenotype in our patients. We currently study patient fibroblasts in order to further characterize the peroxisomal defect caused by this novel *PEX5* mutation.

P06.49-S
The frequency of POLG1 gene mutations in Hungarian patients with mitochondrial disorders and the analysis of phenotype - genotype correlation

A. Kekesi[1], *A. Gal*[1], *V. Remenyi*[1], *V. Harsfalvi*[1], *K. Komlosi*[2], *B. Melegh*[2], *M. J. Molnar*[1];
[1]*Institute of Genomic Medicine and Rare Disorders, Budapest, Hungary,* [2]*Department of Medical Genetics, University of Pécs, Pecs, Hungary.*

In the background of mitochondrial disorders both mtDNA and nuclear DNA mutations can be detected. POLG1 is one of the most important gene responsible for the intergenomial communication of the two genomes. POLG1 gene mutations may cause a wide range of clinical symptoms. However many POLG1 mutations have been published the phenotypic spectrum is increasing.
Aims: The frequency of the POLG1 mutations in patients with intergenomial communication disturbance and their phenotype-genotype correlation was analyzed.
Patients and methods: 100 Hungarian patients with mitochondrial diseases were investigated. Most of them had mitochondrial abnormalities and multiple mtDNA deletion in the muscle tissue. The mtDNA deletion was investigated by long PCR, the POLG1 gene was sequenced.
Results: In the POLG1 gene of our cohort 7 pathogenic mutation was detected in 6 families. Segregation analysis detected 9 further family members harbouring the pathogenic mutations. In our cohort 3 SNPs showed association with valproate toxicity, 1 SNP was a genetic modifying factor. The most common clinical symptoms were myopathy (50%), neuropathy (34%), ataxia (34%), depression (34%), PEO (17%), epilepsy (17%), ptosis (17%), lipomas (17%), hypoacusis (17%). In 1 case with Alper's syndrome valproate toxicity resulted in fatal outcome.
Conclusion POLG1 mutation is a common genetic cause of the mitochondrial disorders. It is recommended to investigate at first in patient with mitochondrial disease having mendelien inherited PEO, ataxia, myopathy, epilepsy and psychiatric disorders. In cases with epilepsy the predisposing SNPs to valproate toxicity in the POLG1 gene shall be screened to avoid the serious side effects.

P06.50-M
Very high prevalence of infantile Pompe disease in the Bushinengue population of French Guyana as a result of founder effect and endogamy

A. Verloes[1], *N. Elenga*[2], *Y. Poulain*[3], *S. Zedong*[3], *F. Kugbe*[3], *S. Buende*[3], *I. Amoune*[3], *N. Parez*[3], *G. Carles*[4], *R. Boukhari*[5], *C. Hermine*[6], *C. Bazurko*[6], *C. Caillaud*[7], *R. Froissart*[8], *H. Ogier de Baulny*[9], *M. Nacher*[6], *J. Benoist*[10];
[1]*Department of Genetics, Robert DEBRE University Hospital, PARIS, France,* [2]*Dept of Pediatrics, Regional Hospital, Cayenne, France,* [3]*Dept of Pediatrics, Regional Hospital, Saint Laurent-du-Maroni, France,* [4]*Dept of Obstetrics, Regional Hospital, Saint Laurent-du-Maroni, France,* [5]*Dept of Biochestry, Regional Hospital, Saint Laurent-du-Maroni, France,* [6]*Centre d'Investigation Clinique Antilles Guyane, Cayenne, France,* [7]*Department of biochemistry, Necker-Enfants-Malades Hospital, PARIS, France,* [8]*Department of biochemistry, Lyon University Hospital - GH Est, PARIS, France,* [9]*Department of Metabolic Disorders, Robert DEBRE University Hospital, PARIS, France,* [10]*Department of Biochemistry, Robert DEBRE University Hospital, PARIS, France.*

Pompe disease (Glycogen storage disease type II or acid maltase deficiency) is an autosomal recessive metabolic disorder caused by an accumulation of glycogen in the lysosome due to deficiency of the lysosomal acid alpha-glucosidase enzyme. The infantile form of Pompe disease is a rare lysosomal storage disorder usually symptomatic before age 1, with universally fatal outcome before age 4 in absence of enzyme replacement therapy. Incidence of neonatal Pompe disase is usually 1/150000 birth in most country, except Taiwan, where its incidence is evaluated around 1/15000. We have identified 17 newborns with infantile Pompe disease born in 10 years in the same maternity to parents from the Bushinengue tribes living at the frontier between french Guyana, an overseas French department, and Suriname. This population descends from African-onset slaves who escaped to the Amazonian forest and settled along the lower Maroni River in the nineteen century, where they grew as a geographical and cultural isolate population till recently. Genetic investigation revealed that all patients were homozygous or compound heterozygous for 2 mutations: p. Arg854* that has already been reported in the african-american population, and p.Gly648Ser, previously considered to be a mild variant. Despite probable incomplete detection, the raw incidence of infantile Pompe disease in the area is at least 1/2000 births, corresponding to a heterozygote frequency of 1/22. Early detection allowed us to put under enzyme replacement therapy the last 3 cases, which where all CRIM positives. Implementation of systematic newborn screening will be implemented in Guyana by mid 2014.

New insights into PPARG regulation mechanisms: the unexplored impact of alternative splicing on its function

M. Aprile[1], *M. R. Ambrosio*[1,2], *V. D'Esposito*[2], *F. Beguinot*[2,3], *P. Formisano*[2,3], *V. Costa*[4], *A. Ciccodicola*[1];
[1]*Institute of Genetics and Biophysics, Naples, Italy,* [2]*Department of Translational Medical Sciences (DiSMeT), University of Naples "Federico II", Italy, Naples, Italy,* [3]*Institute of Experimental Endocrinology and Oncology (IEOS), CNR Naples, Italy, Naples, Italy,* [4]*Institute of Genetics and Biophysics „Adriano Buzzati-Traverso" (IGB), National Research Council (CNR), Naples, Italy.*

The nuclear receptor PPARγ is a key regulator of cell proliferation and differentiation, including adipogenesis. Defects in PPARγ signaling are implicated in metabolic syndrome, cardiovascular diseases and cancer. The wide number of ligands, coregulators and target genes, combined to different protein isoforms and alternative transcripts, determines the complexity of PPARγ biological role.
Notably, our group identified a new PPARG isoform (γORF4) with a dominant negative effect toward PPARγ, suggesting underestimated aspects of its regulation. We also recently described the differential contribution of PPARG canonical transcripts and ORF4 variants to adipocyte differentiation of human mesenchymal stem cells. The analysis demonstrated that PPARG transcription is regulated in a time-specific manner, through differential usage of distinct promoters, also indicating that dominant negative isoforms are actively transcribed and regulated throughout the adipogenesis. Moreover, during this study we identified another PPARG transcript, named Δ5, with features similar to ORF4. Through transfection experiments, the usage of a PPARγ agonist and luciferase assay, we demonstrated its dominant negative activity and an altered ability to regulate cellular proliferation. In order to understand, on a genome-wide scale, the effects of γΔ5 isoform on PPARγ target genes' expression, we also performed a transcriptome analysis by RNA-Sequencing in HEK293 cells over-expressing Δ5, in presence of a PPARγ agonist. Our results indicate that different dominant negative isoforms encoded by PPARG gene may have a relevant, and yet unexplored, role in the biological function of PPARγ, with a potential involvement in physiologic and pathologic conditions, of which PPARγ is a key player.

P06.52-M
Association of rs780094 in GCKR with Metabolic syndrome and related traits were confirmed in Tehran lipid and glucose study

M. S. Daneshpour[1], *M. S. Fallah*[1,2], *B. Sedaghatikhayat*[1], *A. Ebrahimi*[1], *K. Guity*[1], *F. Azizi*[3];
[1]Cellular and molecular research center, Obesity Research Center, Research Institute for endocrine sciences Shaheed Beheshti University of Me, Tehran, Islamic Republic of Iran, [2]Kawsar Human Genetics Research Center (KHGRC), Tehran, Islamic Republic of Iran, [3]Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.

Background: The minor T-allele of rs780094 in intronic region of glucokinase regulator gene (GCKR) is reported to be associated with a number of metabolic traits including higher triglyceride levels and lipid metabolite factors in GWA studies mostly European ancestry. Here we report replicating these finding in Iranian population using samples from the Tehran lipid and glucose study (TLGS), a large population-based cohort study. Methods: Among TLGS participant 1777 cases with metabolic syndrome according to ATPIII criteria, were selected and compared to 3909 control. In GCKR gene, rs780094 genotyped using the Centaurus (Nanogen) platform in DeCODE genetics. Association of T-allele with metabolic syndrome and lipid related variables (e.g. triglyceride, cholesterol, HDL and LDL) was tested using plink software after age and sex adjustment. Results: Replicating previous findings TLGS participants showed that T-allele of rs780094 was associated with higher triglyceride levels ($p < 10^{-8}$), higher cholesterol levels ($p < 0.05$) and metabolic syndrome prevalence ($p < 0.0025$). Conclusion: Our findings showed the association between the presence of T allele in rs780094 and metabolic syndrome and related traits among Iranian population and confirmed previous result in other ethnicity.

P06.53-S
Sengers syndrome: case report and review of literature

L. Fenwarth[1], **J. Ghoumid**[1,2], *E. Holinski-Feder*[3], *S. Manouvrier*[1,2], *C. Vincent-Delorme*[1];
[1]Service de Génétique Clinique, Hôpital Jeanne de Flandre, CLAD Nord de France, CHRU Lille, Lille, France, [2]Université Lille Nord de France, Lille, France, [3]Medizinisch Genetisches Zentrum, München, Germany.

Sengers syndrome is a rare autosomal-recessive condition (prevalence < 1/1 000 000) associating congenital cataract, hypertrophic cardiomyopathy, skeletal myopathy and exercise-related lactic acidosis.
We report on a non-consanguineous, full-term, eutrophic child with bilateral congenital cataract. Metabolic investigations were normal. Cataract surgery was early performed. At three weeks and three months of age, during an infectious episode, the infant developed respiratory distress, and deceased from cardiac insufficiency. X-ray revealed cardiomegaly, and severe lactic acidosis was found in blood sample. No genetic analysis could be performed in the patient. Thus we decided to analyse acylglycerol kinase (AGK) gene in both parents in this context.
We identified heterozygous mutations in AGK gene in both parents allowing retrospective diagnosis of Sengers syndrome in the child and clear genetic counselling for the family.
The management of congenital cataract should be very early and exhaustively performed, to exclude Sengers syndrome, considering the risk of cardiac failure during cataract surgery or during any intercurrent infectious episode.
Literature does not propose systematic and consensual investigations for bilateral congenital cataract. However, the wide range of aetiologies of congenital cataracts implies various but specific and appropriate managements. This case highlights the interest of cardiac ultrasounds in congenital cataract investigation.

P06.54-M
Cellular model of polyprenol reductase deficiency: useful tool for SRD5A3-CDG study

A. M. Buczkowska[1], *A. Dziembowski*[1], *D. Lefeber*[2], *E. Swiezewska*[1];
[1]Institute of Biochemistry and Biophysics Polish Academy of Sciences, Warsaw, Poland, [2]Department of Neurology, Radboud University Medical Center, Nijmegen, Netherlands.

Polyprenol reductase encoded by *SRD5A3* gene plays crucial role in the dolichol cycle by catalyzing the conversion of polyprenol to dolichol. Phosphorylated derivatives of dolichol are key molecules in protein glycosylation and glycosylphosphatidylinositol anchor biosynthesis. Decreased content of dolichols due to the mutations in *SRD5A3* gene has catastrophic consequences for the cell since it results in hypoglycosylation of proteins and in human manifests as Congenital Disorders of Glycosylation. SRD5A3-CDG patients have shown a substantial phenotypic variability despite the presence of truncating mutations in all of them. Biochemical and molecular studies on the cellular model of SRD5A3 deficiency are necessary for better understanding of the biological consequences of decreased level of dolichols and identification of the correlation between mutations found in *SRD5A3* with clinical symptoms.
To this end we established an in vitro system of HEK293 cells expressing miRNA silencing endogenous *SRD5A3* in an inducible manner under a tetracycline regulated promoter complemented by mutated variants of *SRD5A3*. Selected cell lines will be used for the analysis of various cellular effects of dolichol deficiency: protein N-glycosylation, O-mannosylation and GPI-biosynthesis, isoprenoid lipid homeostasis, expression of selected genes. Furthermore, the model might be useful for SRD5A3-CDG diagnostics and possible therapy development by maintaining the cellular dolichol/dolichyl phosphate pool at optimal level.

P06.55-S
A homozygous mutation in the transcription factor THAP11 in a patient with methylmalonic aciduria and a severe neurological phenotype

A. Brebner[1], *H. Yu*[2], *D. Watkins*[1], *V. Adoue*[1,3], *T. Pastinen*[1,3], *F. Skovby*[4], *T. H. Shaikh*[2], *D. S. Rosenblatt*[1];
[1]McGill University, Montreal, QC, Canada, [2]University of Colorado School of Medicine, Aurora, CO, United States, [3]McGill University and Genome Quebec Innovation Centre, Montreal, QC, Canada, [4]The Juliane Marie Centre, Rigshospitalet, Copenhagen, Denmark.

Inborn errors of vitamin B_{12} (cobalamin) metabolism result in homocystinuria and methylmalonic aciduria, either alone or in combination. The most common error, *cblC* caused by mutations in *MMACHC*, results in the combined metabolic phenotype. We recently described a biochemically similar inborn error, *cblX*, caused by mutations in the gene for the X-linked transcriptional coregulator HCFC1, which activates the transcription of *MMACHC*. The *cblX* patients were originally diagnosed as *cblC*; however they have a severe neurological and milder biochemical phenotype than most *cblC* patients (Yu *et al*. AJHG, 2013, 93:5). One patient, characterized as *cblC* by complementation analysis, had no mutations in either *MMACHC* or *HCFC1* by Sanger sequencing. Clinically, he had methylmalonic aciduria, encephalopathy, profound mental retardation, seizures and tetraplegia and died at age 10. His biochemical manifestations were mild, with higher cellular function of both cobalamin-dependent enzymes than normally seen from *cblC* patients and no homocysteine elevation. Sequencing of patient genomic DNA identified a homozygous mutation, c.240C>G (p.F80L) in *THAP11*, the gene encoding a zinc finger transcription factor that functions with HCFC1. The mutation affects a residue located in a conserved zinc finger-containing domain, two residues away from P78, responsible for interacting with the zinc ion, and is predicted to be probably damaging by Polyphen-2. F80 is conserved to zebrafish and in 9/12 human THAP proteins. Transcriptome profiling showed significant down-regulation of the same group of genes, including *MMACHC*, in fibroblasts from *cblX* and the *THAP11* patient.

P06.56-M
Rogers syndrome (thiamine responsive megaloblastic anemia syndrome): the success of multidisciplinary approach

V. Mikstiene[1], *J. Songailiene*[1], *J. Byckova*[2], *G. Rutkauskiene*[3], *E. Jasinskiene*[4], *R. Verkauskiene*[4], *E. Lesinskas*[2], *A. Utkus*[1];

Hospital of Lithuanian university of Health Sciences, Kaunas Clinics, Kaunas, Lithuania, [4]Department of Endocrinology, Hospital of Lithuanian University of Health Sciences, Kaunas Clinics, Kaunas, Lithuania.

Thiamine responsive megaloblastic anemia syndrome is a rare autosomal recessive metabolic disorder. Only ~80 cases have been described mainly in consanguineous families. A gene SLC19A2 coding high affinity thiamine transporter mediating vitamin B1 uptake through cell membrane has been identified. Classic triad of features is characteristic to the disease - megaloblastic anemia, deafness and non-type I diabetes.
We report a 3y old boy born in nonconsanguineous family. From the early days the boy was easy irritable and suffered with common affecto-respiratory spasms. The psychomotor abilities developed according to age. The slowdown of speech development was noticed from the 7th month of life. Insulin dependent non-type 1 diabetes was diagnosed at the age of 1y. At the age of 1.5y the profound bilateral hearing loss was diagnosed and cochlear implantation performed with good auditory and speech outcomes. During 3rd year of life severe megaloblastic anemia without folic acid or vitamine B12 deficiency and bilateral maculopathy has developed. The coding sequence of GJB2 gene was analyzed and genotype c.[313_326delAAGTTCATCAAGG G];[=] (p.[(Lys105Glyfs*5)];[=]) was identified. MtDNA 1555A>G mutation was not revealed. The patient had slightly elevated branched chain amino acids (Leu, Ile, Val) in plasma. The clinical diagnosis of TRMA syndrome was suspected and daily supplementation with thiamine 100mg started. The condition of the patient markedly improved several days after the initiation of treatment - therapy has positive effect on anemia and glycemia, also psychological status of the child clearly improved. The results of SLC19A2 gene molecular testing will be achieved in the near future.

P06.57-S
Tyrosinemia type II (Richner-Hanhart syndrome): a new mutation in the TAT gene

J. Pavelic[1], *R. C. Betz*[2], *K. Fumić*[3], *V. Čulić*[4];
[1]*Rudjer Boskovic Institute, Zagreb, Croatia,* [2]*Institute of Human Genetics, Bonn, Germany,* [3]*University Hospital Zagreb, Zagreb, Croatia,* [4]*University Hospital Split, Split, Croatia.*

In the present study we report the clinical features and the molecular genetic investigation of the tyrosine aminotransferase (*TAT*) gene in a young girl from Croatia with Richner-Hanhart syndrome, mainly suffering from photophobia, hyperkeratosis of the palmes and soles and slight neurological abnormalities. Sequencing analysis of the *TAT* gene revealed a novel homozygous missense mutation c.1250G>A (p.R417Q) in exon 12, and herewith confirmed the clinical diagnosis. Showing the first symptoms in babyhood, at the age of 8 years it was for the first time clinically diagnosed that the patient suffers from tyrosinemia type II and a therapy with tyrosine and phenylalanine reduced diet has been started successfully. All symptoms disappeared within 2-4 weeks. Since that time, we have been following the girl until today for more than ten years. She is in a good condition, and attends the normal high school program.

Neurological impairment is frequent among heterozygote women for X-linked Adrenoleukodystrophy - A clinical, neurophysiological and biochemical study

L. B. Jardim[1], *C. T. Habekost*[1], *P. Schestatsky*[1], *V. F. Torres*[2], *V. F. Torres*[2], *D. M. Coelho*[2], *C. R. Vargas*[1], *V. Torrez*[1], *L. V. C. Portela*[1], *F. S. Pereira*[1], *U. Matte*[2];
[1]*Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil,* [2]*Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil.*

Background: Neurologic impairments in female heterozygotes for X-linked Adrenoleukodystrophy (X-ALD) are poorly understood. Our aims were to describe the neurological and neurophysiological manifestations of a cohort of X-ALD heterozygotes, and to correlate them with age, disease duration, mutations, X-inactivation and serum concentrations of a marker of neuronal damage, NSE. Methods: All 45 heterozygotes of our institution, with previous VLCFA and molecular diagnosis, were invited to be evaluated through myelopathy scales JOA and SSPROM, nerve conduction studies and somatosensory evoked responses. X-inactivation pattern was tested by HUMARA methylation assay. Serum NSE was measured by eletrochemiluminescense. Results: Thirty-three heterozygotes were recruited: 29 (87%) were symptomatic. Symptomatic and asymptomatic women presented different m±sd ages (43.9 ± 10.2 versus 24.3 ± 4.6), JOA (14.5 ± 1.7 versus 16.6 ± 0.2) and SSPROM (86.6 ± 7.9 versus 98.4 ± 1.1) scores ($p<0.05$). Both JOA ($r = -0.68$) and SSPROM ($r = -0.65$) correlated with age ($p = 0.0001$, Spearman). Delayed central ascending conduction studies on the lower limbs were present in 72% of all heterozygotes, and correlated with SSPROM ($r = -0.47$, $p = 0.018$, Spearman). NSE values were higher in heterozygotes than in controls (12.9 ± 7 and 7.2 ± 7 ng/ml, $p = 0.012$, Mann-Whitney U).. Mutation severity and inactivation patterns were not associated with neurologic status. Discussion: Neurologic manifestations, clearly related to age, were more common than expected. JOA and SSPROM scales discriminated asymptomatic from symptomatic heterozygotes. Both might be useful tools to follow disease progression, in future studies.

P06.59-S
Should persons with intronic variations of α galactosidase A and stroke be considered ‚manifesting carriers' of Fabry disease?

G. Altarescu[1], *E. Hakam-Spector*[1], *Y. Herskovitz*[1], *R. Beeri*[1], *D. Elstein*[2], *D. A. Zeevi*[1];
[1]*Shaare Zedek Medical Center, Medical Genetics Institute, Jerusalem, Israel,* [2]*Shaare Zedek Medical Center, Gaucher Unit, Jerusalem, Israel.*

Persons with unexplained early-onset stroke have been targeted for screening surveys for Fabry disease, the most common of the three X-linked lysosomal disorder, because Fabry patients with stroke are more likely to have the life-threatening progressive cardiac and renal manifestations and would therefore most benefit from early diagnosis and intervention with enzyme replacement therapy (ERT). Among 173 Israeli patients with unexplained cryptogenic stroke screened for mutations in the Fabry α galactosidase A (GLA) gene, sequencing identified four with 2-4 GLA intronic variants, one of whose father and three sisters had the same variants. Two variants, c.640-16A>G (g.10115A>G) in intron 4 and c.1000-22C>T (g.10956C>T) in intron 6, were common to all patients; only one male with a deletion in intron 2 had low residual enzyme activity; both he and the father had decreased mRNA expression. X-chromosome inactivation was not highly skewed in the six females. Nonetheless, these cases differ largely from those in the literature of carriers of intronic variants with multi-system Fabry disease. These current patients may not benefit from ERT, raising the question whether intronic variants alone are disease-causing or whether these patients should be considered ‚manifesting carriers' of an X-linked recessive disease.

P06.60-M
A pilot study on an expanded newborn screening program in Palestine

S. A. Khatib, *A. Ayyad;*
Alquds University Medical School, Jerusalem, Palestinian Territory.

Objective: Until this day newborns in Palestine are being screened for phenylketonuria and congenital hypothyroidism only. However, a number of other metabolic diseases have been recognized amongst the population, including amino acid and urea cycle disorders. The study was conducted in an effort to investigate the possibility of finding such cases in newborns throughout the West Bank of Palestine. In addition, reference ranges for a number of amino acids and urea cycle intermediates will be established.
Study Design: A cross-sectional observational study design was used and the study was conducted in all 12 districts of the West Bank. Convenience sampling was used to recognize the study newly born participants. The sample size was 4240 and an informed consent form was collected from all parents. The study blood collection cards were collected over a one year period by Ministry of Health staff. The study cards were shipped to the University of Liege Human Genetics Department in Belgium for analysis using tandem mass spectrometry.
Results: Statistical analysis showed a significant relationship between weight and some amino acid levels. A significant difference between some amino acid levels and the districts was also observed. The reference range for each amino acid and urea cycle intermediates tested was calculated based on the non-parametric percentile method as indicated by CLSI C28-A3.
Conclusion: Based on our established reference ranges for each analyte the results showed that 22.5% of the tested samples (955) had at least one amino acid level in the upper 2.5% of the population.

P06.61-S
First experience of idursulfase enzyme replacement treatment in patients with Hunter syndrome in Bashkortostan Republic (Russia)

T. Nekrasova[1], *Y. Timasheva*[2];
[1]*Centre of Children Psychoneurology and Epileptology, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics USC RAS, Ufa, Russian Federation.*

Mucopolysaccharidosis type II (MPS II, Hunter syndrome, OMIM309900) is a rare X-linked recessive lysosomal storage disorder caused by deficiency of the enzyme iduronate-2-sulphatase, resulting in accumulation of glycosaminoglycans (heparin sulfate and dermatan sulfate), multisystem organ failure and early death.
In the Republic of Bashkortostan (Russia), enzyme replacement therapy with idursulfase (recombinant iduronate-2-sulphatase) was established since 2011. Five patients with confirmed Hunter syndrome, aged between 3.5 and 12 years, were registered for the program. Patients had been treated with weekly intravenous infusions of idursulfase for 24 months. At the beginning of the treatment, all patients showed moderate to severe neurological

abnormalities, including hydrocephaly, ventriculomegaly, and white matter lesions, as well as other symptoms, such as facial and thoracic deformities, joint stiffness, exudative otitis media, hepatosplenomegaly and intellectual disability. After at least 9 months of treatment, urinary glycosaminoglycans levels had decreased, and liver and spleen size were reduced. Idursulfase treatment was well tolerated (adverse reactions occurred in none of the patients). However, cognitive development had shown clear tendency to decline over time, resulting in severe mental retardation by the end of second year of treatment. Our experience of enzyme replacement therapy of Hunter syndrome provides an evidence of the beneficial somatic effects and also suggests the importance of early diagnosis of the disease which might lead to more favorable impact on cognitive development of patients.

P07.01-S
ACTN1 : identification of novel mutations in a cohort of Italian IMTP patients

M. Faleschini[1], *C. Marconi*[2], *R. Bottega*[3], *T. Pipucci*[2], *G. Baj*[4], *P. Noris*[5], *A. Pecci*[5], *C. L. Balduini*[5], *M. Seri*[2], *A. Savoia*[3];
[1]Department of Medical Sciences, University of Trieste, Trieste, Italy, [2]Medical Genetics Unit, Policlinico S. Orsola-Malpighi, University of Bologna, Bologna, Italy, [3]Institute for Maternal and Child Health – IRCCS Burlo Garofolo, Trieste, Italy, [4]Department of Life Sciences, BRAIN Centre for Neuroscience, University of Trieste, Trieste, Italy, [5]Dipartimento di Medicina Interna, Università di Pavia-IRCCS Policlinico San Matteo Foundation, Pavia, Italy.

Inherited macrothrombocytopenia (IMTP) is a highly heterogeneous group of inherited disorders characterized by a low platelet count and abnormally platelet size. Even though IMTP-causing mutations have been reported in several genes, only 50% of patients have to date a molecular diagnosis.
In March 2013 Kunishima and colleagues identified alpha-actinin 1 (ACTN1) as a new gene responsible for IMTP which accounted for 5,5% of cases in Japanese population. To evaluate the frequency of ACTN1 mutations in the Italian population, we performed a screening in 160 probands in which all the known forms of IMTP were previously excluded. Ten, including 8 novel, different missense have been identified in 11 patients. All except one (p.D666V) segregated with the macrotrombocytopenia within the families. In vivo transfection experiments in Hela cells were performed to demonstrate the pathogenicity of the variants identified. Except for p.D666V, preliminary data indicate that the missense mutations are associated with disorganization of cytoskeleton, as determined different co-localization of mutant and wild type actinin-a with actin. Further studies will be needed to determine how these mutations may lead to the onset of disease.

P07.02-M
Simultaneous silencing of Mcl-1 and survivin expression by small interfering RNA and enhancement of chemosensitivity in human acute myeloid leukemia cells

E. Sakhinia[1], *H. Karami*[2], *B. Baradaran*[3], *M. Asghari Estiar*[4], *A. Esfahani*[5], *M. Sakhinia*[6];
[1]Department of Medical Genetics, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran, [2]Department of Biochemistry, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran, [3]Immunology Research Center, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran, [4]Department of Medical Genetics, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran, [5]Hematology and Oncology Research Center, Shahid Ghazi Hospital, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran, [6]Faculty of Medicine, University of Liverpool, Liverpool, United Kingdom.

Anti-apoptotic genes such as Mcl-1 or survivin may be responsible for resistance to apoptosis induced by chemotherapeutic drugs. The aim of this study was to investigate whether the knockdown of Mcl-1 or survivin expression by small interfering RNA (siRNA) would sensitize HL-60 acute myeloid leukemia cells to etoposide. Knockdown of Mcl-1 or survivin expression was confirmed by quantitative real-time PCR and Western Blotting. The effects of Mcl-1 or survivin down-regulation on the chemosensitivity of the cells was assessed by the MTT assay. Cell viability and apoptosis were also determined using the trypan blue exclusion assay and the annexin V/PI double-staining method, respectively. Transfection of siRNAs markedly decreased the expression levels of both Mcl-1 and survivin genes in a time-dependent manner. Down-regulation of Mcl-1 or survivin significantly inhibited the proliferation and enhanced the chemosensitivity of the cells. Furthermore, pretreatment with siRNAs clearly enhanced the etoposide-mediated apoptosis of the leukemic cells. Surprisingly, siRNA co-transfection had a more antileukemic effect relative to the single siRNA transfection. Our study demonstrates that a triple approach involving siRNA-mediated silencing of the Mcl-1 and survivin along with chemotherapeutic drugs could potentially be used to lower the effective doses of the chemotherapeutic drugs and reduce drug-related toxicities.

P07.03-S
Role of the mutations identified in the 5'UTR of ANKRD26 responsible for an inherited form of thrombocytopenia

C. Gnan[1], *L. Arnoldo*[2], *M. Faleschini*[3], *D. De Rocco*[3], *R. Sgarra*[2], *G. Manfioletti*[2], *A. Savoia*[1];
[1]IRCCS Burlo Garofolo, Trieste, Italy, [2]Department of Life Sciences, Trieste, Italy, [3]Department of Medical Sciences, Trieste, Italy.

The joint application of clinical and genetic investigations has greatly expanded the knowledge of inherited thrombocytopenias, leading to characterization of new forms, such as ANKRD26 related disease (ANKRD26-RD). ANKRD26-RD is characterized by thrombocytopenia and bleeding tendency, as well as an increased risk of leukemia. Since the identification of ANKRD26, as the gene responsible for the disease, 12 different mutations, all localized in a short stretch of 22 nucleotides in the 5'UTR, have been identified. To further investigate their effect, we tested the activity of the basal promoter together with the wt or the mutant 5'UTR in a reporter assay. In a megakaryocytic cell line, mutations generated a statistically significant increase of the luciferase activity, suggesting that the 5'UTR plays a role in inhibiting the expression of ANKRD26 during megakaryopoiesis. Consistent with this hypothesis, ANKRD26 is expressed in human CD34+ and BFU-E but it is hardly detectable in megakaryocytes. Bioinformatic analysis revealed putative binding sites for transcription factors in the region hit by mutations. In order to identify these factors, we performed electrophoretic mobility shift assay (EMSA). Among different complexes of the same size in both wt and mutant samples, we observed an additional band generated by two mutant probes. Experiments of super-shift EMSA are in progress to characterize the pathogenetic factor(s) that could interfere with the physiological control of the ANKRD26 expression.

P07.04-M
HBB gene mutation spectrum of beta-thalasemia patients from Turkey

G. Toksoy[1], *Z. Karakaş*[2], *H. Kayserili*[3], *V. Karaman*[1], *S. Başaran*[1], *Z. Uyguner*[1];
[1]Department of Medical Genetics, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey, [2]1Department of Pediatric Haemotology, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey, [3]1Department of Medical Genetics, Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey.

Beta-thalasemia is defined by the absence or decrease of beta globin via mutations of the HBB gene and is one of the most common hereditary disorders existing in Turkey. With the mean carrier frequency of β-thalassemia being 2.1% in the general population, and rates as high as 10% concentrated in certain regions of the country, hemoglobin electrophoresis of the individuals at premarital stage and molecular diagnosis of the carrier individuals for genetic counseling cannot be overstated. Targeted diagnosis of the HBB gene mutations can be readily obtained using commercially available reverse dot blotting kits. A sequence analysis of the complete HBB gene covering UTR and near-gene regions provides a 99% mutation detection rate. We report here a summary finding of HBB gene analysis for 163 Turkish patients, along with their family members totaling 248 individuals, referred with beta-thalassemia indications covering the period of 2010-2014. 39 were found to have homozygous, 31 possessed compound heterozygous and 63 possessed heterozygous mutations. Overall, a total of 205 alleles were found to have mutations. The first 15 frequented mutations covered 88% of the entirety of all mutations. The summary range is as follows: c.93-21G>A (IVS1+110G>A) 30.7%; c.135delC (p.ser45fs) 7.8%; c.92+1G>A (IVS-I-1) 7.8%; c.25_26delAA (p.Lys9Valfs) 5.9%; c.20A>T (p.Glu7Val) 4.9%; c.92+6T>C (IVS-I-6) 4.9%. We discuss that the commercial targeted kits detect up to 80% of the HBB mutations for our patients. Sequence analysis of the HBB gene from 5' promoter (-250bp) to 3' promoter region (*250bp) contributes 15% to the mutation detection rate.

P07.05-S
Identification of two novel mutations in NLRP3 gene in Italian patients with Cryopyrin-associated periodic syndrome (CAPS)

L. D'Agruma[1], *M. Rendina*[1], *A. Rella*[1], *M. Miscio*[1], *A. De Cata*[2], *F. Molinaro*[2], *L. Zelante*[1];
[1]Servizio di Genetica Medica, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, [2]UOC Medicina Interna, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy.

Cryopyrin-associated periodic syndrome (CAPS) is an autoinflammatory syndrome caused by mutations in NLRP3 gene. Three clinical types exist: familial cold autoinflammatory syndrome (FCAS), Muckle-Wells Syndrome (MWS) and chronic infantile neurological, cutaneous and articular (CINCA) syndrome. More than 150 different diseases-causing mutations have been reported in NLRP3 with more than 80% of them localized in exon 3.
We report here two cases of CAPS in Italian patients harbouring two de novo mutations. The first case is a 20 years old boy with CINCA. He has severe phenotype with clinical features mimicking those of juvenile rheumatoid arthritis, including recurrent episodes of skin rash, fever, arthralgia, and cen-

tral nervous system involvement. In this patient was identified a c.913G>A (p.D305N) mutation in the exon 3 of the NRLP3 gene. The analysis of the parents did not show the same mutation. Mutations at the codon 305 of NRLP3 gene have been described but not the Asp >Asn substitution. The second case is a 35 years old woman with FCAS. She showed recurrent episodes of skin rash, fever, arthralgia and conjunctivitis after generalized exposure to cold. In this patient the c.2113C>A (p.Q705K) mutation in exon 3 of the NRLP3 gene has been identified. Also in this case the analysis of the parents did not show the same mutation. In conclusion, we report two de novo mutations in NLRP3 gene in CAPS italian patients and we suggest the molecular screening of NRLP3 gene in patients with a strong suspicious of autoinflammatory syndrome.

P07.06-M
IPEX-like syndrome: beyond FOXP3 analysis

M. Vignoli[1,2], *S. Ciullini Mannurita*[1,2], *K. Goudy*[3], *L. Passerini*[3], *A. Tommasini*[4], *A. İkincioğulları*[5], *G. Guariso*[6], *R. Bacchetta*[3], *E. Gambineri*[1,2];
[1]*Department of "NEUROFARBA", section of Child's Health, University of Florence, Florence, Italy,* [2]*"Anna Meyer" Children's Hospital, Florence, Italy,* [3]*San Raffaele Telethon Institute for Gene Therapy, Division of Regenerative Medicine, Stem Cells and Gene Therapy, San Raffaele Scientific Institute, Milan, Italy,* [4]*IRCCS Burlo Garofalo, Paediatric Immunology Laboratory, Trieste, Italy,* [5]*Department of Pediatrics, Division of Pediatric Immunology and Allergy, Ankara University Faculty of Medicine, Ankara, Turkey,* [6]*Unit of Paediatric Gastroenterology, Department of Women's and Children's Health, University Hospital of Padova, Padova, Italy.*

IPEX-like patients have clinical features resembling IPEX syndrome (Immune-dysregulation, Polyendocrinopathy, Enteropathy, X-linked) without mutations in the *FOXP3* gene (Xp11.23), that encodes a transcriptional regulator critical for the development and function of $CD4^+CD25^+$ regulatory T cells. These cells are indispensable for the maintenance of immune self-tolerance and homeostasis by suppressing aberrant or excessive immune responses.
IL2Ralfa and *STAT5b* are two genes whose deficiency has been associated with IPEX-like syndrome and both encode proteins involved in FOXP3 pathway. *IL2Ralfa* codes for the alfa subunit (CD25) of the receptor complex for IL2, and the interaction between IL2-IL2Ralfa is the first step that trigger *FOXP3* trascription.
In this study we describe the identification of three different point mutations affecting *IL2R*alfa one of them was recently published by our group and the other two were never reported in literature.
All variations are missense mutations leading to a single aminoacid substitution that modify the protein structure. Two are located in exon 4 and alter the "sushi" domain that seems to be fundamental for IL2-IL2Ralfa interaction, the third mutation determines the substitution of a cysteine that may be involved in the formation of a disulfide bond, thus causing the alteration of the tertiary structure of the receptor.
Cytofluorimetric analysis revealed total absence of CD25 expression in all three patients, strengthening the hypothesis that these mutations cause the disruption of the receptor structure thus leading to its degradation. Further studies are ongoing to better characterize the consequence of these mutations from the molecular and cellular point of view.

Immunophenotypic profile of erythroid extracellular vesicles obtained from peripheral blood of patients with Diamond-Blackfan Anemia

S. Macrì[1], *R. Crescitelli*[1], *E. Pavesi*[1], *C. Botto*[2], *P. Quarello*[3], *C. Vizziello*[4], *P. Notari*[4], *U. Ramenghi*[2], *S. R. Ellis*[5], *I. Dianzani*[1];
[1]*Department of Health Sciences, University of Eastern Piedmont, Novara, Italy,* [2]*Department of Public Health and Pediatric Sciences, University of Turin, Turin, Italy,* [3]*Pediatric Onco-Hematology, Regina Margherita Children's Hospital, Turin, Italy,* [4]*Chemical Clinical Analysis laboratory, SCDU, Azienda Universitaria Ospedaliera Maggiore della Carità, Novara, Italy,* [5]*Department of Biochemistry and Molecular Biology, University of Louisville, Louisville, KY, United States.*

Diamond-Blackfan Anemia (DBA) is a rare inherited anemia. Heterozygous mutations in one of 11 ribosomal protein genes cause defective ribosome biogenesis. Erythroid progenitors (BFU-E and CFU-E) in bone marrow (BM) show a proapoptotic phenotype. Suspicion of DBA is reached after exclusion of other forms of BM failure syndromes and the diagnosis is confirmed by mutations analysis. To improve DBA diagnosis, we tested a new approach based on the study of extracellular vesicles (EVs). EVs have been isolated from plasma of patients with DBA and appropriate controls by differential centrifugations and analyzed by flow cytometry. To study erythroid EVs we evaluated three erythroid markers: CD34, CD71 and CD235a. EVs immunophenotypic profiles of 8 patients with DBA, 20 healthy controls and 10 patients with other hematological diseases have been characterized. We were able to identify different clusters: CD71+/CD34-, CD34+/CD71low and CD235a+. In all gates the absolute number of EVs/µl has been evaluated. Only the CD34+/CD71low population is significantly different between patients with DBA and controls ($p< 0,05$). This population that is always present in healthy controls, is absent in patients with DBA. The absence of CD34+/CD71low population in DBA patients plasma is in agreement with the low level of erythroid progenitors in the patients' BM. The area under the ROC curve that compares patients with DBA and healthy controls is 0.92. Further analyses are needed to ascertain whether this assay may be used in the clinics.

P07.08-M
Analysis of rRNA maturation in patients with Diamond-Blackfan anemia

S. Parrella[1], *A. Aspesi*[1], *E. Pavesi*[1], *S. Macrì*[1], *E. Garelli*[2], *A. Carando*[2], *P. Quarello*[3], *U. Ramenghi*[2], *S. R. Ellis*[4], *I. Dianzani*[1];
[1]*Department of Health Sciences, University of Eastern Piedmont, Novara, Italy,* [2]*Department of Public Health and Pediatric Sciences, University of Torino, Torino, Italy,* [3]*Pediatric Onco-Hematology, Regina Margherita Children's Hospital, Torino, Italy,* [4]*University of Louisville, Louisville, KY, United States.*

Diamond-Blackfan anemia (DBA MIM # 105650) is an inherited erythroid aplasia caused by mutations in 11 genes encoding ribosomal proteins of the small (RPS) or the large (RPL) subunit. The 28S, 5.8S and 18S rRNAs are transcribed as a single precursor that is processed into mature rRNAs, which form the ribosomal subunits with the RPs. Mutations in a RPS or a RPL alter the processing of 18S or 28S and 5.8S rRNAs, respectively. The analysis of pre-rRNA by Northern blot in cell models or lymphoblastoid cells from patients shows different patterns of precursors depending on which RP is mutated.
Mutation analysis of 11 genes is needed to confirm the diagnosis. We have looked whether rRNA analysis of activated lymphocytes could improve the DBA diagnostic approach. We extracted total RNA from activated lymphocytes of patients with DBA (4 mutated in RPS19, 1 in RPS17, 2 in RPL11, 4 in RPL5 and 5 with unknown mutations). Northern blot analysis was performed using appropriate probes. All the patients with a mutation in a RPL showed the accumulation of a 32S precursor that is visible also by ethidium bromide staining. Northern blot analysis allowed to discriminate patients with mutations in RPS19 from those with mutations in RPS17. We observed the rRNA maturation defect also in a patient with a mutation in RPL5 after stable remission from the disease.
This is the first demonstration of rRNA abnormalities in patient lymphocytes. rRNA processing analysis is a useful approach to direct the subsequent mutational screening.

P07.09-S
A case of factor X (FX) deficiency caused by novel mutations Q56K, Q104X

H. Koo;
Yonsei University College of Medicine, Seoul, Korea, Republic of.

Background
Inherited deficiency of coagulation factor X(FX) is a rare bleeding disorder with prevalence of 1 per 500,000 in general population. Mostly, the condition is associated with missense mutation, which is a valuable clue.
Case and results
A six month-old infant was hospitalized due to fever, lethargy and seizure with no significant medical history. Symptoms were attributable to brain abscess subsequently diagnosed. For operability evaluation, prothrombin time (PT) and activated partial thromboplastin time tests were performed, and the results were prolonged to 121.6 seconds and 109.1 seconds, respectively. Coagulation factor activities were also measured. Factor II, V, X activities were 80%, 99% and 1%, respectively. Factor VII, VIII, IX, XI and XII activities were all in normal ranges. FX activity of the parents was not tested due to refusal of family study. FX of the patient was sequenced on coding regions and exon-intron boundaries. We found 1 missense mutation and 1 nonsense mutation of FX (c.C343A in exon 4, c.C487T in exon 5) that correspond to amino acid substitution Q56K and stop codon at Q104, respectively. Both amino acids are located in EGF-like-domain 1.
The patient suffered hematochezia, hematuria, subdural hemorrhage and hemarthrosis which were all irrelevant to the operation. Bleeding was treated with tranexamic acid and fresh frozen plasma with monitoring of FX activity which increased from 1% to 22%.
Conclusion
The amino acid substitution of glutamine to lysine at EGF-like-domain 1 is probably related to functional inactivation of coagulation FX. Confirmation by expression study will be required.

P07.10-M
Study of IL-1β and IL-1RA gene polymorphisms in familial Mediterranean fever (FMF)

J. Ibrahim[1,2], *E. Chouery*[3], *J. Lecron*[2], *A. Mégarbané*[3], *M. Medlej-Hashim*[1];
[1]ER030-EDST, Faculty of Sciences II, Lebanese University, Beirut, Lebanon, [2]Laboratoire Inflammation, Tissus Epithéliaux et Cytokines, EA4331, Poitiers University, Poitiers, France, [3]Medical Genetics Unit, Faculty of Medicine, Saint Joseph University, Beirut, Lebanon.

Objectives. Familial Mediterranean fever (FMF) is a recessively transmitted autoinflammatory disease, caused by mutations in the MEFV gene. The pro-inflammatory cytokine IL-1β has been implicated in the pathogenesis of FMF and the balance between IL-1β and its receptor antagonist IL-1RA plays an important role in the development of the disease. Since polymorphisms in the IL-1 gene cluster have been suggested to have an effect on IL-1β and IL-1RA production, our aim was to determine a possible association of specific polymorphisms in IL-1β and IL-1RA genes with susceptibility to and/or severity of FMF.
Subjects and Methods. Forty-two genetically confirmed FMF patients and 42 controls were genotyped for IL-1β(-511C/T), IL-1β(-31T/C) and IL1-1β(+3954T/C) polymorphisms by PCR- digestion. The IL-1RA VNTR was identified by fragment-size analysis. IL-1β and IL-1RA levels were evaluated by Luminex in supernatants of PBMC cultures of 30 FMF patients with and without 24h stimulation of monocytes by LPS.
Results. The CC genotype and C allele at positions -31 and +3954 of IL-1β gene were observed more frequently in FMF patients than in controls. No significant difference was observed in the genotypic and allelic frequencies of the IL-1β(-511) polymorphism and IL-1RA VNTR. FMF patients carriers of IL-1β(-31) CC genotype were associated with a 2 fold increase in LPS-induced IL-1β secretion, compared to patients carrying other genotypes.
Conclusion. These results indicate that IL-1β gene polymorphisms at positions -31 and +3954 may be associated with susceptibility to FMF. IL-1β(-31) may also contribute to the severity of the disease, probably by modulating IL-1β secretion.

P07.11-S
Host genotype-pathogen interactions in the PBMC cells of healthy individuals identify critical immune regulators

U. Võsa[1,2], *Y. Li*[3], *S. Withoff*[3], *M. Netea*[4], *C. Wijmenga*[3], *V. Kumar*[3];
[1]Department of Biotechnology, Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia, [2]Estonian Genome Center, University of Tartu, Tartu, Estonia, [3]Department of Genetics, University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [4]Department of Medicine, Nijmegen Institute for Infection, Inflammation & Immunity (N4i), Radboud University Medical Center, Nijmegen, Netherlands.

Immune response to infection or vaccination is significantly influenced by host genetic components and autoimmune disease associated genetic variants may have stronger influence on such a response. One way to investigate the role of genetics in differential susceptibility to infection is to correlate the gene expression levels response to stimulation with autoimmune disease associated SNPs. We performed a pilot experiment by stimulating peripheral blood mononuclear cells (PBMC) of 46 volunteers with four different pathogenes for 4 and 24 hours. Gene expression profile was determined with Illumina arrays and genotype of 366 autoimmune disease-associated SNPs were genotyped using Immunochip. Linear model with stimulation status, genotype and stimulation-genotype interaction term was fitted for each probe and SNP. Due to the small sample size, we were not able to identify globally significant pathogen-genotype interactions after multiple testing correction, so possibly relevant interactions were prioritized based on uncorrected p-values, allelic trends and effect size differences between unstimulated and stimulated conditions. 133 SNPs showed interaction effect for at least one probe. The most significant interaction was between rs6087990 and a gene encoding macrophage receptor (uncorrected P=3.72×10-5). We were also able to identify SNP-gene pairs showing similar stimulation-genotype interaction in case of several different stimulations. These genes may play role in the disease susceptibility and serve as possible candidates for functional studies. The methods and preliminary results from this study reveal novel insights into the role of autoimmune SNPs and underscore the importance of large scale genotype-environment interaction studies in future.

A gluten free diet (GFD) is the most common diet worldwide. It is not only an effective treatment for celiac disease, but also commonly followed by individuals with gut complaints. How a GFD affects the human microbiome is largely unknown. We studied changes in the gut microbiome in healthy individuals following a short-term GFD.
23 healthy volunteers followed a GFD for 4 weeks. Stool samples were collected before the start of the diet, then at weekly intervals during the GFD and again at weekly intervals for 4 weeks on normal diet after a wash-out period. The samples were sequenced using 454 sequencing of the 16s rDNA (hyper variable region 3 to 4). We used closed reference picking to cluster reads into OTUs using the 2013 GreenGenes reference. Function imputation of the OTUs, is performed used PiCRUSt and HUMAnN.
We observed a limited difference of the GFD intervention, with the intra-subject variation being larger than the effect from a short-term diet change. However, we did observe that family *Veillonellaceae* (class *Clostridia*) was significantly less present in the GFD samples (p=6.58e−05, q=0.0132). Based on richness of the samples we were able to define two groups which show a difference in response to a GFD period. The lower richness group showed more bacterial variation in composition during the diet change. Furthermore, sixteen gene pathways showed significant association to the change in diet. In conclusion, in this we observed changes in microbiome and gene composition associated to a GFD.

P07.13-S
A dominant-negative GFI1B mutation causes autosomal dominant gray platelet syndrome

L. Van Laer[1], *D. Monteferrario*[2], *N. Bolar*[1], *K. Hebeda*[3], *S. Bergevoet*[2], *H. Veenstra*[2], *B. Laros*[2], *M. MacKenzie*[2], *E. Fransen*[1,4], *G. Van Camp*[1], *F. Preijers*[2], *S. Salemink*[5], *W. van Heerde*[2], *G. Huls*[2], *J. Jansen*[2], *M. Kempers*[5], *B. van der Reijden*[2], *B. Loeys*[1];
[1]University of Antwerp and Antwerp University Hospital, Antwerp (Edegem), Belgium, [2]Laboratory of Hematology Nijmegen Centre of Molecular Life sciences, Radboud University Medical Centre, Nijmegen, Netherlands, [3]Department of Pathology, Radboud University Medical Centre, Nijmegen, Netherlands, [4]StatUa Center for Statistics, University of Antwerp, Antwerp, Belgium, [5]Department of Clinical Genetics, St. Radboud University Medical Centre, Nijmegen, Netherlands.

Gray platelet syndrome (GPS) is a hereditary, usually autosomal recessive bleeding disorder caused by defective production of α-granules in platelets. The α-granule deficiency may be attributed to the failure of megakaryocytes to efficiently route proteins into α-granules, thereby hampering their maturation. We describe a large family with an autosomal dominant type of GPS characterized by mild to severe bleeding complications. In addition to gray platelets lacking α-granules, affected individuals had other GPS-associated phenomena like thrombocytopenia, emperipolesis, myelofibrosis and decreased expression of platelet factor 4. To determine the disease causing mutation we performed linkage analysis and identified a candidate locus on chromosome 9q34 (LOD score 3.9). We considered GFI1B (Growth factor independence 1B), located within this region, an excellent candidate gene because of its function as a transcriptional repressor essential in erythroid and megakaryocyte lineages. We identified a nonsense mutation in exon 6 (c.859C>T, p.Gln287*) that co-segregated with the GPS. The mutated transcript was not targeted for nonsense-mediated mRNA decay, resulting in a protein truncated within its 5th zinc finger, a domain essential for DNA binding. Using luciferase reporter assays we demonstrated that the truncated GFI1B protein was unable to repress gene expression and that it inhibited wild type GFI1B in a dominant-negative manner. Subsequently, we performed an immunophenotypical analysis of affected family members. Myeloid and erythroid lineages were unaffected, but we observed aberrant platelets and dysplastic abnormalities and disturbed lineage marker expression in GFI1B-mutated megakaryocytes. These studies define GFI1B to be key to megakaryocyte development, platelet production and α-granule biogenesis.

P07.15-S
Deletion between HLA-A and HLA-G genes is associated to HLA-A*23~HLA*G01:04~UTR-3~HLA*E01:01 and HLA-A*24~HLA*G01:04~UTR-3~HLA*E01:03:01 haplotypes

A. Mihidjai[1], *K. Barton*[1], *V. Ferreira*[1], *F. Carlini*[1], *C. Picard*[1,2], **J. Di Cristofaro**[1];
[1]UMR7268 ADES, Marseille, France, [2]Immuno-genetics laboratory, Etablissement Français du Sang Alpes Méditerranée, Marseille, France.

The genetic region between HLA-A and HLA-G covers 300 kb and is highly polymorphic. A large-scale deletion of 50 kb between these loci associated to HLA-A*23 and HLA-A*24 has been described. This deletion includes many genes and pseudogene, as HLA-H.
We showed in a study conducted in a Malian population that HLA-A alleles display LD with HLA-G alleles and UTR; HLA-A*23:01:01~HLA-G*01:04~UTR3 haplotype displaying the highest frequency. This strong LD could be emphasized by a deletion occurring between those two loci, thus reducing the recombination rate between HLA-A and HLA-G. This haplotype

conservation might also be the result of a specific biological effect, as HLA-G*01:04 has been associated with high sHLA-G production and that HLA-A*23:01~HLA-G*01:04 haplotype may constitute a risk factor for allograft rejection in renal transplantation. Interaction with other immune effectors as HLA-E could also be incriminated. We showed that 2 haplotypes in Tswa Pygmies, HLA-G*01:04~E*01:03:01 and G*01:04~E*01:01 exhibited LD values.

The aim of our study is to explore the region between HLA-A and -E. We genotyped HLA-A, -G, -H and -E alleles in 71 french samples and explore their association.

We found that 11 haplotypes represent 75% of all the haplotypes. HLA-H deletion was exclusevely associated with A*23~HLA*G01:04~UTR-3~HLA*E01:01 and HLA-A*24~HLA*G01:04~UTR-3~HLA*E01:03:01 haplotypes. A new HLA-H*02:04(:02) allele was descibed and associated with A*11~HLA*G01:01~UTR-7~HLA*E01:01.

This study suggests that the HLA region between HLA-A and -E loci displays a haplotype conservation that might be the results of biological function. This haplotype conservation has to be further studied to understand their clinical implication.

P07.16-M
HLA-DRB1 genotyping in romanian patients with early rheumatoid arthritis

A. Martinescu, *L. Hanzu-Pazara, M. Suta;*
Ovidius University, Faculty of Medicine, Constanta, Romania.

As being the most debated polygenic disease, rheumatoid arthritis elicits great interest in the study of association with genetic factors in various ethnic and racial groups. Some of the HLA-DRB1 alleles are encoding shared epitope amino acids that are not conferring the same risk in various populations.

Our study focuses on the evaluation of the distribution of HLA-DRB1 alleles in Romanian patients with early rheumatoid arthritis, along with controls by using PCR- SSP method.

HLA-DRB1 allele genotyping showed statistically significant differences given by a higher allele frequency for *04, *01 and *14. Also, in our study was observed a lower frequency for *03,*11,*13 and *15 alleles in patients group compared with controls. Using a high resolution kit for HLA-DRB1 *04 group we found a high frequency for *0404 and *0408 alleles, in contrast with *0401 and *0402 which were significantly lower in patients than in controls. *0403, *0405 were not associated with early rheumatoid arthritis in our group diagnosed according with new classification criteria ACR/EULAR 2010.

Results of our study are demonstrating the need of a continuous work of allele tracing and associating with rheumatoid arthritis, especially in cases early diagnosed in order to create sufficient premises for instituting a correct and possibly long term remissive treatment.

Keywords: early rheumatoid arthritis; HLA-DRB1; allele distribution

Genetic association of childhood psoriasis to the IL22 promoter is linked to higher promoter activity and increased IL-22 production in T cells

P. Nikamo[1], *S. Cheuk*[1], *J. Lysell*[1], *C. Enerbäck*[2], *K. Bergh*[1], *N. Xu Landén*[1], *L. Eidsmo*[1], *M. Ståhle*[1];
[1]*Karolinska Institutet, Dermatology Department, Stockholm, Sweden,* [2]*Ingrid Asp Psoriasis Research Center, Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden.*

Psoriasis is a common, immune-mediated and genetically complex skin disease. Recent large-scale studies have reported a number of psoriasis susceptibility genes. Most of these genes were identified in large cohorts not defining the clinical phenotypes and exploration of genes in distinct subtypes of psoriasis is missing. We recently reported that stratification according to age at onset was helpful in dissecting the genetic profile of early onset psoriasis. Here we investigated the genetic association to *IL22* in three psoriasis populations: disease onset between 0-9, 10-20 and 21- 40 years. *IL22* encodes for a cytokine with an established role both in psoriasis skin pathology and in host defense, thus exemplifying delicate balance between autoimmunity and control of infection. Herein we report strong association to regulatory elements in the *IL22* promoter confined to onset of psoriasis before puberty. The associated *IL22* variants contain putative binding sites for the transcription factor aryl hydrocarbon receptor, which is a potent inducer of *IL22* expression in T cells. We next compared the transcriptional activity between a high-risk and a low-risk gene variant in a luciferase assay which consistently resulted in significantly higher activity from the high-risk construct. Furthermore, in children carrying a high risk variant, T cells from peripheral blood produced significantly more IL-22 after *ex vivo* stimulation compared to children with a low-risk genotype. These data indicate that genotypes in the *IL22* promoter enhancing IL-22 production is preferentially enriched in psoriasis with onset before puberty and may predispose to development of psoriasis at an early age.

P07.18-M
Whole exome sequencing as a tool for detection of the genetic basis of inherited thrombocytopenias

B. D. Johnson, *G. C. Lowe, S. Drake, S. J. Fletcher, J. Fütterer, D. J. MacDonald, S. P. Watson, N. V. Morgan, UK GAPP Study Group;*
University of Birmingham, Birmingham, United Kingdom.

Thrombocytopenia is a common aspect of platelet function disorders (PFDs) which account for a significant proportion of bleeding diatheses. Identification of the genetic basis of congenital thrombocytopenias is often a difficult task due to the variability in clinical presentation and the relative redundancy of known platelet receptors and signalling pathways. DNA-based analysis has therefore previously played a confirmatory role dependant on platelet function testing to validate candidate mutations. Using a novel approach underpinned through the Genotyping and Phenotyping of Platelets (GAPP) study we have extended the DNA-based analysis, especially in cases where a qualitative defect is observed, to unravel the underlying genetic defects in patients diagnosed with inherited thrombocytopenia. The combination of platelet function testing, including flow cytometry, with whole exome sequencing provides a complete and complementary platform for efficient and cost effective investigation. Additional integration of a database of 338 platelet-related genes into our analysis improves detection and allows for the identification of variants in novel genes for further functional studies. To date our unique workflow has confirmed 14 mutations in 21 index cases, including two in novel genes with previously unreported mechanisms within platelet formation or function. Whole exome sequencing is therefore an effective tool to study the molecular genetics of inherited thrombocytopenias with excellent applicability for patient investigation when coupled with platelet function testing.

P07.19-S
Mutation spectra of the ITGB2 gene in Iranian families with Leukocyte Adhesion Deficiency type 1

V. R. Yassaee[1,2], *S. Boosaliki*[2], *F. Hashemi-Gorji*[1], *P. Dashti*[2], *N. Parvaneh*[3], *M. Piryaei*[2];
[1]*Genomic Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Dept. of Medical Genetics, Faculty of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*Research Group for Immunodeficiencies, Pediatrics Center of Excellence, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Leukocyte adhesion deficiency (LAD) type 1 is a rare, autosomal recessive disorder characterized by the triad of symptoms including recurrent bacterial infections, impaired wound healing, primarily localized to skin and mucosal surfaces. Beta-2 integrin subunit (ITGB2) gene located on 21q22.3 responsible for neutrophil dysfunction and impaired leukocyte cell adhesion. A total of 19 consanguineous families with typical LAD1 were investigated. Blood samples were collected after informed and written consent was obtained. Isolated DNA derived from subjects was amplified using intronic primers. The entire sequence of the ITGB2 gene, including regulatory region, coding regions and exon-intron boundaries were analyzed for any alteration by PCR and Sanger sequencing. A total of 10 mutations scattered throughout the ITGB2 gene were ascertained in the 15 subjects. Six different types of mutations previously reported, including IVS4-6 C>A, c.382G>T (Asp128Tyr), c.715 G>A (Ala239Thr), IVS7+1G>A, c.843DelC (Asn282fsX41), c.1907DelA (Lys636fsX22) and four novel mutations consist of IVS5-11G>T, c.576dupC (Asn193GlnfsX72), c.706 G>A Gly236Arg, IVS7+1G>T were identified. Moreover, two compound heterozygote and five homozygote mutations were detected in exon 6, suggested this region of ITGB2 gene might be a hot spot. This is the first comprehensive report of ITGB2 gene analysis in Iranian families with LAD1. Our results indicated that mutations distributed across the ITGB2 gene. Every population should develop a mutation database for their own rare genetic disorders. However, we suggest that to make a private database, appropriate screening strategy could be started with common alleles initially.

P07.20-M
Identification of monoallelic forms of Bernard-Soulier syndrome

D. De Rocco[1], *E. Nicchia*[1], *C. Greco*[2], *P. Noris*[3], *C. Cagioni*[3], *A. Pecci*[3], *V. Bozzi*[3], *F. Lanza*[4], *C. L. Balduini*[3], *A. Savoia*[2,1];
[1]*Department of Medical Sciences, University of Trieste, Trieste, Italy,* [2]*Institute for Maternal and Child Health – IRCCS Burlo Garofolo, Trieste, Italy,* [3]*University of Pavia and IRCCS Policlinico San Matteo Foundation, Pavia, Italy,* [4]*INSERM UMR-S949/EFS-Alsace, Strasbourg, France.*

Bernard-Soulier syndrome (BSS) is a rare inherited macrothrombocytope-

nia caused by mutations in *GP1BA, GP1BB* and *GP9*, the genes encoding for three subunits of the GPIb-IX-V complex, which is the platelet receptor for von Willebrand factor (vWF). In addition to the biallelic form, a less severe autosomal dominant form (monoallelic) of BSS is due to mutations identified so far in *GP1BA* or *GP1BB*. Except for p.Ala172Val (Noris et al, 2012), which is relatively frequent at least in the Italian population, other mutations have been reported only in single families. In order to evaluate the frequency of the monoallelic form in our thrombocytopenic cohort, we selected 120 probands with large platelets and no mutations in candidate genes. In 11 cases we found heterozygous mutations in *GP1BA* (n=4), *GPIBB* (n=6) and *GP9* (n=1). In addition to 4 variants previously identified in biallelic BSS patients, the others are all novel mutations. They are classified as missense (n=8), nonsense (n=1) or frame-shift (n=2) mutations. Segregation analysis within the families showed that only the affected individuals carry the mutations. Functional studies are in progress to determine the effect of the mutations on GPIb-IX-V complex formation and its capacity to interact with vWF. Considering that half of the patients with inherited thrombocytopenia remain without a molecular diagnosis, we could estimate that the frequency of the monoallelic form of BSS could account for 5% of the cases. This suggest that monoallelic BSS should be always taken into consideration in the differential diagnosis of inherited thrombocytopenia.

P07.21-S
MHC and the 1000 genomes: genotyping from exome data

S. Juhos[1], *K. Rigo*[1], *P. Gourraud*[2], *G. Horvath*[1];
[1]*Omixon Biocomputing, Budapest, Hungary,* [2]*University of California San Francisco, San Francisco, CA, United States.*

The publicly available 1000 genomes (1KG) data is still a valuable source of scientific discovery after years of its release. We have demonstrated previously that HLA typing of MHC-I genes is possible from 1KG exome data for HapMap samples. In this study we are aiming to determine types for MHC-II genes and for any 1KG exome samples passing certain quality control (QC) conditions. We are presenting the generation and interpretation of these QC values. Besides the HLA genes we are showing typing results for other polymorphic MHC genes like TAP1, TAP2, MICA and MICB. The HLA genotype assignations were compared to classical HLA typing obtain by sequencing techniques. Typing a diverse set of genes of MHC sheds light on linkage disequilibrium and makes it comparable to the previously known HapMap statistics. Furthermore, differences in results from different exome capturing kits are also to be presented.

Sarcoidosis is a multiorgan inflammatory disorder of unknown aetiology. The most probable pathophysiology of sarcoidosis, the dysregulation of the immune response strongly suggests benefits from a better understanding of the role of the immune mediating genes (e.g. MHC genes) in sarcoidosis susceptibility.
We present results from a Finnish case-control discovery sample as well as three independent replication studies from the Swedish, Dutch and Czech populations. We studied four genes in the MHC Class III region (LTA, TNF, AGER, BTNL2) and HLA-DRA in relation to HLA-DRB1 alleles to detect variants predisposing to sarcoidosis and to identify genetic differences between patient subgroups.
Patients with sarcoidosis (n=805) were further subdivided based on the disease activity and the presence of Löfgren syndrome. In a meta-analysis, seven SNPs were associated with non-Löfgren sarcoidosis (NL; the strongest association with rs3177928 in HLA-DRA, P=1.79E-07, OR=1.9) and eight with Löfgren syndrome (LS; the strongest association with rs3129843 in BTNL2/HLA-DRA region, P= 3.44E-12, OR=3.4) when compared with healthy controls (n=870). The high LD between SNPs and an HLA-DRB1 challenged the result interpretation. In addition to these SNPs, population-specific associations for sarcoidosis were observed.
In conclusion, there is clear evidence that polymorphisms in the BTNL2 and HLA-DRA have a role in sarcoidosis susceptibility. Most importantly, our study revealed sarcoidosis-related variants that were shared across ethnicities as well as ethnicity-specific genetic markers. Future functional studies are required to reveal the causal variants of these associations and the immunogenetic basis related to sarcoidosis.

P07.23-S
Impact of immunogenetic polymorphisms in predisposition to lymphoid malignancies in NBS patients

H. Akopyan, *O. R. Hnateyko, N. Markevych, H. Makukh, K. Sosnina, I. Kovaliv;*
Institute of Hereditary Pathology of National Academy of Medical Sciences, Lviv, Ukraine.

The Nijmegen breakage syndrome (NBS) is a recessive genetic disorder, resulting in high predisposition to developing a malignancy. The 5bp deletion (c.657-661del) in the NBN gene is founder mutation for Slavic populations. In Ukraine 40 NBS cases were diagnosed, and in 12 cases (30%) lymphoid malignancies has been developed at age 5-12 years. It remains unclear why the carriers of same mutation are implemented in a different morbidity. The purpose of this study was looking for immunogenetic criteria for tumor developing in NBS patients. Interleukin-10 (IL-10) and interferon-gamma (IFN-γ) play a key role in controlling the immune response and SNPs IL-10 -1082 A/G and IFN-γ +874A/T respectively can significantly affect their expression. Patients with severe outcome (multiple chronic recurrent inflammation, developing of tumor, death) and moderate course of disease were comparatively investigated. The distribution of IL-10 1082AA, 1082GG and 1082AG genotypes in cases of severe and mild outcome established as 42.9% and 33.3%, 35.7% and 33.3%, 21.4% and 33.3% respectively. The distribution of IFN-γ 874AA, 874AT and 874TT genotypes in groups of patients with severe and mild outcome was 20.0% and 29.4%, 40.0% and 58.82%, 40.0% and 11.86% respectively. The results allow to suggest, that severe outcome in NBS may depends on carrying of IL-10 1082AA genotype, associated with decreased anti-inflammatory activity, and IFN-γ 874TT genotype, known by increased pro-inflammatory properties. In conclusion, disruption in balance of pro- and anti- inflammatory cytokines may strongly affect NBS course.

P07.24-M
MEFV gene mutations in pediatric patients with PFAPA syndrome in Slovenia

D. Perko[1], *N. Toplak*[1], *T. Avčin*[1], *M. Debeljak*[2];
[1]*UMC Ljubljana, University Children's Hospital, Department of Allergology, Rheumatology and Clinical immunology, Ljubljana, Slovenia,* [2]*UMC Ljubljana, University Children's Hospital, Unit for Special Laboratory Diagnostics, Ljubljana, Slovenia.*

Introduction: PFAPA syndrome is the most common autoinflammatory fever disorder in childhood, characterized by recurrent fever, aphthous stomatitis, pharyngitis and adenitis. Mutations in the *MEFV* gene are known to cause syndrome with PFAPA overlapping symptoms (Familial Mediterranean Fever), which is common in eastern Mediterranean population, but rarely reported in patients from Slovenia.
Objective: The aim of this study was to assess the frequency of *MEFV* gene mutations in pediatric patients with PFAPA syndrome from Slovenia.
Methods: We collected clinical and laboratory data and results of genetic testing of *MEFV* gene of PFAPA patients under the age of 18, who were followed from the beginning of 2006 to the end of 2013. All 10 exons and intron/exon regions of gene were directly sequenced.
Results: In total, 91 PFAPA patients were tested for *MEFV* gene mutations. All of them were under the age of 18, mean age at diagnosis was 7 years. The ratio of women to men was 1:1.
15 patients (16%) were found to have at least one mutation. 11 patients (12%) were heterozygote and 4 patients (4%) were compound heterozygote, 3 with R408Q/P369S and 1 with K695R/I591T mutation. The overall number of mutation found was 19. The most frequent was K695R(26%), followed by R408Q(16%), P369S(16%), E148Q(10%), I591T(10%), M694V(5%), S730F(5%), A289V(5%) and A744S(5%).
Conclusion: In order to evaluate effect of these mutations on PFAPA phenotype, we are planning to determine the carrier rate in healthy Slovenian population and evaluate genotype-phenotype correlation in *MEFV* gene mutation positive patients.

P07.25-S

A new gene involved in an autosomal dominant form of common variable immunodeficiency (CVID)

V. Di Pierro[1], *R. Zuntini*[1], *E. Bacchelli*[2], *A. Schaffer*[3], *B. Grimbacher*[4], *I. Quinti*[5], *S. Ferrari*[1];
[1]*S.Orsola-Malpighi University Hospital, Bologna, Italy,* [2]*University of Bologna, Bologna, Italy,* [3]*National Institutes of Health, Bethesda, MD, United States,* [4]*Center for Chronic Immunodeficiency, UniversitatsKlinikum, Freiburg, Germany,* [5]*Center for Primary Immunodeficiency, University of Roma La Sapienza, Roma, Italy.*

Common variable immunodeficiency (CVID, MIM#607594) is the most common symptomatic primary antibody deficiency in adults. It includes a heterogeneous group of disorders characterized by defects in the terminal stage of B lymphocyte differentiation, whose underlying genetic defects remain unknown in the majority of cases.
We studied a five-generation Italian family with an autosomal dominant form of CVID through whole exome sequencing, giving priority to the variants within a 9.2 Mb candidate genomic interval on chromosome 3q27.2-q29 previously identified by genome-wide linkage analysis. Since no causative mutation was identified by whole exome sequencing, we performed a whole genome high resolution SNP array analysis, which allowed to detect a ~ 880 kb tandem duplication in 3q27.3, located inside the candidate linkage region and involving 8 genes: *ST6GAL1*, *RPL39L*, *RTP1*, *MASP1*, *RTP4*, *SST*, *RTP2* and *BCL6*.
The expression pattern analysis in control peripheral blood lymphocytes (PBL) of all genes included in the duplicated region revealed that only *ST6GAL1*, *RPL39L*, *RTP4* and *BCL6* are expressed in mature circulating lymphocytes, allowing us to exclude the remaining four genes from further investigations. Preliminary qRT-PCR analyses conducted on affected vs unaffected subjects showed a significant upregulation of *RTP4* in affected members (t-test, $p < 0.0001$). This finding suggests *RTP4* overexpression as a possible pathogenetic mechanism underlying CVID in this family. RTP4 is a Golgi chaperone and we hypothesize that it might be involved in the regulation of the Unfolding Protein Response (UPR), a key process of plasma cell differentiation.

P07.26-M

A family based exome sequencing identifies ADA2 deficiency as a novel cause for PIDD

L. Trotta[1], *A. Zavialov*[2], *S. Hämäläinen*[3], *H. Almusa*[1], *M. Lepisto*[1], *T. Hautala*[4], *M. Ilander*[5], *S. Mustjoki*[6], *K. Porkka*[6], *M. Seppänen*[7], *J. Saarela*[1];
[1]*Institute for Molecular Medicine Finland (FIMM), Helsinki University, Helsinki, Finland,* [2]*Turku Centre for Biotechnology P.O. Box 123, FI-20521, Turku, Finland,* [3]*Department of Medicine, Kuopio University Hospital P.O.B. 1777, Puijonlaaksontie 2, 70211, Kuopio, Finland,* [4]*Department of Internal Medicine, Oulu University Hospital, Oulu, Finland,* [5]*5Department of Virology, Haartman Institute, University of Helsinki, Helsinki, Finland,* [6]*Hematology Research Unit, Department of Medicine, University of Helsinki and Helsinki University Central Hospital, Helsinki, Finland,* [7]*Immunodeficiency Unit, Division of Infectious Diseases, Helsinki University Central Hospital, Hospital District of Helsinki and Uusimaa. Aurora Hospital, Helsinki, Finland.*

Primary immunodeficiency diseases (PIDD) encompass a wide and heterogeneous group of disorders caused by mutations in genes with immune function. The molecular mechanisms behind many forms are not yet known. The significant clinical and immunological heterogeneity of PIDD often delay the diagnosis making treatment challenging. Few thousand individuals are expected to suffer from PIDD in Finland, where the unique genetic background has proven to be very useful in identifying genes for monogenic disorders. An exome sequencing analysis of a Finnish PIDD family characterized by recurrent prolonged bacterial infections complicated by basal cerebral and frontal infarcts, subarachnoidal hemorrhage and occasional small aneurysms, has identified compound heterozygous mutations in the CECR1 gene not previously implicated in PIDD. The affected individuals carried a splice donor site mutation leading to nonsense mediated decay (NMD) of the allele and a rare missense variant, highly conserved and predicted deleterious. Analysis of the patient sera confirmed that the protein product (ADA2) of the mutated gene had no measurable activity. ADA2 is a member of the adenosine deaminase family, which also includes ADA1, a known cause of severe combined immune deficiency (SCID). ADA2 is a secreted protein in which binds to cell surface via proteoglycans, may degrade extracellular adenosine and has been shown to induce T cell-dependent differentiation of monocytes into macrophages and stimulate macrophage proliferation. Thus ADA2 deficiency is a plausible cause for the immunodeficiency complicated by infarcts and subarachnoidal hemorrhage in this family. The ongoing functional analyses will shed further light on molecular defects of the disease.

Primary Sjögren's syndrome (pSS) is a complex chronic autoimmune disease characterized by the inflammation of the exocrine glands leading to dry eyes and impaired salivary flow. Apart from glandular symptoms, systemic manifestations such as arthritis and chronic fatigue are common, and 75% of the patients have autoantibodies in their sera. PSS patients have a 15 fold increased risk of developing B cell lymphoma. Increasing evidence suggests an epigenetic contribution in the pathogenesis of autoimmune diseases, including pSS. Epigenetic modifications represent a dynamic link between genotype, environment and phenotype, by for example modulating gene expression. As methylation of the DNA base cytosine is considered as a prototypic epigenetic mark, our aim was to investigate the role of DNA methylation in pSS. We performed a genome-wide DNA methylation study in purified CD19+ B cells from 17 pSS patients and 28 healthy controls using Illumina HumanMethylation450 BeadChip arrays which cover about 486,000 CpG sites across the genome. Significant differentially methylated CpG sites between patients and controls were identified. We found disease-associated changes in DNA methylation in pSS and highlight pathways that may contribute to the pathogenesis of this autoimmune disease.

Palmoplantar pustular psoriasis (PPP) is a chronic inflammatory skin disease characterized by sterile pustules, erythema and hyperkeratosis on palms and soles. In at least 25% of PPP cases, psoriasis vulgaris (PsV) is also present and many patients suffer from psoriatic arthritis. Smoking and female sex are more frequent in PPP compared to PsV. So far, there are no confirmed genetic risk factors for PPP. Recently, in generalized pustular psoriasis (GPP), an extreme manifestation of pustular psoriatic disease, homozygous and compound-heterozygous mutations in *IL36RN* have been identified to be causal.The same mutations have been described to be more frequent in a group of 139 European PPP patients.Here, we recruited a group of >140 PPP patients,most of them were female and smokers (>60%, respectively). About half of them had a manifestational age of ≤40 years.We could confirm previous data showing that the frequency of the HLA-C risk allele, the major genetic risk factor for PsV, was comparable to the frequency of controls, indicating that PPP is genetically different from PsV. We further analyzed *IL36RN* for mutations in coding exons and for intragenic deletions/duplications. We identified three heterozygous carriers of mutations and no carriers of copy number variants. Compared to a population-based control group of 4.300 European individuals, there was no significant difference in the frequency of *IL36RN* mutations.Our data indicate that PPP is genetically distinct both from PsV and GPP. Further effort is needed to identify genetic factors contributing to PPP.

Primary immunodeficiencies (PIDs) are inborn defects in the immune system affecting about 1 in 500 people. In this present study we show that understanding the functional and/or genetic defect in patients suffering from severe PIDs can provide us new leads for treatment. Here we studied three patients suffering from severe recurrent viral infections with Herpes Simplex virus (HSV). The infections were caused by HSV2 in two of the patients, with no history of other infections, while the third patient was initially diagnosed with HPV6 papillomatosis and she developed recurrent HSV infections later in life. We isolated and stimulated PBMCs from patients and controls, and stimulated them with various ligands among which the double

stranded RNA ligand poly:IC. Cytokine production was measured in patients and compared to controls, and a specific defect in poly I:C-induced interferon-gamma was detected. Substitution therapy with interferon-gamma was successfully administered to all patients, leading to impressive amelioration. Additionally, we performed exome sequencing in all 3 patients, aiming to understand the genetic basics of the underlying immunodeficiency. While this genetic analysis did not identify one common cause of the primary immunodeficiency, rare variants in candidate genes SYK, IFIH1 and EIF3E were identified that may have caused the aberrant interferon signaling. In summary. These preliminary results indicate that patients with recurrent viral HSV infections may have genetic heterogeneous forms of primary immunodeficiencies; however, they show a common functional defect in double stranded RNA-induced IFNgamma, and common replacement therapy with interferon-gamma was shown to be an effective treatment.

P07.30-M
Allele specific expression of HLA haplotypes associated to autoimmune diseases

A. Zhernakova, *J. Fu, D. Zhernakova, L. Franke, C. Wijmenga;*
University medical centre Groningen, Groningen, Netherlands.

HLA is strongly associated with many autoimmune diseases, including rheumatoid arthritis (RA), celiac disease (CD) and type 1 diabetes (T1D). For many diseases the association is established, but the underlying mechanisms are unknown. For example, heterozygosity for DR3-DQ2/DR4-DQ8 is a stronger risk factors to T1D compared to homozygosity for both DR3-DQ2 and DR4-DQ8 alleles. We aimed to study the downstream effect of HLA haplotypes by looking for allele specific gene expression (ASE) and haplotype expression quantitative trait loci (eQTLs) in HLA alleles associated to autoimmune diseases. We selected individuals heterozygous for DR3-DQ2/DR4-DQ8 and homozygous for both alleles (T1D and CD risk haplotypes), and individuals heterozygous for DR4-DQ8/DR4-DQ7 and homozygous for these alleles (RA risk haplotypes). We run RNAseq to quantify gene expression and performed eQTL and ASE analysis in these individuals. In total, 90 individuals were selected for this analysis. We observed different expression of multiple genes in HLA locus in DR3-DQ2/DR4-DQ8 heterozygous individuals, in compare with both homozygous group. In particular, HLA-DQA2, HLA-DQB1 and HLA-DQB9 (P-value Wilcox test <0.001 for all three genes). ASE analysis of individuals heterozygous for DR3-DQ2/DR4-DQ8 indicated ASE effect for multiple variants located in TAP2 gene, which plays a role in antigen presentation. In DR4-DQ8/DR4-DQ7 analysis we identified multiple eQTLs in the HLA locus, as well as allele specific effect on SNPs located in DOA genes.

Phenotypic analysis of Peptidylarginine deiminase type 4 knock-out mice

A. Suzuki[1], *Y. Kochi*[1], *H. Shoda*[2], *K. Fujio*[2], *E. Kanno*[1], *R. Yamada*[3,1], *K. Yamamoto*[2,1];
[1]*RIKEN, Yokohama, Japan,* [2]*Department of Allergy and Rheumatology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,* [3]*Center for Genomic Medicine, Kyoto University, Kyoto, Japan.*

Rheumatoid arthritis (RA) is well-known as an autoimmune disease and is a chronic inflammatory disorder characterized by the destruction of multiple joints. Many genome wide association studies were performed and multiple RA-susceptibility loci and autoimmune-susceptibility loci have been identified. These studies suggested that multiple genes and its functions were related with disease causing and development. Previouly, peptidylariginine deiminase type 4 **(**PADI4) was identified as a susceptibility gene for RA in a Japanese population by case-control association study (Ref 1). PADI4 is a member of the PADI gene family and converts arginine residue (peptidylarginine) to citrulline residue (peptidylcitrulline). PADI4 is highly expressed in bone marrow, macrophages, neutrophils and monocytes. PADI genes are important genes in RA, because only PADs (translated protein from PADI genes) can provide antigens of ACPA, which are specific antibodies of RA. To evaluate the importance of PADI4 gene in the progression of RA, we generated Padi4 -/- DBA1J mice. We used Padi4-/- mice to show that PAD4 is significantly affected to progress of collagen induced arthritis (CIA), well known as an RA model animal. In Padi4-/- CIA mice sera, the concentrations of serum anti-CII IgM, IgG, and levels of inflammatory cytokines decreased significantly rather than in WT CIA mice. Futhermore, the transcription levels of inflammatory cytokines in CD11b positive splenocytes from Padi4 -/- CIA mice are also significantly lower than those from WT CIA mice. As the results, we suggested that Padi4 enhanced collagen-initiated inflammatory responses. 1) Suzuki, A. et al Nat. Genet.34, 395-402 (2003)

Identification of susceptibility loci associated with primary Sjögren's syndrome by genome-wide association study

I. Song[1,2], *H. Chen*[3], *C. Chen*[3], *C. Chen*[1], *J. Wu*[1];
[1]*Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan,* [2]*Graduate institute of Life Science, National Defense Medical Center, Taipei, Taiwan,* [3]*Rheumatology, Immunology and Allergy Division, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Primary Sjögren's syndrome (PSS) is one of the most common autoimmune diseases which primarily affect women, with a female-male ratio of 9:1. To identify the susceptibility genes predisposing individuals to PSS, we conducted genome-wide association analyses comparing 242 PSS female patients with 1444 female controls, recruited from the Han Chinese population residing in Taiwan. In discovery GWAS, SNPs in the MHC region of chromosome 6 and the GTF2I gene of chromosome 7 were found to be associated with PSS. In particular, SNP rs117026326 on chromosome 7 showed the highest association (P value = 6.71 × 10-13). The two loci were previously reported to be associated with PSS. Replication with additional samples is now under process. Our study confirmed the associations between the two loci and PSS.

P07.34-M
Functional analysis of genetic risk factors for canine SLE-related disease complex and identification of genetic risk factors for human SLE

F. H. G. Farias[1], *M. Wilbe*[2], *S. V. Kozyrev*[1], *D. Leonard*[3], *H. Bremer*[4], *J. Dahlqvist*[1], *A. Hedlund*[4], *G. R. Pielberg*[1], *U. Gustafson*[2], *M. Eloranta*[3], *H. Hansson-Hamlin*[4], *G. Andersson*[2], *L. Rönnblom*[3], *K. Lindblad-Toh*[1,5];

Dogs represent an excellent model to study complex genetic disorders including many autoimmune diseases that they share with humans. A systemic lupus erythematosus (SLE)-related disease complex, which shows similarities to human SLE, has high prevalence in Nova Scotia duck-tolling retriever (NSDTR) dogs. Genome-wide association analyses have identified five candidate loci in NSDTR containing several genes. Detailed analysis of the candidate loci identified variants that alter the expression of several of these genes. Multiple genes involved in T-cell activation show expression differences, but regulatory mutations also alter expression of genes such as BANK1, involved in human SLE. As a proof of concept, the genes and pathways identified in dogs and also genes relevant for human SLE were sequenced in 140 Swedish human SLE patients. Patients were divided in 9 pools according to disease manifestation and a group of healthy Swedish controls was also sequenced. Targeted Nimblegen + Illumina sequencing of 219 genes and their regulatory elements resulted in approximately 250x coverage per individual. We detected 4276 novel SNPs (not present in 1000genomes or dbSNP137) of which 1258 SNPs were found only in cases. Seventeen genes showed ≥ 5 novel case-only variants. Of these, three genes were previously associated to human SLE and 14 were novel candidate genes. From the top genes, ten variants that show strong regulatory potential have been selected and being evaluated for their importance for gene expression and correlation with clinical phenotypes. Several variants appear to be potential regulators of specific SLE sub-phenotypes.

P07.35-S
Deep analysis of TCR repertoires of twins by next generation sequencing

M. V. Pogorelyy, *I. V. Zvyagin, M. E. Ivanova, D. A. Bolotin, D. M. Chudakov, Y. B. Lebedev, I. Z. Mamedov;*
Shemyakin–Ovchinnikov Institute of bioorganic chemistry RAS, Moscow, Russian Federation.

Immune system interacts with great diversity of pathogens. Receptors involved in antigen recognition - BCRs (B-cell receptors) and TCRs (T-cell receptors) - are not encoded in genome due to its limited capacity, but generated by V(D)J recombination. For a long time, no instrument to estimate TCR diversity in individual organism has been available. Next generation sequencing methods (NGS) have created the possibility of deep TCR profiling. Here, we aimed to estimate the role of genetic factors in TCR repertoire formation by sequencing TCR repertoires of monozygotic and dizygotic twins.
16 cDNA TCR libraries were generated and sequenced on Illumina platform.
Surprisingly, the overlap of amino acid sequences of CDR3 region in TCR clonotypes was not greater in MZ twin pairs and depended on sample size

only. However, the number of identical clonotypes was higher for monozygotic twins in the abundant clonotypes subset, representing mainly antigen-experienced T cells. At the same time V-segment usage is more similar in twin pairs for clonotypes before and after thymic selection.
We also showed that the ratio of clonotypes with identical CDR3 and V-segments (coding for CDR1 and CDR2) to clonotypes with identical CDR3 is higher in twin pairs in the abundant clonotypes subset.
All these features were not observed in a dizygotic twin pair, which probably reflects the impact of genetic factors on TCR repertoire formation.

P07.36-M
A novel StripAssay identifies genetic variants modifying beta-thalassemia disease severity

H. Puehringer, B. Rauscher, **C. Oberkanins**;
ViennaLab Diagnostics GmbH, Vienna, Austria.

Background: The clinical phenotype of patients with beta-hemoglobinopathies is extremely heterogenous, ranging from nearly asymptomatic forms of thalassemia intermedia to severe transfusion-dependent thalassemia major. The wide phenotypical variability is associated with the type of beta-globin mutation, the co-inheritance of alpha-thalassemia and the ability for persistent production of fetal hemoglobin (HbF) in adult life. For the latter, three different quantitative trait loci, accounting for 20-50% of HbF variation, have been identified by now. Single nucleotide polymorphisms (SNPs) in the gamma-globin gene promoter (HBG2), in the BCL11A gene and the HBS1L-MYB intergenic region lead to increased residual HbF levels in adults. Methods: A teststrip-based reverse-hybridisation assay was developed for the simultaneous detection of SNPs in the HBG2 (g.-158 C>T), BCL11A (rs1447407, rs10189857), HBS1L-MYB (rs28384513, rs9399137) genes. Results: The new StripAssay enables the concomitant identification of genetic variants known to influence beta-thalassemia disease severity. Based on the presence of positively modifying alleles, and combined with alpha- and beta-globin genotyping, it allows the prediction of patients likely to display less severe phenotypes. Favourable properties, such as the rapid DNA extraction protocol, ready-to-use reagents and teststrips, as well as the potential for automation of the hybridisation/detection and interpretation steps, make the StripAssay convenient and easy to perform within less than six hours. Conclusions: Testing for genetic modifiers influencing disease severity will lead to more specific and effective treatment, and support clinical decisions regarding the beginning of transfusion therapy in beta-thalassemia patients. Furthermore, the knowledge about prognostic markers has implications for genetic counselling and prenatal diagnosis.

P07.37-S
Family with inherited thrombocytopenia and homozygous pathogenic variant in *FYB* gene

H. A. Hamamy[1], *P. Makrythanasis*[1], *N. Al-Allawi*[2], *A. A. Muhsin*[3], *S. E. Antonarakis*[1,4];
[1]*Univesity of Geneva, Geneva, Switzerland,* [2]*Univesity of Dohuk, Dohuk, Iraq,* [3]*Jin Center, Dohuk, Iraq,* [4]*University Hospitals of Geneva, Geneva, Switzerland.*

Inherited thrombocytopenias (IT) are a heterogeneous
group of rare diseases characterized by a reduced number of blood platelets.The frequency of IT is probably underestimated because of diagnostic difficulties and because not all the existing forms have yet been identified, and some patients remain without a definitive diagnosis. We report a family with IT with small size platelets seen in several members of a highly consanguineous Kurdish family from Northern Iraq. Genotyping of all affected, their unaffected siblings and parents, followed by exome sequencing revealed a strong candidate pathogenic variant in a homozygous state: a frameshift mutation was detected in the *FYB* gene. The protein encoded by this gene is a cytosolic adaptor molecule expressed by T cells, natural killer (NK) cells, myeloid cells and platelets and is known to be involved in platelet activation and controls the expression of interleukin-2. This is the first report to hypothesize that pathogenic variants in *FYB* gene could cause thrombocytopenia in human.
We propose that *FYB* is the causative gene for this phenotype.

P07.38-M
Distribution of A736V variant of TMPRSS6 gene in beta-globin mutation carriers

A. Toylu[1], *O. Altiok Clark*[1], *T. Bilgen*[2], *A. Kupesiz*[3], *O. Salim*[4];
[1]*Akdeniz University School of Medicine, Dept of Medical Genetics, Antalya, Turkey,* [2]*Akdeniz University School of Medicine, Dept of Medical Biology and Genetics, Antalya, Turkey,* [3]*Akdeniz University School of Medicine, Dept of Pediatric Haematology, Antalya, Turkey,* [4]*Akdeniz University School of Medicine, Dept of Haematology, Antalya, Turkey.*

The genome-wide association studies on the genes related with iron metabolism has been showed that some of the genetic variants were associated with serum iron level and erythrocyte parameters. One of these common variants was A736V in TMPRSS6 gene which regulates serum iron level. Inactivation of TMPRSS6 gene causes iron-deficiency anemia and impairment of iron absorption. It has been found that A736V variant of TMPRSS6 gene is associated with lower levels of serum iron and erythrocyte MCV with higher levels of serum hepcidin protein. It was also shown that inhibition of TMPRSS6 has a therapeutic effect on Beta-thalassemic mice. However the frequency of this variant among Beta-thalassemia patients is unknown. Related with these data, we aimed to investigate frequency of A736V variant of TMPRSS6 gene among patients carrying beta-globin gene mutations. 93 patients investigated for beta-globin gene mutation with DNA sequencing method were enrolled in this study. A736V (rs855791) variant of TMPRSS6 gene was detected by real-time quantitative PCR method. Erythrocyte parameters and hemoglobin levels were measured and their distributions according to gene variants were analyzed. Frequency of TMPRSS6 gene A736V variant was 0.47 among all patients. There was no association between A736V variant of TMPRSS6 gene and beta-globin gene mutations, hemoglobin levels or erythrocyte parameters. However, frequency of A736V variant was higher among the patients having low levels of hemoglobin or erythrocyte MCV with a wild type beta-globin gene. Further studies are needed for better understanding the relationship between of A736V variant and Beta-thalassemia prognosis.

P07.41-S
Novel 21 nucleotide duplication in alpha1/alpha2 globin gene involves in a variety of hypochromic microcytic anemia from mild to Hb H Disease

S. Farashi[1], *N. Faramarzi Garous*[1], *F. Zeinali*[1], *M. Ashki*[1], *S. Vakili*[1], *H. Imanian*[1], *A. Azarkeivan*[1,2], *H. Najmabadi*[1,3];
[1]*Kariminejad-Najmabadi Pathology and Genetics Center, Tehran, Islamic Republic of Iran,* [2]*Iranian Blood Transfusion Organization, Thalassemia Clinic, Tehran, Islamic Republic of Iran,* [3]*Genetics Research Center, University of Social Welfare & Rehabilitation Sciences, Tehran, Islamic Republic of Iran.*

α-Thalassemia (α-thal) is a common genetic disorder in Iran and many parts of the world. Genetic defects in alpha-globin gene cluster can results in α-thal that may develop clinical phenotype varying from almost asymptomatic to a lethal hemolytic anemia. Loss of one functional α-gene, indicated as heterozygote α+-thal, show minor hematological abnormalities. Homozygosity for α+ or heterozygosity for α⍰-thal have more severe hematological abnormalities due to a markedly reduced α-chain output. At the molecular level, the absence of three α-globin genes resulting from the compound heterozygous state for α⍰- and α+-thal, lead to Hb H disease. Here we present 21 bp duplication consists of 6 amino acids and 3bp of intronic sequence at exon-intron boundary, in the both α-globin genes. This duplication was detected in three patients originated from two different Iranian ethnic groups and one Arab during of more than 12 years. This duplication was found by direct DNA sequencing. The clinical presentation of these patients varies widely from a mild asymptomatic anemia (heterozygote in alpha1globin gene) to a severely anemic state, requiring blood transfusions (duplication in alpha2 globin gene in combination with MED double alpha globin gene deletion) who was diagnosed as an Hb H patient. Third patient who was homozygote for this nucleotide duplication in alpha1 globin gene shows severe hypochromic microcytic anemia and splenomegaly. In the last decade numerous α-globin mutations have been demonstrated the necessity of prenatal diagnosis for α-thal, and this study have contributed another one as an important novel mutation to be considered.

P07.42-M
Recovery of SLAM-SAP signalling pathway factors mRNA expression and invariant NKT cell deficiency characterizes sarcoidosis remission

M. Rijavec, *K. Osolnik, P. Korošec;*
University Clinic of Respiratory and Allergic Diseases Golnik, Golnik, Slovenia.

Invariant Natural killer T Vα24-Jα18-Vβ11 (iNKT) cells play critical role in controlling the strength and character of immune responses and have shown to be important in disorders with increased Th1 responses, such as sarcoidosis. Their exact role as well as factors involved in regulating the development and recruitment of iNKT cells is still to be determined. There is growing evidence that the SLAM-SAP signalling pathway is essential for the development of iNKT cells. In our study we followed up the mRNA expression of SLAM-SAP signalling factors and iNKT cells together with detailed clinical data in newly diagnosed sarcoidosis patients over 4 years.
Detailed clinical, functional, and radiographic evaluation and determination of blood mRNA expression of SLAM-SAP signalling factors and iNKT cells was carried out at presentation and after 3 months, 1 year, and 4 years of disease follow-up in 29 patients with pulmonary sarcoidosis. We also included 28 healthy control subjects.
We demonstrated a decreased expression of SLAM-SAP signalling factors

and marked deficiency of blood and lung iNKT cells in patients with newly diagnosed sarcoidosis. During 4 years of disease follow-up, there was a significant increase in expression of SLAM-SAP signalling factors, mainly *SLAMF1*, *SLAMF6*, and *FYN,* and blood iNKT cells. This increase clearly correlated with improvement in patients' clinical symptoms as after 4 years the disease had gone into remission in the great majority of patients.
Our longitudinal study showed that an increase in expression of SLAM-SAP signalling factors and iNKT cells characterizes the clinical remission of pulmonary sarcoidosis.

P07.43-S
A late diagnosis of NOMID-syndrome /CINCA-syndrome - lessons to learn

K. Becker;
Labor Krone, Bad Salzuflen, Germany.

The case of a 10 ½ year old boy from Germany is presented with a new diagnosis of NOMID syndrome, also known as CINCA-syndrome, the rarest and most severe of the Cryopyrin-associated periodic syndromes (CAPS), which are genetic syndromes of autoinflammation. The diagnosis was delayed despite many clinical clues including the typical non-itching maculopapular rash which was present from the neonatal period, raised inflammatory markers on many occasions without detectable infectious pathogens, progressive macrocephaly with hydrocephalus, evolving short stature, progressive optic atrophy, progressive deafness, progressive arthropathy and other non-specific haematological and immunological abnormalities. In addition, the patient had episodic conjunctivitis and finger clubbing. Periodic fever does not always occur in this condition and in the case of this patient was completely absent. This patient was treated for several years with growth hormone in the absence of a diagnosis without any improvement of his short stature. Early diagnosis of these patients is vital because treatment with interleukin -1-receptor antagonists is now well established and very effective. Untreated, the patients may develop a destructive arthropathy, blindness, profound deafness and renal failure secondary to amyloidosis. The macrocephaly, hydrocephalus and short stature result from the chronic aseptic meningitis. The disease is caused by mutations (mostly new dominant) in the NLRP3 gene, which may be mosaic and thus are sometimes only detectable by next generation sequencing.

Chromosome 15q11.2 imbalances associated with neuropsychiatric and developmental disorders - array-CGH findings in a cohort of 1000 patients

L. M. Pires[1], *S. I. Ferreira*[1], *J. Ferrão*[1], *N. Lavoura*[1], *F. Ramos*[2], *A. Beleza-Meireles*[2], *J. B. Melo*[1,3,4], *I. M. Carreira*[1,3,4];
[1]*Laboratório de Citogenética e Genómica, Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal,* [2]*Serviço de Genética Médica, Hospital Pediátrico, CHUC, Coimbra, Portugal,* [3]*CIMAGO – Centro de Investigação em Meio Ambiente, Genética e Oncobiologia, Coimbra, Portugal,* [4]*CNC- Centro de Neurociências e Biologia Celular, Universidade de Coimbra, Coimbra, Portugal.*

Array-Comparative Genomic Hybridization has led to the knowledge that some copy number variants (CNVs) correspond to susceptibility loci for developmental disorders. CNVs at chromosomal region 15q11.2 involving 4 known genes, TUBGCP5, CYFIP1, NIPA2 and NIPA1, are of challenging interpretation due to their presence both in normal populations and in individuals with diverse developmental disorders. In a cohort of 1000 patients analyzed by Agilent 180K oligonucleotide array-CGH we identified 12 patients with 15q11.2 imbalances, 9 deletions and 3 duplications, 7 females and 5 males. Four of the 12 patients had additional genomic imbalances. The patients presented with global developmental delay, dysmorphisms, ID, epilepsy, mirocephaly, amongst others. To date, we were only able to determine inheritance in 4 patients, 2 deletions maternal in origin, 1 paternal, and a de novo duplication. The proximal breakpoint was common in 11 of the 12 patients, while the distal breakpoint was variable, but similar in some patients. The 4 previously mentioned genes were involved in the genomic imbalances of all the patients, except in the patient with the distinct proximal breakpoint, where TUBGCP5 gene was in normal copy number. Functional data have revealed that TUBGCP5, CYFIP1 and NIPA1 genes are expressed in developing mammalian brain and are involved in processes such as microtubule nucleation, interaction with other proteins and nervous system development and regulation, respectively To date, there is still no straight interpretation when a 15q11.2 genomic imbalance is detected, but in this cohort further evidence was given that this region is associated with neuropsychiatric disorders.

P08.02-M
Overgrowth and developmental delay associated with a 200 kb deletion in 16p11.2 in two families

C. Zweier[1], *M. Krumbiegel*[1], *H. Peters*[2], *A. Reis*[1];
[1]*Institute of Human Genetics, Erlangen, Germany,* [2]*Institute for Medical and Human Genetics, Berlin, Germany.*

Due to a high density of segmental duplications, the short arm of chromosome 16 is prone to a number of recurrent rearrangements. A common 600 kb microdeletion or -duplication in 16p11.2 has been associated with autism, intellectual disability, schizophrenia, and mirrored weight and head circumference phenotypes. An adjacent, but separate distal 200 kb region in 16p11.2, which contains the SH2B1 gene, has been associated with isolated obesity as well as developmental delay. Both aberrations are associated with high variability and incomplete penetrance.
We now report on two families harboring the 200 kb microdeletion in 16p11.2. Both index patients were initially referred with suspected Sotos syndrome due to tall stature, obesity and developmental delay. After normal NSD1 testing molecular karyotyping showed the 200 kb deletion in 16p11.2 in both patients as well as in patient 2's brother who had mild obesity and unspecific moderate intellectual disability. In both families the deletion was maternally inherited. Interestingly, patient 2, but not her cognitively more severely affected brother, additionally harbored a microduplication 1q21.1, which has been recurrently associated with variable and incompletely penetrant developmental delay, intellectual disability, behavioural anomalies and large head circumference. Both aberrations were inherited from the mother, who was obese but otherwise healthy and without cognitive problems. These two families further characterize the variable spectrum of phenotypes associated with the 200 kb microdeletion in 16p11.2. Our findings in family 2 also show that not even the co-occurrence of two ID-associated microaberrations necessarily leads to cognitive impairment.

P08.03-S
Clinical and molecular characterization of a patient with de novo 2.8 Mb deletion of 17q24.2-q24.3

M. Hančárová[1], *M. Malíková*[1], *J. Dráborá*[1], *M. Trková*[2], *Z. Sedláček*[1];
[1]*Department of Biology and Medical Genetics, Prague, Czech Republic,* [2]*Gennet, Prague, Czech Republic.*

Microarray methods contributed to the identification of many rare microdeletion syndromes including that associated with deletions of 17q24.2-q24.3, characterized mainly by growth retardation, microcephaly, developmental delay, speech delay, intellectual disability, feeding problems, and teeth and facial abnormalities. Seven patients have been described in detail since 2008, and additional cases with only limited clinical information are listed in databases. It becomes evident that not all 17q24.2-q24.3 deletions share a single common region of overlap.
We report a 12-year-old girl with a normal karyotype who shows clinical features consistent with the syndrome. SNP array analysis revealed a 2.8 Mb long deletion of 17q24.2-q24.3 (chr17:65,281,651-68,017,013; hg19). FISH analysis confirmed the deletion and showed its de novo origin. The deletion affects 18 protein-coding RefSeq genes including PRKAR1A, MAPK2K6, and the ABCA gene cluster. Some of the genes could be candidates for the clinical symptoms and some are predicted to exhibit haploinsufficiency, for instance PRKAR1A, encoding a postsynaptic density protein associated with Carney complex, or BPTF producing a transcript in fetal brain which binds FMRP and encodes a transcriptional regulator. Only much smaller population copy number polymorphisms are present in the region. The deletion of our patient overlaps two groups of previously reported deletions. Despite the proximity of the deleted regions, the candidate genes could be distinct. Identification of additional cases will help to define the genes involved and their role in predisposition to neuropsychiatric phenotypes, as well as the emerging genetic heterogeneity within the 17q24.2-q24.3 microdeletion syndrome.
Supported by CHERISH, NT/14200, 00064203 and CZ.2.16/3.1.00/24022.

Deletions of 1p34.3, encompassing the *AGO1*, *AGO3,* and *AGO4* genes, in five children with microcephaly and intellectual disability

P. Prontera[1], *M. Tokita*[2,3], *P. Chow*[2,3], *G. Mirzaa*[2,3], *N. Dikow*[4], *B. Maas*[4], *B. Isidor*[5], *C. Le Caignec*[5], *L. Penney*[6], *G. Mazzotta*[7], *L. Bernardini*[8], *A. Battaglia*[9], *D. Earl*[2,3], *E. Donti*[1];
[1]*Medical Genetics Unit, University and Hospital of Perugia, Perugia, Italy,* [2]*Division of Genetic Medicine, University of Washington, Seattle, WA, United States,* [3]*Seattle Children's Hospital, Seattle, WA, United States,* [4]*Institute of Human Genetics, Heidelberg University, Heidelberg, Germany,* [5]*Génétique Médicale, Centre Hospitalier Universitaire de Nantes, Nantes, France,* [6]*Department of Pediatrics, Dalhousie University, Halifax, NS, Canada,* [7]*School of Specialization in Childhood Neurology and Psychiatry, University of Perugia, Perugia, Italy,* [8]*Mendel Laboratory, IRCSS Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Foggia, Italy,* [9]*The Stella Maris Clinical Research Institute for Child and Adolescent Neurology and Psychiatry, Calambrone, Pisa, Italy.*

Small RNAs (miRNA, siRNA, and piRNA) regulate gene expression through RNA interference (RNAi), a process that has emerged as a fundamental principle of normal cellular function. The Argonaute (AGO) proteins are critical mediators of the RNAi pathway and constitute a highly conserved family of genes found in almost all eukaryotes. Four AGO genes are present in humans, three of which (AGO 1, 3, and 4) reside in a cluster on chromosome 1p35p34.

The possible effects of germline AGO mutations or dosage alterations in humans is not known, however, animal models deficient for AGO proteins display developmental brain defects including a reduction in total number of neurons and glia. Moreover, different studies have established that miRNA and siRNA are prevalently or exclusively expressed in the brain, where they play an essential role in the development and function of the central nervous system (CNS).

We describe five patients with hypotonia, microcephaly, intellectual disability, and facial dysmorphisms, in whom array-Comparative Genomic Hybridization revealed overlapping de novo microdeletions of the chromosomal region 1p34.3. The minimal critical region is a segment of approximately 694 Kb that encompasses the AGO1, AGO3, and AGO4 genes.

We propose that the neurocognitive deficits present in these patients are due to deletion of the 1p34.3 region and resulting haploinsufficiency of several AGO genes. It seems plausible that the 1p34.3 deletion syndrome may eventually be recognized as a neurodevelopmental disorder associated with RNAi deregulation, however, further investigation is necessary to prove this.

P08.05-S
Two brothers with 2q23 microdeletion syndrome inherited from their mosaic father

M. Fannemel[1], *E. Ormerod*[1], *T. Barøy*[2], *D. Misceo*[2];
[1]*Oslo University Hospital, Oslo, Norway,* [2]*Oslo University Hospital and University of Oslo, Oslo, Norway.*

Patient 1, the older brother, is 13 years old and has moderate intellectual disability. He communicates by single words, pointing and some signing. He walked at 4 years. He uses diapers, suffers from constipation and manifests aggressive outbursts and stereotypic movements. His sleeping pattern is disturbed by periods of awakeness. He has teeth enamel erosions. His twin sister, with Apert syndrome, died at 2 years. Patient 2, the younger brother, is 6.5 years and has moderate intellectual disability. He speaks a few words and infrequently combines two words. He has a heart murmur, enamel teeth erosions and periodic sleep problems. He is restless and active.

ArrayCGH of the patients and father showed a deletion of chr2q23.1(148705701-148926786 bp), including the MBD5, considered critical in the 2q23.1 microdeletion syndrome. By FISH the deletion in the father was found to be a mosaicism found in 73% of lymphocytes. Assessment of the mosaicism level in additional tissues is ongoing. The father received speech therapy in childhood and has dyslexia. He completed secondary school with low-average marks, and did not finish high school. He has been working as a manual worker in the same factory for 18 years. In patient 2 and his father aCGH detected also a chr15q26.1(9022468-90255068 bp) deletion, including PLIN1. PLIN1 mutations cause dominant familial partial lipodystrophy type 4, but the effect of PLIN1 haploinsufficiency is unknown. Patient 2 and his father, but not Patient 1, are obese.

To our knowledge this is the first familial case of the 2q23 microdeletion syndrome.

P08.06-M
Microdeletion of 8q21 region: clinical and molecular analysis based on a new case

M. Kucharczyk[1], *K. Iwanicka-Pronicka*[2], *M. Kugaudo*[1,3], *A. Cieślikowska*[1], *A. Jezela-Stanek*[1], *K. Chrzanowska*[1], *M. Krajewska-Walasek*[1];

Submicroscopic deletion of 8q21.11 is a rare cause of intellectual disability, developmental delay and craniofacial dysmorphy. Hypotonia, impaired balance, sensorineural hearing loss, abnormal behaviour as well as mild fingers and toes anomalies are frequently observed. To date, 13 cases, including 5 from the same family, have been clinically and molecularly characterized. Here we report on the case of a 14-year-old girl with moderate mental retardation, numerous dysmorphic features (a round face with full cheeks, high forehead, ptosis, long and downslanting palpebral fissures, short philtrum, Cupid's bow of the upper lip, down-turned corners of the mouth, micrognathia, high palate, low-set and prominent ears, and short neck), short stature and overweight. At birth, microtia of the right ear with external auditory duct stenosis and atrial septal defect were diagnosed. Muscle tone was unremarkable. Other features comprise small hands with camptodactyly of fifth and second fingers of the opposite hands, unilateral transversal crease, and valgus, flat feet. Auto-aggressive behaviour, autism and sleep problems were also noted. Whole-genome microarray analysis revealed a 5.19 Mb deletion of 8q21.11q21.13 region encompassing 19 genes. The phenotypic and genetic findings of our patient will be compared with those of previously reported patients. We indicate several candidate genes, providing new data supporting further genotype-phenotype studies. Our results suggest that haploinsufficient genes within the deleted region, e.g. ZFHX4/STMN2, FABP4/FABP5 and HEY1, could underlie the intellectual impairment, excess weight and cardiovascular disorders, observed in 8q21 microdeletion. This study was supported by MNiSW Grant No. 0193/IP1/2013/72.

P08.07-S
Clinical and molecular delineation of the emerging 8q22.3 microdeletion syndrome

C. Venegas-Vega[1,2], *M. Guardado*[3], *E. Juarez*[3], *G. Zafra*[4,2], *J. Berumen*[3,2];
[1]*Hospital General de Mexico, Servicio de Genetica, Mexico DF, Mexico,* [2]*Facultad de Medicina, UNAM, Mexico DF, Mexico,* [3]*Hospital General de Mexico, Servicio de Medicina Genomica, Mexico DF, Mexico,* [4]*Hospital Español, Servicio de Genetica, Mexico DF, Mexico.*

Background: Five patients with deletions that involving chromosome 8q22.2-q22.3 has been recently reported. Four patients shared a similar craniofacial phenotype with microcephaly, blepharophimosis, uni or bilateral ptosis and little facial expression. They have moderate to severe intellectual disability (ID) and impairment or absent speech. These carrying an overlapping region deletion of 3.87 Mb (hg19:100.69-104.56). The other patient not showed this facial gestalt but presented moderate ID, and speech impairment. She presented the shorter deletion of 1.92 Mb (hg19:102.01-103.93). **Methods and Results:** Here, we described on 18-year-old female patient with microcephaly, unilateral ptosis, moderate ID and speech impairment. CytoScan HD array analysis identified a 2.95 Mb 8q22.2-q22.3 deletion. The comparation of the present patient with the above five cases contribute to narrow down the critical region in 8q22.3 of ~1.47 Mb (hg19:101.95-103.42). Furthermore, we analyze the gene functional roles and probability of haploinsufficiency (HI) of this genomic region; resulting the ubiquitin protein ligase E3 component N-recognin-5 (*UBR5)* gene as the best candidate for the phenotype. *UBR5* belongs to ubiquitin/proteasome system (UPS). Neurodevelopmental genetic disorders involving alterations in UPS have been described such as Angelman syndrome (*UBE3A*), Johanson-Blizard syndrome (*UBR1*) and X-linked intellectual disability type Nascimento (*UBE2A*). Recently, mutations in ubiquitin protein ligase E3B *(UBE3B)* in a blepharophimosis-ptosis-intellectual disability syndrome, which fits Kaufman oculocerebrofacial syndrome have been recognized. **Conclusions:** We suggested that this novel 8q22.3 microdeletion syndrome had a variable expressivity and proposed that the HI of *UBR5* could lead to this peculiar craniofacial phenotype and ID of this novel genomic disorder.

We report the case of a girl affected by mild mental retardation, macrocephaly and microcytic anemia. Clinical examination did not reveal significant dysmorphic features, except for frontal bossing and mild hypertelorism. Also her mother presents with mild intellectual disability.

Array-CGH analysis detected a 493.1 Kb telomeric deletion on chromosome 16p13.3, which was found to be maternally inherited. Further examination of mother's medical history revealed that she was also affected by microcytic anemia, which had been treated with oral iron therapy without benefit. The deletion involves the two alpha-globin genes (HBA1 and HBA2), explaining the haematological defect.

Deletions of 1.5 and 2 Mb involving the telomeric short arm of chromosome 16 cause the contiguous gene syndrome ATR-16 (MIM #141750) characterized by alpha-thalassemia, mental retardation and variable dysmorphic features (downslanting palpebral fissures, mild hypertelorism, broad nasal bridge, small ears and a short neck with webbing). Haploinsufficiency of SOX8 (MIM #605923) is thought to be responsible for intellectual disability. The deleted region in our patient does not include SOX8, whereas it comprises 31 genes whose function is still partially unknown, except for HBA1 and HBA2.

To our knowledge this is the smallest 16p13.3 telomeric deletion characterized by mental retardation and microcytic anemia, narrowing the critical region and pointing at other candidate genes for intellectual disabilities. Moreover this is the first case of inherited ATR-16 syndrome.

P08.09-S

Intellectual disability and autistic behavior due to de novo microduplication of Xq28 involving part of the AFF2 (FMR2) gene. Is this a plausible explanation?

N. Bukvic[1], *C. Cesarano*[2], *C. Ceccarini*[2], *A. D'Aprile*[2], *D. C. Loconte*[3], *M. Chetta*[4], *V. Bruni*[3], *R. Pietrobono*[5], *E. Tabolacci*[6], *A. Manghisi*[1], *W. Latanzzi*[7], *F. FRAXE is an X-linked form of intellectual disability characterized by mild to moderate cognitive impairment, speech delay, hyperactivity, and autistic behavior. The folate-sensitive fragile site FRAXE is located in Xq28 approximately 600 kb distal to the fragile X syndrome fragile site (FRAXA) and harbors an unstable GCC triplet repeat adjacent to a CpG island in the 5' UTR (untranslated region) of the AFF2 (FMR2) gene. The disorder results from amplification and methylation of the GCC repeats and consequence silencing of AFF2. Although chromosome abnormalities (mostly deletions) that disrupt AFF2 have been reported with mild-moderate intellectual disability, microduplication of Xq28 that partially involved AFF2 has not been described as a potential cause of FRAXE. We performed clinical and molecular characterization of patient with 301 kb interstitial de novo duplication at Xq28 (chrX:147˙490˙437-147˙791˙737bp)(GRCh37/hg19). This genomic mutation leads to the duplication of part of 5' UTR region of the AFF2 (FMR2) gene which could be inactivated due to this genomic change. Namely, duplication of this segment potentially could have the same effects as amplification and methylation of an unstable GCC triplet repeats. That's why we are performing experiments aimed to study genic expression/metilation. As our patient had cognitive impairment, speech delay, hyperactivity and mild dysmorphism, we predict that partial duplication of AFF2 in our patient could be the cause of his phenotype.

Gecz*[2], *M. Ursini*[1], *M. Miano*[1]; [1]*IGB-CNR, Naples, Italy,* [2]*Dep. of Paediatrics, University of Adelaide, South Australia, Australia,* [3]*SISSA, Trieste, Italy,* [4]*Neuromed, Pozzilli, Italy,* [5]*Inserm U1091 Diabetes Genetics Team, Nice, France,* [6]*Centre for Epigenetics, University of Copenhagen, Copenhagen, Denmark,* [7]*Second University of Naples, Naples, Italy,* [8]*University of Basilicata, Potenza, Italy.*

Neurophenotypes linked to Aristaless-related homeobox (ARX) mutations present a huge spectrum of brain diseases including cortical malformations, malignant epilepsy and intellectual disability (ID). We have recently identified a crucial disease path, linking functionally ARX to another XLID/Epilepsy gene, Lysine-specific demethylase 5C (KDM5C). It encodes an H3K4me2/3 demethylase required in neuronal differentiation. We found that ARX mutations, affecting PolyAlanine tracts or HD domain, cause functional damages of the ARX-KDM5C interaction, which severity depends on the type of alteration. In Arx KO embryonic brain and ES-oriented GABAergic neurons, a defective ARX-KDM5C-H3K4me3 path has been found. We tested in vitro correction of KDM5C-H3K4me3 defects, ideally through endogenous physiological mechanisms. We explored three different approaches: transcription factor targeting, gene knock-up by SINEUP non-coding RNA technology and epigenetic modifications. To UP-regulate transcription, we forced KDM5C transcription by PHF8/ZNF711 stimulation, a transcriptional complex that seems to not synergize with the action of ARX. To UP-regulate translation, taken advantage of SINEB2 lncRNAs (SINEUPs) acting as activators of translation, we generated synthetic lncRNAs antisense to KDM5C gene. In SINEUP KDM5C-transfected neuronal cell lines, we obtained increased levels of endogenous KDM5C protein. To achieve epigenetic correction of KDM5C path, we screened also a number of compounds targeting chromatin enzymes. A strong compensation of KDM5C down-regulation has been obtained at crucial time-point of neuronal commitment upon treatment with an HDAC inhibitor. Ongoing efforts to define rescue strategies may help to identify useful tools towards drug discovery for ARX XLID/Epilepsy phenotypes and many other disorders with malignant seizure.

P08.11-S

Defining a link between retinoic acid and autism: molecular approximation for exome sequencing results

O. A. Moreno-Ramos[1], *A. Olivares*[2], *N. B. Haider*[2,3], *M. C. Lattig*[1]; [1]*Universidad de los Andes, Bogotá, Colombia,* [2]*Schepens Eye Research Institute, Massachusetts Eye and Ear Infirmary, Boston, MA, United States,* [3]*Department of Ophthalmology, Harvard Medical School, Boston, MA, United States.*

Autism spectrum disorder (ASD) is a range of complex neurodevelopmental conditions principally characterized by dysfunctions linked to mental development. The understanding of its genetic basis is difficult, mainly because the high allelic and locus heterogeneity together with the variable symptomatology. Therefore, multiple approaches have been applied to understand its genetic basis. Thousands of clues have emerged from initial exome sequencing (ES) studies, identifying possible de novo Novel (DNN) mutations associated to ASD. Since most of the variants reported to date were found mostly in Caucasian or European descendant, we applied ES in a cohort of Colombian - South American (admixed population) trios. In this previous study, we found two DNN non-synonymous mutations in genes ALDH1A3 and FOXN1 in the same child. Using bioinformatic approximations, we were able to locate several Retinoic Acid Response Elements (RARE) upstream of both genes in humans, as well as in mice. Chromatin immunoprecipitation (ChIP) followed by QPCR determined the relationship between Retinoid Acid Receptor ß (RARß) in adult piriform cortex and in embryonic whole brain.

P08.12-M

Array Comparative Genome Hybridization (aCGH) in children with autistic spectrum phenotype

V. Oikonomakis, K. Kosma, M. Tzetis, E. Fryssira, N. Pervanidou, A. Xaidara, A. Syrmou, S. Rigoglou, **S. Kitsiou-Tzeli**, *E. Kanavakis;*
Department of Medical Genetics, Medical School, University of Athens, Athens, Greece.

Aim: Autism or autistic spectrum disorders (ASD), are a group of complex neurodevelopmental disabilities, affecting social interaction and communication skills (Rosti R O et al 2013). Only α few cases of chromosomal abnormalities are identified by conventional cytogenetic techniques while molecular karyotype allows for the detection of submicroscopic genomic rearrangements providing a diagnostic yield ranging from 10% to 18% (Shen Y 2010). **Material- Methods:**. A total of 629 patients were studied by the Department of Medical Genetics, from which 114 fulfilled the the autism/ ASD clinical criteria The arrays used were high definition1X244K and 4X180K with the additional ability of SNP identification for the detection of uniparental disomy UPD and /or copy neutral loss of homozygosity (LOH).. All patients were referred by Clinical Geneticists after detailed evaluation and normal conventional karyotype. **Results:** Submicroscopic genomic rearrangements (CNVs), 0.08-19.01 Mb in size were detected in 55/114 subjects with autism or ASD, with the following most important genes previously implicated in the etiology of autism or ASD: *NRXN1, SHANK3, DOCK8, ZNF92, ASMT, HSFX1, KCNH7, CHRFAM7A, CHRNA7, KCND2, CNTNAP3, MAOA, MAOB, STS, VCX* **Conlusions** The identification of genetic alterations (CNVs) in a affected child with autism/ ASD allows more specific consultaion to the family about diagnosis, prognosis and recurrent risks, while genetic reevaluation with aCGH is also warranted in adult autism patients.

P08.13-S

Phenotype of 20 novel autosomal recessive cognitive genes- a report from Iran

K. Kahrizi[1], *A. Tzschach*[2,3], *M. Garshasbi*[1], *C. Hu*[2], *S. Abedini*[1], *H. Ropers*[2], *H. Najmabadi*[1]; [1]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Max Planck Institute for Molecular Genetics, Berlin, Germany,* [3]*Institute of Human Genetics, University of Tübingen, Tübingen, Germany.*

After releasing 50 novel intellectual disability (ID) genes by Najmabadi et al. in 2011, most of researchers working on cognitive pathway in human and animal models were interested in phenotypically aspect of some of these genes to reach the function of changes in mouse, drosophila and human brain.

From 50 novel candidate genes of ID that have been reported, 20 families had additional features that some of them could have been related to the effect of these genes on neuronal networking. Ten out of 20syndromic families with microcephaly or neurological symptoms were selected and MRI was performed for one or two affected siblings in each family. In the previous study, homozygosity mapping, coupled by conventional sequencing or next generation sequencing (NGS) were used to define underlying genetic defects.

From total of 10 families, eight families showed different types of abnormalities as periventricular leukoencephalopathy, reduced cerebral cortex, pachygyria, polymicrogyria, small corpus callosum and cerebellar hypoplasia on MRI including subjects with mutations in CAPN10, TAF2, CNKSR1, WDR45L, ERLIN2, PARP1 and SLC31A1 genes. Three syndromic families had normal brain architecture (ZBTB40, KIF7 and TMEM135).

More detailed of syndromic families have been described based on the table of novel cognitive genes published by Najmabadi et al. in Nature Oct 2011.

P08.14-M

Mutation in CAPN10 Causing Intellectual Disability in Two Independent Iranian Families with Overlapping Phenotypes

M. Oladnabi[1], *L. Musante*[2], *Z. Fattahi*[1], *H. Hu*[2], *S. Abedini*[1], *M. Hosseini*[1], *T. Wienker*[2], *K. Kahrizi*[1], *H. Najmabadi*[1], *H. Ropers*[2];
[1]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Department of Human Molecular Genetics, Max-Planck Institute for Molecular Genetics, Berlin, Germany.*

Intellectual disability (ID) is a broad diagnosis encompassing a wide variety of phenotypes and severities. There are many reasons why the genetics of intellectual disability have been difficult to unravel, but the most important are extensive genetic and phenotypic heterogeneity in autosomal-recessive (AR) inheritance of ID. Therefore, our joined researches on ID started in 2003 with abroad centers to elucidate the molecular causes of ARID in Iran. As a part of this collaboration, whole genome homozygosity mapping and exome sequencing was performed to identify novel genes and mutations in two Iranian families affected with ID.
In our previous study, published in Nature 2011, we reported on a mutation in CAPN10 gene In a consanguineous Iranian family with syndromic ID. In the current study, two novel nonsense mutations were discovered in two unrelated Iranian families with ID in CAPN10 gene, which encodes calpain10 protein eight isoforms and involves in brain function, NIDDM and other cellular activities. In this study, in addition to the above mentioned mutations, we observed overlapping clinical findings including microcephlay, ID and distinct brain MRI features in two independent Iranian families. Here, our aim was to introduce CAPN10 as a promising candidate gene in syndromic ID.

P08.15-S

De novo single exon deletion of AUTS2 in a patient with profound intellectual disability

D. Babikyan, *S. Midyan, A. Hovhannisyan, A. Gasparyan, T. Sarkisian;*
Center of Medical Genetics and Primary Health Care, Yerevan, Armenia.

The autism susceptibility candidate 2 (AUTS2) gene has a critical role in early brain development with its strong expression in fetal and adult brain. Association of AUTS2 with intellectual disability (ID), autism spectrum disorders, and other neurodevelopmental disorders has recently gained more attention. Genomic rearrangements and copy number variations (CNVs) involving AUTS2 have been implicated in a range of neurodevelopmental disorders with or without congenital malformations and dysmorphic features. Here we report a 127 kb de novo deletion encompassing exon 5 of AUTS2 at 7q11.22 which result in inframe deletion of 10 amino acids. The deletion was detected by SNP-array analysis applying InfiniumHD whole-genome genotyping assay with the HumanCytoSNP-12 BeadChip (Illumina Inc.). Obtained data were analyzed with Illumina GenomeStudio and QuantiSNP software. The single exon deletion was detected in a 10 year-old female patient with severe speech disorder, intention tremor, fine motor activity deficit, behavior disturbance, residual lesion in the CNS, and intracranial hypertension. This is one of the smallest de novo intragenic deletions of AUTS2 described in patients with neurodevelopmental disorders. Along with the review of previously reported 20 cases with small pathogenic CNVs and 4 cases with different de novo balanced translocations of 7q11.2 interrupting the AUTS2 gene with severe profound to borderline ID without autistic features or delayed psychomotor development with mild to moderate autism, this report provides additional insight into the clinical spectrum of AUTS2 disruptions.

P08.16-M

Whole exome sequencing detected a novel PHF6 mutation as the cause of Börjeson-Forssman-Lehmann syndrome in four males in a Danish pedigree

N. M. Gammelager[1], *I. S. Pedersen*[2], *V. Q. Le*[2], *T. H. Soerensen*[3], *L. L. Bjerregaard*[3], *A. Ernst*[2], *S. Vaeth*[1], *T. J. B. Lyngbye*[4,5], *H. Krarup*[2], *M. B. Petersen*[1,6];
[1]*Department of Clinical Genetics, Aalborg University Hospital, Aalborg, Denmark,* [2]*Section of Molecular Diagnostics, Department of Clinical Biochemistry, Aalborg University Hospital, Aalborg, Denmark,* [3]*Department of Pediatrics, Aalborg University Hospital, Aalborg, Denmark,* [4]*Department of Pediatrics, Aarhus University Hospital, Aarhus, Denmark,* [5]*Centre for Deafblindness and Hearing Impairment, Aalborg, Denmark,* [6]*Department of Clinical Medicine, Aalborg University, Aalborg, Denmark.*

Börjeson-Forssman-Lehmann syndrome (BFLS) is a rare X-linked mental retardation syndrome. BFLS was first described in 1962, and in 2002 the PHF6 gene at Xq26 was identified as the responsible gene.
Approximately 20 cases have been reported with mutations in the PHF6 gene. At least 12 different PHF6 mutations have been found in both familial and sporadic cases, predominantly missense and truncation mutations. Five recurrent mutations have been reported, which arose independently.
The main clinical features are normal birth weight, feeding problems and hypotonia in infancy, developmental delay, mild/moderate mental retardation, large ears, short toes, small genitalia, gynaecomastia, truncal obesity, tapered fingers, and coarsening of facial features.
We report a Danish family with four boys with developmental delay aged 3-12 years. They were related as brothers/cousins with mothers being sisters. All four boys had normal birth weight, poor suck, hypotonia, developmental delay, no language, big ears, small penis and testes, tapered fingers, and broad distance between 1st and 2nd toes. The pedigree was consistent with X-linked inheritance. Whole-exome sequencing was performed by exome capture (AgilentSureselect) followed by sequencing of all exons and exon/intron boundaries at the X chromosome. A hemizygous mutation p.M1V in the PHF6 gene was found in all four boys and in heterozygosity in the two mothers and the grandmother. The mutation alters the start codon where a p.M1T mutation has been reported previously. The mutation caused BFLS in the four affected boys with three unaffected carrier females. BFLS might be underdiagnosed due to its rather unspecific phenotypic characteristics.

P08.17-S

TALEN-mediated mutagenesis as a tool to generate disease models for diseases caused by dominant de novo mutations

C. A. Biagosch[1,2], *S. Hensler*[3], *R. Kühn*[3], *T. Meitinger*[1,2], *H. Prokisch*[1,2];
[1]*Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany,* [2]*Institute of Human Genetics, Technische Universität München, München, Germany,* [3]*Institute of Developmental Genetics, Helmholtz Zentrum München, Neuherberg, Germany.*

Engineering of the mouse germline has long been used to create targeted mutants. The TALEN-mediated approach based on embryo microinjection of TALENs was shown to result in up to 50% efficiency of germline mutated offspring. As TALENs can modify one or two copies of the target gene either before or after genome replication, mutant genotypes identified in the founder generation may represent heterozygous, compound heterozygous or mosaic state. The high efficiency could allow the generation of mouse models for diseases caused by dominant de novo mutations. Here we tested this approach to generate a mouse model for X-linked dominant neurodegeneration caused by de novo mutations in WDR45. After microinjection of TALEN mRNA surviving Embryo's have been transferred in groups of 10 into the oviducts of 3 pseudopregnant females resulting in 19% mutated founders (5/26). Mutations are deletions between 10 and 57bp in length with a predicted frameshift in 80% of mutations. From the in situ design and delivery of the TALENs (~1month), over in vitro testing in cell culture to the in vivo injection into embryo's (~2months) until the genotyping of the founder mutants it only takes 4-5 months. Hence, this presents an innovative tool to investigate de novo arising mutations in mosaic status which would be embryonic lethal.

P08.18-M

NR2F1 mutations cause optic atrophy with intellectual disability

[1]*Radboud university medical center, Nijmegen, Netherlands,* [2]*Bartiméus, Institute for the Visually Impaired, Zeist, Netherlands,* [3]*Baylor College of Medicine, Houston, TX, United States,* [4]*Texas Children's Hospital, Houston, TX, United States,* [5]*Howard Hughes Medical Institute, Chevy Chase, MD, United States.*

Optic nerve atrophy and hypoplasia can be primary disorders or can result from trans-synaptic degeneration arising from cerebral visual impairment (CVI). CVI comprise a class of disorders of the projection and/or interpretation of visual input in the brain, and symptoms can consist of low vision, visual field defects and abnormal visual behavior. Here we report six individuals with CVI and/or optic nerve abnormalities, born after an uneventful pregnancy and delivery. The affected individuals show mild to moderate intellectual impairment, without specific facial dysmorphisms. In three patients large optic disc excavations were seen, which are, until now, only reported in CVI caused by perinatal damage. In four of the affected persons *de novo* heterozygous missense mutations in *NR2F1* were identified. In the two other affected individuals SNP array investigations revealed heterozygous deletions on 5q14.3q15 of 0.84 Mb and 2.83 Mb encompassing 4 and 5 genes, respectively, including *NR2F1*.
NR2F1 encodes a nuclear receptor protein that regulates transcription. A luciferase reporter assay showed that missense mutations in the zinc-finger DNA-binding domain and the putative ligand-binding domain decrease NR2F1 transcriptional activity. Additionally, previous studies in KO mice has indicated that the protein is important for neurodevelopment, including oligodendrocyte differentiation (partly in vitro experiment), cortical patterning, and guidance of thalamocortical axons, as well as eye and optic nerve development.

In conclusion, these findings indicate that *NR2F1* plays an important role in the neurodevelopment of the visual system and that its disruption can lead to optic atrophy with intellectual disability.

P08.19-S
Chromosomal microarray analysis of patients with intellectual disability, autism or multiple congenital anomalies presenting for genetic services

O. Palumbo, *P. Palumbo, R. Stallone, T. Palladino, L. Zelante, M. Carella;*
IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy.

Copy number variations (CNVs) are the most common identifiable causes of intellectual disability/developmental delay (ID/DD), autism spectrum disorders (ASDs), or multiple congenital anomalies (MCAs). Chromosomal microarray analysis (CMA), with a 10-20% diagnostic yield, can identify CNVs≤1 Mb. We report our experience with the use of the Affymetrix SNP Arrays in 1600 Italian patients during the past 6 years (2008-2013). We identified CNVs with a high score of pathogenicity in 415 (27%) patients. Among them 143 (34.4%) showed a CNV overlapping with a known syndrome, 272 (65.6%) a likely pathogenic rearrangement. Of particular interest, we found some CNVs useful to further delineate the clinical features associated with deletions in 8q12.1q12.3, in 15q25.2, in 17q21.31, in 2q24.1q24.2, in 22q11.2, and duplications in 16p13.3 and in 11p13. Some CNVs were useful to describe new syndromes such as a 1.7 Mb deletion in 3q13.2q13.31. Also, we have identified a large group of small CNVs (< 1.0 Mb) encompassing, either in whole or in part, functionally related genes to the phenotypes such as CASK, CNTN6, SNTG2, HIP1, DLG2, NRXN1, MCPH1 and CHL1 genes. Among these small CNVs, we have reported a FOXP1 gene microdeletion in a boy with autism and speech delay, and a de novo interstitial deletion of 0.122 Mb at 2q24.2 region harboring only TBR1 gene in a boy with moderate to severe intellectual disability. Variants of uncertain significance (VOUS) because unreported, containing genes of uncertain clinical significance or non-genic but potentially regulating nearby gene expression, were identify in 128 individuals (8%).

P08.20-M
The Cohen syndrome-associated protein COH1 functions as Golgi matrix protein required for Golgi integrity

S. Wenke[1], *J. Kühnisch*[2,3], *T. Maritzen*[4], *S. Bachmann*[1], *H. Hennies*[5], *D. Horn*[6], *V. Haucke*[4];
[1]*Institute of Vegetative Anatomy, Charité - Universitätsmedizin Berlin, Berlin, Germany,* [2]*Institute of Medical and Human Genetics, Charité - Universitätsmedizin Berlin, Berlin, Germany,* [3]*Max-Planck-Institute for Molecular Genetics, FG Development and Disease, Berlin, Germany,* [4]*Laboratory for Molecular Pharmacology and Cell Biology, Leibniz-Institute for Molecular Pharmacology, Berlin, Germany,* [5]*Cologne Center for Genomics, University of Cologne, Berlin, Germany,* [6]*Institute of Medical Genetics and Human Genetics, Charité - Universitätsmedizin Berlin, Berlin, Germany.*

Mutations in the COH1 (VPS13B) gene cause autosomal recessive Cohen syndrome, which is mainly characterized by mental retardation, postnatal microcephaly, pigmentary retinopathy, and intermittent neutropenia. However, the biochemical characteristics, cellular localization, or functional role of the encoded protein COH1 (3997aa) have so far not been addressed. Our cell biological analysis showed strong co-localization of COH1 with the cis-Golgi marker protein GM130, which was preserved even upon chemical disruption of the Golgi architecture. Further biochemical analysis showed that COH1 is a peripheral membrane protein similar to its remote homologue, Vps13p in yeast. Vps13p has been found to regulate anterograde and retrograde vesicular transport of transmembrane proteins between the prevacuolar compartment and the trans-Golgi network. Consequently, we found that loss of COH1 upon RNAi impairs the ability of the Golgi ribbon to (re)assemble and thus induces fragmentation into mini-stacks. Moreover, we found that COH1 regulates the formation of Golgi-derived membrane tubules consistent with its predicted function in intracellular membrane traffic. Further protein-protein interaction studies identified COH1 as a potential effector protein of the Golgi-associated small GTPase RAB6, emphasizing a role of COH1 for Golgi-related vesicle transport. Thus, our accumulated evidence suggests COH1 as a molecular regulator of antero- and retrograde Golgi membrane trafficking. As RAB6-associated Golgi transport critically regulates neuronal development and neuron function the Cohen syndrome pathology is likely caused by a failure of intracellular vesicle transport.

P08.21-S
De novo heterozygous mutations in beta-catenin 1 (CTNNB1) appear to be a frequent cause of intellectual disability (ID)

A. Kuechler[1], *B. Albrecht*[1], *K. Cremer*[2], *C. Czeschik*[1], *E. Graf*[3], *H. Lüdecke*[1], *T. Wieland*[3], *A. M. Zink*[2], *H. Engels*[2], *T. M. Strom*[3], *D. Wieczorek*[1];
[1]*Institut für Humangenetik, Essen, Germany,* [2]*Institute of Human Genetics, Bonn, Germany,* [3]*Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany.*

Intellectual disablity (IQ<70) affects up to 3% of the general population. Until recently, the underlying cause was unclear in about half of the affected individuals. The introduction of whole exome sequencing (WES) techniques enables elucidating the genetic background of ID.
We performed WES in a cohort of 250 individuals with unexplained ID and identified heterozygous de novo CTNNB1 mutations in five unrelated individuals (three frameshift, one stop, and one splice mutation). All five patients have severe motor delay, profound speech impairment, hypotonia of the trunk and hypertonia of the legs. The craniofacial phenotype comprises microcephaly (4/5) and some consistent facial features - a broad nasal tip, small alae nasi, long philtrum and thin upper lip vermillion.
Beta-catenin is a key downstream component of the canonical Wnt signaling pathway, and acts as a negative regulator of centrosome cohesion. Whereas somatic gain-of-function mutations have already been found in various tumor types, germline loss-of-function mutations were suspected in animal models to influence neuronal development and maturation. This was supported by the finding of dominant inactivating CTNNB1 mutations as a cause of ID in 3/865 patients (0.35%, deLigt etal., 2012). Their phenotype was additionally characterized by absent/limited speech, microcephaly and spasticity with severely impaired walking.
Our finding of five individuals in our cohort of 250 (2.0%) suggests that CTNNB1 loss-of-function mutations might be a more frequent cause of ID than estimated from the data of deLigt and colleagues. Our data further emphasize the importance of Wnt signalling in human brain development and/or function.

P08.22-M
Deletions limited to CTNND2 cause mild intellectual disability

S. Azzarello-Burri[1], *R. Asadollahi*[1], *E. Bijlsma*[2], *J. Andrieux*[3], *A. Dieux*[4], *D. FitzPatrick*[5], *A. Ekici*[6], *A. Baumer*[1], *B. Oneda*[1], *A. Reis*[6], *O. Jenni*[7], *A. Rauch*[1];
[1]*Institute of Medical Genetics, University of Zurich, Zurich, Switzerland,* [2]*Department of Clinical Genetics, Center for Human and Clinical Genetics, Leiden University Medical Center (LUMC), Leiden, Netherlands,* [3]*Institut de Génétique Médicale, Hôpital Jeanne de Flandre, CHRU de Lille, Lille, France,* [4]*Clinique de Génétique Guy Fontaine, Hôpital Jeanne de Flandre, CHRU de Lille, Lille, France,* [5]*MRC Human Genetics Unit, MRC Institute for Genetic and Molecular Medicine, University of Edinburgh EH4 2XU, United Kingdom,* [6]*Institute of Human Genetics, Universität Erlangen-Nürnberg, Erlangen, Germany,* [7]*Child Development Center, University Children's Hospital Zurich, Zurich, Switzerland.*

Using chromosomal microarray testing we detected a 113 kb de novo out of frame deletion encompassing exons 4-7 of CTNND2 in a patient with borderline ID. This gene was mapped to the cri-du-chat syndrome critical region in chromosome 5p15.2 and encodes a regulator of neuronal migration. CTNND2 was considered responsible for the severe intellectual disability in cri-du-chat syndrome patients with terminal deletions. Extended deletion mapping however indicated that interstitial deletions restricted to the CTNND2 locus produce a milder level of intellectual disability. The girl was born at term with no complication and normal measurements. Apart from 2 episodes of acute subglottic laryngitis there were no remarkable health problems. Developmental milestones were within normal limits. The patient was referred to developmental testing because of behavioural issues and was diagnosed with mild intellectual disability. She showed a dissociated cognitive profile with better language than nonverbal functions (full scale IQ 77) and suffered from short attention span, poor executive functioning and impaired working memory. Three other patients with deletions limited to CTNND2 were found in the DECIPHER database. One patient had a 413 kb deletion with mild intellectual disability, autism and hypotonia. The other patient showed a 479 kb deletion with learning difficulties, behavioral problems and autism spectrum disorder. In the third patient a 154 kb deletion was detected. He showed intellectual disability and neurological problems which may be caused by an additional unidentified disorder. We assume that CTNND2 haploinsufficiency is a novel cause of mild neurodevelopment features.

P08.23-S
A familial case of 15q26.3 microduplication

S. Puusepp[1,2], *O. žilina*[1,3], *K. Kuuse*[1], *K. Õunap*[1,4];
[1]*Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia,* [2]*Department of Human Biology and Genetics, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia,* [3]*Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [4]*Department of Pediatrics, University of Tartu, Tartu, Estonia.*

The "15q overgrowth syndrome" has been associated with the very distal 15q duplication. At least 26 cases with trisomy of 15q25-26qter have been published, of which approximately 70% have presented with overgrowth and about 65% have been the result of a parental balanced translocation. Overgrowth has been associated with the dosage effect of *IGF1R* (insulin-like growth factor 1 receptor) gene located on 15q26. However, about 50% of

patients with larger duplications of distal 15q (15q21-24qter, including the *IGF1R* gene) on the contrary presented with growth retardation, although a few authors have reported overgrowth as well.
We report 12 and 8 years old brothers with identical 0.77 Mb microduplications in 15q26.3 region (chr15: 101,031,538-101,802,565, Hg19). The elder sib presents with postnatal overgrowth - at the age 12 his height is 175 cm (+4 SD), but his birth length was 52 cm (0 SD). The younger sib has normal growth (+1 SD). In addition, they both present with expressive speech disorder, some facial and hand microanomalies, and poor fine motor skills. Their father has overgrowth (+2.5 SD), prominent facial features and presented with dysarthria in childhood. Therefore, the duplication is with high probability of a paternal origin (analysis in work). This is the smallest "pure" 15q26 duplication reported so far. Interestingly, the *IGF1R* gene is not duplicated in our patients. Furthermore, they demonstrate variable clinical phenotype. Therefore, we give further evidence that a more complex pathogenesis for the development of somatic overgrowth should exist in case of distal 15q duplication.

P08.24-M
6p21.33 microdeletion associated with EHMT2 haploinsufficiency and intellectual disability

K. Kurosawa[1], *I. Ohashi*[1], *Y. Kuroda*[1], *T. Naruto*[1], *T. Saito*[1], *M. Masuno*[2];
[1]*Kanagawa Children's Medical Center, Yokohama, Japan,* [2]*Kawasaki University of Medical Welfare, Kurashiki, Japan.*

Microdeletion of 6p21 is a rare condition that has been described in patients with multiple congenital malformation and intellectual disability. We report on a patient with a 0.4 Mb microdeletion in 6p21.33 and intellectual disability. The genomic loss contained 30 RefSeq genes ncluding *EHMT2* which is a primary enzyme for mono- and dimethylation at Lys 9 of histone H3 (H3K9me1/2), and plays critical roles in various biological processes. The 6-year-old boy was referred for evaluation of intellectual disability and macrocephaly. He was born at 37 weeks of gestation to a 32-year-old G1 P1 mother and 34-year-old father after uneventful pregnancy. The birth weight was 2418 g, length 45 cm, and head circumference 33 cm. His psychomotor development was delayed. He achieved head control at 4 months, sitting at 10 months, and walking alone at 2 years. He spoke his first word at 2.5 years. He never had seizures and his hearing was normal. His height was 106 cm (-1.7 SD), weight 20.3 kg (-0.3 SD), and head circumference 53.5 cm (+1.4 SD) respectively. Brain MRI at age of 4 years showed incomplete rotation of the bilateral hippocampus. *EHMT2* is a human homologue of mouse G9a that exists predominantly as a G9a-GLP heteromeric complex. The human homologue of the GLP is *EHMT1*, which is a causative gene responsible for Kleefstra syndrome with characteristic facial dysmorphism and severe intellectual disability. This case provides insight into the etiological mechanism of histone modification and human development.

P08.25-S
EPHA1 as a new candidate gene for autosomal recessive non-syndromic intellectual disability

R. V. Gulkovskyi[1,2], *G. Volynets*[1], *S. Chernushyn*[1], *S. Kravchenko*[1], *L. A. Livshits*[1,2];
[1]*Institute of Molecular Biology and Genetics of NASU, Kyiv, Ukraine,* [2]*Taras Shevchenko Kiev National University, Kyiv, Ukraine.*

We report a Ukrainian family consisted of healthy and non-consanguineous parents and two affected children with moderate intellectual disability (ID) and similar psychoneurological symptoms. Biochemical and CGH-array investigations revealed no genetic abnormalities in children.
Whole exome sequencing performed in family members identified two non-synonymous variants c.1475G>A and c.1891G>A in the EPHA1 gene. Both affected siblings were compound heterozygotes while father and mother were heterozygous carriers for the c.1891A and c.1475A variants respectively. C.1475G>A and c.1891G>A frequencies analyses in 300 healthy Ukrainian controls revealed that the c.1475T allele frequency was 1,2% while the c.1891A was not found. EphA1 belongs to Eph receptors family implicated in axon guidance control but it was not previously associated with ID. To understand a possible effect of these substitutions the mutant EphA1 proteins' tertiary structures were predicted. As it turned out the substitutions are located in important functional domains of EphA1. The substitution of positive charged Arg492 to uncharged Gln492 (c.1475G>A) is in the fibronectin type III repeat of EphA1 ectodomain involved in signal transduction and binding with ligands or protein-partners. The substitution Gly631Arg (c.1891G>A) is in the glycine-rich region of EphA1 tyrosine kinase domain responsible for ATP binding. We assume the c.1475G>A and c.1891G>A mutations may cause changes in conformational flexibility and solubility of these EphA1 domains resulting in impaired Eph signal transduction.
Predicted structural EphA1 changes and low c.1475A and c.1891A frequencies allow us to hypothesize that missense mutations in the EPHA1 gene may be responsible for autosomal recessive non-syndromic intellectual disability.

P08.26-M
Mutations in FOXP1 result in a recognizable mental disability phenotype

B. L. Callewaert[1], *A. Dheedene*[1], *F. F. Hamdan*[2], *J. Michaud*[2], *D. Lederer*[3], *S. Moortgat*[3], *B. Menten*[1];
[1]*Center for Medical Genetics, University Hospital of Ghent, Ghent University, Ghent, Belgium, Ghent, Belgium,* [2]*Center of excellence in Neuromics of Université de Montréal, Montréal, QC, Canada,* [3]*Institut de pathologie et de génétique, Gosselies, Belgium.*

Mental retardation with or without minor dysmorphic features represents a major challenge in clinical genetics. Over a decade ago, the introduction of arrayCGH analysis introduced the concept of reverse genetics in clinical practice identifying recurrent phenotypes in patients with similar molecular defects. With the increasing resolution of arrayCGH analysis, monogenic defects can sometimes be readily identified. A careful clinical description of the concurrent phenotype may therefore direct specific gene analyses in patients with similar phenotypes ('gestalt' diagnosis) or may prioritize variant analysis through next-generation sequencing of gene panels or exomes.
We present three novel patients with FOXP1 mutations. All patients presented with moderate to severe intellectual disability with nearly absent speech, patient 3 additionally had tonic-clonic seizures, horizontal nystagmus, spastic tetraparesis and aggression. The facial features in these patients included a frontal upsweep, a broad forehead, broad and bent palpebral fissures, hypertelorism, a bulbous nasal tip, prominent nasolabial folds and a wide mouth. These striking features and the identification of a de novo 420kb intragenic deletion on arrayCGH analysis in patient 1 enabled us to identify a FOXP1 mutation (p.R525X) by direct sanger sequencing in patient 2 and to prioritize data analysis in a large gene panel analysis for mental disability in patient 3 (p.W508X mutation in FOXP1).
We further delineate the clinical phenotype due to FOXP1 mutations. Our and literature data evidence an emerging and recognizable syndrome. In the era of exome/genome analysis the clinical definition of phenotypes remains important to order to enable genotype-phenotype correlations.

P08.27-S
Triplet repeat-primed (TRP)-PCR changes the paradigm for Fragile X Syndrome (FXS) testing: Experience from the Greenwood Genetic Center

M. J. Basehore, *J. R. Jones, M. J. Friez;*
Greenwood Genetic Center, Greenwood, SC, United States.

Virtually all clinical testing for FXS revolves around the determination of the length of the CGG repeat tract in the 5'UTR of the Fragile X Mental Retardation (*FMR1*) gene. Repeat lengths generally fall into four categories, where <45 CGG repeats is accepted as normal, 45-54 repeats is the intermediate range (gray zone), 55-200 repeats is considered the premutation range, and >200 repeats is a full mutation. Diagnostic testing for FXS has traditionally employed both standard PCR and Southern blot techniques since they provide distinct, yet overlapping, levels of resolution and complementary pieces of information. However, newer PCR protocols such as TRP-PCR have the potential to allow amplification of full mutations, thereby providing a method of screening for expansions at the *FMR1* locus. The molecular diagnostic laboratory at the Greenwood Genetic Center has offered FXS testing for nearly 25 years. In 2010, we implemented a validated, lab-developed *FMR1* PCR assay utilizing commercially available TRP-PCR reagents (Abbott Molecular) into our routine diagnostic workflow. Here we summarize our experience with the TRP-PCR assay, discuss how the implementation of this assay has changed our diagnostic workflow, and compare the hands-on time, cost, and turn-around time for the samples tested over the past four years to these statistics for samples tested prior to the implementation of the TRP-PCR assay. In conclusion, the implementation of the TRP-PCR assay has allowed us to drastically reduce the hands-on time, turn-around time, and number of Southern blots performed for samples submitted to our laboratory for diagnostic FXS testing.

P08.28-M
A pilot study for prenatal and preconceptional Fragile-X syndrome screening in the Balearic Islands

R. Alfaro Arenas[1,2], *D. Heine Suñer*[1,2,3], *N. Marlowe*[4], *J. Rosell*[1,2,3], *Balearic Islands Fragile X Study Group;*
[1]*Hospital Universitari Son Espases, Palma de Mallorca, Spain,* [2]*Institut d'Investigacions Sanitaries de Palma (Idispa), Palma de Mallorca, Spain,* [3]*Centro de Investigación Biomedica en Red de enfermedades raras (ciberer), Palma de Mallorca, Spain,* [4]*Abbott Molecular, Des Plaines, IL, United States.*

The Fragile X-syndrome (FXS) is caused by the expansion of a CGG triplet located in the 5'region of the FMR1 gene and is one of the most frequent

causes of hereditary intellectual disability. The estimated incidence of FXS in males in the Spanish population is 1 in 2500 with full mutation and about 1 in 250 with premutation (Fernandez-Carvajal et al. 2009). In women, although the prevalence in Spain of premutation has not been established, estimates in other western countries range from approximately 1/150 to 1/250. Given the severity of the disease, its high incidence in the general population, the exclusively maternal expansion, the familial and social impact of the FXS, and the high level of detection of current techniques (99%), we think that screening for FXS in women of reproductive age is a reliable and desirable option. Therefore, we have initiated a pilot study in the Balearic Islands to determine the feasibility and acceptability of prenatal and/or preconceptional screening in women of childbearing age. The results obtained so far, in a total of 3118 women (252 preconceptional and 2866 prenatal) indicate a high acceptability of testing both, in women that are referred for prenatal or preconceptional consultation. Surprisingly, the incidence of carriers of a premutation (55-200 repeats) is (to date) very high: 1 in 97, which may indicate a higher prevalence than previously thought. We will present updated results based on a total of approximately 3500 women.

P08.29-S
GPM6A is duplicated in a patient with learning disability and influences cholesterol response and long-term memory in *Drosophila melanogaster*

A. Gregor[1], *J. M. Kramer*[2], *M. van der Voet*[2], *I. Schanze*[1,3], *A. Reis*[1], *A. Schenck*[2], *C. Zweier*[1];
[1]Institute of Human Genetics, Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany, [2]Department of Human Genetics, Radboud University Medical Centre, Nijmegen, Netherlands, [3]Institute of Human Genetics, University Hospital, Magdeburg, Germany.

In a patient with learning disability and behavioral anomalies we identified a *de novo* duplication of *GPM6A* by routine chromosomal microarray testing. Glycoprotein M6A (GPM6A) is a neuronal transmembrane protein of the PLP/DM20 family that associates with lipid rafts and promotes filopodia formation. GPM6A variants have not yet been implicated in cognitive impairment. An increase of membrane protrusions in our patient's lymphoblastoid cells supports a functional effect of this dosage alteration. To further study the function of GPM6A/m6 and the effects of m6 overexpression and knockdown, we employed *Drosophila melanogaster* as a model organism. We could show that, as described for other animal models, expression of *Drosophila* m6 is stress responsive. Using the courtship conditioning paradigm, we demonstrated that correct m6 levels are necessary for proper long term memory function, which indicates dosage sensitivity of m6 and supports a causative role of the *GPM6A* duplication for the cognitive impairment found in our patient. Defects in the close homolog *PLP1* are causative for Pelizaeus-Merzbacher disease (PMD), a severe demyelinating neurodevelopmental disorder. Prompted by recent results on successful therapy of phenotypes in PMD mice by the administration of a cholesterol-enriched diet, we investigated if the cellular phenotype of GPM6A/m6 dosage alterations could also be improved by cholesterol. Indeed, cholesterol supplementation partially improved the phenotypes observed in patient cells with GPM6A overexpression as well as in flies with m6 knockdown. Together with other recent findings, these data point to an involvement of cholesterol metabolism in the pathomechanisms of some ID forms.

P08.30-M
A Novel HCFC1 mutation associated with X-Linked Intellectual Disability

C. Sismani, *C. Koufaris, A. Alexandrou, L. Kokkinou, C. Ioannidou, P. Evangelidou, V. Anastasiadou, P. C. Patsalis;*
The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

X-Linked Intellectual Disability is a heterogeneous disorder with a variable phenotypic spectrum. Currently over 90 XLID genes have been found to be implicated in XLID. The host cell factor C1 (HCFC1) gene is located on chromosome Xq28 and is a member of the host cell factor family. A mutation in HCFC1 has been previously found to be associated with XLID in a non syndromic XLID family namely MRX3. Currently very few studies exist that further confirm HCFC1 as an XLID gene.
We present an XLID family with two affected sons having mild intellectual disability epilepsy and no congenital abnormalities. Fragile X analysis and array-CGH using a chromosome X exon-specific array were performed and revealed normal results. Subsequently, next generation whole exome sequencing analysis for both brothers was performed on Illumina HiSeq 2000 following Agilent SureSelect sample preparation (20x coverage). Reads were aligned using the Burrows-Wheeler Aligner and the Genome Analysis Tool Kit. Autosome variants and variants present in dbSNP 135 were filtered out. Analysis of rare X chromosome variants present in both brothers revealed a non-synonymous mutation in exon 4 of HCFC1 (p.Ala897Val). This mutation is located within GABP2 and ZBTB17 binding domains. Previous screening studies of patients have reported variants within the GABP2 binding domain p.Gly876Ser in an individual with autism spectrum disorder (Piton et al., 2011) and p.Ala864Thr in a patient with mental retardation (Tarpey et al., 2010). The mutation was confirmed by Sanger sequencing in both patients and their mother. Extended family studies are ongoing.

P08.31-S
HDAC8 duplication in a patient with de Lange -like phenotype

L. R. Bettini[1], *S. Redaelli*[2], *S. Maitz*[1], **M. Mariani**[1], *A. Cereda*[3,1], *F. Crosti*[2], *A. Selicorni*[1];
[1]Pediatric Department at Monza Brianza per il Bambino e la sua Mamma (MBBM) Foundation, San Gerardo Hospital, Monza, Italy, [2]Genetic Department, San Gerardo Hospital, Monza, Italy, [3]Pediatric Department, Papa Giovanni XXIII Hospital, Bergamo, Italy.

K.K., female, was referred to our attention with a previous clinical diagnosis of Silver Russel syndrome. Prenatal ultrasound were normal. No prenatal cytogenetic examination was performed. She was born at 40+5 week of gestational age through cesarean section; birth weight was 2,320 (< 3rd pc), length was 45 cm (< 3rd pc), head circumference was 30 cm (< 3rd pc). The karyotype was normal (46,XX). Major malformations were excluded. We evaluated her at 6 years and a half; she showed prominent eyes, long thick eyelashes, posteriorly rotated ears, high nasal bridge; short and mild micrognathia and hirsutism. Her weight was 18,900 Kg (10th pc), length 110,5 cm (3-10th pc) and head circumference was 46,5 cm (<<3rd pc); she also presented severe mental retardation. Hands and feet X-rays showed hypoplasia of the 5th meacarpal and the 5th metatarsal. A CGH-array showed duplication of a part of HDAC8 gene (exon 5 and 6) from nt 71,630,467 to nt 71,697,179. HDAC8 gene was recently found implicated in Cornelia de Lange syndrome with variable clinical expressivity. Up now only complete deletion or mutation of the gene have been described. No reports of duplication of this gene are available. Our patient shows some clinical features related to de Lange syndrome also if her phenotype is not classic at all. Expression study are in progress in order to define the biological consequences of this finding and the relationships with the phenotype.

P08.32-M
Clinical characterization of a patient with a complex rearrangement involving duplication and deletion of 9p and 9q

M. Martin-DeSaro[1], *J. Valdes-Miranda*[2], *A. Perez-Cabrera*[2], *S. Cuevas-Covarrubias*[3];
[1]Medical Genetics Department, Hospital Materno Infantil ISSEMyM, Toluca, México., Toluca, Mexico, Mexico, [2]Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Toluca, Mexico, Mexico, [3]Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico D.F., Mexico.

Rearrangements of the distal región of 9p are an infrequent chromosome imbalance in human beings. Trisomy 9p is the fourth most frequent chromosome anomaly in life-born and was characterized as a clinically recognizable syndrome, Rethoré syndrome. Kleefstra syndrome, previously named 9q subtelomeric deletion syndrome, is either caused by a submicroscopic deletion in 9q34.3 or an intragenic mutation of EHMT1. We report the first case with 9p duplication and 9q deletion in a Mexican patient. Patient was referred for dysmorphic facies and congenital heart disease. Clinical examination revealed brachycephaly, upslanting palpebral fissures, depressed nasal bridge, anteverted nares, long filtrum, downturned mouth, lingual protrusion, low set and cupped ears, short neck, small hands with clinodactyly and aberrant palmar creases, left testicle shrink and small feet. He presented an abnormal development. Conventional karyotyping reported 46, XY, add(9)(q34.3), 21 pstk+. Microarray analysis showed 9p24.3p23 (203,861-11-,842,172)x3, 9q34.3 (138,959,881-139,753,294)x3, 9q34.3 (139,784,913-141,020,389)x1. All procedures were normal in both parents. Partial duplication of 9p is one of the most commonly detected autosomal structural abnormalities in live born. It seems that the high frequency of the partial trisomy 9p may indicate a particular breakpoint sensitively of one or more regions of chromosome 9p. Patients with partial duplication of 9p display considerable phenotypic similarity. Our patient with a duplication of 11.6 Mb, from 9p24.2 to 9p23 displays some features like upslanting palpebral fissures, downturned corners of the mouth and developmental delay. In spite of the great duplication region, the major clinical findings in our patient corresponded to the deletion region.

P08.33-S
Exome sequencing in carriers of 1q21.1 CNV

C. Badduke[1], *L. Zhang*[2], *F. Tang*[3], *D. Cowieson*[2], *H. Bagheri*[4], *S. Lewis*[5], *A. Volchuk*[2], **E. Rajcan-Separovic**[4];
[1]University of British Columbia, Vancouver, BC, Canada, [2]Division of Advanced Diagnostics-Metabolism Toronto General Research Institute University Health Network, Toronto, ON, Canada, [3]Univeristy of British Columbia, Vancouver, BC, Canada, [4]Child and Family Research Institute, Vancouver, BC, Canada, [5]Child and Family Research Institute, UBC, Vancouver, BC, Canada.

The 1q21.1 CNV is associated with a variable clinical phenotype and normal to delayed neurodevelopment. We performed whole genome transcription and exome sequencing analysis in 5 subjects from 2 families with 1q21.1 deletion (3 subjects) and duplication (2 subjects), in search for genetic changes that could affect the phenotype. The subjects had variable learning difficulties. A pathogenic variant in the ATF6 gene from 1q22-23, which plays a role in endoplasmatic reticulum stress response, was detected in the mildly affected father and his more severely affected child with 1q21.1 duplication. It was validated by Sanger sequencing and associated with reduced ATF6 RNA and protein expression in patient lymphoblast cell lines. However, the ER stress response, as measured by induction of known ER stress genes (GPR78, Dnajb9, Sdf2l1) in response to tunicamycin was not altered in patient vs control cell lines. No candidate pathogenic mutation that could be linked to altered gene expression status and/or phenotype was found in the 3 subjects with the 1q21.1 deletion, either in the CNV region or genome-wide. Interestingly, for all 5 subjects with 1q21.1 CNV a larger number of the 107 genes implicated in ER stress response showed altered expression in comparison to controls on the whole genome expression array (15-28% in subjects in comparison to 0-6% in controls). Perturbed ER stress response caused either by dysfunction of genes from 1q21.1, genome wide, or both, could play a role in the observed phenotypic variability and result in more severe developmental abnormalities in unfavourable environmental circumstances.

Chromosomal microarray analysis (CMA) is nowadays the most adopted clinical test for patients with unexplained intellectual disability (ID), developmental delay (DD), and congenital anomalies. Its use has revealed its capacity in detecting copy number variants (CNVs) as well as regions of homozygosity which, upon their distribution on chromosomes, indicate uniparental disomy or parental consanguinity that is suggestive of an increase of occurrence of recessive disease. We screened 149 Lebanese probands having ID/DD and 99 healthy controls using the Affymetrix Cyto 2.7M and SNP6.0 arrays. We reported all identified CNVs that we divided into groups and confirmed the utility of this CMA technique in the detection of parental consanguinity in 42 cases (28.2%). Pathogenic CNVs were identified in 11.4% of the patients. We reviewed and reported the genotype/phenotype correlation in a patient with a 1q44 microdeletion, as well as defined the minimal critical regions responsible for the 10q26 and the 16q monosomy syndromes. Several likely causative CNVs were also detected, of which, new homozygous microdeletions (9p23p24.1, 10q25.2, and 8p23.1) in 3 patients issued from consanguineous parents (patient's ROH size ≥ 66 Mb), involving genes that are reported as potential candidates. However, the clinical interpretation of several other CNVs remains uncertain. Among those, 2 microdeletions touching ATRNL1 and the 3'UTR of SOX5. These CNVs of unknown significance were inherited from the patients' normal parent, which requires a screening of more ethnically matched controls in order to obtain enough evidence for their classification.

Unbalanced translocations involving chromosome 4p associated with complex phenotypes: report of 3 cases

M. Budisteanu[1], *S. Papuc*[1], *A. Tutulan-Cunita*[1], *C. Burloiu*[2], *I. Minciu*[2], *M. Cristea*[1], *I. Borcan*[1], *A. Arghir*[1];
[1]*Victor babes National Institute of Pathology, Bucharest, Romania,* [2]*Alex. Obregia Clinical Hospital of Psychiatry, Bucharest, Romania.*

Large imbalances of chromosome 4p, either deletions (associated with Wolf-Hirschhorn syndrome, WHS) or duplications have a defined clinical phenotype. Here, we present 2 situations of genetic abnormalities involving 4p16.3 region. Three patients were referred for genetic testing: 2 siblings, a 16 years old boy and a 12 years old girl, both with the same phenotype, including dysmorphic features, severe mental retardation; severe speech delay; hyperkinesias, aggressivity; epilepsy; skin allergic reactions. An 8 years old girl, with pre- and postnatal growth retardation, severe psychomotor retardation, spastic quadriparesis, dysmorphic features, cleft palate, bilateral congenital cataract, severe epilepsy with status epilepticus episodes. aCGH on an 105K Agilent platform was done according to manufacturer's recommendations; the results were validated by FISH. In the two siblings, aCGH revealed the same genetic abnormality: arr 4p16.3p16.1(72,447-8,373,151)x3,10q26.3(130,977,858-135,434,178)x1 pat. The balanced t(4;10)(p16.1;q26.3) translocation was detected by FISH in the genome of the patients' father. In the second case, aCGH showed another genetic anomaly involving 4p16.3 region: arr 4p16.3p16.1(72,447-9,371,067) x1,8p23.3p23.1(176,452-8,094,773)x3. The genetic investigations of the parents were normal. The 4p region includes over 140 genes, many included in OMIM Database as involved in various pathologies. The 10q deleted region consists of over 60 genes, many also described in the OMIM Database. The 8p duplicated region has a size of 8 Mb and includes 116 genes. The complexity of the phenotype, both for deletion and duplication of 4p16.3 region, of these cases can be explained by the association of other genetic anomalies (10q deletion and 8q duplication, respectively). Copy number variants are frequent in autism spectrum disorders and generalized epilepsy. In this study, we performed comparative genomic hybridization assay (aCGH) using Agilent Microarray Kit, 4x180K in a preselected sample of 36 Bulgarian patients with epilepsy and intellectual disability (ID). The region most often engaged in copy number changes included 15q11.2-15q12. In 7 patients (19.4%) CNVs were located in 15q12. Five of them harbored microduplications in GABRG3 gene, 1 patient showed microduplication in GABRB3 gene and in 1 patient both rearrangements were present. Aberrations in 15q11.2 region were observed in 2 patients. One of them was a 0.161 Mb deletion, including SNURF/SNRPN upstream reading frame. In the other patient, a 2.608 Mb duplication covering 36 genes was revealed. Genomic region on 15q11-13 is involved in many clinically important rearrangements. These include aberrations of various sizes which can affect the neuronal differentiation by disrupting normal epigenetic control and gene expression. All Bulgarian patients with CNVs harboring 15q12 shared a common clinical phenotype of severe ID, speech impairment or complete lack of speech, different types of seizures, facial dysmorphisms, microcephaly and behavior abnormalities of the autistic spectrum. In contrast, the two patients with 15q11.2-rearrangements displayed different clinical characteristics and milder forms of mental retardation. Our results are in line with the central role of GABAergic systems in ID and epilepsy. Further studies are needed to investigate the parental origin and elucidate the effect of the CNVs and the phenotype-genotype correlations. We describe the characterization of a gene for mild non-syndromic autosomal recessive intellectual disability (ID) in two unrelated families, one from Austria, the other from Pakistan. Genome-wide single nucleotide polymorphism (SNP) microarray analysis enabled us to define a region of homozygo-

sity-by-descent (HBD) on chromosome 17q25.1. Whole exome sequencing and analysis of this region in an affected individual from the Austrian family identified a 5bp frameshifting deletion in the *METTL23* gene. By means of Sanger sequencing of *METTL23*, a nonsense mutation was detected in a consanguineous ID family from Pakistan for which homozygosity-by-descent mapping had identified a region on 17q25. Both changes lead to truncation of the METTL23 protein, which disrupts the predicted catalytic domain and alters the cellular localization. 3D-modelling of the protein indicates that METTL23 is strongly predicted to function as a S-adenosyl-methionine (SAM)-dependent methyltransferase. Expression analysis of METTL23 indicated a strong association with heat shock proteins, which suggests that these may act as a putative substrate for methylation by METTL23. A number of methyltransferases have been described recently in association with intellectual disability. Disruption of METTL23 presented here supports the importance of methylation processes for brain function and development.

Targeted next generation sequencing in a new cohort of 996 individuals with Intellectual Disability

D. Grozeva[1], *K. Carss*[2], *O. Spasic-Boskovic*[1], *Z. Hussain*[1], *Y. Xu*[1], *A. Hackett*[3], *M. Field*[4], *J. Gecz*[5], *A. Renieri*[6], *M. I. Tejada*[7], *J. Floyd*[2], *U. K10K Consortium*[2], *M. Hurles*[2], *F. L. Raymond*[1];
[1]*Department Medical Genetics, University of Cambridge, Cambridge, United Kingdom,* [2]*The Wellcome Trust Sanger Institute, Cambridge, United Kingdom,* [3]*Genetics of Learning Disability Service, Hunter Genetics, Waratah, Australia,* [4]*Department of Medical Genetics,* Royal North Shore Hospital , St. Leonards, Australia, [5]Women's and Children's Hospital, The University of Adelaide, Adelaide, Australia, [6]Genetica Medica, Università degli Studi di Siena e Azienda Ospedaliera Universitaria Senese Policlinico "Le Scotte", Siena, Italy, [7]Molecular Genetics Laboratory, Department of Genetics, BioCruces Health Institute, Cruces University Hospital, Plaza de Cruces s/n, 48903, Barakaldo, Spain.

We screened DNA from 996 individuals with Intellectual Disability (ID) for variants in known genes and candidate genes for ID in order to identify the cause of disease. Overall, we investigated the coding sequence of 565 candidate genes in individual cases affected with moderate to severe ID.
We observed 8225 non-synonymous variants passing quality control criteria and frequency filter (<1% in internal and population controls). The rate of loss of function (LoF) variants (frameshift, nonsense or canonical splice site) was 0.43 per person. Overall, we have identified pathogenic LoF mutations in 11% of the cases (110 out of 996) affecting known genes previously reported to harbour mutations causing ID. LoF mutations in ATRX, CC2D2A, ARID1B and CUL4B were the most commonly observed (frequencies varied from 0.4% to 0.6%). The interpretation of the vast number of missense mutations in known genes proved to be more challenging, as rarity of variant is insufficient to assign pathogenicity in such a genetically heterogeneous phenotype.
Although the cohort consisted of predominantly non-syndromic ID cases, the yield of mutations in genes associated with a syndromic phenotype was high, for example, ATRX, CC2D2A, CHD7 and ARID1B. This suggests that the distinction between syndromic and non-syndromic ID is an increasingly artificial concept in a genotype-driven diagnostic era.

Next Generation Sequencing offers the opportunity to identify new mutations and increasing the proportion of patients with ID receiving a genetic diagnosis. We have analyzed a cohort of 102 adult patients affected by ID, psychiatric diseases and minor dysmorphic features, identifying a genetic cause of ID in 28 (27,5%). We recruited 9 trio cases negative for fragile X syndrome, chromosomal and subtelomeric rearrengements and pathogenic copy number variants. The exome was captured with Agilent sure select technology, multiplexed, and sequenced in an Illumina HISeq2000 lane. Potential damaging variants detected were selected and filtered (condel score, EVS, 1000genomes, dbSNP). Variants were finally confirmed by Sanger sequencing. We detected an average of 8624 non-synonymous variants in the cases, of which an average of 23 were de novo. Frequency and functionality based filtering reduced the number of potential candidate ID genes harbouring de novo variants to 1-10 per case. In 5 cases, potential disease-causing variants were identified in genes previously implicated in ID syndromes: One case was compound heterozygous for two RPGRIP1L rare missense variants, two cases carried a de novo mutation in (an in-frame deletion in UBE3A and a missense variant in MLL), one familial case was carrying a rare variant in TCF4 and in the last case a frameshift deletion was identified in SATB2. Two cases were compound heterozygous for two very rare or novel variants in two different potential ID candidate genes, and in the remaining two cases, no candidates were identified. Work supported by FIS grants: PI080778 and PI10/01710.

P08.40-M
The degree of Intellectual Disability is significantly associated with an excess of Runs of Homozygosity (ROH)

I. Gandin[1,2], *F. Faletra*[2], *M. Carella*[3], *V. Pecile*[2], *G. Ferrero*[4], *E. Belligni*[4], *P. Palumbo*[3], *O. Palumbo*[3], *P. Bosco*[5], *C. Romano*[5], *C. Belcaro*[1], *D. Vozzi*[2], *A. P. d'Adamo*[1,2];

Several recent studies focused on the effect of extended homozygosity on highly complex and polygenic traits where recessive inheritance may play an important role. Since excess of homozygosity might increase the risk for disorders like schizophrenia, Alzheimer disease and autism, we have set out a study to investigate the effect of ROHs on the degree of Intellectual Disability (ID). About 370 unrelated individuals with ID were collected and classified into mild/moderate ID (MM-ID) for IQ ranging from 35-40 to 70-75 and severe/profound ID (SP-ID) for IQ below 35-40. High-density SNP array data were processed with the aim of detecting and analyze ROHs. Since different array platform were used, homozygosity and ROHs mean length were compared in MM-ID vs SP-ID separately in each dataset. Results were then combined for a meta-analysis. Our data revealed an association between the amount of homozygosity and the degree of ID, according to the recent findings on autism (Gamsiz et al., 2013). Accounting for principal components to control population stratification, we tested for ROHs mean length and detected significantly ($p<0.005$) longer stretches in SP-ID compared to MM-ID. Weaker association was detected in burden ROH analysis, showing an increase of the percentage of genome covered by ROHs for SP-ID cases. Extent of ROHs seems to contribute to the pathogenesis of ID, suggesting that autosomal recessive variants have a crucial role on the modulation of the severity of ID that still need to be investigated.

P08.41-S
A familial interstitial 14 Mb deletion of 5p13p14 associated with a mild phenotype challenges the current genotype-phenotype correlation attributed to the MR III region

K. Steindl[1], *B. Oneda*[1], *R. Baldinger*[1], *P. Joset*[1], *P. Hunkeler*[2], *A. Rauch*[1];
[1]*Institute of Medical Genetics, University of Zurich, Zurich, Switzerland,* [2]*Children's Hospital, Department of Developmental Paediatrics, Zurich, Switzerland.*

Varying degrees of developmental delay or intellectual disabilities and dysmorphic features appear to be strongly associated with deletions involving 5p. Most of these deletions are associated with cri du chat syndrome. These deletions can be terminal, interstitial, or associated with complex chromosomal rearrangements. To establish the genotype-phenotype of 5p deletions many efforts had be done in the last years in dissecting the phenotype and three different critical regions had been determined. But there had been controversaries about the relationship between MR and deletions of MRI-II encompassing bands 5p13.2p14.3. Deletions limited to this region were reported to show no phenotype, but to aggravate the phenotype in case of accompanying aberrations (Zang X., et al. 2005). We now observed a novel 3- generation family with a interstitial deletion del(5)(p13.2p14.3) limited to MRIII without additional rare CNVs in microarray testing. The index patient, a 15 years old girl, showed learning disability (IQ 75), microcephaly, high pitched voice and a subtle facial phenotype. The patients mother and grandmother had the same deletion and likewise the learning disabilities, the high pitched voice and subtle facial features, but no microcephaly. In contrast to the current literature we therefore propose that deletions limited to the MRIII region have a mild, but distinct phenotype with particular emphasis on the high pitched voice.

P08.42-M
Inverted triplication of 7q11.22 embedded within the 7q11.21q11.23 duplication segment in a child with stigmata dysplastica, developmental and speech delay

T. Hovnik[1], *J. Kovač*[1], *S. Bertok*[2], *M. Avbelj Stefanija*[2], *M. Volk*[3], *L. Lovrečič*[3], *D. Neubauer*[4], *T. Battelino*[2];
[1]*Center for Medical Genetics, University Children's Hospital, Ljubljana, Slovenia,* [2]*Department of Pediatric Endocrinology, Diabetes and Metabolic Diseases, University Children's Hospital, Ljubljana, Slovenia,* [3]*Clinical Institute of medical Genetic, UMC, Ljubljana, Slovenia, Ljubljana, Slovenia,* [4]*Department of Child, Adolescent & Developmental Neurology, University Children's Hospital, Ljubljana, Slovenia.*

Introduction: A q-arm of human chromosome 7 harbours many copy number variants (CNV) with known pathogenic significance. Chromosome 7q11.23 duplication syndrome (OMIM#609757) is a multisystem develop-

mental disorder with mild craniofacial anomalies and increased incidence of congenital anomalies. Williams-Beuren syndrome (WBS; OMIM#194050) is caused by ~ 1.8-Mb hemizygous deletion on chromosome 7q11.23. WBS triplication syndrome with similar but more severe clinical features has been also described.

Case presentation: We present a 3-years-old boy with developmental and severe speech delay, dysmorphic signs, bilateral cryptorhidism and hypoplasic corpus callosum. Cytogenetic and molecular analysis revealed a complex de novo chromosomal rearrangement which we characterize as inverted triplication of 7q11.22 segment embedded within larger 7q11.21q11.23 duplication.

Methods and results: Molecular characterization by array-CGH revealed a 1.93-Mb duplication of segment 7q11.21, 5.27-Mb triplication of segment 7q11.21q11.22 and 1.33-Mb duplication of segment 7q11.23. Further molecular cytogenetic investigation was performed with multiple combinations of specific FISH probes. Metaphase and interphase FISH confirmed the location of triplication 7q11.22 segment within the 7q11.21q11.23 duplication. Additional FISH analysis revealed that triplicated 7q11.22 segment on derivative chromosome 7 was inverted. Parental cytogenetic analysis demonstrated de novo origin of this complex chromosomal rearrangement.

Conclusions: Although chromosomal imbalances are the major cause of developmental delay, large de novo CNVs are relatively rare events. We have identified a novel complex rearrangement on chromosome 7, duplication with embedded inverted triplication also known as DUP-TRP/INV-DUP structure. Triplication of segment 7q11.22 is probably generated by long range inverted repeats which still need to be identified.

Identification of novel variants in PIGQ, PGAP3 and PIGY further implicate the GPI pathway in the pathogenesis of neurodevelopmental abnormalities

A. T. Pagnamenta[1], *H. Martin*[1], *M. F. Howard*[1], *A. Goriely*[1], *Y. Murakami*[2], *K. Hudspith*[1], *C. Anzilotti*[1], *S. J. L. Knight*[1], *H. Stewart*[3], *E. Blair*[3], *T. Kinoshita*[2], *P. Donnelly*[1], *J. C. Taylor*[1], *U. Kini*[3];

[1]*University of Oxford, Oxford, United Kingdom,* [2]*Osaka University, Osaka, Japan,* [3]*Oxford University Hospitals NHS Trust, Oxford, United Kingdom.*

Around 30 genes are required for glycosylphosphatidylinositol (GPI) biosynthesis. Mutations in many of these are reported to cause a spectrum of neurodevelopmental abnormalities. Here we describe novel mutations in three members of this pathway.

Whole genome sequencing was applied to a sporadic patient with severe early-onset epilepsy. This approach identified a homozygous *PIGQ* splice mutation, resulting in exon skipping and defective GPI biosynthesis. Additionally, autozygosity mapping and exome sequencing were combined to investigate two consanguineous Pakistani families where multiple affected individuals presented with intellectual disability and microcephaly. In the first family, seizures were present in 2/3 affected individuals. A homozygous p.G92D mutation was detected in *PGAP3* that co-segregated with disease. Affected individuals had elevated alkaline phosphatase, a marker for defective GPI biosynthesis. Functional studies using CHO cells confirmed the mutation influenced GPI-anchor remodelling. For the second family, the concurrent release of ENCODE data prompted us to examine UTR variants and a c.-540G>A variant was detected in *PIGY* which co-segregated with disease. Disruption of an SP1 binding motif suggested that the variant might influence gene expression. IonTorrent sequencing confirmed that in heterozygote carriers ~9% of transcripts were expressed from the mutant allele.

Our work strengthens the role of the GPI pathway in the pathogenesis of neurodevelopmental abnormalities. Although *PIGQ* and *PIGY* both encode subunits of N-acetylglucosaminyltransferase, the range of phenotypes seen in the families described recapitulates the pleiotropic effects of defective GPI biosynthesis as a whole. This study also highlights the importance of assessing UTR variants during analysis of exome data.

P08.44-M

Careful consideration is necessary in *MECP2* testing and allele drop out

E. Bettella, *R. Polli, E. Leonardi, A. Murgia;*

Laboratory of molecular genetics of neurodevelopment, Department of Women's and Children's Health, Padua, Italy.

Allele drop out (ADO) leads to the preferential amplification of one of two allele due a series of reasons among which the occurrence of sequence mismatch within a primer-binding site or a complex DNA motif. The drop out can cause false results during PCR amplification and be responsible of potential pitfall in diagnosis. It is known that genomic DNA sequences can assume different complex secondary structures which can prevent DNA replication and transcription and, if altered by mutations, may be responsible of ADO events in PCR amplification. An example of these genomic DNA motifs are repetitive guanine-rich sequences, known as G-quadruplexes, on one strand and the complementary cytosine-rich sequences on the opposite strand, known as i-motifs. G-quadruplexes and i-motifs are present within the coding sequence of the *MECP2* gene.

Here, we report a case of ADO detected during *MECP2* molecular analysis in two unrelated patients with Rett syndrome. In both girls, the mutations were in exon 4 of the *MECP2* gene (c.1137delC and c.1151_1201del50; c.1163C>T) and were detected as seemingly homozygous. The mutations are located in the *MECP2* WW binding domain and fall in a region where a number of small deletions/single point mutations have been reported in literature.

Under the assumption of ADO, we have investigated the presence of the wildtype allele with a change in PCR condition and the primers.

We prove that the complexity of exon 4 sequence leads to allele amplification failure and that allele drop out is a technical risk in *MECP2* molecular analysis.

Xq28 duplications encompassing MECP2 have been described in male patients with a severe neurodevelopmental disorder associated with hypotonia and spasticity, severe learning disability, stereotyped movements and recurrent pulmonary infections. We report on standardized brain magnetic resonance imaging (MRI) data of 30 affected patients, including 5 symptomatic females, carrying a MECP2 duplication, the size of which varied between 228 kb and 11.7 Mb. The aim of this study was to compare brain MRI results to seek recurrent malformations and attempt to determine whether variations in imaging features could be explained by differences in the size of the duplications. We showed that 90% of patients had brain MRI abnormalities, and that they shared certain non-specific brain malformations such as corpus callosum abnormalities (n=20), ventricular dilatation (n=9), reduced volume of the white matter (WM) (n=12), increased T2 signals in posterior periventricular WM (n=6), and vermis hypoplasia (n=5). The occipito-frontal circumference could be highly variable since it was >+2DS in 5 patient and <-2DS for 4 patients. Among the 9 patients with dilatation of the lateral ventricles, 6 (67%) had a duplication involving L1CAM. The only patient harbouring bilateral posterior subependymal nodular heterotopia also carried a FLNA gene duplication. We could not demonstrate a link between periventricular WM hypersignals / delayed myelinisation and duplication of IKBKG. These results show that patients with MECP2 duplications share certain common but non-specific brain abnormalities. These imaging features, therefore, do not constitute a diagnostic clue. We did not clearly demonstrate a genotype-imaging phenotype correlation.

We report the case of a 12 years old boy admitted to our observation in

the first year of life with severe neonatal encephalopathy. Since birth, the clinical conditions have been worsening during time. Now he shows severe mental retardation, dysmorphic features, extreme generalized hypotonia, white matter leucomalacia, drug-resistant epilepsy, blindness, genitourinary and gastrointestinal abnormalities, generalized joint laxity and recurrent respiratory tract infections. High resolution karyotype was normal. Subtelomeric FISH probes identified a derivative 9 of an unbalanced translocation t (9p;Xq) with monosomy 9p and Xq disomy. FISH studies of the parents revealed that the alterations were de novo in the patient. Array CGH was performed and identified two rearrangements: a 6Mb deletion on chromosome 9 from p24.3 to p24.1 and a 5Mb duplication on chromosome X from q28 to qter. This double rearrangement has never been described in literature. Our patient presents urogenital birth defects, facial dysmorphism (possibly due to the 9p deletion) and developmental regression, axial hypotonia, Hirschsprung disease, feeding difficulties, recurrent infections, epilepsy, absence of language, white matter disease (typically related to the Xq28 duplication). Several genes, included in the deleted (KANK1, DMRT1, SLC1A) and in the duplicated region (MeCP2, L1CAM), are known to have an important role in the Central Nervous system development. This report allows to compare the phenomics of our patient to the other cases described in literature, to contribute to the knowledge about genotype-phenotype correlation and to provide new informations for future studies about the 9p24.3-pter and Xq28-qter regions and the genes included.

Exome sequencing identifies candidate gene for MEHMO syndrome

M. Skopkova[1], *D. Stanikova[1,2], K. Brennerova[2], J. Ukropec[1], D. Danis[1], M. Novotova[3], L. Ticha[2], T. Kurdiova[1], B. Ukropcova[1], J. Stanik[1,2], I. Klimes[1], D. Gasperikova[1];*
[1]Diabgene & Diabetes Laboratory, Institute of Experimental Endocrinology SAS, Bratislava, Slovakia, [2]First Department of Pediatrics, School of Medicine, Comenius University, Bratislava, Slovakia, [3]Institute of Molecular Physiology and Genetics SAS, Bratislava, Slovakia.

The patient is a 3,5 years young boy suffering from severe psychomotor delay, microcephaly, epilepsy, and multiple endocrine disorders (i.e. obesity, diabetes, hypogenitalism, and partial deficiency of pituitary hormones). There are no other living male members in the mother's family, as mother's brother and grandmother's brother died in the first months of life. The clinical picture and family history indicated towards the MEHMO syndrome, an X-linked disease which has been described in three families only.
Exome sequencing of proband's DNA revealed 23 previously unreported variants on X chromosome as confirmed also by Sanger sequencing. Haplotype analyses showed only 3 of them to be shared with proband's mother and his mother's mother. Only one of them, a variant in EIF2S3 gene, is in the region of X-chromosome previously described to be associated with MEHMO syndrome. EIF2S3 encodes a γ subunit of eukaryotic translation initiation factor 2 (eIF2) that is responsible for transporting the initiator Met-tRNAiMet to the 40S ribosomal subunit. Point mutations in this gene were previously described in two families with intellectual disability. The variant found in the patient is a frame-shift mutation with premature stop codon influencing 8 last amino acids of the protein. In-sillico analyses evaluate this change as disease causing.
Our results support the role of EIF2S3 as a candidate gene, disruption of which might significantly contribute to this severe clinical symptomatology.

New insights on cognitive and structural brain imaging phenotype in primary microcephaly due to ASPM mutations

s. passemard[1], *m. Schaer[2], M. Laurent[1], K. Hernandez[1], O. Boespflug Tanguy[1], T. Billette de Villemeur[3], M. Elmaleh[1], P. Gressens[4], A. Verloes[1], S. Eliez[1];*
[1]hopital robert debré, paris, France, [2]Service Médico-Pédagogique, Département de psychiatrie, Université de Genève, geneve, Switzerland, [3]hopital Trousseau, paris, France, [4]Inserm U1141, hopital robert debré, paris, France.

Primary recessive microcephaly (MCPH) caused by ASPM mutations is a model of abnormal brain development linked to neural progenitors proliferation defects. MCPH is defined as a homogenous reduction of cerebral volume principally affecting the cortex. The reduction of brain volume has been correlated to cognitive disabilities. However, correlation between cognitive functions and structural brain phenotype has not yet been well established in genetic microcephalies. Here, we provide evidence that specific cognitive functions are preserved in ASPM-related patients and this is correlated with their structural brain changes. General intelligence, memory scales and structural brain magnetic resonance imaging scans were acquired from 6 ASPM-related patients. Using cranial MRI, we measured the volume of the different brain structures and focused on the analyze of the cortical volume, surface and thickness. These microcephalic patients have a normal mnesic functioning and preserved hippocampal volume compared to other cortical areas. Unlike most previous data that linked microcephaly to mental retardation, these findings suggest i) that these microcephalic ASPM-related patients are able to learn despite their cognitive disabilities and ii) that other master genes than ASPM are necessary for the development of hippocampus formation and function.

P08.49-S
Microduplication 17q12 in a patient with microcephaly and moderate psychomotor delay

M. R. Sanso'[1], *M. H. N. Contri[2], A. Fratoni[3], A. Castiello[4], M. Ferrari[5], F. Raviglione[6], F. Di Nuovo[1];*
[1]Pathology and Cytogenetics Unit , G. Salvini Hospital, Garbagnate Milanese, Italy, [2]Child Neuropsychiatry , G. Salvini Hospital, Garbagnate Milanese, Italy, [3]Pediatrics Unit, G. Salvini Hospital, Rho, Italy, [4]Diagnostica e Ricerca San Raffaele, Milano, Italy, [5]Università Vita-Salute San Raffaele, Milano, Italy, [6]Child Neuropsychiatry Unit, G.Salvini Hospital, Rho, Italy.

17q12 microduplication is a very rare genomic rearrangement associated with a variable phenotype, consisting of intellectual disability/developmental delay of various degree, epilepsy, behavioral problems, brain abnormality, esophageal atresia, renal, heart and ocular anomalies.
We report a case of a 9 years-old boy born from no consanguineous healthy parents.
Array-CGH analysis has revealed a 1,8 Mb de novo microduplication of chromosome region 17q12 : arr[hg19]17q12 (34,906,638-36,756,170)x3 dn
The proband presents microcephaly without dysmorphic features, moderate mental retardation, language delay, learning disabilities and impulsive behavior. Brain Magnetic Resonance is normal. EEG shows multifocal spikes and waves.
The microduplication extends from gene GGNBP2 to gene SRCIN1 and encompasses 20 genes in 17q12.
The neurologic phenotype seems to be associated with gene LHX1. Lhx1 is expressed in the brain and is implicated in Purkinje cell differentiation in the developing cerebellum as well as in migration of motor axon to the limbs. Lhx1 knockout mice shows anencephaly. These data support the hypothesis that LHX1 is a dosage-sensitive gene, involved in neurological phenotype of patients with 17q12 microduplication. Additional studies are needed to further delineate the phenotypic impact of expression of this gene.
Clinical features of this syndrome may depend on the size of microduplication variable for different breakpoints, the insertion site and/or orientation of duplicated fragment in the genome as well as additional genetic factors such as incomplete penetrance. The survey of this case contributes to extend the correlations among the phenotype and the genotype of this peculiar syndrome.

Syndromic intellectual disability diagnosis by combined use of MLPA kits

C. Rusu[1], *R. Popescu[1], M. Gramescu[1], E. Braha[1], L. Butnariu[1], M. Panzaru[1], A. Sireteanu[2];*
[1]University of Medicine and Pharmacy, Iasi, Romania, [2]Children's Hospital, Iasi, Romania.

Intellectual disability (ID) is a common disorder, with major consequences for individual, family and society. Due to clinical and genetic heterogeneity, in about 50% of cases an etiologic diagnosis cannot be established. The aim of this study was to evaluate the ability of a combination of MLPA kits to establish the diagnosis in 380 patients with syndromic ID. All patients were assessed for chromosome imbalance using standard karyotype and MLPA analysis using SALSA P064 or P096 kit, if the phenotype was suggestive for a microdeletion syndrome (subgroup A - 188 patients), or subtelomeric kits, if the phenotype was not suggestive for a microdeletion syndrome (subgroup B – 192 patients). Abnormal results detected by both MLPA kits were further characterized using appropriate follow-up MLPA kits (Telomere Follow-up set, P029-B1, P250-B2). In subgroup A we identified 27 patients with microdeletions (14.3%). In subgroup B 8 patients showed an aberrant telomeric signal detected by only one of the two MLPA kits, 31 patients showed abnormal results detected by both MLPA kits (~16%), and 153 patients had normal results. In summary, the combined use of MLPA kits led to the diagnosis in 58 out of 380 patients (15.2%). The use of follow-up MLPA kits allowed us both to confirm abnormalities and to determine their size, which facilitated the interpretation of the clinical significance of these rearrangements. For laboratories that do not have yet access to microarray technology, using several MLPA kits represents an effective strategy for establishing the diagnosis in ID patients.

P08.51-S
Expanding the phenotype of a recurrent *de novo* Mutation in *PACS1*

D. Bartholdi[1], *D. Gadzicki[2], D. Döcker[1], M. Menzel[3], B. Schmorl[2], M. Schubach[3], F. Stellmer[4], S. Biskup[1,3];*
[1]Institute of Clinical Genetics, Stuttgart, Germany, [2]Endokrinologikum, Hannover,

Germany, [3]CeGaT, Center for Genomics and Transcriptomics, Tübingen, Germany, [4]genteQ, Hamburg, Germany.

The PACS (phosphofurin acidic cluster sorting) proteins represent a family of multifunctional membrane traffic regulators that mediate organ homeostasis. Recently, exome sequencing revealed identical *de novo* mutations in *PACS1* in two unrelated individuals with intellectual disability and remarkably similar facial features (Schuurs-Hoeijmakers et al. *AJHG* 2012). Functional experiments indicated that the mutation exerts a dominant-negative effect by affecting the ability of PACS1 to mediate the specification and migration of SOX10-positive cells in the neural crest.

Here, we describe a third patient carrying the identical heterozygous *de novo* missense mutation c.607C>T; p.R203W in exon 4 of *PACS1* (NM_018026.3). The patient is a 2 year-old boy with developmental delay, congenital heart defect (atrio-ventricular septal defect), low levels of immunoglobulins and borderline microcephaly. His facial features are strikingly similar to the two patients described by Schuurs-Hoeijmakers et al.: He has hypertelorism, long eyelashes, downslanting palpebral fissures, a wide mouth with thin upper lips, downturned corners and a flat philtrum. His ears are low-set and rotated.

The combination of his features (congenital heart defect, hypotonia, developmental delay, facial dysmorphisms) initially prompted us to analyse the genes of the RAS/MAPK pathway. However, this did not lead to establishing a diagnosis. Finally, exome sequencing revealed the previously described *de novo* missense mutation in *PACS1*.

In summary, the recurrent *de novo* mutation c.607C>T; p.R203W in *PACS1* causes a phenotype characterized by developmental delay/intellectual disability, variable organ malformations and highly recognisable facial features.

P08.52-M

Whole exome sequencing approach to reveal the genetic aspects of extreme phenotypic variability of Incontinentia Pigmenti

M. I. Conte[1], *M. Paciolla[1], A. Pescatore[1], E. Esposito[1], I. Agliata[1], M. B. Lioi[2], M. G. Miano[1], M. V. Ursini[1], F. Fusco[1];*

[1]Institute of Genetics and Biophysics 'Adriano Buzzati-Traverso', IGB-CNR, Naples, Italy, [2]University of Basilicata, Potenza, Italy.

Incontinentia pigmenti (IP, MIM308300, 1/10.000) is an X-linked dominant neuroectodermal disease associated with skin defects and with extracutaneous manifestation (ocular, dental, hair, nail and central nervous system_ CNS defects) at variable frequency. In 30% of IP patients CNS anomalies (seizures, encephalopathy, encephalomyelitis, ischemic stroke) are reported. IP patients carry a mutation in the IKBKG/NEMO gene (IKBKG/Nuclear Factor kappaB, Essential MOdulator) that encodes for NEMO/IKKgamma regulatory protein of the IKK complex, required for the activation of the canonical NF-kappaB pathway. We collected a large cohort of IP patients with an high variability of clinical phenotype. A variable CNS defect was observed, even in IP families with the identical NEMO mutation. The skewed X-chromosome inactivation could only partially explain this variability thus modifier loci may contribute to the severity of IP phenotype. Here we present an IP trios-family with both child and mother with NEMOdel4_10 deletion: in the mother only skin defects were present, in the child also a severe mental retardation with neuromuscular defects were reported. We have designed an exome-sequencing approach to identify the modifier genes. From exome-enriched library and sequencing a list of single nucleotide/indels variants were produced. We will present candidate genes selected by applying combined filtering method to exclude benign and inherited variants and prioritizing the genes implicated in well-established pathways associated to NF-kB and neurogenesis. The identification of modifier genes able to influence the severity of IP phenotype will be useful to anticipate the outcome of the IP disease in order to apply a personalized therapeutic iter.

P08.53-S

NGS based whole X-exome analysis reveals a familial WDR45 missense mutation in 3 males with intellectual disability and brain iron accumulation

A. Dufke[1], *U. Grasshoff[1], C. Dufke[1], V. Kalscheuer[2], C. Schroeder[1], S. Beck-Wödl[1], A. Tzschach[1], T. Nägele[3], O. Riess[1], P. Bauer[1], I. Krägeloh-Mann[4];*

[1]University of Tübingen, Institute of Medical Genetics and Applied Genomics, Tübingen, Germany, [2]Max Planck Institute for Molecular Genetics; Department of Human Molecular Genetics, Berlin, Germany, [3]University of Tübingen, Department of Neuroradiology, Tübingen, Germany, [4]University Children's Hospital Tübingen, Paediatric Neurology and Developmental Medicine, Tübingen, Germany.

X-exome sequencing in an adult male patient with intellectual disability, epileptic seizures during childhood and otherwise normal somatic development revealed a novel missense mutation c.698G>A; p.R233H at a highly conserved position in WDR45 (Xp11.23). Segregation analysis confirmed the presence of the mutation in his two similarly affected younger monocygotic twin brothers and their healthy mother with skewed X-inactivation (15:75). The mutation could be excluded in the maternal grandfather and both healthy maternal uncles of the patients. De novo mutations in the autophagy gene WDR45 have been previously described in patients with BPAN (beta-propeller protein-associated neurodegeneration), a recently established subtype of neurodegeneration with brain iron accumulation (NBIA). Mutations in WDR45 have been associated with an X-linked dominant form of NBIA, predominantly affecting females and presumed to be nonviable in males with germline mutations. Similar phenotypes in few reported males and females have been attributed to somatic mosaicism in surviving males and skewing of X-inactivation of females. A retrospective evaluation of brain MRI in the index patient at the age of 10 years was not suspicious for iron deposition. Axial MR images (mesencephalon) at the age of 19 years show clear hypointensity of the substantia nigra on T2w images and also on T2*, indicative of pathological iron accumulation. The primary developmental delay and stable course of the disease until young adulthood and transmission of the mutation via a healthy carrier expends the clinical spectrum of the WDR45 associated phenotype in X-linked intellectual disability.

P08.54-M

TRPC5 et KLHL15 are candidate genes for X-linked intellectual disability

N. Philip[1,2,3], *C. Mignon-Ravix[1,2], P. Cacciagli[1,2,3], N. Choucair[1,2,4], C. Missirian[3], M. Milh[1,2,5], A. Mégarbané[1,2,4], T. Busa[3], S. Julia[6], N. Girard[2,7], C. Badens[1,2,3], L. VILLARD[1,2];*

High-resolution array comparative genomic hybridization (a-CGH) enables the detection of intragenic rearrangements, such as single exon deletion or duplication. This approach can lead to the identification of new disease genes. We report the analysis of 54 male patients presenting with intellectual deficiency (ID) and a family history suggesting X-linked (XL) inheritance or maternal skewed X-chromosome inactivation (XCI), using a home-made X-chromosome specific microarray covering the whole human X-chromosome at high resolution. The majority of patients had whole genome array-CGH prior to the selection and we did not include large rearrangements such as MECP2 and FMR1 duplications. We identified 4 rearrangements considered as causative or potentially pathogenic, corresponding to a detection rate of 8%. Two CNVs affected known XLID genes and were therefore considered as causative (IL1RAPL1 and OPHN1 intragenic deletions). Two new CNVs were considered as potentially pathogenic as they affected interesting candidates for ID. The first CNV is a deletion of the first exon of the TRPC5 gene, encoding a cation channel implicated in dendrite growth and patterning, in a child presenting with ID and an autism spectrum disorder (ASD). The second CNV is a partial deletion of KLHL15, in a patient suffering from severe ID, epilepsy and anomalies of cortical development. In both case, in spite of strong arguments for clinical relevance, we were not able at this stage to confirm pathogenicity of the mutations and the causality of the variants identified in XLID remains to be confirmed

P08.55-S

Central nervous system developmental disorder in Noonan syndrome: a genomic approach

G. Baldassarre[1], *M. Crippa[2], F. Dutto[1], I. Bestetti[2,3], A. Mussa[1], A. Sironi[2], C. Molinatto[1], M. Cirillo Silengo[1], P. Finelli[2,3], G. B. Ferrero[1];*

[1]Department of Pediatrics, Torino, Italy, [2]Laboratory of Medical Cytogenetics and Molecular Genetics, Milano, Italy, [3]Department of Medical Biotechnology and Translational Medicine, University of Milano, Milano, Italy.

Noonan syndrome (NS – OMIM 163950) is a multisystemic dominant disorder with a prevalence of 1/1000-1/2500 live births. It is clinically and genetically heterogeneous, with mutations in several genes of the RAS/MAPK pathway detectable in up to 75% of cases. Pathogenesis of central nervous system (CNS) developmental anomalies has not been thus far fully enlightened. We have applied the *multiple hit hypothesis* to study in deep the pathogenic mechanisms implicated in NS related CNS anomalies. In this oligogenic model, point mutations and genomic rearrangements cooperate in an additive manner in the pathologic development of CNS. Using array CGH technology, we analyzed 15 samples of selected patients with molecularly confirmed diagnosis of NS and a severe impairment of CNS. We found 37 rare CNVs (one/several per patient) most of them inherited from an healthy parent. According to the Database of Genomic Variants 12/37 were never reported and 25/37 were reported in very few cases. Based on the function of the genes mapping in the identified CNVs, 10/37 (27%) were probably involved in the pathogenesis of CNS anomalies observed in our patients. We provided first data supporting the hypothesis that CNS involvement in NS does not depend exclusively on single gene mutations but also on the

concurrent presence of other genomic penetrant variants. These results represent an initial assumption for the application of the *multi-hit hypothesis* in the dissection of the NS pathogenesis. Further studies on larger cohorts are deserved to better define the meaning and the clinical implications of these findings.

P08.56-M
NPAS3-related copy number variants: a role in developmental delay?

L. Badalato[1], *S. M. Nikkel*[1], *I. J. Anderson*[2], *M. P. Dinulos*[3], *S. E. Vallee*[4], *E. Baxter*[5], *J. McGowan-Jordan*[1], *J. A. Rosenfeld*[6], *C. M. Armour*[1];
[1]*Children's Hospital of Eastern Ontario, Ottawa, ON, Canada,* [2]*University of Tennessee Genetics Center, Knoxville, TN, United States,* [3]*The Geisel School of Medicine at Dartmouth, Hanover, NH, United States,* [4]*Dartmouth-Hitchcock Medical Center, Lebanon, NH, United States,* [5]*British Columbia Cancer Agency, Vancouver, BC, Canada,* [6]*Signature Genomic Laboratories, PerkinElmer, Inc, Spokane, WA, United States.*

Neuronal PAS domain-containing protein 3 (NPAS3) is a transcription factor expressed primarily in developing and adult brain tissues. Current evidence suggests it is involved in neuronal development and maturation, and it has recently been highlighted as potentially playing a key role in the evolution of the human brain. Clinically, NPAS3 has been identified as a candidate gene for schizophrenia, and numerous studies have supported this association. In addition, several cases of learning disabilities in patients with disruptions of this gene are reported, but this association remains relatively unexplored. Here, we present four unrelated individuals with small copy number variants (CNVs) within NPAS3: two intragenic duplications and two intragenic deletions. These CNVs range between 111-460kb in length and encompass exonic sequences within the NPAS3 gene. All four patients had variable degrees of developmental delay, and three had subtle distinctive facial features. Two patients also had macrosomia and macrocephaly, while the other two had autistic features and behaviour issues, including psychosis in one individual. In contrast, CNVs involving exonic sequences in NPAS3 have only been seen in one of over 19,000 controls. In summary, these four cases support an association between NPAS3 and developmental delay. This association is compatible with this gene's postulated effects on neuronal development, and suggests that abnormal function of NPAS3 may be implicated in other cases of non-specific cognitive impairment.

P08.57-S
A 9q21.3 microdeletion involving the NTRK2 gene as a possible cause of intellectual disability

E. Karásková, *M. Hančárová, A. Puchmajerová, J. Drábová, Z. Sedláček;*
Department of Biology and Medical Genetics, Prague, Czech Republic.

Microarray analyses identify new common copy number variants (CNVs) and microdeletion/microduplication syndromes. However, some CNVs are unique and no comparison with similar genotypes (and phenotypes) is available to assist in deciding about their causality.
We identified a twelve-year old stigmatized female patient with growth failure, microcephaly, severe psychomotor retardation, hypotonia, muscular atrophy, hip dislocation, foot deformity, vesicoureteral reflux and congenital heart disease. Her karyotype was normal. SNP array analysis (Illumina HumanCytoSNP-12) revealed a unique 1.7 Mb long deletion in 9q21.3 (chr9:86,595,071-88,357,495; hg19) flanked by segmental duplications. FISH analysis of the family confirmed that the aberration was de novo. It removed 5 protein-encoding RefSeq genes. The NTRK2 gene encodes a neurotrophin receptor involved in the regulation of brain development, neurotransmission and synaptic function. Therefore NTRK2 is a good candidate gene for intellectual disability (ID). A missense NTRK2 mutation has been described in a boy with ID and obesity, and NTRK2 was considered also in autism and other psychiatric disorders. The mouse homologue of another deleted gene, AGTPBP1, is associated with neurodegeneration.
Just one literature report exists describing a much more severely affected patient with a slightly larger deletion involving NTRK2. Remarkably, the deletion in our patient corresponds to an inversion described in several unaffected individuals. The presence of the inversion and segmental duplications at the breakpoints could indicate a specific mechanism predisposing to rearrangements. However, the inversion could not be identified in any of the parents of the patient.

P08.58-M
Co-occurrence of *TCF4* and *FOXG1* genes deletions in a 15-year-old girl

E. Kuchinskaya[1,2], *M. Rehnberg*[1], *M. Stefanova*[1];
[1]*Department of Clinical Pathology and Clinical Genetics, University hospital, Linköping, Sweden,* [2]*Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden.*

Both Pitt-Hopkins syndrome and a congenital variant of Rett syndrome are rare genetic syndromes with similar clinical features and development.
Here we report the first case of co-existence of Pitt-Hopkins syndrome and a congenital variant of Rett syndrome. A 15-year-old girl was born after a second uneventful pregnancy of healthy young non-consanguineous parents. Normal delivery and birth growth parameters (head circumference at the 10th percentile). Shortly after the birth the girl presented with hypotonia, poor sleep pattern, unexplained irritability and episodes of crying, delayed development and early closure of fontanel (at 3 months). During the infancy she developed absence seizures without EEG changes. At the age of 15 years she was found to have a postnatally developed microcephaly, seizures, ataxic gait, severe intellectual disability with absent speech, drooling, self-mutilation, and stereotypic behaviour. Patient's dysmorphic features were highly suggestive of Pitt-Hopkins syndrome: Deep set eyes, strabismus, prominent nasal bridge, wide mouth with everted lower lip, thenar hypoplasia, tapering fingers, fetal pads, and hypoplastic nails. MLPA analysis revealed a heterozygous deletion of exons 4b-6 of the *TCF4* gene and a heterozygous deletion of the *FOXG1* gene, both *de novo.* Chromosome analysis and SNP of the only exon array were normal. No changes were revealed by sequence analysis of *TCF4*.
We speculate that co-existence of two different gene mutations is not as exceptional as commonly thought in the field of monogenic disorders. Additionally, the contribution of each deletion to the phenotype is discussed.

P08.59-S
Exome sequencing reveals a rare TSEN54 mutation in an Iranian family with Ponto Cerebellar Hypoplasia

R. Jazayeri[1], *H. Hu*[2], *Z. Fattahi*[1], *L. Musante*[2], *T. Wienker*[2], *H. Ropers*[2], *H. Najmabadi*[1], *K. Kahrizi*[1];
[1]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Department of Human Molecular Genetics, Max-Planck Institute for Molecular Genetics, Berlin, Germany.*

Ponto Cerebellar Hypoplasia (PCH) is a heterogeneous group of autosomal recessive disorders characterized by an abnormally small cerebellum and brainstem. PCH type 2 (PCH2), the most frequently subtypes, is characterized by cerebellar hypoplasia affecting the hemispheres more severely than the vermis and progressive cerebral atrophy, microcephaly, dyskinesia, seizures progressive microcephaly from birth, extrapyramidal dyskinesia and dystonia. This study was designed to find the genetic defect in a consanguineous Iranian family with two affected children, by means of homozygosity mapping and exome sequencing. Clinical examination of the affected individuals in this family showed microcephaly and severe intellectual disability. Cerebellar hypoplasia in brain MRI was present in one affected individual. Linkage analysis with the use of Affymetrix Axiom® Array platformrevealed two promising intervals (LOD score 1.927) onchromosomes 17 and 20. Exome Sequencing with 96% at 20x depth of coverage in one affected individual, detected a previously rare known homozygous missense mutation in TSEN54 gene (c.371G>T, p.G124V) which was about 9 Mbps, located in the second interval on chromosome 17. Albeit this is a known mutation, but it is considered as a rare mutation in PCH patients. Co-segregation analysis of the identified mutation was confirmed with Sanger sequencing. This data shows that combination of homozygosity mapping and exome sequencing in populations with high rate of consanguinity could be applied as an efficient technique for molecular genetics practice of clinically and genetically heterogeneous diseases.

P08.60-M
Identified A Novel Mutation in CDK5RAP2 Gene in Iranian Family with Autosomal Recessive Primary Microcephaly Using Whole Exome Sequencing

S. Abedini[1], *L. Musante*[2], *H. Hu*[2], *M. Hosseini*[1], *Z. Fattahi*[1], *R. Jazayeri*[1], *T. Wienker*[2], *K. Kahrizi*[1], *H. Najmabadi*[1], *H. Ropers*[2];
[1]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Department of Human Molecular Genetics, Max-Planck Institute for Molecular Genetics, Berlin, Germany.*

Introduction:Autosomal recessive primary microcephaly (MCPH) is a congenital disorder caused by impaired neurogenic mitosis lead to defect in brain development. This disorder is heterogeneous genetically and characterized by reduced head circumference (-2 SD or more) under age and sex-based mean and mild to severe intellectual disability. So far, 12 genetic loci (MCPH1-12) with twelve corresponding genes (MCPH1, WDR62, CDK5RAP2,CASC5, ASPM, CENPJ, STIL,CEP135, CEP152, ZNF335,PHC1and CDK6) have been identified for this disease.Using whole-exome sequencing (WES) as a new pioneer technology and diagnostic tool, we can provide an opportunity for identifying the causal mutations with more efficient and cost-effectiveness in Iranian patients with autosomal recessive primary microcephaly. Case presentation:We report an Iranian family with two affected individuals with moderate intellectual disability, large toes and primary microcephaly with consanguineous marriage. We performed WES for one affected and focused

on genes associated with microcephaly and homozygous variants. We identified a homozygous novel frameshift mutation in CDK5RAP2 in the affected individual. Sanger sequencing confirmed the presence of the homozygous mutation in the other affected and heterozygous state for parents and normal siblings. Discussion:WES led to cost-effectiveness and rapid identification of novel frameshift deletion in CDK5RAP2 in Iranian family with primary microcephaly. We can facilitate genetic counseling for this family. To date, only five different mutations have been reported for CDK5RAP2 gene which most of them were from Pakistan. Moreover, this study implies that WES is a suitable diagnostic tool for identifying mutations responsible for MCPH families.

P08.61-S
New case of biallelic *TRMT10A* deficiency identified by exome sequencing confirms the associated phenotype of primary microcephaly with intellectual disability and short stature

M. Zweier *[1], *L. Gogoll* *[1], *P. Joset*[1], *M. Papik*[1], *O. Hasselmann*[2], *K. Steindl*[1], *A. Rauch*[1];
[1]*Institute of Medical Genetics, University of Zurich, Schlieren-Zurich, Switzerland,*
[2]*Department of Pediatric Neurology, Ostschweizer Kinderspital, St. Gallen, Switzerland.*

Recently a mutation in the *TRMT10A* gene was identified in a large consanguineous family of Moroccan origin defining a new syndrome of young onset diabetes, short stature and microcephaly with intellectual disability. By linkage analysis and exome sequencing a homozygous nonsense mutation was identified in all three affected siblings. The protein encoded by *TRMT10A* (also *RG9MTD2*), which was proposed to have tRNA methyltransferase activity, was shown to be ubiquitously expressed with enriched levels in the affected tissues brain and pancreatic islets and to be absent in lymphoblasts from the affected siblings. We now report a new case of biallelic *TRMT10A* deficiency in a girl born to apparently non-consanguineous parents of Kosovo origin. By exome sequencing in our patient we identified a homozygous nonsense mutation (c.379C>T) in the *TRMT10A* gene. Of note, this is the same mutation as recently reported, introducing a premature stop codon at position 127 of the protein. Our patient presented with primary microcephaly, intrauterine onset borderline growth, mild intellectual disability and fine motor problems, a high palate with uvula bifida and minor facial features such as long narrow face with narrow palpebral fissures, long thin nose and small mouth. At age 4 years a seizure disorder started. Notably, at age 8 years, our patient did not yet manifest diabetes, which was of adolescent onset in the previously described family. In conclusion, our report of a novel patient confirms the phenotype of the novel syndrome associated with biallelic *TRMT10A* deficiency including short stature and microcephaly with intellectual disability.

P08.62-M
Analysis of MECP2, CDKL5, and FOXG1 genes in Czech patients with Rett syndrome and Rett-like features

D. Zahorakova[1], *A. Puchmajerova*[1], *A. Baxova*[2], *P. Martasek*[1];
[1]*Department of Pediatrics, 1st Faculty of Medicine and General Teaching Hospital, Charles University in Prague, Prague, Czech Republic,* [2]*Institute of Biology and Clinical Genetics, 1st Faculty of Medicine and General Teaching Hospital, Charles University in Prague, Prague, Czech Republic.*

Background: Rett syndrome is a severe X-linked dominant neurodevelopmental disorder primarily caused by de novo MECP2 mutations. Clinical features include developmental regression at the age of 6-18 months, acquired microcephaly, autistic behavior, loss or severe impairment of speech and purposeful hand use, stereotypic hand movements, gait apraxia, and seizures. CDKL5 mutations have been identified in early-onset seizure variant and FOXG1 mutations in congenital variant of Rett syndrome. We report the results of mutation analysis of these genes in Czech patients with Rett syndrome and mental retardation with Rett-like features. **Materials and methods:** MECP2 was analyzed in 416 patients, CDKL5 was analyzed in 59 patients, and FOXG1 was analyzed in 20 patients. MECP2 and CDKL5 were analyzed by high-resolution melting analysis and DNA sequencing. FOXG1 was analyzed by DNA sequencing. Large deletions and duplications were analyzed by MLPA analysis (MRC-Holland). **Results:** Pathogenic mutations in the MECP2 gene in were identified in 45 patients with classic Rett syndrome, 7 patients with atypical Rett syndrome, 11 patients with Rett-like features, and 1 patient with autism. CDKL5 mutations were found in 2 patients with early-onset seizures and Rett-like phenotype. No FOXG1 mutation was detected in this study. **Conclusions:** MECP2 mutations are common in classic Rett syndrome patients, but they are less frequent in atypical or Rett-like phenotypes. However, analysis of MECP2 in these patients should not be discouraged. More patients should be examined to determine frequencies of CDKL5 and FOXG1 mutations in Czech Republic. Supported by grants NT 13120-4/2012, UNCE 204011/2012, MZCR RVO-VFN64165/2012.

P08.63-S
Ageing in Rett Syndrome: Characteristics of long term survivors reported through the British Isles Rett Syndrome Survey (BIRSS)

A. Hryniewiecka-Jaworska[1], *H. Archer*[2], **A. J. Clarke**[1];
[1]*Cardiff University School of Medicine, Cardiff, United Kingdom,* [2]*University Hospital of Wales, Cardiff, United Kingdom.*

We report what is known about the health and wellbeing of thirty women of at least 40 years with Rett syndrome (RTT). The study is based on longitudinal data from the British Isles Rett Syndrome Survey (BIRSS). These 30 women have a clinical diagnosis of RTT: 24 women of 40-49 years, five women of 50-59 years and one older woman of 64 years. Tweny nine women were diagnosed with classic RTT and one with atypical RTT (AR).
MECP2 mutations were identified in 14 of the 18 women tested. There were six missense mutations; one early truncating; two late truncating; three C-terminal deletions and two large deletions. A simplified Smeets severity score was calculated for every decade of the women's lives. Little increase in severity was observed and, for most, the severity rating was 'mild'.
Factors contributing to disease severity have been assessed. Findings include: (1) severity of phenotype is milder amomg older women, indicating survival advantage; (2) depression among middle-age RTT may be a substantial but under-recognised problem; (3) menopause does not seem to occur earlier than in other women; (4) nutrition standards from the general population will often be inapplicable; (5) multiple opportunities exist to prevent functional decline through detailed attention to the quality of the medical and social care.
There is a particular need to increase awareness of RTT amongst staff caring for older adults with disabilities so that they can identify and meet the needs of their adult patients with RTT.

P08.64-M
Italian brother and sister with familial Xp22.12 microduplication including RPS6KA3 gene and phenotype description

A. Fabretto, *P. Costa, F. Faletra, P. Gasparini, V. Pecile;*
Institute of Maternal and Child Health IRCCS Burlo Garofolo, Trieste, Italy.

RPS6KA3 gene is responsible of Coffin Lowry Syndrome, but recent studies have demonstrated that microduplication of this gene can cause nonsyndromic X-linked ID, ADHD and localization-related epilepsy. The RPS6KA3 gene encodes a member of the ribosomal S6 kinase family. RSK proteins are activated by MAPK proteins in response to growth factors, polypeptide hormones, and neurotransmitters. RSKs appear to have important roles in cell cycle progression, differentiation, and survival. Further studies have evidenced that the presence of a small amount of residual enzymatic activity may be sufficient to maintain normal osteoblast differentiation and has also been linked to cognitive performance, with higher level of intellectual function.
Our case describes a brother and a sister affected by intellectual disabilities, language delay and behavioural difficulties, with more severe clinical manifestations in the affected male. Both show some dysmorphic features as very large and long nose, mild hypotelorism and dental crowding. The boy performed some instrumental exams as cerebral NMR and CT, which didn't reveal any major cerebral malformation, but showed an absent pneumatisation of the sphenoid sinus, moreover no other skeletal abnormalities were found. No seizures were reported, except during pharmacological sleeping EEG, some low waves in the right frontal area were identified. The boy had previously performed some molecular exam as FMR1 and COH1 mutation screening and karyotype, all normal. We performed high density SNPs-array analysis, which revealed a 512 Kb microduplication on Xp22.12 (19.842.599-20.355.406) in both brother and sister. The duplication was inherited from the mother who is completely asymptomatic.

P08.65-S
Exploring the effect of adducins genetic variability on cognition in schizophrenia

M. Bosia[1,2], *A. Pigoni*[3], *L. Zagato*[4], *L. Merlino*[4], *N. Casamassima*[4], *C. Lorenzi*[1], *A. Pirovano*[3], *E. Smeraldi*[1], *P. Manunta*[4], *R. Cavallaro*[1];
[1]*San Raffaele Scientific Institute,Department of Clinical Neurosciences, Milan, Italy,* [2]*Institute for Advanced Study, Center for Neurolinguistics and Theoretical Syntax, Pavia, Italy,* [3]*Università Vita-Salute San Raffaele, Milan, Italy,* [4]*San Raffaele Scientific Institute,Nephrology and Dialysis, Milan, Italy.*

Schizophrenia is a chronic disease characterized by cognitive impairment. Biological bases of cognitive deficits are still poorly understood and may lie in insults in the neurodevelopmental process. Synapses structural proteins are claimed to have an ethiopathogenic role in schizophrenia and a more direct effect on core cognitive functions. Adducins family proteins seem of great interest, as they are fundamental constituents of synaptic structures, involved in actin cytoskeleton assembly-disassembly responsible of synaptic plasticity. In particular, ADD2 is prominently expressed in brain tissues and previous researches reported a role of this gene in memory and lear-

ning processes, commonly impaired in schizophrenia. Based on this rationale, we analyzed three common genetic variants of Adducins, ADD1 G1532T (rs4961), ADD2 C1797T (rs4984) and ADD3 IVS11+386A>G (rs3731566) in a sample of 342 patients with schizophrenia, assessed with a broad battery evaluating core cognitive domains that are typically impaired in schizophrenia. The analysis showed significant effects of ADD1 genotype on executive function (p<.025)and of ADD2 genotype on several domains: working memory (p<.003), verbal fluency (p<.018), verbal memory (p<.001), abstract reasoning (p<.009), cognitive flexibility (p<.02570) and sustained attention (p<.010). Moreover an interaction effect of ADD1 and ADD3 genotypes was observed on symbol coding (p<.029) and verbal memory (p<.027). Our findings suggest that genes involved in synaptic building and plasticity, such as Adducins, may have a key role in cognitive impairment in schizophrenia and may help us to better understand the ethiopathogenesis of the disease.

P08.66-M
The power of Next Generation Sequencing in identifying mutations in non-specific ASD-ID phenotypes: the example of SHANK3

H. Poquet[1], *M. Willems*[2], *J. Thevenon*[1], *C. Redin*[3], *M. Lefebvre*[1], *C. Redin*[1], *A. Mosca-Boidron*[1], *C. Thauvin-Robinet*[1], *Y. Duffourd*[1], *S. Lumbroso*[2], *B. Gerard*[3], *J. Mandel*[3], *J. Rivière*[1], *A. Piton*[3], *L. Olivier-Faivre*[1];
[1]*CHU, Dijon, France,* [2]*CHU, Montpellier, France,* [3]*IGBMC, Strasbourg, France.*

Autism Spectrum Disorders (ASDs) comprise a range of early onset neurodevelopmental conditions of varying severity, with or without Intellectual Disability (ID), characterized by impairments in relatedness and communication, accompanied by restricted interests and repetitive stereotyped behaviors. SHANK3 haploinsufficiency implicated in Phelan-McDermid 22q13 microdeletion is one of the more prevalent monogenic causes of ASD, explaining at least 0,5% of cases, but the indication of *SHANK3* sequencing in patients with ASD and ID remain difficult. Here we report on two patients with *de novo SHANK3* mutations identified by next generation sequencing (NGS). Patient 1, aged 15, was part of a cohort of 40 patients screened by exome sequencing for undiagnosed severe ID, and a truncating mutation was identified in *SHANK3* (c.4381C>T ; p.Gln1461*). Patient 2, aged 10, was part of a cohort of 106 patients with ID screened by targeted NGS of 220 ID genes, and a causative heterozygous truncating mutation of *SHANK3* was identified (c.2955_2970dup;p.Pro992Argfs*325). They both had normal measurements, severe ID, developmental and speech delay with acquisition of a few words and secondary regression with absence of speech, attention deficit and behavioral disorders necessitating treatment, autistic traits, insomnia and tantrum. Patient 1 had eating and digestive difficulties, patient 2 had distal spasticity, epilepsy from age 5, and facial dysmorphic features. These two clinical presentations appear nonspecific within the ASD-ID spectrum. After reviewed the other patients with *SHANK3* mutations, we argue that NGS will be helpful to determine patients with *SHANK3* mutations in the absence of clear distinctive clinical features.

Interpretation of TCF4 Variants Requires mRNA Splicing Analysis in Patients with Pitt-Hopkins Syndrome

M. Nasser[1], *L. Drévillon*[1], *J. Ghoumid*[1], *A. Briand-Suleau*[1], *T. Gaillon*[1], *V. Bodereau*[1], *A. Aissat*[2], *A. Hinzpeter*[1], *S. Whalen*[3], *L. Pasquier*[4], *J. Amiel*[5], *M. Goossens*[1], *E. Girodon-Boulandet*[1], *D. Héron*[3], **I. Giurgea**[1];
[1]*Groupe Hospitalier Henri Mondor-Albert Chenevier, Créteil, France,* [2]*INSERM U955, Equipe 11, Créteil, France,* [3]*Groupe Hospitalier Pitié Salpêtrière, Paris, France,* [4]*CHU de Rennes, Rennes, France,* [5]*Hôpital Necker Enfants Malades, Paris, France.*

Background: Pitt-Hopkins syndrome (PTHS) combines severe intellectual disability (ID), hyperventilation, and a characteristic facial gestalt. The disease-causing gene TCF4 encodes a basic helix-loop-helix (bHLH) transcription factor. Patients carry de novo TCF4 deletions, truncating mutations, or missense mutations located chiefly in the bHLH domain. Variants that do not fall into one of these categories are difficult to interpret. We describe a comprehensive mRNA analysis method for assessing TCF4 variants of uncertain significance (VUS). Methods and Results: Using leukocytes from patients and minigene assays, we documented impaired splicing for the synonymous variant c.1071A>G p.(Ala357Ala), and for the only two missense variants outside the bHLH domain that are described to date, c.1073G>T p.(Gly358Val) and c.1604A>G p.(Asp535Gly). All assessed variants result in aberrant splicing and premature termination codons (PTC). Conclusions: All TCF4 mutations reported so far in PHTS are either missense mutations located in the b-HLH domain or result in a PTC. Splicing tests ought to be performed in patients with de novo TCF4 VUS, especially missense mutations lying outside the bHLH-specifying domain, even in the absence of in silico prediction for a splicing defect.

P08.69-S
A novel X-linked trichothiodystrophy associated with a nonsense mutation in RNF113A

M. A. Corbett[1], *T. Dudding*[2], *P. A. Crock*[3,4], *E. Botta*[5], *L. M. Christie*[2], *L. Hobson*[1], *J. Boyle*[2], *A. Mansour*[6], *K. L. Friend*[1], *J. Crawford*[1], *G. Jackson*[7], *L. Vandeleur*[1], *A. Hackett*[2], *M. R. Stratton*[8], *G. Turner*[2], *J. Gecz*[1], *M. Field*[2];
[1]*University of Adelaide, North Adelaide, Australia,* [2]*Genetics of Learning Disability Service, Hunter Genetics, Newcastle, Australia,* [3]*Paediatric Endocrinology and Diabetes, John Hunter Children's Hospital, Newcastle, Australia,* [4]*University of Newcastle, Newcastle, Australia,* [5]*Istituto di Genetica Molecolare CNR, Pavia, Italy,* [6]*The Children's Hospital at Westmead, Westmead, Australia,* [7]*Brain Research Institute, Florey Neurosciences Institutes, West Heidelberg, Australia,* [8]*The Wellcome Trust Sanger Institute, Hinxton, United Kingdom.*

Trichothiodystrophy (TTD) describes a group of rare autosomal recessive disorders that variably affect a wide range of organs derived from the neuroectoderm. The key diagnostic feature is sparse, brittle, sulphur deficient hair that has a "tiger-tail" banding pattern under polarizing light microscopy. At the molecular level, TTD genes have a role in DNA damage repair pathways.
We describe two male cousins affected by TTD with microcephaly, profound intellectual disability, sparse hair, aged appearance, short stature, facial dysmorphism, seizures, immunoglobulin deficiency, multiple endocrine abnormalities, cerebellar hypoplasia and partial absence of the corpus callosum and absence of photosensitivity. Mutations in known TTD genes were ruled out. Obligate female carriers showed 100% skewed X-chromosome inactivation suggesting a potentially X-linked disorder. Linkage analysis localised the disease allele to a 7.75 Mb interval from Xq23 - q25. Sanger sequencing of 737 X-chromosome, Vega genes and whole exome sequencing was used to identify a nonsense mutation in the highly conserved RNF113A gene (c.901 C>T, p.Gln301*) ruling out other possible X-linked variants. The mutation segregated with the disease in the family and was not observed in over 10,000 control X chromosomes from public and in-house data. The mutation markedly reduced RNF113A protein expression in extracts from lymphoblastoid cell lines derived from the affected individuals. Knockdown of orthologs of RNF113A in model organisms strongly support a role for the gene in DNA repair and neurogenesis. The association of RNF113A mutation with TTD identifies a new locus for these disorders on the X-chromosome.

P08.70-M
An hiPSCs based *in vitro* model of Angelman Syndrome and dup15 Autism

F. La Carpia[1], *M. Gentile*[2], *C. Schwartz*[3], *G. Neri*[1], *F. Gurrieri*[1], *E. Sangiorgi*[1];
[1]*università cattolica del sacro cuore, roma, Italy,* [2]*Dipartimento Materno-Infantile ASL, Bari, Italy,* [3]*Greenwood Genetic Centre, Greenwood, SC, United States.*

UBE3A gene maps on 15q11q13 chromosome and encodes for the protein E6AP, an Ubiquitine-ligase involved in protein degradation process. The gene is maternally imprinted in central nervous system and different studies show that loss of expressed copy causes Angelman Sydrome (AS) while the duplication of 15q11q13 represents the genetic cause in 1-3% of autistic patients (dup15 Autism). Using 2 cohorts of AS and dup15 autism patients, we applied induced Pluripotent Stem cells (iPSCs) technology and neuronal differentiation to identify molecular targets of a dys-regulated dosage of UBE3A. To generate iPSCs we used 4 canonical factors identified by Yamanaka (c-Myc, Klf-4, Oct3/4 e Sox2) through retroviral or lentiviral vectors. We performed 14 attempts and in 13 we generated cells that we defined as "partially reprogrammed" because they lost their typical fibroblasts morphology, but died after passaging. In the last experiment we used a commercial lentiviral vector with the same 4 pluripotency factors making a dup15 hiPSCs cell line positive to pluripotent expression markers; further characterizations are still ongoing. Once we have hiPSCs we will proceed with neuronal differentiantion. With our experiments we confirm that the hiPSCs genesis is a stochastic process with a successful rate of 0.1-2% and that no standard protocol exists. In the other hand this new challenging and arduous technology give to the scientists the possibility to understand the pathogenetic mechanisms in tissues that for obviously reasons are difficult to study.

P08.71-S
Maternal uniparental isodisomy of chromosome 4 in a subject with mild intellectual disability

P. Palumbo, *O. Palumbo, M. Leone, R. Stallone, T. Palladino, L. Zelante, M. Carella;*
Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy.

Uniparental Isodisomy (iUPD) is a rare condition characterized by the inheritance of two homologous chromosome from one parent and the absence of the homologous chromosome from the other parent. Several mechanisms of UPD formation have been previously decribed, including trisomy rescue, monosomy rescue and gamete complementation. Problems associated to

UPD are homozigosity of autosomal recessive inherited mutations and aberrant genomic imprinting. iUPD of chromosome 4 is a rare conditions. To date only few cases are reported, with heterogeneous phenotype, and all were maternal. We describe a patient with mild intellectual disability and slight speech delay, harboring maternal iUPD of chromosome 4 detected by high resolution SNP-array and confirmed by microsatellite analysis. Our patient did not show any dysmorphic feature and did not present any other anomaly. To the best of our knowledge, this is the second patient carrying maternal chromosome 4 iUPD that show a behavioral phenotype. Chromosome 4 maternal iUPD is a sporadic and rare event, that may present little or not distinguishable phenotype. Thus, it seems unlikely that important maternally imprinted genes are on this chromosome. Because iUPD is associate with a complete unmasking of recessive mutations, it is possible that such mutation could be responsible for the intellectual disability in our patient, and this hypothesis could justify the phenotypic variability among other reported cases. It will be useful to study further cases with chromosome 4 paternal iUPD, in order to compare clinical phenotype and to exclude or confirm the presence of paternally imprinted genes on chromosome 4.

P08.72-M
X- Chromosome imbalances by array-CGH - from single gene to chromosomal regions imbalances

I. M. Carreira[1,2,3], *S. I. Ferreira[1], A. Jardim[1], A. Mascarenhas[1], M. Pinto[1], E. Matoso[4], M. Venâncio[5], L. Ramos[5], J. B. Melo[1,2,3];*
[1]Laboratório de Citogenética e Genómica, Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal, [2]CIMAGO – Centro de Investigação em Meio Ambiente, Genética e Oncobiologia, Coimbra, Portugal, [3]CNC- Centro de Neurociências e Biologia Celular, Universidade de Coimbra, Coimbra, Portugal, [4]Laboratório de Citogenética, Hospital Pediátrico, CHUC, Coimbra, Portugal, [5]Serviço de Genética Médica, Hospital Pediátrico, CHUC, Coimbra, Portugal.

Array-Comparative Genomic Hybridization (array-CGH) has increased the diagnostic yield in patients with intellectual disability (ID), autism spectrum disorders and multiple congenital anomalies due to its improved resolution. X-chromosome has been focus of attention due to the bias in the affected male-to-female ratio and to the knowledge of X-linked genes associated with ID. With array-CGH we can either detect single gene imbalances, chromosomal region imbalances and even aneuploidies. In a cohort of 1000 patients studied by Agilent 180K oligonucleotide array-CGH we have detected several X-chromosome imbalances. Single gene deletions involving ZNF41 or IL1-RAPL1 genes were equitably observed in 8 patients; DMD imbalances in 3 females and SHOX gene duplications in 1 female and 9 males. We also detected an intragenic deletion in SLC9A6 gene associated with Christianson syndrome that segregated in the family. In 6 patients we identified Xp22.31 duplications, 3 females, 1 male with maternal inheritance and 2 males whose inheritance was not yet determined. We identified chromosome Xq27.1q28 interstitial duplications in 2 males, 1 maternally inherited and the other not yet determined. We also found other genomic imbalances but in single cases: a complex rearrangement with multiple imbalances at Xp22.33p22.2 in a male patient, maternally inherited; an Xp11.3p11.23 duplication in a female with ID whose mother is also affected and a case of triple X in an autistic female. The challenge with X-chromosome imbalances is to interpret their impact on the phenotype, due to the presence of some alterations in the normal population and to X-chromosome inactivation in females.

P08.73-S
Mutations in the P54NRB/NONO gene cause a novel syndromic XLID with a slender built-macrocephaly gestalt

M. Langouet[1], *M. Rio[1], S. Moutton[1], K. Siquier-Pernet[1], C. Bole-Feysot[1], N. Cagnard[1], P. Nitschke[1], A. Munnich[1], D. Mircsof[2], P. Seebeck[3], S. Brown[2], J. Amiel[1], L. Colleaux[1];*
[1]Imagine Institute, Paris, France, [2]Institute of Pharmacology and Toxicology, Zurich, Switzerland, [3]Center for Integrative Rodent Physiology, Zurich, Switzerland.

We report on two unrelated and sporadic patients presenting a novel syndromic XLID featuring macrocephaly, severe elocution disability with open bite, high arched palate, malar hypoplasia, a thin nasal bridge with deviated nasal septum, slender build, and scoliosis. Brain MRI showed a thick corpus callosum. High-throughput sequencing identified two distinct mutations (c.1131G>A and c.1394dup, p.Asn466Lysfs*13) in the *P54NRB/NONO* X-linked gene. P54NRB/NONO belongs to the DBHS (Drosophila Behaviour Human Splicing) protein family. In mammals three members belong to this family: P54NRB/NONO, PSPC1, and PSF/SFPQ. DBHS proteins are multifunctional nuclear proteins implicated in multiple aspects of RNA production and processing. Beyond RNA production, they also play a role in RNA surveillance (binding and retaining hyper edited RNA in the subnuclear bodies named paraspeckles), as well as in the control of mammalian circadian rhythms. Finally, PSF and P54NRB have also been implicated in dendritic RNA transport.
We demonstrated that both mutations lead to complete absence of the P54NRB/NONO protein and overexpression of the two other DBHS proteins. In patients' cells, whole transcriptome analysis revealed severe gene expression deregulation, and reporter assays showed reduced circadian clock amplitude. Finally, CT scans analysis of *P54nrb/Nono*-deficient mice demonstrate a dramatic flattened nose phenotype that may mimic the severe malar hypoplasia observed in patients.
These findings demonstrate the existence of a recognizable XLID syndrome due to mutations in *P54NRB/NONO,* and highlight the crucial role of DBHS proteins in brain development and function.

P08.74-M
The *KIAA2022* duplication found by high-resolution custom-designed array CGH in Polish patient with X-linked intellectual disability

S. O. Rzonca[1], *A. Charzewska[1], M. Janeczko[2], M. Nawara[1], D. Hoffman-Zacharska[1], J. Bal[1];*
[1]Institute of Mother and Child, Warsaw, Poland, [2]University Children's Hospital of Cracow, Cracow, Poland.

The X-linked intellectual disability (XLID) is a common, clinically complex and genetically heterogeneous disease arising from mutations in genes along the X chromosome. Approximately 5-10% of XLID cases in males are due to the presence of copy number variations (CNV). The array-based comparative genomic hybridization (aCGH) using NimbleGen custom assays (720K) dedicated for X chromosome was performed for 45 patients with the family history suggesting X-linked intellectual disability, excluded mutation in *FMR1* and *ARX* genes and normal results in MRX-MLPA test. In 7 out of 45 patients (15.5%) the molecular defect was identified. In one patient, the 363 kb microduplication (hg: 73,899,064-74,262,928) encompassing *KIAA2022* gene was found. According to DECIPHER CNVs database, reported microduplication *KIAA2022* gene, could be associated with XLID. The duplication was identified in a male patient with moderate intellectual disability that was also present in his four male relatives (brother, mother's 2 brothers and son of mother's sister). The female relatives of the patient were unaffected that supports the X-linked recessive inheritance. The KIAA2022 protein, also known as XPN, is related to neurite extension and regulation of the cell-cell, cell-matrix adhesion and migration. The copy number variations and point mutations in the *KIAA2022* gene have been recently found to be causative for intellectual disability. Therefore, we postulate that the found variant involving *KIAA2022* gene can be pathogenic and related to clinical features observed in our patient with XLID.

P08.75-S
Identification of intellectual disability genes in female patients with skewed X-inactivation

N. Fieremans[1,2], *S. Belet[1,2], H. Van Esch[1], K. Devriendt[1], F. Martinez[3], E. De Baere[4], F. Roelens[5], A. Jansen[6], S. Seneca[6], P. Marynen[1], G. Froyen[1,2];*
[1]KU Leuven, Leuven, Belgium, [2]VIB, Leuven, Belgium, [3]Hospital Universitario La Fe, Valencia, Spain, [4]Ghent University, Ghent, Belgium, [5]H-Hartziekenhuis, Roeselare, Belgium, [6]UZ Brussel, Brussels, Belgium.

Intellectual disability (ID) is a very heterogeneous disorder and the etiology remains unknown in about 50% of cases. Traditionally, X-linked ID (XLID) studies focused on males from XLID families due to the hemizygous state of the X chromosome. Females can be carrier of the mutation but are generally not affected due to inactivation of the mutant X chromosome in most of their cells (skewing). Previously we identified two female patients with RETT-like phenotypes caused by a de novo microduplication at Xq18, including *MECP2*. While carrier females of *MECP2* duplications are generally unaffected due to skewing of X-inactivation, these 2 females show complete inactivation of the apparently normal X chromosome. By exome sequencing, we identified a mutation in *ATRX* located on the other X, which might have caused the skewing in that patient forcing the *MECP2* duplication to be expressed. Since this two-hit mechanism could also occur in other female ID patients with skewed X-inactivation, we analyzed the X-inactivation pattern of 147 ID females, which revealed a higher percentage (6.8%) of extreme skewing (≥ 90% skewing) than reported in the general population (4.0%). X chromosome-array-CGH analysis of these skewed females revealed two de novo aberrations on Xp11 that could explain their ID phenotypes. Exome sequencing revealed a further two promising variants. Our data thus demonstrate that skewing can be used to screen for (novel) genetic mutations resulting in XLID in females.

P08.76-M
Microduplication of Xp22.31 region involving the STS gene in two males with intellectual disability

I. Sansović, *L. Morožin Pohovski, I. Barišić;*
Children's Hospital Zagreb, University of Zagreb Medical School, Zagreb, Croatia.

Genomic instability is a feature of the human Xp22.31 region: deletions, duplications, triplications and other complex rearrangements were identified

at this locus. Submicroscopic duplication of Xp22.31 has been reported as either a possible cause of neurobehavioral phenotypes or a benign variant. Recently, two large cohorts of patients with the microduplication at Xp22.31 were reported. The size of the Xp22.31 duplication varied between 149 kb and 1.9 Mb and mostly included the steroid sulfatase (STS) gene. Patients with Xp22.31 recurrent duplications generally presented with a neurocognitive and behavioral phenotype, including developmental delay. The STS gene could be a candidate gene contributing to the abnormal phenotype in Xp22.31 duplication.

Here we report 2 boys with the microduplication of Xp22.31 found by MLPA analysis. The duplication was minimum 246,2 kb in size and included STS and HDHD1A genes. Both of them presented with mild to moderate intellectual disability/developmental delay mainly affecting speak ability, behavioural abnormalities and minor facial dysmorphisms. Proband B also had a hypotonia. The mother of proband A, carrying the same duplication, had a mild intellectual disability.

Our cases overlap with those previously described in most clinical features. Although there is no clear evidence to support pathogenicity of the Xp22.31 duplication, there is still enough evidence to consider the Xp22.31 duplication as a risk or modifier factor for intellectual disability and behavioural problems. We hope that the description of these two cases will contribute to the phenotype delineation and elucidation of the role of Xp22.31 duplication.

P08.77-S
Xq12 and Xq13 submicroscopic duplications in a single patient: confirming the existence of a new X-linked disorder and narrowing the critical region.

E. Alfei[1], *S. D'Arrigo*[1], *C. Pantaleoni*[1], *F. Novara*[2], *R. Ciccone*[2], *O. Zuffardi*[2], *F. Natacci*[3]; [1]*Developmental Neurology Division, Carlo Besta Neurological Institute, I.R.C.C.S. Foundation, Milano, Italy,* [2]*Medical Genetics, University of Pavia, Pavia, Italy,* [3]*Medical Genetics Unit, "Ca'Granda" Ospedale Maggiore Policlinico, I.R.C.C.S. Foundation, Milano, Italy.*

In 2012 Kaya et al. reported three related patients with a recurrent duplication Xq12-q13.3 with mental retardation, autism, seizures and dysmorphic features. The duplicated region (9.4 Mb) contains numerous genes and the authors pointed out the possible role of an increased dosage of specific genes focusing on their presumed role in developmental delay and autism. Subsequent reports (Prontera et al. 2012; Wentz et al. 2013) described 4 more patients with a variable association of severe global developmental delay, microcephaly, dysmorphism and autism spectrum disorder, all carrying a duplication in the Xq12-q13.3 region, supporting the existence of a clinically recognizable X-linked recessive disorder. We describe a further patient affected by global developmental delay, epilepsy, autistic traits and carrying two non-contiguous duplications detected by array CGH, involving Xq12 and Xq13 regions. Detailed clinical description is provided and compared to previous reported cases. Due to the narrowed size of the duplicated regions (123 Kb and 509 Kb, respectively), this case helps to redefine the region of interest for this condition. The two duplications in our patients involve 13 genes, and 7 of them are mainly expressed in the nervous system (*OPHN1, SNX12, MED12, NLGN3, GJB1, ZMYM3, TAF1*) and all, except for *SNX12*, are involved in the pathogenesis of a known human disease. Our observation provides further evidence of the existence of a new genomic condition, helping to define the corresponding clinical phenotype, and to identify a more definite critical region.

P08.78-M
Xq28 duplication detected by SNP-array in two girls with microcephaly, intellectual disability and neurological features

V. Parisi[1], *L. Sinibaldi*[1], *P. Castelluccio*[2], *S. Loddo*[1,3], *G. Serra*[4], *H. Goel*[5,6], *B. Albrecht*[7], *G. Baujat*[8], *B. Torres*[1], *A. Novelli*[1], *A. Battaglia*[9], *L. Bernardini*[1]; [1]*Mendel Laboratory; "Casa Sollievo della Sofferenza" Foundation, Rome, Italy,* [2]*UOSC Medical genetics, "A. Cardarelli" Hospital, Naples, Italy,* [3]*Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy,* [4]*Institute of Child Neuropsychiatry, University of Sassari, Sassari, Italy,* [5]*Hunter Genetics, Waratah, Australia,* [6]*University of Newcastle, Callaghan, Australia,* [7]*Institut f. Humangenetik, Universitätsklinikum Essen, Essen, Germany,* [8]*Département de Génétique, Hôpital Necker-Enfants Malades, Paris, France,* [9]*Stella Maris Clinical Research Institute for Child and Adolescent Neuropsychiatry, Pisa, Italy.*

We report on two girls carrying a *de novo* Xq28 microduplication, distal to *MECP2*, overlapping for about 90Kb, including *RPL10*, *DNASE1L1*, *TAZ*, *AT-P6AP1*, *PLXNA3* and *GDI1* genes. X chromosomes resulted randomly inactivated in the first case while the test was not-informative in the second. Our first patient is the eldest daughter of an apparently healthy, non-consanguineous couple. Birth weight and length were around the 10th percentile and head circumference was 33cm (<<10th percentile). The girl had poor suction and anomalies of the face and extremities. At 19 months she had a generalized epileptic seizure followed by other episodes. Brain MRI showed dilatation of the ventricular system and evidence of small brain. Our second patient is the second daughter of an apparently healthy, non-consanguineous couple born at 39 weeks by cesarean section for small gestational age. The auxological parameters were all below the 3rd percentile. At birth, brain MRI showed mild hypoplasia of corpus callosum and cerebellum. She had generalized hypotonia, hyporeactivity, sucking deficit, seizures, and congenital heart disease. Physical examination showed microcephaly, dysmorphic features of the face and extremities. *GDI1* has been associated with ID and non-syndromic microcephaly in a high percentage of males. Our patients and the revision of cases from literature and DECIPHER database strengthen the *GDI1* involvement in intellectual disability and microcephaly not only in male but also in female subjects. Of note, neurological and neuroimaging abnormalities, such as ventricular system enlargements, cerebellar or corpus callosum hypoplasia are recurrent clinical features associated with this rare microduplication syndrome.

P08.79-S
Mutations in *YY1* cause intellectual disability and a distinct facial appearance

A. T. Vulto-van Silfhout[1], *J. H. M. Schuurs-Hoeijmakers*[1], *L. E. L. M. Vissers*[1], *B. W. M. van Bon*[1], *W. M. Nillesen*[1], *A. P. M. de Brouwer*[1], *A. Zada*[1], *J. Andrieux*[2], *P. G. Brunner*[1], *K. Kosaki*[9], *A. Rauch*[10], *B. B. A. de Vries*[1], **D. A. Koolen**[1]; [1]*Radboud university medical center, Nijmegen, Netherlands,* [2]*Hopital Jeanne de Flandre, Lille, France,* [3]*Rouen University Hospital, Rouen, France,* [4]*CSS-Mendel Institute, Rome, Italy,* [5]*Rigshospitalet, Copenhagen, Denmark,* [6]*Birmingham Women's Hospital, Birmingham, United Kingdom,* [7]*Baylor College of Medicine, Houston, TX, United States,* [8]*Our Lady's Children's Hospital, Dublin, Ireland,* [9]*Keio University School of Medicine, Tokyo, Japan,* [10]*University of Zurich, Zurich, Switzerland.*

Background - Trio-based exome sequencing of 10 patients with intellectual disability (ID) previously identified a *de novo* missense mutation in *YY1*, a transcription factor with an important role in various biological processes, such as proliferation, differentiation, embryogenesis, apoptosis, and tumor development. To ascertain whether the mutation in *YY1* was causative for the patient's phenotype, we set out to identify additional patients with *de novo* mutations in *YY1*.

Methods - Targeted resequencing of *YY1* and further exome sequencing studies in a cohort of patients with unexplained ID were performed. Detailed phenotype information of patients with mutations in *YY1* was compared.

Results - We identified three additional patients with *de novo* mutations in *YY1* (two missense and one nonsense mutation). The four mutations all occurred in the region containing the zinc finger domains of *YY1*, which is involved in DNA binding. All four patients had ID, intrauterine growth retardation and similar facial dysmorphism, including facial asymmetry, broad forehead, full upper eyelids, flat malar region, full nasal tip, thick alae nasi and a Gingko leaf-like shape of the upper lip.

Conclusions - We show that *de novo* mutations in the zinc finger domains of the transcription factor YY1 cause ID, low birth weight, and overlapping facial dysmorphism, including a distinctive shape of the upper lip.

P08.80-M
Mutations in ZBTB18 are responsible for intellectual disability

A. Röpke, *C. Müller-Hofstede, A. Bohring, A. Bröcher, M. Hoffmann, P. Wieacker; Institut für Humangenetik, Münster, Germany.*

Microdeletions of 1q43q44 were described in patients with intellectual disability (ID) with limited or no expressive speech, microcephaly, dysmorphic features, abnormalities of the corpus callosum, hand and foot abnormalities, and seizures. Different genes were predicted as candidate genes for the microcephaly (AKT3), abnormalities of the corpus callosum (ZBTB18), and seizure (FAM36A, C1orf199, HNRNPU). Recently, a mutation in the ZBTB18 gene was identified in a patient with ID and further signs of the 1q43q44 microdeletion syndrome. Knock-out mice with loss of Znf238 die at birth with neocortical defects but a brain-specific knock-out of this gene in mice causes microcephaly, reduced thickness of the cortex and agenesis of the corpus callosum. The ZBTB18 gene acts as a transcriptional repressor of key neurogenic genes such as NeuroG2 and NeuroD1 or ID2 and ID3. Here, we describe two patients carrying de novo mutations in ZBTB18, one patient with a missense mutation (p.R495G) and a further patient with a nonsense mutation (p.E286X). The first patient, a 23 years old woman, demonstrated a non-syndromic ID with mild facial dysmorphic signs. The other patient, a 7 years old boy, showed ID, facial abnormalities, significant speech and motor developmental delay. In both patients normal karyotypes (550 bands), array-CGH results and normal FMR1 gene analyses were shown. Our results indicated that ZBTB18 is responsible for neurogenic development and mutations within ZBTB18 cause ID with variable phenotypic abnormalities.

P08.81-S
Klinefelter syndrome: 48, XXXY aneuploidy in a patient with mild mental retardation and psychotic personality traits

M. F. Hernandez-Amaris[1], *H. Pachajoa*[1,2];
[1]*Universidad Icesi, Cali, Colombia,* [2]*Fundacion Clinica Valle del Lili, Cali, Colombia.*

Klinefelter syndrome is the most common aneuploidy in males with a prevalence of 0.1-0.2% in the general population, which rises up to 3% in males with fertility issues, although only 35% of cases are diagnosed. The affected males tend to be tall, have narrow shoulders, wide hips, sparse body hair, gynecomastia and small testis; they present androgen deficiency and azoospermia. Besides the previous physical characteristics, there have been reports on the expression of behavioral and cognitive traits that tend to be very variable, possibly according to the type of aneuploidy, with an established association between the number of extra X chromosomes and cognitive deficit, and a not so clear association of different chromosomal variants of Klinefelter and psychotic behavior, with some authors proposing the origin of the extra chromosome as a determinant of different behavioral traits. Here is presented the case of a 13 years old male with karyotype 48,XXXY, who besides presenting the classical physical features, is under psychiatric treatment because of presenting trouble at home and at school for being aggressive and impulsive. A review on the literature is made, concluding on the importance of an opportune starting of hormonal therapy and a multidisciplinary approach including endocrinology, pediatrics, genetics, neuropsychology and psychiatry when needed.

P09.001-S
4H (Hypomyelination, Hypodontia and Hypogonadotropic Hypogonadism) syndrome caused by POLR3B mutations

F. Faletra[1], *E. Rubinato*[2], *S. Nieder*[2], *G. Bernard*[3], *P. Gasparini*[1,2];
[1]*Institute for Maternal and Child Health - IRCCS "Burlo Garofolo", Trieste, Italy,* [2]*University of Trieste, Trieste, Italy,* [3]*Departments of Pediatrics Montreal Children's Hospital, McGill University Heath Center, Montreal, QC, Canada.*

Leukodystrophies are a heterogeneous group of inherited neurodegenerative disorders characterised by alterations of Central Nervous System white matter. Several clinical forms have been described and genes involved in generating the hypomyelinating leukodystrophy, but recently, mutations in *POLR3A* and *POLR3B* genes have been reported to cause a specific syndrome named 4H characterized by the association of the hypomyelination with hypodontia and hypogonadotropic hypogonadism. We visited a 27-year-old female born from a non consanguineous mating with a leukodystrophy and an unlikely clinical / endocrinological diagnosis of Pelizaus - Merzbacher syndrome. Her phenotype was characterized by teeth alterations (neonatal tooth and permanence of deciduous dentition), thin hair, high myopia, hypogonadotropic hypogonadism, and minor dysmorphic features. Moreover, a gradual, but consistent motor and cognitive deterioration was noted. Putting together all the clinical, radiological and phenotipic characteristics of the proband a clinical diagnosis of 4H syndrome has been made. Subsequently, a Sanger sequence of the entire coding region and the flanking exon/intron boundaries of *POLR3A* and *POLR3B* has been performed. The analysis revealed the two mutations p.V523E and p.G695fs*5 in the *POLR3B* gene. This case further expands the knowledge about the role of the *POLR3B* gene in generating the 4H syndrome.

P09.002-M
A familial 9q22.1q22.31 deletion of 3.8 Mb, challenging interpretation of large, inherited copy-number variation

A. C. tabet[1], *L. perrin*[1], *S. Toujani*[1], *J. Leger*[1], *V. Vantalon*[1], *C. dupont*[1], *L. bouffard*[1], *E. pipiras*[2], *A. Delahaye*[2], *B. Benzacken*[2], *A. Verloes*[1];
[1]*Robert Debre Hospital APHP, paris, France,* [2]*Jean Verdier Hospital APHP, Bondy, France.*

Chromosomal microarray analysis are now the first-line diagnostic test for patients presented with intellectual disability, autism, or multiple congenital anomalies. An ongoing challenge for the clinician and biologist is the interpretation of copy number variation. Many tools have been proposed in order to facilitate their interpretation including linking data to several genome browsers, gene contains and prioritization, inheritance of the copy-number variation (CNV) and the size of the variant. Indeed, large CNV (>500 kb) are supposed to be strongly associated with morbid consequences. We report on a large 9q22.1q22.31 deletion of 3.8 Mb identified by whole genome SNP array (HumanCytoSNP-12, Illumina) in a 6 year old girl presented with growth retardation and Attention-Deficit/Hyperactivity Disorder (ADHD). Neuropsychological evaluation excluded a mental retardation. The deletion encompassed 24 genes, was inherited from her apparently normal father. Nevertheless, the familial history was marked by hyperactivity and dyslexia in the father's childhood. The older sister presented also with ADHD and carried the same deletion. Grandparents will be further analyzed. We discuss the implication of this CNV in the abnormal phenotype of the two sisters. Our observation highlights the difficulties of interpretation of CNV particularly in case of large CNV inherited from an unaffected parent. Moreover, regarding ongoing discussions about application of microarray in prenatal diagnosis, our case allowed us to postulate that the size is not sufficient to prejudge the pathogenicity of the CNV.

P09.003-S
aCGH for neurological disorders in paediatric population at Clinical Institute of Medical Genetics, UMC Ljubljana

M. Volk[1], *L. Lovrecic*[1], *S. Bertok*[2], *B. Gnidovec Stražišar*[3], *B. Peterlin*[1];
[1]*Clinical Institute of Medical Genetics, UMC Ljubljana, Ljubljana, Slovenia,* [2]*Department of Paediatric Endocrinology, Diabetes and Metabolic Diseases, University Children's Hospital, UMC Ljubljana, Ljubljana, Slovenia,* [3]*Department of Child, Adolescent & Developmental Neurology, University Children's Hospital, UMC Ljubljana, Ljubljana, Slovenia.*

Array comparative genomic hybridization (aCGH) is a quick method to analyze the whole genome for imbalances at a higher resolution. In conventional diagnostic settings aCGH is used as a first-tier diagnostic test in the group of patients with unexplained developmental delay (DD) and/or idiopathic intellectual disability and/or dysmorphic features and/or multiple congenital anomalies.
AIM: Our aim was to evaluate the diagnostic yield/clinical utility of aCGH in the group of children with neurological disorders at Clinical institute of Medical Genetics Ljubljana, tested in 2012-2013.
PATIENTS AND METHODS: We included 244 children, 91 with DD and/or dysmorphic features, 44 with epilepsy, 34 with autism, 45 with developmental abnormalities of the CNS, and 30 with abnormal muscle tone. DNA was hybridized to Agilent 180K or 60K Human CGH microarrays. Discovered genomic imbalances were interpreted according to the data in Internet databases (ISCA, DECIPHER, ECARUCA) and scientific publications cited in PubMed.
RESULTS: Altogether, 37 pathogenic copy number variations (CNVs) were found that could explain the phenotype of patients (Table 1). In addition, 26 variants of unknown significance (VUS) were detected, most of them de novo. Eleven patients (4,5%) had complex CNVs.
CONCLUSION: We found out that pathogenic CNVs were causative in 15% of cases with neurological disorders with/or without dysmorphic features or CNS developmental abnormalities. Our data demonstrate that aCGH is an important diagnostic tool in neuropediatrics.

Table 1. CNVs in different phenotype groups

Phenotype	Number of tested patients	Pathogenic CNV	VUS	Diagnostic Yield (pathogenic CNVs)
DD with or without dysmorphic features	91	22	10	24.2%
Developmental abnormalities of the CNS	45	5	6	11.1%
Abnormal muscle tone	30	2	4	6.7%
Epilepsy	44	6	3	13.6%
Autism	34	2	3	5.9%

P09.004-M
Genetic analysis of amyotrophic lateral sclerosis in the Slovenian population

K. Vrabec[1], *D. Glavač*[1], *B. Rogelj*[2], *M. Ravnik-Glavač*[1];
[1]*Faculty of Medicine, Ljubljana, Slovenia,* [2]*Institute Jožef Štefan, Ljubljana, Slovenia.*

Background: Amyotrophic lateral sclerosis (ALS) is a complex neurodegenerative disease characterised by progressive degeneration and loss of upper and lower motor neurons in the cerebral cortex, brainstem and spinal cord leading to death due to respiratory failure within 2-5 years from onset. The most common genes involved in the disease process are *SOD1*, *FUS*, *TARDBP* and *C9ORF72*.
Patients and methods: Blood samples from 72 Slovenian ALS patients were collected and the exons of genes of interest were PCR amplified followed by Sanger sequencing on ABI310 Genetic Analyzer. In case of *C9ORF72* repeat-primed PCR was performed followed by fragment length analysis on ABI310 Genetic Analyzer. Results were analyzed using Gene Scan software.
Results: Genotyping of genes *SOD1*, *FUS*, *TARDBP* and *C9ORF72* revealed some changes in the DNA sequence. In *SOD1* gene two mutations (V15M and G94C) were detected. Sequencing of *FUS* and *TARDBP* genes did not reveal any amino acid changes. Although two substitutions were detected, R522R (G>A) in *FUS* and L330L (A>G) in *TARDBP*. The latter was not previously described. In 2 ALS patients we detected expansion of repeats in the first intron of *C9ORF72*.
Conclusions: This study represents first genetic analysis of Slovenian ALS patients. Our findings are in concordance with other studies provided on European ALS patients. Of these four analyzed genes repeat expansion in

C9ORF72 remains the most common cause of ALS although for the majority of cases the main causes are yet to be revealed.

P09.005-S
Aging-related genes modulate the early altered expression in young 3xTg-AD mice hippocampi: a whole transcriptome approach

M. D'Aurora[1,2], *S. Sperduti*[1,2], *L. D'Onofrio*[1,2], *A. Granzotto*[2], *S. L. Sensi*[1,2], *L. Stuppia*[3,2], *V. Gatta*[3,2];
[1]*Department of Neuroscience and Imaging, "G. d'Annunzio" University, Chieti, Italy,* [2]*Center of Excellence on Aging (Ce.S.I.), Chieti, Italy,* [3]*Department of Psychological, Humanities and Territorial Sciences, School of Medicine and Health Sciences, "G. d'Annunzio" University, Chieti, Italy.*

Alzheimer's disease (AD) is a multifactorial neurological condition associated with a genetic profile that is still not completely understood. In this study, using a whole gene microarray approach, we investigated age-dependent gene expression profile changes occurring in the hippocampus of young and old transgenic AD (3xTg-AD) and wild type (WT) mice. The aim of the study was to assess similarities between aging- and AD-related modifications of gene expression and investigate possible interactions between the two processes.
Global gene expression profiles of hippocampal tissue obtained from 3xTg-AD and WT mice at 3 and 12 months of age (m.o.a.) were analyzed by hierarchical clustering. Interaction among transcripts was then studied with the Ingenuity Pathway Analysis (IPA) software, a tool that discloses functional networks and/or pathways associated with sets of specific genes of interest.
Cluster analysis revealed the selective presence of hundreds of upregulated and downregulated transcripts. Functional analysis showed transcript involvement mainly in neuronal death and autophagy, mitochondrial functioning, intracellular calcium homeostasis, inflammatory response, dendritic spine formation, modulation of synaptic functioning, and cognitive decline.
Thus, over-expression of AD-related genes (such as mutant APP, PS1, and tau, the three genes that characterize our model) appears to favor modifications of additional genes that are involved in AD development and progression.
The study also showed overlapping changes in 3xTg-AD at 3 m.o.a. and WT mice at 12 m.o.a., thereby suggesting altered expression of aging-related genes that occurs earlier in 3xTg-AD mice.

P09.006-M
The role of p35/CDK5 regulation by miR-15/107 family in Alzheimer's disease

S. Moncini[1], *M. Lunghi*[1], *A. Valmadre*[1], *F. Fontana*[2], *M. A. Denti*[2], *P. Riva*[1], *M. Venturin*[1];
[1]*Dipartimento di Biotecnologie Mediche e Medicina Traslazionale - Università degli Studi di Milano, Milan, Italy,* [2]*Centre for Integrative Biology, Università degli Studi di Trento, Trento, Italy.*

Alzheimer's disease (AD) is characterized by the presence of β-amyloid plaques and neurofibrillary tangles of hyperphosphorylated Tau. CDK5 kinase has a key role in abnormal phosphorylation of Tau and β-Amyloid Precursor Protein (APP). CDK5 is activated by p35, encoded by CDK5R1, whose expression can be modulated by miR-103/107, members of the miR-15/107 group, a family of microRNAs involved in AD pathogenesis.
In our study, we observed a significant reduction of p35 levels in cells transfected with miR-103/107, -15a and -16 precursors compared to control, while the transfection with antisense LNA molecules for miR-15/107 group leads to increased CDK5R1 transcript and p35 levels, suggesting the action of the whole miR-15/107 family on CDK5R1 expression.
We thus hypothesize that reduced levels of miR-15/107 in AD can lead to Tau and APP hyperphosphorylation via upregulation of p35 levels and consequent enhanced CDK5 activity. In order to test this hypothesis, we are studying CDK5R1 and miR-15/107 expression and the CDK5 activity on Tau and APP in frozen brain tissues (hippocampus, temporal cortex and cerebellum) from 12 AD patients and 7 control individuals. In the temporal cortex and hippocampus most miRNAs are downregulated in AD compared to control samples, while in the cerebellum all miRNAs show a similar expression between AD patients and controls, with the exception of miR-107 and miR-15a which are more expressed in AD patients. Interestingly, CDK5R1 mRNA levels are higher in AD hippocampus, but not in temporal cortex and cerebellum tissues, compared to controls.
Project supported by FIRB2008 grant (RBFR0895DC_002).

P09.007-S
Human APP overexpression alters spontaneous quantal release at Drosophila larvae neuromuscular synapse

A. N. Vasiliev[1], *E. A. Guseva*[1], *G. A. Kislik*[2], *V. V. Kravtsova*[1], *S. V. Sarantseva*[2], *I. I. Krivoi*[1];
[1]*Saint-Petersburg State University, Saint-Petersburg, Russian Federation,* [2]*B.P. Kontantinov Petersburg Nuclear Physics Institute, National Research Centre „Kurchatov Institute", Gatchina, Russian Federation.*

While amyloid-beta-protein (Aβ) has been implicated in development of Alzheimer's disease, the exact functional role of amyloid precursor protein (APP) is still unclear. In our study, neuromuscular junction of transgenic *Drosophila melanogaster* lines was used as a model to analyze changes in presynaptic function caused by APP overexpression. Miniature excitatory junction potentials (mEJPs) were recorded intracellularly from muscles 6 and 7 in third instar larvae at room temperature in HL3 solution. Confocal microscopy with cytochemistry was also used. It was observed that the mEJP amplitude distribution in control was bimodal with peaks at 0.46 mV and 0.74 mV; only rare giant mEJPs were observed. Human *APP* gene expression in motor neurons decreased mean mEJPs frequency ($p<0.01$) from 2.5/s in control up to 1.6/s, while fraction of giant mEJPs (mean amplitude 1.41 mV) increased up to 29%. In addition, enhanced axon branching and decreased expression of synaptobrevin was observed. Co-expression of human *APP* and *β-secretase* genes (production of Aβ and decrease in APP level) recovered both mean mEJPs frequency and quantity of giant mEJPs to control values. The resting membrane potentials, time course of mEJPs as well as peaks of their amplitudes bimodal distribution never differs significantly from control line. Distributions of mEJPs latencies in all *Drosophila* lines were best fitted as a mono-exponential decay as predicted by the Poisson model. Our data suggests that APP overexpression disturbs molecular machinery of vesicular exocytosis without alteration in the random nature of spontaneous release. Supported by St.Petersburg State University grants #1.50.1621.2013 and #1.38.231.2014.

P09.008-M
An increase in X chromosome aneuploidy rates in the Alzhemer's disease brain can hallmark both neurodegeneration and aging

Y. B. Yurov[1,2,3], *S. G. Vorsanova*[1,2,3], *T. Liehr*[4], *I. Y. Iourov*[1,2,5];

Post-zygotic mosaic aneuploidy is common in the normal and diseased human brain. Somatic chromosomal mosaicism affecting the brain is, probably, the result of disturbances of adult neurogenesis/gliogenesis during the early ontogeny. It was proposed that aneuploidy of the brain is somehow involved in pathogenesis of neurodegenerative brain disorders including Alzheimer's disease (AD). Here, we have analyzed X chromosome aneuploidy (a feature of aged cell populations) in the brain tissues of females with/without AD. Molecular cytogenetic analyses were performed by multiprobe/quantitative FISH and interphase chromosome-specific multicolor banding (ICS-MCB) in 10 AD and 10 age/sex matched control samples, scoring 160,000 cells per each sample set. In AD, the mean rate of aneuploidy (2.79%, 95% CI 1.88-3.69) was two times higher than in control (1.32%, 95% CI 0.92- 1.71%); P =0.013 (Mann-Whitney U-test). An AD sample demonstrated mosaic aneuploidy (X chromosome loss) confined to the hippocampus in about 10% of cells. More than 75% of cells with X chromosome aneuploidy were NeuN-negative (non-neuronal cells; glia and, probably microglia). These preliminary data indicate that somatic (post-zygotic) chromosome instability causes large-scale genomic variation in a significant proportion of hippocampal cells in AD. In context of a causal relationship between brain aging and AD pathogenesis, our findings suggest that X chromosome aneuploidy can contribute to both brain aging and neurodegeneration in females with AD. We speculate that mosaic aneuploidy in the brain is a new non-heritable genetic factor predisposing to AD. Supported by BLR 11/002, the Russian Federation President Grant (MD-4401.2013.7), and RFBR 12-04-0021.

Background. Despite enormous investigative efforts, the pathological basis for Alzheimer's disease (AD) remains unclear. It has been suggested that AD is mediated by pathological angiogenesis. Angiogenin is a angiogenic ribonuclease whose activity is related to its ability in regulating ribosomal RNA (rRNA) transcription [Cronin 2006]. Mutations in the coding region of ANG (Entrez Gene ID 283) have been detected in Amyotrophic Lateral Sclerosis

(ALS) and Parkinson's disease (PD). A decreased level of ANG protein was found in AD patients serum [Kim 2012]. Objectives. to investigate the role of the ANG gene in AD. Methods. Genetic analysis of ANG gene was done in a cohort of 509 AD patients and 417 healthy volunteers over 65 years of age using Sanger sequencing of the coding regions. Results. Genetic analysis showed the presence of a nonsynonymous mutation in heterozygosis in position g.2162012 causing the change of a lysine to a Stop codon (K73X). This new mutation was found in two AD patients (0.48% of the whole AD cohort): patient 1 is a man, 69 years old, with family history of dementia; patient 2 is a woman, 74 years old, with no familiarity for AD or dementia. No mutations were found in control subjects. Discussion and conclusion. This study suggests that ANG gene mutations may be associated with rare cases of AD. Interestingly, the K73X mutation may be specific for AD, since it has not been found in the numerous genetic studies on ALS and PD so far reported, proposing an important specificity mutation-disease.

Dog as an animal model for idiopathic epilepsy: identification of common risk variants in the ADAM23 gene

L. L. E. Koskinen[1,2,3], *E. H. Seppälä*[1,2,3], *M. Arumilli*[1,2,3], *P. Jokinen*[1,2,3], *E. Nevalainen*[1,2,3], *R. Viitmaa*[4], *T. Jokinen*[4], *H. Lohi*[1,2,3];

Idiopathic epilepsy (IE) is a common neurological disease in human and dog. Relatively few risk genes have been identified for common IE to date. We have used dog as an animal model for human focal and generalised epilepsy to identify disease risk genes. The seizure characteristics are similar between the two species and reduced genetic heterogeneity of purebred dogs is advantageous for genetic studies. Recently, we identified a risk locus for IE in the Belgian Shepherd breed on CFA37 in a genome-wide association study (GWAs). GWAs meta-analysis of 158 cases and 179 controls in three other breeds suggested association to the same locus (p=2.9e-07). To investigate this locus further, we performed targeted next-generation sequencing at the locus. Twelve Belgian Shepherd cases and twelve controls were selected for the sequencing based on homozygosity for the risk and non-risk haplotypes. Thirty-six variants unique for the cases were identified in the sequencing experiment. All variants located in the ADAM23 gene region. Twenty-seven variants were selected for validation in 235 cases and 320 controls from four dog breeds. Association analysis yielded a strong signal at the locus (p=5.3e-11). Haplotype analysis suggests a common risk haplotype in all studied breeds. This indicates that there is a common genetic risk factor for epilepsy in several dog breeds. ADAM23 interacts with LGI1 and LGI2, both known causative genes for Mendelian forms of epilepsy, and plays a role in synaptic transmission. Based on the genetic association and gene function, ADAM23 is a potential risk gene for epilepsy.

High resolution array Comparative Genomic Hybridization (array-CGH) in syndromic microcephaly: clinical interpretation and genotype-phenotype correlation

E. Tsoutsou[1], *M. Tzetis*[1], *K. Giannikou*[1,2,3], *S. Psoni*[1], *V. Oikonomakis*[1,2], *E. Kanavakis*[1,2], *H. Fryssira*[1];

[1]Department of Medical Genetics, Medical School, University of Athens, Athens, Greece, [2]Research Institute for the Study of Genetic and Malignant Disorders in Childhood, "Aghia Sophia, Children's Hospital, Athens, Greece, [3]Alexander S. Onassis Public Benefit Foundation, Athens, Greece.

Introduction: Microcephaly can be either isolated with no additional anomalies, or it may coexist with other neurological entities and/or multiple congenital anomalies, known as syndromic microcephaly. Although many syndromic cases can be classified based on the characteristic phenotype, some others require further investigation. **Aim:** The present study describes the application of high resolution array-comparative genomic hybridization (array-CGH), as a diagnostic tool for the study of patients with syndromic microcephaly in order to identify clinically relevant copy number variations (CNVs). We evaluate the MRI findings with patients' clinical profile and the underlying molecular findings. Material and **Methods:** From a cohort of 210 unrelated patients, who were referred for genetic evaluation due to syndromic microcephaly of unknown etiology, accompanied by at least one further pathological manifestation, 50 undiagnosed cases underwent array-CGH analysis. In all cases previous standard karyotype as well as other genetic tests were negative. High resolution 4x180K and 1x244K Agilent arrays (>170.000 and >236.000 probes respectively, average resolution 8.9Kb) were used in this study. **Results:** In 32 out of 50 patients (64%) featuring microcephaly among other phenotypic anomalies, array-CGH revealed significant aberrations (microdeletions and/or microduplications) ranging in size from 0.015 to 31.6 Mb and encompassing important genes related with syndromic microcephaly. 25/50 patients (50%) had abnormal MRI findings and in 19 of 25, arrays-CGH revealed pathogenic CNVs. **Conclusion:** Array-CGH contributes to the elucidation of undefined syndromic microcephalic cases, by permitting the discovery of plausible novelmicrodeletion and/or microduplication syndromes and contributing to more precise genotype-phenotype correlations.

Città della Salute e della Scienza, S.C.D.U. Medical Genetics, Torino, Italy, [6]Department of Human Genetics, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, United States, [7]The Guangdong Enterprise Key Laboratory of Human Disease Genomics, BGI-Shenzhen, Shenzhen, China, [8]National Institute for Health and Welfare (THL) Public Health Genomics Unit, FIN-00251, Helsinki, Finland, [9]Division of Human Genetics, The Children's Hospital of Philadelphia, Philadelphia, PA, United States, [10]Department of Pediatrics, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States.

CLN5 mutations (13q21.1-q32) are reported in severe autosomal recessive forms of neuronal ceroid lipofuscinoses (vLINCL, OMIM*608102), characterized by rapid death of cortical neurons and intracellular accumulation of autofluorescent lipopigment material. The clinical course includes progressive intellectual and motor deterioration, seizures, and visual failure. Typical CLN5 forms have an onset between 4-7 yrs.

We describe two italian siblings affected by an adult form of ataxia, who presented with a homogeneous phenotype characterized by onset between 54-56 yrs, walk difficulties, dysarthria. Progressive cognitive decline associated to visual loss, ascribed to glaucoma, appeared only after few years of disease. Neurological evaluation at 61yrs. showed nystagmus and head/truncal tremor, and no sensory-motor neuropathy. MRI showed severe cerebellar atrophy and mild cortical atrophy of both hemispheres.

Exome sequencing identified a homozygous c.935G>A (p.S312N) transition in CLN5 gene, never reported before nor present in Exome variant Server (http://evs.gs.washington.edu/). Alignment of orthologous sequences and in silico softwares predict the substitution Ser>Asn to be disease causing.

We studied the subcellular localization of the mutated protein, transfecting the CLN5*S312N-pCMV plasmid in Hek293 cells: as reported for vLINCL mutations, p.S312N seemed to affect trafficking and maturation of the CLN5 protein, resulting in its accumulation in ER compartment and indicating that misfolding may be the major cause for its retention.

We speculate this mutation acts as mild or modifier genes/epigenetics factors may contribute to this late clinical onset.

Our results further demonstrated the power of exome sequencing in identifying genes disease causing, especially when linked to atypical phenotypes.

ARSACS is the second most frequent form of hereditary spastic ataxia after Friedreich's ataxia. ARSACS is caused by mutations in the *SACS* gene encoding for sacsin which is partially localized to the mitochondria. The function of sacsin is still poorly understood. Recently, the mitochondrial network abnormal was observed in immortalized fibroblasts of two Quebec's patients (Girard, *2012*). We searched for point mutations and gene dosage anomalies in *SACS* using direct sequencing and customized CGH array in 325 patients presenting with progressive spastic ataxia and age at onset < 45 years recruited through the SPATAX network. We obtained primary cultures from skin fibroblasts from ten ARSACS patients. On these fibroblasts we performed a labeling of the mitochondrion using the Mitotracker Green®. We identified 42 different mutations in a total of 32 patients carrying two mutations

in *SACS*. Customized CGH array on the two only patients carrying one heterozygous truncating mutation were revealed no anomalies. The diagnosis of ARSACS was confirmed in 13% of our cohort, the largest series of ARSACS patients reported. Mean age at onset was 4 years but late-onset > 25 years was observed. Although demyelinating neuropathy and cerebellar atrophy were frequently associated with spastic ataxia, the clinical spectrum appeared larger than previously. Analysis of the mitochondrial network in all patients' fibroblasts revealed altered mitochondrial shape associated with a significant decrease of the mitochondrial mass. These alterations observed in the mitochondrial network of ARSACS patients bring a real interest to study the role of sacsin regarding the mitochondrion.

The 901bis pedigree of ataxia is linked to SCA37 locus

H. San Nicolàs Fernàndez[1], *J. Corral Seijas*[1], *L. De Jorge López*[1], *B. Campos Estela*[1], *M. Corral Juan*[2], *C. Roig Arnall*[3], *I. Sánchez Díaz*[2], *C. Serrano Munuera*[4], *A. Matilla Dueñas*[2], *V. Volpini Bertran*[1];
[1]*Bellvitge Biomedical Research Institute, IDIBELL, L'Hospitalet de Llobregat, Spain,* [2]*Health Sciences Research Institute Germans Trias I Pujol, IGTP, Badalona, Spain,* [3]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain,* [4]*Hospital de Martorell, Martorell, Spain.*

Autosomal dominant spinocerebellar ataxias (SCAs) are a clinically, genetically and pathologically heterogeneous group of movement disorders defined by variable degrees of cerebellar ataxia and often accompanied by additional cerebellar and non-cerebellar symptoms. The clinical symptoms are triggered by neurodegeneration of the cerebellum and its relay connections. Recently we report the clinical and genetic findings from Spanish kindred (901 family) presenting a cerebellar phenotype characterised by ataxia, atypical early-altered vertical eye movements, variable severity, no evidence of anticipation, age at onset ranging from 35 to 64 years and Cranial CT or MRI showing cerebellar atrophy in several patients without brainstem involvement. We have found significant linkage with the highest two-point LOD score Z_{max} = 3.831 at theta = 0.00 (P < 0.001), between the locus trait and D1S2742, assuming an age-dependent penetrance model with twelve liability classes. Multipoint analysis and haplotype reconstruction traced this novel SCA locus to a 0.66-cM interval flanked by D1S200 and D1S2742 (multipoint Z_{max} = 6.052). The Human Genome Nomenclature Committee (HGNC) has assigned it as SCA37. We presented here another ataxia pedigree (901bis family) with 5 affected members over a total of 17 individuals, which show a multipoint lod score of 3.0 to respect the same genetic markers used in the 901 family. This family comes from the same region than the previous 901 and probably has a common founder ancestor. The linkage results from this pedigree reinforces the hypotheses of linkage from the same ataxia locus trait localized in 1p and named SCA37.

P09.015-S
Reduction of neurological symptoms in Ataxia Teleangiectasia patients by Intra-Erythrocyte infusion of Dexamethasone (EryDex)

L. Chessa, *M. Piane, IEDAT-01 trial group;*
University La Sapienza, Roma, Italy.

Ataxia Teleangiectasia (AT) is a neurodegenerative disorder characterized by early onset ataxia, oculocutaneous telangiectasias, immunodeficiency, recurrent infections, radiosensitivity and cancer proneness. No drug therapies are approved for treating AT; recent observational studies showed beneficial effect of steroid treatment.
To avoid side effects of long-term steroid administration we developed a method for encapsulation of dexamethasone sodium phosphate into autologous erythrocytes (EryDex) allowing the slow release of dexamethasone for up to one month.
The efficacy and safety of EryDex treatment was evaluated in an open-label, single-arm study on 22 AT patients (F:M=1) confirmed molecularly, with a monthly infusion for six consecutive months. Primary efficacy assessment was the International Cooperative Ataxia Rating Scale (ICARS) which best score is 0, while the worst 100. Significant improvements in ICARS were noted in the intention to treat (ITT) population (n=22; p=0.02) and in patients completing the study (PP, n=18; p=0.01), with a mean reduction of 4 points for ITT and 5.2 points for PP. EryDex was well tolerated, without steroid side effects.
At the end of the trial four patients continued Erydex treatment for 27 months (until now) and their ICARS variations were compared to those of four AT who discontinued. A mean ICARS score reduction of 11 points (range -4 to -19) was detected in the patients of the extended study, while a mean increase of 7 points (range + 1 to +14) was found in controls. This confirms the safety of infusion therapy suggesting that Erydex treatment could delay the progression of the disease.

P09.016-M
Eight new ATM gene alterations in Polish patients with ataxia-telangiectasia

M. Podralska[1], *A. Stembalska*[2], *R. Ślęzak*[2], *A. Lewandowicz-Uszyńska*[3], *B. Pietrucha*[4], *S. Kołtan*[5], *J. Wigowska-Sowińska*[6], *J. Pilch*[7], *M. Mosor*[1], *I. Ziółkowska-Suchanek*[1], *A. Dzikiewicz-Krawczyk*[1], *R. Słomski*[1];
[1]*Institute of Human Genetics, Poznań, Poland,* [2]*Wroclaw Medical University, Department of Genetics, Wrocław, Poland,* [3]*Wroclaw Medical University, 3rd Department and Clinic of Pediatrics, Immunology and Rheumatology of Developmental Age, Wrocław, Poland,* [4]*Department of Immunology, The Children's Memorial Health Institute, Warszawa, Poland,* [5]*Department of Pediatrics, Hematology and Oncology, Institute of Pediatrics, Medical Academy, Bydgoszcz, Poland,* [6]*Department of Developmental Neurology University of Medical Sciences, Poznań, Poland,* [7]*Department of Child Neurology, Medical University of Silesia, Katowice, Poland.*

Ataxia-telangiectasia (AT, MIM#208900) is neurodegenerative and immunodeficiency disorder, is inherited in an autosomal recessive manner. AT results from mutations in the ataxia telangiectasia mutated (ATM) gene. We studied the entire ATM gene coding sequence for mutations using PCR-HD, PCR-SSCP and MLPA techniques. 38 changes in ATM sequence were detected in 25 AT families. The mutation types are diverse, including 18 nonsense (58,1%), 10 splicing (32.3%), 2 missense alterations (6,4%) and 1 large genomic deletion (3,2%). Only 2 mutations have been found in homozygous state ([c.4007_4008insA; c.4007_4008insA], [c.9021_9022insA; c.9021_9022insA]). Most frequent mutations among our AT patients are: c.6095G>A (7 times), c.7630-2A>C (6), c.5932G>T (5), c.7010_7011delGT (2). Several families had newly diagnosed DNA alterations in Polish population (8/38; 21,1%). New detected variants were: c.8441delC, c.6145T>G, c.434T>G, c.6754_6754delAfsX5, c.4007_4008insA, c.7606G>A, c.3402+30_3402+32delATC, deletion of 62 and 63 exons of gene. The effects of two missense changes were predicted to be pathogenic by in silico analysis. The c.3402+30_3402+32delATC was identified in 3 AT families (12%) and none of control samples. According to data from the NHLBI Exome Sequencing Project the ATC deletion allele has a frequency of 0.11% total alleles studied and is not observed in the homozygous state. In this study, we confirmed status of recurrent mutations, but also detected new changes in ATM sequence. Most of the Polish patients are compound heterozygotes and none of them having the same combination of mutations, what makes molecular diagnostic more difficult.
Supported by grant NN401098240 from the Ministry of Science and Higher Education in Poland.

P09.017-S
Finding patients with Parkinson's disease (PD) which are heterozygotes for Atp7b gene in Russia

E. Y. Ilyechova[1], *M. N. Karpenko*[1,2], *I. V. Milyukhina*[1], *L. V. Puchkova*[2,1];
[1]*Institute of Experimental Medicine, Saint Petersburg, Russian Federation,* [2]*St. Petersburg State Polytechnical University, Saint Petersburg, Russian Federation.*

Significant part of PD patients are heterozygotes for Wilson's disease (WD). WD is a monogenic, autosomal recessive disease characterized by toxic copper accumulation in brain and liver, which results in hepatolenticular degeneration. The major biochemical manifestation of WD is reducing of serum copper status (CS) indexes: copper and ceruloplasmin concentration as well as oxidase activity. Atp7b gene encoding copper transporting ATPase P1 type that takes part in copper excretion and cuproenzimes metallation in Golgi complex is responsible for WD. In heterozygotes for WD, CS is ½ of wide type. Common mutations in ATP7B of patients with WD and PD are not the same.
The blood sera of 50 PD patients without regard to gender with severity indexes 1-4 (Hoehn and Yahr scale) were analyzed for copper (FAAS), ceruloplasmin (immunoelectrophoresis and immunoblotting), and SOD3 (ELISA) concentration as well as oxidase and SOD3 activities (p-phenylenediamine and quercetin assay, respectively). Multivariate statistical analysis showed that low levels of CS correlated with early onset of PD. Analysis of the primary structure of the exon 14, which encodes a nucleotide binding domain of the ATPase and contains the most common mutation associated with WD, showed that none of the 30 patients with PD (who are putative heterozygous for WD according to biochemical parameters) contain these mutations. However, C1079G was found in 11 patients of this group. This mutation in patients with WD has not been described previously.
Revealing heterozygous WD carriers among the PD patients may permit to treat these cases of PD more specifically.

P09.018-M
Genetic contribution to Attention Deficit Hyperactivity Disorder (ADHD) in 320 Spanish patients

C. Gómez Sánchez[1], *R. Riveiro Álvarez*[1], *V. Soto Insuga*[1], *M. Rodrigo Moreno*[1], *P. Tirado Requero*[2], *J. Carballo Belloso*[1], *C. Ayuso García*[1];
[1]*Fundación Jiménez Díaz, Madrid, Spain,* [2]*Hospital Universitario la Paz, Madrid, Spain.*

Introduction Attention-deficit hyperactivity disorder (ADHD) is one of the most common neurobehavioral disorders of childhood, characterized by age-inappropriate levels of inattention, hyperactivity and impulsivity. Despite its high heritability (76%), the results of association studies have been inconsistent and poor replicated. The aim of this study was to replicate in a Spanish cohort, the association of previously reported gene variants. **Patients and Methods** 324 children and adolescents (6-17 years old) diagnosed with ADHD according to DSM-IV-TR, and 344 controls were recruited. Patients and controls were genotyped for 23 genetic variants: *DAT1:* rs2550948, rs261759, rs2652511, VNTR-3UTR, VNTR-Intron8; *DRD2:* rs1800497; *DRD4*: rs3758653, VNTR-Exon-3, VNTR-Promotor, *SLC6A4*: VNTR-Promotor, VNTR-Intron-2; *HTR2A*: rs7322347; *NET1:* rs28386840, r5569; *ADRA2A*: rs553668, rs1800544; *LPHN3*: rs1397458, rs2305339, rs6551655; *COMT:* rs4680; *FADS2:* rs498793; *SNAP25:* rs3746544; *DDC* :rs6592961. Pearson's X^2 test, and Hardy-Weinberg equilibrium were used to assess genetic association. **Results** The most significant associations found in this study were: NET1-rs28386840 A/T genotype was significantly increased in both ADHD patients (OR:1.54, p: 0.027) and combined-ADHD subtype (OR:1.72, p:0.0043). DAT1-5/5 genotype resulted increased in inattentive-ADHD patients (OR:2.13, p:0.052) **Discussion and Conclusion** The difficulties found identifying risk ADHD associated gene variants could be explained by the heterogeneity and complexity of this disorder. Further studies designed to examine the contribution of gene-gene or gene-environment interaction are needed. In addition, the use of endophenotypes instead of DSM-IV diagnoses could improve the detection of genetic effects.

P09.019-S
Variation in the phenotype of Machado-Joseph disease (MJD/SCA3): the role of mitochondrial DNA (mtDNA) haplogroups

A. Ramos[1,2], *C. Santos*[3], *M. Raposo*[1,2], *M. de Araújo*[1,2], *M. Lima*[1,2];
[1]*Centre of Research in Natural Resources (CIRN), Department of Biology, University of the Azores, Ponta Delgada, Portugal,* [2]*Institute for Molecular and Cell Biology (IBMC), University of Porto, Porto, Portugal,* [3]*Unitat d'Antropologia Biològica, Departament BABVE, Universitat Autònoma de Barcelona, Barcelona, Spain.*

Mitochondrial dysfunction has been implicated in the pathogenesis of several neurodegenerative disorders, such as Machado-Joseph disease (MJD), a late onset poly-Q ataxia that results from an unstable expansion of a CAG tract in the ATXN3 gene. The CAG expansion size is incompletely correlated with the age at onset, highlighting the existence of genetic modifiers. Although the way by which mitochondria is involved in the neurodegenerative cascade is still unknown, mitochondrial DNA (mtDNA) haplogroup-specific polymorphisms have been associated to other poly-Q disorders. To evaluate whether mtDNA variation contributes to MJD phenotype, namely to age at onset (AO), we determined the mtDNA haplogroups in 113 MJD patients with Azorean ancestry, by sequencing the mtDNA hypervariable region I. The frequency of mtDNA haplogroups in unrelated patients (n=68) was similar to the one previously described for the general Azorean population. MJD patients classified as haplogroup J present a significantly earlier onset (mean AO of 33 years). Haplogroup W seems to have a protective effect, causing a delay in onset (mean AO of 51 years). Although haplogroup J has already been implicated in other neurodegenerative disorders, there are no previous reports of an association between haplogroup W and disease. In conclusion, our results suggest that mitochondrial single nucleotide polymorphisms defining these haplogroups could modify AO in MJD. The complete mitochondrial genome of MJD patients classified as J and W haplogroup were further sequenced in order to better understand the impact of the haplogroup-defining variants on mitochondrial function and their interaction in MJD phenotype.

P09.020-M
Transcriptional profile of Machado-Joseph Disease (MJD): mTOR signaling pathway is dysregulated in blood cells of patients

M. Raposo[1,2], *C. Bettencourt*[3], *G. Coppola*[4], *A. Ramos*[1,2], *N. Kazachkova*[1,2], *A. Rodrigues*[5,6], *P. Maciel*[5,6], *B. Bettencourt*[7,2], *J. Bruges-Armas*[7,2], *D. Geschwind*[4], *M. Lima*[1,2];

Machado-Joseph disease (MJD; MIM #109150; ORPHA98757), or spinocerebellar ataxia type 3 (SCA3) is a protein misfolding-associated disease, being the worldwide most prevalent autosomal dominant ataxia as well as the second more common polyglutamine (polyQ) disorder. Abnormal conformation of mutated ataxin-3, promotes a gain of a toxic function compromising several cellular mechanisms, namely transcription. Gene expression profiling arrays have the potential to contribute to advances in the understanding of mechanisms related with disease pathophysiology, often suggesting new potential targets for treatment. In MJD, however, the analysis of gene expression changes has been limited to animal and cellular models; thus far, transcriptional changes in MJD patients have not been investigated. In the present study we used microarrays to evaluate a global gene expression profile in blood samples of 12 MJD patients, compared with 12 normal controls. Ingenuity pathway analysis (IPA) software was used to analyze the most dysregulated pathways in MJD. Thirty pathways were found to be dysregulated (log p-value False Discovery Rate (FDR) adjusted > 3); amongst these, mammalian target of rapamycin (mTOR) signaling is observed, with significantly dysregulated expression levels in 211 genes (p-value FDR adjusted < 0.05). mTOR has been described as influencing a variety of molecular processes including protein synthesis and autophagy. Moreover, rapamycin, which inhibits the activity of mTOR, is pointed as having neuroprotective effects in several neurodegenerative disorders, mainly by induction of autophagy. The present results highlight the potential of mTOR inhibitors as potential therapeutic compounds that should be investigated for MJD.

Three SNP haplotypes in Neuroligins may correlate to autism susceptibility

M. Landini[1], *A. Mezzelani*[1], *I. Merelli*[1], *M. Raggi*[2], *F. Ciceri*[2], *L. Villa*[2], *M. Molteni*[2], *A. Marabotti*[3,1], *L. Milanesi*[1];

Autism is a neurodevelopmental disorder showing a striking sex bias with a male:female ratio of 4:1. Despite some genetic variants are causative for autism in about 17% of cases, its etiology is still largely unknown. Increasing evidences highlight the possible role of environmental factors, such as infections, xenobiotics and drugs in enhancing autism genetic susceptibility. Among genetic variants, we focused on the X-linked neuroligins that are involved in synaptic plasticity, are mutated in a few number of autistic patients, and are hemizygous in males. Hence we analyzed NLGN-3 and NLGN-4X in 52 Italian autistic cases (male:female=4,6:1) and in 31 healthy siblings (male:female=1:1,1) by Sanger sequencing. Among the other variants, in NLGN-4X, we found 2 de novo SNPs and 3 SNPs in non-coding regions (1 intronic and 2 in the 3'UTR), giving 2 different haplotypes: one was new and one was already described in a non-specific mental retardation Chinese patients. In NLGN-3, we found 3 already described intronic SNPs in haplotype block. The 3 haplotypes have statistical significance in autistics comparing to the minor allele frequencies (MAF) from the 1000-Genomes Project CEU. Interestingly, healthy siblings, half of which were female, have a middle statistical significance between autistics and MAF-CEU. As these SNPs map to non-coding regions, they could be involved in the genetic susceptibility to trigging environmental factors (probably lacking in siblings), and, being located on X-chromosome, could explain the male prevalence of autism. ACKNOWLEDGEMENTS: Italian Ministry of Health "GR-2009-1570296" project, Italian Ministry of Education, University and Research "InterOmics" Flagship project.

P09.022-M
Diagnostic utility of microarray analysis to detect rare CNVs in autism spectrum disorders

N. Brison[1,2], *S. Iqbal*[1], *W. De la Marche*[3,2], *J. Steyaert*[3,2], *I. Noens*[4,2], *S. Van Vooren*[5], *G. Thijs*[5], *K. Devriendt*[1,2], **H. Peeters**[1,2];
[1]*Center for Human Genetics, UZ Leuven, Leuven, Belgium,* [2]*Leuven Autism Research Consortium (LAuRes) , University of Leuven, Leuven, Belgium,* [3]*Department of Adolescent and Child Psychiatry, University of Leuven, Leuven, Belgium,* [4]*Department of Parenting and Special Education, University of Leuven, Leuven, Belgium,* [5]*Cartagenia, Leuven, Belgium.*

Background: The genetic causes of Autism Spectrum Disorders (ASDs) are heterogeneous and still unknown in the majority of cases. Copy number variant (CNV) detection is part of routine clinical workup. An interesting paradigm for clinical practice is that each rare CNV may account for only a small proportion of variance in ASD at population level but may have large effects in particular families. We aim to evaluate family and patient specific characteristics that may alter the clinical utility of autism risk variants. **Material and methods:** The study contains 466 clinically well characterized patients with ASD from 392 families. Individuals were genotyped by either Affymetrix SNP 6.0 array, OGT Oligo array or Illumina Omni2.5-8v1 SNP array. Genotype data of each platform were preprocessed and normalized by limiting the resolution to 200 Kb and developing customized analysis protocols per platform to detect smaller variants in targeted regions. A filtering pipeline specific for ASD was developed using standard and customized Cartagenia

Bench software applications. **Results:** We present a family based study on the validity of CNV detection in ASD using microarray analysis. The clinical utility of this screening is evaluated for different parameters (e.g. sporadic versus familial ASD, IQ, comorbidity). In some cases, we found a better diagnostic performance of the higher resolution platforms. **Conclusion:** We contribute to the diagnostic utility and indication of rare CNV detection in ASD families with respect to clinical presentation and family history.

P09.023-S
Genetic evidence that hyperactive Th2 and NK immune pathways contribute to the pathogenesis of Autism Spectrum Disorder

I. S. Piras[1,2], *S. Gabriele*[1], *V. Napolioni*[1], *R. Sacco*[1], *A. M. Persico*[1,2];
[1]*Unit of Child and Adolescent NeuroPsychiatry & Laboratory of Molecular Psychiatry and Neurogenetics, University „Campus Bio-Medico", Rome, Italy,* [2]*Mafalda Luce Center for Pervasive Developmental Disorders, Milan, Italy.*

Converging evidence suggests that abnormal immunity is involved in the pathophysiology of Autism Spectrum Disorder (ASD) both in children and adults. Altered immune processes include ongoing neuroinflammation in post-mortem brains, elevated pro-inflammatory cytokines in cerebrospinal fluid and blood, altered immune cell function, presence of brain-specific auto-antibodies, and dysregulated immune transcriptome. One strategy to assess whether dysimmunity contributes to ASD pathogenesis or represents a collateral by-standing effect is to investigate whether functional SNPs known to influence immune gene expression or function are associated with ASD. We genotyped 484 simplex and 18 multiplex families with an ASD proband at 34 known functional SNPs located in 26 immune genes involved in all major immune pathways. Statistically significant opposite transmission patterns between ASD and unaffected siblings were evident for rs2243250 (*IL4*) and rs231775 (*CTLA4*), with the combination of high *IL4* expression and low *CTLA4* function alleles associated with autism and the opposite alleles overtransmitted to unaffected siblings. Similarly, at rs361525 and rs2430561, functional SNPs located in the *TNFA* and *IFNG* genes, the combination of high expression alleles was associated with autism, while the opposite alleles were protective. These results indicate that common variants conferring hyper-responsive Th2 (*IL4* and *CTLA4*) and NK (*TNFA* and *IFNG*) activation also confer autism vulnerability. Hence previously-reported increases in plasma Th2 cytokine levels and NK cell activation are not mere by-standing effects, but are instead part of the pathophysiological cascade resulting in autistic disorder in a sizable subgroup of patients.

P09.024-M
Array-CGH contribution to Child & Adolescent Neuropsychiatry: update and prospectives

C. Lintas[1], *S. Gabriele*[1], **C. Picinelli**[2], *I. S. Piras*[2], *R. Sacco*[1], *M. Verdecchia*[1], *A. M. Persico*[1,2];
[1]*Unit of Child and Adolescent NeuroPsychiatry & Laboratory of Molecular Psychiatry and Neurogenetics, University „Campus Bio-Medico", Rome, Italy,* [2]*Mafalda Luce Center for Pervasive Developmental Disorders, Milan, Italy.*

Many behavioral disorders display prominent genetic underpinnings. We have thus introduced array-CGH analysis (Agilent, 180K) in our routine clinical assessment of all autistic and cognitively impaired children, as well as in the presence of high familial loading and/or dysmorphology. Blood samples were collected from 176 families and genetic counselling has already been provided to 65 of them. Eight families are multiplex, yielding a total of 81 patients. Proband diagnoses include: 52 autism, 9 cognitive disabilities, 4 developmental delay, 4 generalized dyspraxia, 3 learning disabilities and 9 other disorders. Patients were divided into 5 classes based on array-CGH results: [1] certainly causal CNV, N=12 (15%); [2] probably causal CNV, N=23 (28%); [3] rare variant of uncertain interpretation, N=19 (23%); [4] common variant without causal role, N=20 (25%); [5] negative result, N=7 (9%). Array-driven medical diagnostic work-up was prescribed to 10 (12,3%) patients and 3 parents, while drug therapies or supplements were prescribed to 4 (7,5%) patients. The diagnostic work-up was positive in 3 patients and 1 parent, while therapies were ineffective in 1 case and still pending evaluation in the other three. Array-CGH is thus a powerful clinical tool, provided its focus includes the functional role of duplicated or deleted genes, their presence in neurodevelopmental disorder databases and possible imprinting. Currently the main limitation is the translation of this knowledge into effective drug therapies. Array-CGH data will be especially useful when drugs currently undergoing phase II-III trials and potentially beneficial to specific subgroups of patients, will become available.

Band-like brain calcification (BLC) or pseudoTORCH syndrome: A report of six Egyptian families with expansion of the phenotypic and mutational spectrum

M. S. Zaki, *M. S. Abdel-Hamid, M. Y. Issa, G. M. H. Abdel-Salam;*
National Research Centre, Dokki,, Egypt.

Band-like brain calcification (BLC) or pseudo TORCH syndrome is a rare autosomal recessive with distinctive clinical and neuroimaging. Severe microcephaly, early onset seizures, profound developmental delay together with band-like calcification in brain, simplified gyral pattern and polymicorgyria are the hallmark of the syndrome. In 2010 O'Driscoll et al. attributed BLC to homozygous mutation in occludin (OCLN) gene through a description of 5 families from a worldwide series including an Egyptian one. Since then, a single family was reported associated with extracranial phenotype namely renal involvement due to cortical calcification. Herein we describe eight patients derived from six Egyptian Families with BLC. All presented at early life with severe microcephaly, failure to acquired developmental skills, growth arrest and mixed seizures types with predominance of the myoclonic. Patients showed a unique calcification pattern; subcortical band, basal ganglia, dentate nucleus and pons. Molecular analysis revealed that two families were linked to known genetic mutations while four families had novel mutations in OCLN gene. Three of our patients deceased at the end of the first year of life. Interestingly, the single patient with novel mutation in exon 5 had non-neurological manifestations including high imperforate anus and genital anomalies. Further, he had the best life performance with fairly controlled seizures and achieved few skills although no comparable neuroimaging findings were present. This study is considered the largest series with BLC from same ethnic group. Assigning more families will allow delineation of the phenotype-genotype spectrum of BLC.

P09.026-M
Association study of 240,000 rare coding variants in bipolar patients and controls from Germany and Norway

S. Herms[1,2], *P. Hoffmann*[1,2,3], *T. W. Muehleisen*[3], *S. Djurovic*[4], *F. D. Degenhardt* [2,5], *A. Forstner*[2,5], *M. Rietschel*[6], *M. M. Noethen*[5,2], *O. Andreassen*[4], *S. Cichon*[1,3,7];
[1]*Genomics Research Group, Department of Biomedicine, University of Basel, Basel, Switzerland,* [2]*Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany,* [3]*Institute of Neuroscience and Medicine (INM-1), Research Center Juelich, Juelich, Germany,* [4]*KG Jebsen Centre for Psychosis Research, Division of Mental Health and Addiction, Oslo University Hospital & Institute of Clinical Medicine, University of Oslo, Oslo, Norway,* [5]*Institute of Human Genetics, University of Bonn, Bonn, Germany,* [6]*Department of Genetic Epidemiology in Psychiatry, Central Institute of Mental Health Mannheim, Univ. of Heidelberg, Mannheim, Germany,* [7]*Division of Medical Genetics, University Hospital Basel, Basel, Switzerland.*

Genome-wide association studies (GWAS) of bipolar disorder (BD), a highly heritable disorder of mood with a lifetime prevalence of approximately 0,5-1% in all populations world-wide, have identified several common genetic risk factors. It is currently unclear, to what extent low-frequency and rare variants contribute to disease development. A valid hypothesis seems to be that low-frequency and rare variants in coding gene regions have a higher probability to have a functional (deleterious) effect. This subset of human genetic variation might therefore be enriched for disease-relevant variants. The Illumina HumanExome arrays make particularly this window of genetic variation accessible for association studies. This array contains 240'000 rare markers derived from exome sequencing. That array was used to test 1314 bipolar patients (895 from Germany, 419 from Norway) and 2700 controls (2366 / 339). Genotypes were exproted from a single GenomeStudio project to minimize clustering artifacts. Statistical analysis was performed using Cochrane-Mantel-Hansel test statistics. Clusters for all associated variants were checked by zCall and manually. The two variants with the strongest association to bipolar disorder were found in the gene SYNE2. Interestingly, common variants in another member of the same gene family (SYNE1) had shown genome-wide significant association in the discovery step of the first mega-analysis of bipolar disorder performed by the international Psychiatric Genomics Consortium (PGC; Sklar et al. 2011). We are currently aiming to follow-up this and other strong findings of our analysis in independent samples of bipolar disorder genotyped on the HumanExome array.

Clinical profile of paediatric Brown-Vialetto-VanLaere syndrome

M. Ryten[1], *C. Hammond*[1], *M. Lim*[2], *D. Josifova*[1];
[1]*Guy's Hospital, London, United Kingdom,* [2]*Evelina Children's Hospital, London, United Kingdom.*

Brown-Vialetto-Van Laere Syndrome (BVVLS) is an autosomal recessive neurological disorder presenting with progressive sensorineural hearing loss and bulbar neuronopathy, followed by a mixed picture of upper and lower motor neuron palsies. Until recently there has been no treatment available for this progressive neurodegenerative disorder. However, the discovery that it is caused by mutations in the riboflavin transporter genes, SLC52A2 and SLC52A3, have led to the use of riboflavin supplementation and there is growing evidence to suggest that this may be an effective treatment. This makes the identification of this disorder particularly important and led us to review clinical information about the phenotype of children

with BVVLS. Our cohort consisted of patients diagnosed at the Molecular Diagnostic Laboratory at Guy's and St. Thomas Hospital and by our collaborators in Germany and Iceland, as well as molecularly-confirmed reports in the literature. After excluding patients with insufficient clinical data available, we identified a total of 28 SLC52A2 and 15 SLC52A3 patients for analysis. We identified differences in the clinical presentation and progress of these two patient groups. In particular, while hearing loss, muscle weakness and bulbar palsy were common clinical features in both patient groups, amongst SLC52A2 mutation carriers, ataxia and optic atrophy were also surprisingly common. These findings suggest that BVVLS may have a wider clinical phenotype than presently appreciated. This is an important observation given emerging evidence that it can be ameliorated using riboflavin supplementation.

Background and Purpose - CADASIL, a rare autosomal dominant disorder caused by NOTCH3 mutations, is characterized by vascular smooth muscle and endothelial cells abnormalities, altered vasoreactivity and recurrent lacunar infarcts. Vasomotor function may represent a key factor for disease progression. Tetrahydrobiopterin (BH4), essential cofactor for nitric oxide synthesis in endothelial cells, ameliorates endothelial function. We assessed whether supplementation with sapropterin, a synthetic BH4 analogue, improves endothelium-dependent vasodilation in CADASIL.
Methods -- In a 24-month, multicenter randomized, double-blind, placebo-controlled trial, CADASIL patients aged 30-65 years were randomly assigned to receive placebo or sapropterin 200-400 mg b.i.d. The primary endpoint was change in the reactive hyperemia index by peripheral arterial tonometry (RH-PAT) at 24 months. We also assessed the safety and tolerability of sapropterin. Analysis was done by intention-to-treat (ITT).
Results -- The ITT population included 61 patients. We found no significant difference between sapropterin (n=32) and placebo (n=29) in the primary endpoint (mean difference in RH-PAT changes 0.19 (95% CI -0.18;0.56)). RH-PAT increased after 24 months in 37% of patients on sapropterin and 28% on placebo; however, after adjustment for age, sex and clinical characteristics, improvement was not associated with treatment arm. The proportion of patients with adverse events was similar on sapropterin and on placebo (50% vs 48.3%); serious adverse events occurred in 6.3% vs 13.8%, respectively.
Conclusions -- Sapropterin was safe and well-tolerated at the average dose of 5 mg/kg/day, but did not affect endothelium-dependent vasodilation in CADASIL patients.

Comparison of NOTCH3 expression in fibroblasts from CADASIL patients versus normal controls

R. Mazzei[1], C. Ungaro[1], F. L. Conforti[1], S. Bianchi[2], A. Magariello[1], A. Patitucci[1], M. Muglia[1], M. T. Dotti[2], A. Federico[2], **A. Qualtieri**[1]*;*
[1]National Research Council, Mangone (CS), Italy, [2]Department of Neurological, Neurosurgical, and Behavioural Sciences, University of Siena, Siena, Italy.

CADASIL is an inherited cerebrovascular disease caused by mutations in the NOTCH3 gene, encoding a protein belonging to the Notch receptor family. Notch signalling is involved in a broad spectrum of function, from the cell proliferation to apoptosis. Recently it has been shown that it is expressed in adult human tissues such as peripheral blood lymphocytes (PBLs) and fibroblasts. Our aim was to evaluate Notch3 protein expression in human fibroblasts from CADASIL patients.
We perform the investigation on the fibroblasts from four CADASIL patients and a normal subject. The patients were genetically characterized, and carried a C174Y, a R332C, a c.341-24_26delAAC, a R61W mutations, respectively. Fibroblasts were grown in DMEM with 10% FBS, Glutamine, Streptomycin-Penicillin. At 80% of confluence, cells were washed in TBS and fixed on a slide with paraformaldehyde.
The slides were treated with a mouse anti Human Notch3 antibody that recognizes the extracellular domain ECD and a rabbit antibody that recognizes the intracellular domain NICD. Anti-mouse and anti-rabbit secondary antibodies revealed the primary antibodies.
Different patterns of localization were detected. In cells with mutation R61W an immunoreactive predominance of the intranuclear NOTCH3 NICD, and in cells from patients with R332C mutation an immunoreactive predominance of the N3ECD extracellular NOTCH3 domain was observed when compared both with cells from normal subject, and with the remaining CADASIL cells.
The obtained results show that in CADASIL fibroblasts the mutation type is associated with a relative differential localization of Notch3. This likely might be due to alterations in the protein processing.

P09.030-M
aCGH reevaluation reveals clinically relevant CNVs, in patients with previously unexplained developmental delay / ASD, candidate for exome sequencing. Presentation of selected cases.

K. Varvagiannis[1,2]*, E. Ranza[2], E. Stathaki[2], S. Gimelli[2], F. Sloan-Béna[2], S. E. Antonarakis[1,2], A. Bottani[2];*
[1]University of Geneva Medical School, Geneva, Switzerland, [2]Geneva University Hospitals - HUG, Geneva, Switzerland.

Array comparative genomic hybridization (aCGH) constitutes a first-tier diagnostic test for individuals with unexplained developmental delay (DD) or autism spectrum disorder (ASD) with an estimated diagnostic yield of about 15% to 20%. The advent of exome sequencing has revolutionized the diagnostic process in the remainder of undiagnosed patients, allowing the identification of causal mutations in an additional 25% to 55% of such patients, depending on the different studies' criteria.
Over the last few years, copy number variation databases have accumulated significant amounts of data, often facilitating the task of distinguishing between benign and pathogenic copy number variants and the delineation of novel, recurrent, microdeletion/microduplication syndromes.
We present selected cases of patients, candidate for exome sequencing analysis. Reevaluation of aCGH data allowed re-classification of variants of previous unknown clinical significance, to the category of clinically relevant CNVs overlapping newly recognized DD/ASD genes such as *CAMTA1*, *RB1-CC1*, *CNTNAP2* and others.
Our examples demonstrate that aCGH remains a valuable diagnostic tool for the investigation of such patients, and underscore the need to reassess the pathogenicity of previously detected aCGH variants before consideration of exome sequencing.

P09.031-S
CNVs analysis in patients with Cerebellar and Brainstem Congenital Defects (CBCD)

S. Loddo[1,2], V. Parisi[1], F. Mancini[1], C. Cesario[1,2], G. E. Calabrò[1,3], A. Capalbo[1], A. Ferraris[1], A. Novelli[1], **L. Bernardini**[1]*, E. M. Valente[1,4];*
[1]Mendel Laboratory, Rome, Italy, [2]Department of Experimental Medicine, Sapienza University, Umberto I Hospital, Rome, Italy, [3]Department of Hygiene, Preventive Medicine and Public Health, University of Messina, Messina, Italy, [4]Department of Medicine and Surgery, University of Salerno, Salerno, Italy.

Cerebellar and brainstem congenital defects (CBCD) affect about 1 in 3000-4000 live births. Typical clinical signs include hypotonia, ataxia, abnormal ocular movements and psychomotor delay/intellectual disability, but phenotypic variability is wide with possible multiorgan involvement.
With the exception of few autosomal recessive or X-linked conditions, CBCD are frequently sporadic, suggesting that *de novo* mutations or genomic rearrangements may represent common pathogenetic mechanisms.
We analyzed by genomic microarray platforms 83 sporadic CBCD patients, enrolled in a multicentric project focused on studying the genetic causes of CBCD. Eight pathogenic or potentially pathogenic CNVs were detected in 7 patients (8.4%).
Further 11 patients, investigated in our Cytogenetic diagnostic lab for intellectual disability and/or congenital anomalies, have been subsequently included in the CBCD project, since they showed CNVs overlapping to deletions/duplications detected in CBCD patients and/or were affected by CBCD.
Of note, we detected eight deletions that defined three recurrent imbalances. Three deletions were partially overlapping in 3q22.3q26.1, three in 6q25.1q27 and two in 10q26.2q26.3. These three chromosomal regions have been already associated to CBCD, although literature and DECIPHER database revision suggest incomplete penetrance. In addition we report six patients with non-recurrent CNVs: del(2q36.3), dup(6p22.3), inv/dupdel(8p), del(8p21.3p21.2), dup(13q34), dup(Xq28).
These data confirm the crucial role of microarray analysis as a tool to identify

pathogenic CNVs in patients with congenital defects. Our data confirm that CBCD are characterized by high genetic heterogeneity and incomplete penetrance, suggesting the involvement of further mechanisms (modifier genes, environmental factors) in cerebellar and brainstem mal-development.

P09.032-M
The structure and functions of the transcription factor PHOX2B: new insights in the molecular pathogenesis of Congenital Central Hypoventilation Syndrome

D. Belperio[1], *S. Di Lascio*[1], *R. Benfante*[1,2], *D. Fornasari*[1,2];
[1]*Università degli Studi di Milano, Dept. of Medical Biotechnology and Translational Medicine, Milan, Italy,* [2]*CNR-Institute of Neuroscience, Milan, Italy.*

Congenital Central Hypoventilation Syndrome (CCHS) is a very rare neonatal neurological disorder characterized by abnormal ventilatory response to hypoxia and hypercapnia, owing to failure of autonomic respiratory control: affected children hypoventilate during sleep, with possible very severe neurological damages.
Frameshift mutations (5%) and poly-alanine triplet expansions (95%) have been detected in the coding region of the homeobox gene PHOX2B in about 90% of CCHS patients. A correlation between length of the expansion and severity of the respiratory phenotype has been reported. Since some of the mutations alter the sub-cellular localisation, the DNA-binding affinity and the transcriptional activity of the protein, and that mutated PHOX2B proteins can interfere with the activity of the wild-type protein by sequestering it into aggregates, one crucial question concerns the identification of the functional domains of the protein, the role of the poly-alanine tract and the effects of its expansion on the general architecture and function of the protein. We have performed a deletion analysis of PHOX2B and identified two nuclear localization signals in the homeodomain, both required for the complete import of the protein in the nucleus, corresponding to residues necessary for the binding to DNA, and partially blocked by the expanded poly-alanine tract. By using mammalian two-hybrid system we have also demonstrated that PHOX2B can form homo-dimers and we are currently investigating if the mutations alter the dimerization properties of the protein and the potential contribution to the range of phenotypes and pathogenesis in CCHS patients.

P09.033-S
Transcriptional dysregulation and impairment of PHOX2B auto-regulatory mechanism in the pathogenesis of Congenital Central Hypoventilation Syndrome

S. Di Lascio[1], *S. Moncini*[1], *T. Bachetti*[2], *I. Ceccherini*[2], *R. Benfante*[1,3], *D. Fornasari*[1,3];
[1]*Università degli Studi di Milano, Dept. of Medical Biotechnology and Translational Medicine, Milan, Italy,* [2]*Laboratorio di Genetica Molecolare, Istituto Giannina Gaslini, Genova, Italy,* [3]*CNR-Institute of Neuroscience, Milan, Italy.*

The PHOX2B transcription factor plays a crucial role in autonomic nervous system development. In humans, heterozygous mutations of the *PHOX2B* gene lead to Congenital Central Hypoventilation Syndrome (CCHS), a rare disorder characterized by a broad variety of symptoms of autonomic nervous system dysfunction including inadequate control of breathing. The vast majority of patients with CCHS are heterozygous for a poly-alanine repeat expansion mutation of a twenty residues poly-alanine tract in the C-terminus of PHOX2B. Although several lines of evidence support a dominant-negative mechanism for *PHOX2B* mutations in CCHS, the molecular effects of PHOX2B mutant proteins on the transcriptional activity of the wild-type protein have not yet been elucidated. One of the targets of PHOX2B is the *PHOX2B* gene itself, and we have recently demonstrated that mutated PHOX2B variants can actually negatively interfere with the expression of the normal allele. Since in vitro the poly-alanine expanded proteins alter the regulation of other three PHOX2B target genes (*PHOX2A*, *DBH*, *TLX2*) in a promoter-specific manner and that, in CCHS patients, different PHOX2B mutations may affect different target genes, this highlights the importance of identifying PHOX2B target genes in order to get new insights into the molecular pathogenesis of the disease. To this purpose, we carried out Chromatin Immunoprecipitation experiments from IMR32 neuroblastoma cell line, followed by massively parallel sequencing of the co-immunoprecipitated genomic DNA fragments (ChIP-Seq). We are currently validating the most promising candidate target genes by biochemical and functional approaches.

P09.034-M
Molecular investigation of CDKL5 gene in patients with Rett like infantile spasms in Greece-Preliminary results

M. Kouskou, *E. Tzagkaraki, C. Sofocleous, H. Fryssira, S. Psoni, K. Kosma, S. Kitsiou, E. Kanavakis;*
Laboratory of Medical Genetics, National and Kapodistrian University of Athens, Agia Sofia Children's Hospital, Athens, Greece.

A subset of atypical Rett syndrome with infantile spasms or early seizures starting in the first postnatal months is caused by mutations in the Cyclin-Dependent Kinase-Like 5 gene (*CDKL5*) located in the Xp22 region. Mutation screening of *CDKL5* was performed in 20 female and 5 male patients, referred for infantile spasms, who were previously tested negative for methyl CpG-binding protein 2 gene (*MECP2*) mutations. All coding exons (2-21) and intron-exon boundaries of *CDKL5* gene were screened for mutations by Enzymatic Cleavage Mismatched Analysis (ECMA) followed by direct sequencing. A novel frameshift mutation (c.2530delC; p.H844IfsX19) was detected and, due to its deleterious nature, predicted to affect the carboxy-terminal region of the protein. The female patient, aged 10- years-old, presented psychomotor delay and epileptic spasms which began at the second month. Subsequent studies in both parents and in 50 chromosomes from normal subjects failed to detect the c.2530delC mutation indicating that it is probably *de novo* and disease-causative. The novel mutation was directly submitted in the RettBASE (IRSF MECP2 Variation Database) and LOVD databases. Our studies of *CDKL5* gene were carried out in patients with Rett-like phenotypes and epileptic spasms with early onset. The incidence of *CDKL5* mutations in female patients with Rett-like features who were negative for *MECP2* mutations was 5% (1/20), while in female patients with spasms it was 17% (1/6), rates both lower than those reported by other studies (7.8% and 28%, respectively) probably because of their larger sample sizes.

P09.035-S
No evidence for a contribution of CHRNA7 rare variants in autism susceptibility

E. Bacchelli[1], *A. Battaglia*[2], *C. Cameli*[1], *S. Lomartire*[1], *S. Thomson*[3], *J. S. Sutcliffe*[3], *R. Tancredi*[2], *E. Maestrini*[1];
[1]*FaBiT – Dipartimento di Farmacia e BioTecnologie, Bologna, Italy,* [2]*Stella Maris Clinical Research Institute for Child and Adolescent Neuropsychiatry, Calambrone (Pisa), Italy,* [3]*Molecular Physiology and Biophysics, Centers for Molecular Neuroscience and Human Genetics Research, Vanderbilt University, Nashville, TN, United States.*

Recurrent microdeletions of chromosome 15q13.3 are causally associated with a wide range of phenotypic features, including autism spectrum disorder (ASD), seizures, intellectual disability, and other psychiatric conditions. The pathogenicity of the reciprocal microduplications is more uncertain.
Even if the recurrent deletion contains several genes, CHRNA7, encoding for the alpha7 subunit of the neuronal nicotinic acetylcholine receptor, is considered the culprit gene in mediating the neurological phenotypes in patients with the 15q13.3 deletion.
In order to evaluate the role of CHRNA7 rare variants in ASD susceptibility, we have performed copy number variant (CNV) analysis and mutation screening of the coding sequence of CHRNA7 in a sample of 135 ASD individuals from Italy. Rare sequence variation in this gene remains largely unexplored, given the existence of a fusion gene, CHRFAM7A, which includes a partial duplication of exons 5-10 of CHRNA7. Hence, any attempts at sequencing to detect mutations must distinguish between CHRNA7 and CHRFAM7A, making next-generation sequencing approaches unreliable for this purpose.
CNV analysis led to the identification of a CHRNA7 microduplication in a subject with autism and moderate cognitive impaiment. No pathogenic mutations were identified in CHRNA7 coding regions. However, we detected rare variants in the proximal promoter region, previously described to functionally reduce transcription. In conclusion, rare sequence variants in CHRNA7 do not significantly contribute to ASD susceptibility, at least in our clinical sample characterized by low frequency of associated medical comorbidity. This study represents the first sequence variant analysis of the CHRNA7 gene in a sample of idiopathic autism.

Mutations in the CLCN2 gene encoding the brain chloride channel ClC-2 have been recently associated with a rare autosomal recessive leukoencephalopathy, characterized by variable age at onset and clinical features, with specific brain MRI findings caused by chronic white matter edema. We sequenced CLCN2 in 6 patients from 5 families presenting characteristic MRI white matter alterations involving middle cerebellar peduncles, cerebral peduncles, and posterior limb of the internal capsules. We identified

3 homozygous CLCN2 mutations in 5 patients (4F/1M) from 4 families, while one male patient tested negative. One novel homozygous splice-site mutation was identified in a young asymptomatic woman who underwent MRI because of headache. A previously described nonsense mutation was identified in 3 women from 2 apparently unrelated families from Southern Italy. One patient presented at 58y with dystonic posture of the neck, mild postural tremor of the hands, and head tremor. Of the two sisters, one presented at 26y with migraine without aura followed, at 46y, by progressive postural imbalance, hypoacusia and tinnitus, and degenerative retinopathy; her sister, aged 60y, suffers from cluster headhache since 30y with negative neurological examination. Repeated MRI in both sisters show stability of the leukodystrophic pattern. Finally, a novel homozygous missense mutation was found in a male patient presenting asymptomatic leukoencephalopathy discovered during assessment for infertility and azoospermia. This study shows that CLCN2 mutations can be associated with a wide, but relatively mild, phenotypic spectrum and suggests that a second, yet unidentified, gene can be associated with this peculiar white matter disease.

We searched for the molecular basis of Charcot Marie-Tooth neuropathy type 4B (CMT4B) in a consanguineous Bedouin family consisting of the parents and their 4 children. Two of the children were affected, another child presented with slow motor conduction velocity similar to the father who also had mild pes cavus and in-toeing feet. Assuming homozygotization of a founder mutation we used linkage analysis for the known genes affected in CMT to identify the chromosomal locus of the mutation. The genes *PRX, FGD4, SH3TC2, EGR2, NEFL, GDAP1, MPZ,* and *MFN2* were negated by the linkage analyses. Homozygosity was identified for the *SBF2* locus. Sequencing the patients' DNA for *SBF2* identified a homozygous deletion of 12 bases including the acceptor splice site at the 5' of an exon of the gene. The transcript presented a deletion of 19 bases in this exon causing a frameshift that deletes the plekstrin homology domain. Quantitative RT-PCR determined that the stability of this transcript was comparable to that of the normal transcript suggesting that the truncated protein is produced. The parents and the child with slow motor conduction velocity were heterozygotes for the mutation. The mutation causing elimination of the plekstrin homology domain may impair motor conduction velocity in some carriers. This is the first documentation of an effect of a mutation in *SBF2* in the heterozygote state that may act in a dominant negative manner.

Background: Epilepsy is a common neurological condition affecting 0.5-1% of the population. Increasingly, it is being recognised that genetic predisposition underlies most epilepsy. The use of new technologies such as whole exome/genome sequencing and microarrays have led to the identification of several single genes and copy number variants (CNVs) as the cause of epilepsy.
Objective: To identify and discuss causal CNVs in patients with suspected genetic epilepsy
Methods: We studied all 213 patients with epilepsy referred to the Oxford University Hospitals Genetics Laboratory for arrayCGH as part of their clinical diagnostic work up between 2006 and 2013. We classified the abnormal CNVs into "definitely", „probably", "uncertain" and "benign" pathogenicity groups. We studied the epilepsy phenotype of the patients, especially those in the „definitely" and "probably" groups, wherever possible. .
Results: Abnormal CNVs were identified in 69/213 patients (32.4%); single CNVs in 50/69 (72.5%) and multiple CNVs in 19/69 (27.5%) of patients. We classified rare CNVs as „definitely pathogenic" in 18/213 (8.5%), „probably pathogenic" in 12/213 (5.6%) and "uncertain" or "benign" in 39/213 (18.3%). Our most frequent rare CNV was 2p16.3 microdeletion (49,294,769-51,251,557) disrupting the *NRXN1* gene, present in 7/69 (10.1%) patients. Other regions of interest included 2q22, 6q26, 15q11.2, 16p11.2 and 22q11.2. Potential candidate genes will be discussed.
Conclusions: Our study highlights the importance of the use of microarrays in the clinical diagnosis of patients with epilepsy. It discusses 'definitely pathogenic' variants which have been previously reported and potential candidate genes within 'probably pathogenic' CNVs which need further research.

Normal aging of the brain is characterized by changes of its structure and function resulting in decreasing cognitive abilities. However, the age-dependent decline of the cognitive performance (CP) can vary greatly in subjects of the same age. Here we assessed CP-profiles (attention, executive functions, language, and memory) of 482 elderly subjects from a population-based cohort from Germany (1000BRAINS) revealing 323 high-performers (HPs) that cognitively performed better than 159 low-performers (LPs). To detect genetic variants that contribute to these CP-differences, we compared both groups in a genome-wide association study (GWAS).
No SNP reached genome-wide significance (P<5E-8). However, 28 SNPs showed strong-to-moderate evidence for association with CP-differences (P<5E-5). The most significant finding was a SNP located 200 kb upstream of the *KCNH8* gene. The minor allele was significantly over-represented in LPs compared to HPs (38% vs. 26%, OR=1.77, P=1.94E-6) suggesting that it contributes to reduced CP.
Neither the top SNP nor a SNP in strong linkage disequilibrium have received evidence for association with a cognitive endophenotype through a previous GWAS. KCNH8 is expressed in important brain regions and belongs to a family of voltage-gated potassium channels that likely are involved in modulating the overall excitability of neurons (Zou et al., 2003). Our study proposes a promising new candidate gene for CP. However, replication in independent samples is necessary to confirm our result.

P09.040-M

Two novel missense COL4A1 mutations and genetics heterogeneity in porencephaly

G. Vaula[1], *E. Giorgio*[2], *G. Bosco*[1], *M. Conterno*[1], *D. Quartana*[1], *A. Calcia*[2], *C. Mancini*[2], *E. Di Gregorio*[3], *S. Cavalieri*[2], *E. Pozzi*[2], *A. Brussino*[2], **A. Brusco**[2,3];
[1]*University of Torino, Department of Neurosciences, Torino, Italy,* [2]*University of Torino, Department of Medical Sciences, Torino, Italy,* [3]*A.O. Città della Salute e della Scienza, S.C.D.U. Medical Genetics, Torino, Italy.*

COL4A1/COL4A2 mutations have been reported in porencephaly and in small vessels cerebral vascular diseases (CVD), often associated with ocular, renal and muscular features. We screened three families with a broad spectrum of porencephaly and vascular leukoencephalopathy for COL4A1/COL4A2 mutations. In family LEU-1-TO, three patients on two generation presented with leukoencephalopathy variably associated with retinal, deep and periventricular cerebral haemorrages and aneurysms. One subject presented a small periventricular porencephalic lesion. The proband in family LEU-2-TO had a history of congenital glaucoma and cataract, presented a sudden and reversible motor impairment at 14 yrs, followed by progressive gait imbalance in her 30thies. She delivered two newborn severely affected by porencephaly. In the post partum she had an haemorragic stroke. MRI showed parietal haemorrage, diffuse microbleeds, severe leukoencephalo-

pathy and aneurisms of intracranial vessels. In family LEU-3-TO two male brothers presented an overlapping clinical picture with history of recurrent haemorragic strokes in the first two decades and a severe leukoencephalopathy, brain microbleeds and ischemic lacunae at the neuroimages. We identified two novel missense mutations in COL4A1 (c.1249 G>C, p.G417R in LEU-1-TO; c.2662 G>A, p.G888R in LEU-2-TO) by sequence analysis. Both are predicted pathogenic and hit highly conserved Gly residues of the Gly-X-Y repeat in the collagen triple helical domain. As reported for COL4A1 missense changes in the first third of the gene, mutation p.G417R seems associated with a variant phenotype in which porencephalic lesions are not the major characteristic. Patients in family LEU-3-TO, negative for COL4A1/COL4A2, suggest a genetic heterogeneity for this disease.

P09.041-S

The role copy number variations (CNVs) in cryptogenic Cerebral Palsy

R. Segel[1,2], *H. Ben-Pazi*[1,2], *S. Zeligson*[1], *A. Fatal-Valevski*[3,4], *A. Aran*[1,2], *V. Gross-Tzur*[1,2], *D. Shmueli*[5], *N. Shneibaum*[3,4], *D. Lev*[6], *S. Perlberg*[1,7], *L. Deutsch*[8], *E. Levy-Lahad*[1,2];
[1]*Shaare Zedek Medical Center, Jerusalem, Israel,* [2]*Hadassah School of Medicine, Hebrew University, Jerusalem, Israel,* [3]*Tel Aviv Sourasky Medical Center, Tel Aviv, Israel,* [4]*Tel Aviv University, Tel Aviv, Israel,* [5]*Child Development Center, Clalit, Jerusalem, Israel,* [6]*Metabolic-Neurogenetic Clinic, Wolfson Medical Center, Holon, Israel,* [7]*Hebrew University, Jerusalem, Israel,* [8]*Biostatistical Consulting, BioStats, Jerusalem, Israel.*

Background: Cerebral palsy (CP) is an „umbrella term" for congenital, non-progressive motor disability, reflecting multifactorial insults to the developing brain. Etiologic factors include perinatal asphyxia, infection, inflammation, and stroke. However, in many individuals with CP the pathogenesis is unknown. Copy number variations (CNVs) cause various neurodevelopmental conditions. We investigated the prevalence and characteristics of CNVs in individuals with cryptogenic CP.
Methods: 52 participants with non-progressive pyramidal or extra-pyramidal signs since infancy and no identified etiology were enrolled. Individuals with acquired cause (i.e. stroke) were excluded. Analysis was performed using the Affymetrix HD array. CNVs were classified as: pathogenic CNVs, likely pathogenic, or likely benign. Main outcome measures were: clinically significant (pathogenic and likely pathogenic CNVs) or not-significant (likely benign and no CNVs) findings.
Results: 40 CNVs were found in 26/52 (51%) participants. Most CNVs were considered clinically significant (11/26 pathogenic and 5/26 likely pathogenic vs. 10/26 likely benign) and were not previously reported to cause motor disability (12/16). Most CNVs were de-novo. Compared to individuals without clinically insignificant CNVs, individuals with clinically significant CNVs were more likely to have multiple CNVs ($p<0.001$), dysmorphic features ($p=.01$) and non- motor comorbidities ($p=0.03$). In 2/16 participants with clinically significant CNVs the phenotype was characteristic for the genomic findings (SPAT and KANK1 deletions).
Conclusions: Clinically significant CNVs were found in 16/52 (31%) of individuals with cryptogenic CP and were often multiple and de-novo. We recommend that this useful test be performed in individuals with cryptogenic CP *especially in individuals with dysmorphic features and comorbidities.*

Behavioral phenotype in Costello Syndrome with atypical mutation: a case report

P. Alfieri[1], *C. Caciolo*[1], *G. Piccini*[1], *L. D'Elia*[1], *G. Valeri*[1], **M. Tartaglia**[2], *M. Digilio*[1], *B. Dallapiccola*[1], *S. Vicari*[1];
[1]*Bambino Gesu` Children's Hospital, IRCCS, Roma, Italy,* [2]*Istituto Superiore di Sanità, Roma, Italy.*

Costello syndrome (CS) is a rare genetic disorder caused, in the majority of cases, by germline missense HRAS mutations affecting Gly12 promoting enhanced signaling through the MAPK and PI3K-AKT signaling cascades. In general, the neuropsychiatric phenotype in CS is fairly homogeneous with mild or moderate intellectual disability, and a behavior usually characterized by irritability and shyness at younger ages, and sociable personality and good empathic skills after 4-5 years. We report on a 7-year-old boy a heterozygous for a rare duplication of codon 37 (p.E37dup) in HRAS, manifesting an impairment in his social interaction and non-verbal communication with circumscribed interests. The neuropsychiatric evaluation meets the DSM-IV criteria for Pervasive Developmental Disorder-Not Otherwise Specified (PDD-NOS). He showed marked impairment in the use of multiple nonverbal behaviors (eye-to-eye gaze, facial expression, body posture, and gestures to regulate social interaction). Also a neuropsychological battery of tests was used to evaluated the subject. A behavioral treatment was prescribed to reduce aberrant behaviors and compulsions. Regarding communicative aspects, we recommended a speech therapy intervention. After one year the patient and his parents have benefited from these treatments. In conclusion we have investigated a CS patient with an uncommon HRAS lesion showing an atypical profile in which a careful neuropsychological and behavioral evaluation showed the indication to immediately start a behavioral therapy and a speech therapy intervention. These features improve the delineation of the phenotype of individuals with rare HRAS mutations.

P09.043-S

Anticipation of age at death and possible bias in Creutzfeldt-Jacob Disease

D. Gras[1], *J. Brandel*[2], *A. Welaratne*[2], *L. Laplanche*[3], *S. Haik*[4], *A. Brice*[5,1], *J. Feingold*[5,1], **A. Durr**[5,1];
[1]*AP-HP, Fédération de Génétique, Paris, France,* [2]*AP-HP, Cellule Nationale de Référence des Maladies de Creutzfeldt Jakob, Paris, France,* [3]*Assistance Publique–Hôpitaux de Paris Service de biochimie et biologie moléculaire, Paris, France,* [4]*Inserm UMRS1127, Paris, France,* [5]*Inserm UMRS1127/NEB, Paris, France.*

Mutations in PRNP that encodes the prion protein are causative for inherited Creutzfeldt-Jakob disease (CJD). The E200K substitution is the most frequent mutation. Earlier age at death in successive generations has been reported in two clusters, from Israel (Rosenmann et al. Neurology 1999;53(6):1328-9) and Italy (Pocchiari et al. PLoS One 2013;8(4):e60376). No molecular or environmental explanations have been found. The aim was to analyze a possible observational bias in E200K CJD patients from families living in France. Ages at death from 42 parent-offspring pairs from 19 families were collected and compared: parents 63.5 years ±13.9 (range 43 to 90) offspring 59.8 years ±10.4 (25 to 80), indicating a significantly earlier age at death in offspring ($p=.015$ paired t-test). Including ages at last follow-up or at death of an unaffected but obligate carrier-parent, the difference increased to - 9.8 years anticipation $p=.004$. Considering the large range of ages at death and the intra-sib-ship variability, the most obvious bias lies in the fact that sibs could develop disease later in life. When analyzing pairs with at least 50% affected with known ages at death, the anticipation was lost: parents 68.1 ± 19.9 years and offspring 62.8 ± 7.9 years $p=.957$, $n=12$. This result could indicate a possible observation bias. Another hypothesis could be the loss of modifying genes outside inbred clusters. The search for genetic modifiers in familial CJD is of great importance.

P09.044-M

A new autosomal recessive syndrome: Severe developmental delay and dysmorphic features causing by a missence mutation in *FTO* gene

A. Caglayan[1], *B. Tüysüz*[2], *K. Bilguvar*[1], *M. Gunel*[1];
[1]*Department of Neurosurgery, Program on Neurogenetics, Yale School of Medicine, New Haven, CT, United States,* [2]*İstanbul University, Cerrahpasa Medical Faculty, İstanbul, Turkey.*

Fat mass and obesity-associated gene (*FTO*) associated with variation in body weight and metabolic disorders. Recently, Boissel et al. reported a homozygous loss-of-function mutation in a family with nine affected members who had a severe development delay and multiple congenital anomaly. We performed whole-exome sequencing analysis and identified a novel homozygous missense mutation (c.812A>C) within the *FTO* gene in a 9.5 months -old girl with dysmorphic facies and developmental delay. She was the first child from the consanguineous parents. She had microcephaly, prominent metopic ridge, coarse face, long philtrum, microretrognathia, prominent alveolar ridge, antevert nostil, and brachydactyly. She follow up until 4 years and 9 months of age and she gained head control at first year of life, sitting 2 years, walking with help at 4.5 years old of age. She could say only three words at 4 years and 9 months. Denver testing at 4 years old of age confirmed severe developmental delay (DQ:23). Cranial CT imaging showed premature fusion of metopic suture. She also had splenomegaly on abdominal examination and grade-1 esophageal varices on endoscopy. Hearing assessment by auditory brainstem response showed conductive and sensorineural hearing loss. Eye examination revelaed optic atrophy, strabismus, nystagmus and abnormal electroretinogram. The clinical findings of the patient were very similar to first described family. In addition, she had high levels of creatine kinase was persisted since birth. As a result, we report second patient with novel homozygous missense mutation in *FTO* and discuss phenotypic extension of this gene mutations.

P09.045-S

Diagnosing dystonia using a Next-Generation-Sequencing panel

K. Grundmann, *J. Bickmann, U. E. A. Faust, A. Soehn, M. Sturm, O. Riess, P. Bauer;*
Dept of Medical Genetics and Applied Genomics, Tuebingen, Germany.

Dystonias are a heterogeneous group of movement disorders which a strong inherited basis. Overlapping, non-specific features of many dystonias hamper a clear clinical diagnosis and make targeting a specific gene difficult or impossible. We developed a panel of 42 genes for Next Generation Sequencing containing the most relevant dystonia genes and covering the most relevant dystonia phenotypes known so far in order to analyze a cohort of unselected dystonia patients
We have established a selector-based enrichment method (HaloPlex, Agilent)

targeting 42 dystonia genes. A total of 310kb is enriched and sequenced by Illumina MiSeq (2x 150 bp paired-end). A first batch analysis in 27 dystonia patients showed that HaloPlex enrichment provided enrichment efficiency superior to standard whole exome procedures (>95% covered >20 reads; 90-95% of reads on target; mean coverage >500 reads per base).
We identified presumed disease-causing mutations in 2 out of 27 patients including one patient with a DYT6 dystonia and one patient carrying a mutation in SLC2A1. In 7 patients, we identifed so far unknown probable disease-causing variants including mutations in ATP7B, PLA2G6, PARK2, FBCO7, VPS13A and GCDH. This technology enabled the identification of a genetic cause in approximately 7 % of patients in an unselected cohort of dystonia patients in whom the most common genetic form (DYT1) was excluded. Targeted NGS may be a useful and cost-effective method to screen for mutations in multiple genes associated with dystonia.

P09.047-S
Using exome-sequencing for the diagnosis of rare disorders: two siblings affected by a congenital encephalopathy with microcephalia, polymicrogyria and dystonia

F. Incani[1], *C. Cossu*[1], *A. Coiana*[1], *M. L. Serra*[1], *F. Dettori*[1], *L. Saba*[1], *L. Boccone*[2], *M. C. Rosatelli*[1];
[1]*Università degli Studi di Cagliari, Cagliari, Italy,* [2]*Ospedale Regionale Microcitemie, ASL 8, Cagliari, Italy.*

Exome sequencing was performed on two siblings of a Sardinian family affected by a severe, congenital encephalopathy characterized by microcephalia, polymicrogyria and dystonia. MPS was achieved with the platform HiSeq2000 (Illumina). Quality filtered reads were aligned to the human reference hg19. SNPs and in/dels were detected using Samtools and BWA softwares. To obtain a list of candidate genes, the variants were filtered against a set of polymorphisms available in public databases (dbSNP138, 1000Genomes, ESP6500) and prioritized with Ingenuity Variant Analysis software. This analysis led us to identify in both siblings an homozygous variant in a gene of the MBT (Malignant Brain Tumor) family, expressed in mammalian brain. This variation causes a Ser-Asn substitution in one of the MBT domains. The MBT domain is a "chromatin reader", a protein module that recognizes mono/di-methylated lysines on histones tails. The MBT proteins interact with the enzymes that catalyze the histones methylation. This interaction plays a role in the repression of target genes. Although the pathway of the candidate gene is not well characterized, several studies show that its ortholog downregulates genes expressed in the early stages of neuronal development in Drosophila.
In a preliminary study in vitro we have found that the protein binds the dimethyltransferases SUV4-20H demonstrating its involvement in the process of histone methylation.
We speculate that the variant protein in our patients could destabilize the interaction between the MBT domain and the dimethyltransferases, altering the affinity for methylated histones and presumably its repressive properties.

P09.048-M
A new mutation in SYNGAP1 expanding the phenotypic spectrum: a case report

J. Juengling[1], *C. Funke*[1], *I. Steiner*[1], *M. Doecker*[1], *K. Reicherter*[1], *J. Hoffmann*[1], *F. Battke*[1], *G. Kluger*[2], *C. von Stülpnagel*[2], *H. Lerche*[3], *S. Biskup*[1], *K. Hoertnagel*[1];
[1]*CeGaT GmbH, Tübingen, Germany,* [2]*Department of Neuropediatrics, Schön Klinik Vogtareuth, Vogtareuth, Germany,* [3]*Department of Neurology and Epileptology, University of Tübingen, Tübingen, Germany.*

We report a 15 year-old girl presenting with generalized epilepsy and intellectual disability. After normal development in the first two and a half years of life, delayed language development became apparent. At age 3 drop attacks occurred. Later on the patient developed clonic and clonic-tonic seizures, predominantly at night time. Most remarkably, photosensitivity and a special EEG phenomenon occured. Under the treatment with antiepileptic drugs the patient remained nearly seizure-free. Anti-convulsive treatment was stopped at the age of 13, leading to aggravation of the EEG only. Astonishingly, two years later the EEG showed normalization of the paroxysomal activity triggered by eye opening. We performed next generation sequencing (NGS) for a panel of genes known or suspected to be causative in the pathogenesis of seizures. We identified a heterozygous stop mutation (c.348C>A, p.Y116*) in *SYNGAP1* which was validated using Sanger sequencing. Analysis of the parents suggests that the mutation arose *de novo*. The gene *SYNGAP1* encodes an excitatory synapse-specific Ras GTPase and is a major component of the postsynaptic density. It is thought to regulate synaptic strength e.g. by suppressing signaling pathways linked to NMDAR-mediated synaptic plasticity. Mutations in *SYNGAP1* are known to cause autosomal dominant mental retardation type 5 (MRD5). More recently, the publication of *SYNGAP1* mutations in patients with seizures suggested a role in idiopathic generalized epilepsy combined with a variable degree of intellectual disability including severe speech impairment. Our patient shows additional symptoms, expanding the spectrum of phenotypes for patients with *SYNGAP1* mutations.

P09.049-S
Linkage and subsequent exome sequencing analyses in a consanguineous family reveal two novel genes associated with pattern-sensitive idiopathic generalized epilepsy

F. N. Tuncer[1], *S. A. Uğur İşeri*[1], *N. Bebek*[2], *B. Baykan*[2], *U. Özbek*[1];
[1]*İstanbul University, Institute for Experimental Medicine Genetics Department, İstanbul, Turkey,* [2]*İstanbul University, İstanbul Faculty of Medicine, Neurology Department, İstanbul, Turkey.*

Epilepsy is a complex neurological disorder affecting 1% of the world's population. Among different forms of epilepsies, idiopathic generalized epilepsies (IGEs) are characterized by generalized seizures in the absence of detectable brain lesions or metabolic abnormalities. Thus, the primary etiology for this disorder is believed to be genetic. This study includes a consanguineous family diagnosed with pattern-sensitive IGE and aimed to identify novel epilepsy gene(s) to delineate the molecular basis of this intriguing form of IGEs. Physical, neurological, neuroimaging and electroencephalography (EEG) examinations were performed on the subjects recruited with information on family history. There were two affected siblings having pattern sensitivity in form of absence, myoclonic and generalized tonic-clonic seizures. Illumina HumanCytoSNP-12 BeadChip was used in genotyping of affected and five unaffected family members. Genotype data was utilized using easyLinkage Plus interface, where multipoint LOD scores were calculated under the assumption of autosomal recessive inheritance and haplotypes were constructed through GeneHunter. Linkage peak with a LOD score of 3.16 was revealed on Chromosome 22 comprising 113 genes within a 3.72Mb region. To analyze the candidate linkage region and identify any novel epilepsy genes residing outside this region, Illumina HiSeq2000 was used to perform whole exome sequencing on one of the affected sibs. Two genes with homozygous variants were located within the linkage region that segregated with the condition. Our study indicated homozygous variations in a gene encoding brain specific, spliceosome component and a gene with an unknown protein function possibly responsible in a family with pattern sensitive IGE.

P09.050-M
Whole genome SNP genotyping confirms segregation of Unverricht-Lundborg Disease (ULD) with a repeat expansion in CSTB on 21q in a large consanguineous family followed by a novel haplotype based approach identifying the parent of origin and carrier status in the child with Trisomy 21 under the age of onset for ULD

F. Y. Kesim[1], *F. N. Tuncer*[1], *E. Yucesan*[1], *K. Cavusoglu*[1], *M. Calik*[2], *A. Iscan*[3], *S. U. Iseri*[1], *U. Ozbek*[1];

Unverricht-Lundborg disease (ULD) is an autosomal recessive progressive myoclonus epilepsy characterized by generalized myoclonic jerks and tonic-clonic seizures. In this study, we analyzed a large consanguineous family with 10 children from Turkey afflicted with an undiagnosed form of syndromic epilepsy. All 6 affected family members along with 3 unaffected members and the youngest child with trisomy 21 have been genotyped using Illumina 300K SNP array. Linkage analysis was performed utilizing easyLinkagePlus interface under the assumption of autosomal recessive inheritance. Linkage analysis pinpointed a locus on chromosome 21q22.3 with a LOD score of 4.33. CSTB gene which resides within this region was screened for mutations in this family via DNA sequencing and long PCR, as mutations in CSTB have been implicated in ULD. This analysis revealed a dodecamer repeat expansion of almost 40 copies in the promoter region of CSTB in all affected children. We have also analyzed the genotyping data of the youngest child with Trisomy 21, as CSTB resides on this chromosome. It is not possible to detect the carrier status with conventional PCR techniques, as there are 3 copies of the gene. We have first managed to detect parent of origin for trisomy via analyzing the chromosome 21 genotyping data as a trio. Additional haplotype analysis of three copies of chromosome 21 revealed that this individual, who was under the age of onset at the time of the study, has only one copy of the defective allele and probably will not develop ULD.

P09.051-S

Exome sequencing reveals mutations of a solute carrier gene in an autosomal recessive form of epileptic encephalopathy of the first days of life

Epileptic encephalopathy (EE) refers to a clinically and genetically heterogeneous group of devastating disorders characterized by seizures combined with abnormal inter-critic encephalography Age of onset can be a key diagnostic feature for epileptic syndrome definition, treatment and prognosis. We ascertained two multiplex families (including one consanguineous family) consistent with an autosomal recessive inheritance pattern of EE. All seven affected individuals developed seizures in the first day of life, resistant to treatment and leading to repetitive "Etat de mal". Evolution was marked by severe EE with major delay in motor acquisitions and one patient died at 11 years of age. No facial dysmorphism was noted, but oligodontia. Given the similarity in clinical presentation in the two families, we hypothesized that the observed phenotype was due to mutations in the same gene, and performed exome sequencing in three affected individuals. Analysis of rare variants in genes consistent with an autosomal recessive mode of inheritance led to identification of mutations in a solute carrier gene. Causality was confirmed by co-segregation analysis in additional family members. To assess the frequency of alterations of this gene in early onset EE, coding exons were screened for mutations in a cohort of 70 unrelated affected individuals by targeted sequencing on a MiSeq instrument (Illumina). This experiment led to identification of compound heterozygous pathogenic variants in a simplex case with a similar clinical presentation as the other affected patients. These results highlight the value of careful clinical characterization for genetic studies in heterogeneous diseases such as EE.

Epileptic encephalopathies represent clinically and genetically heterogeneous group of disorders of which the majority are of unknown aetiology. It is hypothesized that novel variants may contribute to most of these devastating group of epilepsies. Within recent years the role of *SCN8A* in human disease has become apparent from next generation sequencing studies. Whole-exome sequencing of a parent-offspring trio was used to identify the genetic cause of severe early infantile epileptic encephalopathy in a boy, where previous chromosomal, gene and metabolic investigations revealed no abnormalities. The patient had neonatal seizures, movement disorder, multiple congenital anomalies. He died at the age of 17 months due to respiratory illness. We identified a *de novo* heterozygous missense mutation (c.3979A>G; p.Ile1327Val) in *SCN8A* (voltage-gated sodium-channel type VIII alpha subunit) gene. The variant was confirmed in the proband with Sanger sequencing. Since the clinical phenotype associated with *SCN8A* mutations have previously identified only in a number of cases, these data together with our results suggest that mutations in *SCN8A* can lead to early infantile epileptic encephalopathy or intellectual disability with broad phenotypic spectrum. Additional investigations will be worthwhile to determine the prevalence and contribution of *SCN8A* mutations to epileptic encephalopathy and intellectual disability, and provide insight into the mechanisms of pathogenesis in neurologic diseases. This study was supported by the EuroEPINOMICS grant SARLA 11091E.

Ambroxol and Bromhexine derivatives act promoting on mutant alpha-galactosidase A forms in cell culture systems of Fabry disease

J. Lukas[1], S. Seemann[1], C. Richter[1], A. Pockrandt[1], M. Sharif[2], M. Beller[2], D. Großmann[1], A. Rolfs[1], A. Giese[1];

[1]*Albrecht-Kossel-Institute for Neuroregeneration, Rostock, Germany,* [2]*Leibniz Institute for Catalysis, Rostock, Rostock, Germany.*

Fabry disease (FD) is a rare hereditary disease caused by the absence or deficiency of lysosomal enzyme activity of the glycosylase α-galactosidase A (GLA, EC 3.2.1.22, α-gal A). This enzyme breaks down macromolecular structures of neutral glycosphingolipids. A lack of particular hydrolase activity leads to lysosomal glycosphingolipid storage and subsequently multisubcellular dysfunction. Many mutations in the GLA gene have been identified compromising the enzyme's stability causing a premature proteasomal degradation. Therefore, treatment strategies apply the use of small molecule enzyme inhibitors having the ability to promote enzyme folding and transport intracellularly, the so-called pharmacological chaperones (PC). It was demonstrated that those molecules specifically bind to the (mutated) target enzyme which leads to a thermodynamically favoured conformational change and in turn further cellular transport and an increase of the required activity in the lysosomes. One such compound is 1-Deoxygalactonojirimycine (DGJ). We recently described an auxiliary function of Ambroxol (ABX), a PC described for mutant glucocerebrosidase in Gaucher disease, for the observed DGJ activity in over-expression based cell culture systems of FD. Here, we report the results of a derivatisation project of Ambroxol and the structural analogue Bromhexine that led to the discovery of compounds that preserved the ability to enhance mutant α-gal A activity in combination with DGJ. Structure-function analysis may give indications on the underlying functional mechanism we aim to elucidate. Moreover, our findings did not support the occurrence of a direct compound:enzyme interaction.

P09.054-M

Functional Analysis of *DEPDC5* variants identified in familial focal epilepsy with variable foci (FFEVF) and in cancer.

M. van Kranenburg, **M. Nellist**;

Erasmus MC, Rotterdam, Netherlands.

The target of rapamycin (TOR) complex 1 (TORC1) is an essential regulator of cell growth. Stimulation of TORC1 kinase activity promotes anabolic metabolism, including protein, lipid and nucleotide synthesis. Multiple upstream signals, including growth factors and the availability of nutrients and energy, act through two GTPase activating protein (GAP) complexes to control TORC1 activity. The TSC complex, consisting of TSC1, TSC2 and TBC1D7, is required for growth factor and energy dependent inhibition of TORC1, while the GATOR-1 complex, consisting of DEPDC5, NPRL2 and NPRL3, is required for amino acid-dependent regulation of TORC1. In humans, inactivating mutations in *TSC1* or *TSC2* cause tuberous sclerosis complex, a disease characterised by seizures and benign hamartoma-like lesions. Mutations in *DEPDC5* have been identified in human tumours and were recently described in association with familial focal epilepsy with variable foci (FFEVF). We have investigated the effects of *DEPDC5* variants identified in tumours or in individuals with FFEVF on TORC1 signaling and GATOR-1 complex formation using simple *in vitro* assays. Our functional data demonstrate that some *DEPDC5* mutations result in increased TORC1 activity, similar to pathogenic mutations in *TSC1* or *TSC2*. Functional analysis of *DEPDC5* variants of uncertain clinical significance will help define the role of the GATOR-1 complex in FFEVF and tumour pathogenesis.

P09.055-S

A female with clinical features of FOXG1 syndrome and 1.5-Mb size 14q12 microdeletion located more proximal to *FOXG1*

K. Õunap[1,2], O. Zilina[1,3], A. Kolk[4,2], T. Reimand[1,2,5];

[1]*Department of Genetics, Tartu University Hospital, Tartu, Estonia,* [2]*Department of Pediatrics, University of Tartu, Tartu, Estonia,* [3]*Department of Biotechnology, Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia,* [4]*Children's Clinic, Tartu University Hospital, Tartu, Estonia,* [5]*Department of Biomedicine, Institute of Biomedicine and Translation Medicine, University of Tartu, Tartu, Estonia.*

A severe Rett-like neurodevelopmental disorder is associated with de novo

FOXG1 point mutations or submicroscopic 14q12 deletion, which involve *FOXG1* gene. It is now known as *FOXG1* syndrome which clinically causes postnatal microcephaly, severe mental retardation, absent language, dyskinesia, and dysgenesis of the corpus callosum. More than 30 cases of FOXG1 syndrome have been published. Cases of a submicroscopic 14q12 deletion, involving regulatory elements of *FOXG1*, with the coding region of *FOXG1* being unaffected, are described very seldom. A *cis*-acting regulatory sequence, acting as a silencer, is deleted more than 0.6 Mb distally from *FOXG1* in these cases. We report a new case with clinical features of FOXG1 syndrome and 14q12microdeletion. She was born at term with birth weight 3636g, length 51 cm and head circumference 33.5 cm. Since the birth developmental delay was noticed. At 11 months she has only weak head control, microcephaly (-3 SD), focal epilepsy, deep set and almond shape eyes, protruding tongue, increased muscle tonus and brisk tendon reflexes. Brain MRI showed hypogenesis of the corpus callosum, hypomyelinisation, arachnoid cyst in the left temporal region and subtle pachygyria. Chromosomal microarray analysis revealed 1.5-Mb size 14q12 microdeletion (arr[hg19] 14q12(27,584,943-29,170,974)x1) appeared to be *de novo*. The end of this deletion is 65-kb proximal from *FOXG1* leaving the gene itself intact. There are no known protein-coding genes located in the deleted area. Therefore, we can hypothesize that there is some regulatory element of *FOXG1* located proximal to the gene which deletions can also cause FOXG1 syndrome.

Cy5 Analysis System in molecular diagnosis of Fragile-X Syndrome and Huntington disease

A. Mencarelli[1], P. Prontera[1], **I. Isidori***[1], D. Rogaia[1], V. Ottaviani[1], G. Stangoni[2], E. Donti[1];*
[1]Medical Genetics Unit, University of Perugia, Perugia, Italy, [2]Neonatology, Hospital of Perugia, Perugia, Italy.

Expansion of DNA repeats causes hereditary disorders in humans; our genetic diagnosis center is studying $(CGG)_n$ repeat in the FMR1 gene in Fragile-X Syndrome and $(CAG)_n$ repeat in the HTT gene in Huntington's disease (HD) by a high performing systems, Cy5-labeled **Fragile-X Syndrome** The critical issues in FMR1 analysis usually are:
- discriminate between fully mutated females from normal homozygotes.
- determine the proper CGG repeat size between 110 and 200 repeats
- determine methylation status

We routinely use a combination of two PCR-systems (CE-IVD) to determine the proper CGG repeat size until 200 repeats and alternative methods to Southern Blot (MS-MLPA, High Resolution Melting) to determine methylation status.
Huntington Disease In HTT gene the critical issue is define the exact CAG repeat size considering the small range that exists between premutation (36 repeats) and mutation status (40 repeats). The PCR-system (CE-IVD) we introduced in 2013 in our laboratory includes a positive control that helps to estimate the proper CAG repeat size in sample.
Our results refer to 400 Fragile-X Syndrome suspected cases analyzed from 2010 to 2013 and to 30 Huntington's Disease suspected cases analyzed in 2013. Use of these systems (CE-IVD), high performing, fast and easy, has allowed us to reach good diagnostic results using instruments already supplied in our department.

P09.057-S
Comparison of Friedreich Ataxia Patients with Trinucleotide Repeat Expansions and Point Mutations in FXN-Encoded Frataxin

R. Gavrilova, *R. Dhamija, J. Hesemann, C. Teigen, J. Johnson, M. Ackerman, G. Isaya, M. Patterson, P. Tebben, D. Oglesbee;*
Mayo Clinic, Rochester, MN, United States.

We retrospectively reviewed records of 40 patients with Friedreich Ataxia (FRDA). The majority of patients, 88% had bi-allelic GAA expansions (Group 1, n=35) while 12% were heterozygous for an expansion and point mutation (Group 2, n=5). Group 1 had a mean age of onset of 12.26 years compared to Group 2 with a mean of 5 years. The average age at diagnosis in Group 1 was 17.86 years and 15.2 years in Group 2. Neurological manifestations were the presenting symptom in the majority of both groups at 94% and 80% respectively. Within Group 1, 53% had lost their ability to ambulate at a mean of 10 years after disease onset compared to Group 2 where 50% had lost their ability to ambulate at a mean of 16 years after disease onset. In Group 1, all patients had evidence of cardiac involvement, including 43% having left ventricular hypertrophy (LVH) on echo. In Group 2, all patients had evidence of cardiac involvement with 60% having LVH. Frataxin enzyme levels had a mean of 6 ng/mL (N=2) in Group 1 while the mean for Group 2 was 2.67 ng/mL (N=3).
Genotype-phenotype correlation within FRDA patients is currently not well characterized. A greater percentage (Group 2) of patients with FRDA evaluated at Mayo Clinic do not have the classic bi-allelic expansion as compared to available literature. Patients heterozygous for a GAA expansion and point mutation had an earlier age at onset, but were able to ambulate longer compared to patients with bi-allelic GAA expansions.

P09.058-M
Mitochondrial genome encoding tRNAs sequence in frontotemporal lobar degeneration

I. Oliveira[1], I. Santana[2,3], M. J. Santos[1], D. Duro[3], R. Gaspar[1], D. Luís[1,2], **M. Grazina***[2,1];*
[1]CNC - Center for Neuroscience and Cell Biology - Laboratory of Biochemical Genetics, University of Coimbra, Coimbra, Portugal, [2]Faculty of Medicine, University of Coimbra, Coimbra, Portugal, [3]Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, Portugal.

Frontotemporal lobar degeneration (FTLD) is the second most common type of degenerative dementia, characterized by progressive changes in behaviour, executive dysfunction and/or language impairment. Some patients present clinical and neuropathological overlap with Alzheimer's disease, suggesting similarities in pathophysiology, including mitochondrial DNA (mtDNA) involvement. Mutations in mtDNA, particularly in mt-tRNAs, have been described as an important cause of human disease.
The aim of present work was sequencing the 22 mitochondrial tRNAs genes, ascertaining their involvement in FTLD.
A sample of 70 patients, diagnosed with probable FTLD, was studied (39 females and 31 males; age range: 38-82 years, mean±SD: 63±11 years. Total DNA was extracted from peripheral blood. The 22 tRNA genes sequences were sequenced and variants were submitted to in silico analysis. A total of 28 different sequence variations were identified in 32 patients (46%). According to in silico analysis, 6 variations are probably pathogenic, all causing structure and binding minimum free energy changes. The most frequent variation found is m.12308A>G, in the variable region of mt-tRNALeu2, and it is totally conserved in all mammals tested. The m.15946C>T variation is located in the acceptor stem and it is highly conserved.
Further investigation is needed to better understand the relationship between mtDNA alterations found and FTLD, considering also the involvement of nuclear genes in this disorder. However, this is the first study of complete sequencing of the mt-tRNA genes in FTLD.
Supported by "Fundação para a Ciência e a Tecnologia" (PTDC/SAU-EPI/121811/2010 and PEst-C/SAU/LA0001/2013-2014).

P09.059-S
Assessment of Plasma Glucosylsphingosine as a biomarker for Gaucher Disease

A. Giese*[1], U. Grittner[2], J. Lukas[1], D. Mascher[3], A. Mühl[4], S. Eichler[4], H. Mascher[5], A. Rolfs[1];*
[1]University of Rostock, Albrecht-Kossel-Institute, Rostock, Germany, [2]Institute for Biostatistics and Clinical Epidemiology, Charité-University Medicine, Berlin, Germany, [3]Pharm-analyt Laboratory GmbH, Baden, Austria, [4]Centogene GmbH, Rostock, Germany, [5]Pharm-analyt Laboratory GmbH, Rostock, Germany.

Biomarkers play an essential role in the early detection, and monitoring of metabolic diseases, this also holds true for Lysosomal Storage Disorders (LSDs). The ideal biomarker facilitates the initial diagnosis, evalutates the disease severity and progress and may be assist in determining proper treatment. Here, we analyzed Glucoyslsphingosine for the primary diagnosis and monitoring of Gaucher disease (GD), where a defect in the beta-Glucosidase (GBA) gene leads to the accumulation of glucocsyleramide. Overall, we evaluated the sensitivity and specificity of Glucosylsphingosine by comparing healthy controls, Gaucher patients, Gaucher carriers and patients with other LSDs. The determined cut-off of 12ng/ml yielded a 100% sensitivity and specificity for Glucosylsphingosine. In addition the biomarker was compared to Chitotriosidase and CCL18/PARC, which both are highly elevated in a number of LSDs and reflect the burden of disease on macrophages due to accumulation of macromolecules but are not specific for GD. In addition, Chitotriosidase levels may be normal even in GD patients due to a common 24-bp duplication in the CHIT1 gene. Glucosylsphingosine proved to be more specific and sensitive than Chitotriosidase (p=0.027) and CCL18/PARC (p<0.001). We also assessed long-term data of 19 GD patients before and after onset of enzyme replacement therapy. Overall, Glucosylsphingosine is a reliable biomarker for the primary diagnosis and follow-up of Gaucher Disease. We will proceed with determining the correlation of disease severity, progress of the disease and treatment with varying levels of Glucosylsphingosine.

P09.060-M
Saposin C deficiency: an inherited lysosomal disease caused by rapidly degraded mutant proteins

M. Motta, *M. Tatti, S. Camerini, M. Tartaglia, R. Salvioli;*
Istituto Superiore di Sanità, Roma, Italy.

Saposin (Sap) C is a 80 residues-long glycoprotein functioning as essential cofactor for the lysosomal degradation of glucosylceramide (GC) by gluco-

sylceramidase (GCase). It promotes rearrangement of the organization of lipids in lysosomal membranes and provides GCase greater accessibility to GC substrate. Rare functional deficiency in Sap C results in a rare variant form of Gaucher disease (GD). Sap C has six conserved cysteine residues involved in three disulphide bonds making the protein structure remarkably stable to acid environment and degradation. Five different mutations (*i.e.,* p.C315S, p.342_348FDKMCSKdel, p.L349P, p.C382G and p.C382F), four of them involving a cysteine residue, are known. Here we report on the functional and biological behaviour of disease-associated Sap C proteins. Lipid-binding properties and activating efficiency on GCase of Sap C mutants, analyzed by surface plasmon resonance and biochemical assays, were comparable to those of wild type Sap C. On the contrary, mass spectrometry analyses of protease-treated mutants revealed a rapid degradation of those carrying a mutation involving a cysteine residue. Our data provide evidence that mutant activator protein instability is the underlying pathogenetic mechanism of Sap C deficiency.

P09.061-S
Genetic analysis of glucocerebrosidase (GBA) gene in Italian patients with Parkinson disease and Lewy Body Dementia

F. Consoli[1,2], *S. Petrucci*[1,2], *M. Ginevrino*[1], *M. T. Pellecchia*[3], *L. Bonanni*[4], *A. R. Bentivoglio*[5], *C. Criscuolo*[6], *F. Ciccocioppo*[4], *T. Ialongo*[5], *A. De Luca*[1], *M. Onofrj*[4], *P. Barone*[3], *E. M. Valente*[1,3];
[1]*Mendel Laboratory, Casa Sollievo della Sofferenza Hospital, IRCCS, San Giovanni Rotondo, Italy,* [2]*Department of Experimental Medicine, Sapienza University, Rome, Italy,* [3]*Center for Neurodegenerative Diseases, University of Salerno, Salerno, Italy,* [4]*Department of Neuroscience and Imaging, University G. d'Annunzio of Chieti-Pescara, Chieti, Italy,* [5]*Department of Neurology, Movement Disorder Unit, Catholic University of The Sacred Heart, Rome, Italy,* [6]*Department of Neurosciences, Reproductive and Odontostomatological Sciences, Federico II University, Naples, Italy.*

Gaucher's disease (GD), the most common lysosomal storage disorder, is associated with recessive mutations in the glucocerebrosidase gene (GBA). It is known that GD patients and their heterozygous relatives more commonly develop parkinsonism, and that GBA heterozygous mutations increase of at least 5 times the risk to develop Parkinson's disease (PD) and Lewy bodies dementia (LBD). In this study, we evaluated the frequency of GBA mutations in Italian patients with PD or LBD. To this aim, we used long-template PCR to screen the entire GBA coding region for mutations in 216 patients with PD and 84 with LBD. GBA mutations were identified in 24 of 216 PD (11.1%) and in 4 of 84 LBD (4.7%) cases. Fourteen different GBA heterozygous mutations were detected, including two previously unreported mutations (c.1095G>C [p.Glu365Asp]) and a frameshift mutation (c.1197_1198insCTGTA [p.Met400Leufs*2]).
In conclusion, we report a high frequency of GBA mutations in Italian patients with either PD or LBD, indicating that GBA mutations represent a significant risk factor for these disorders in Italy.

P09.062-M
Genome sequencing identifies a novel mutation in ATP1A3 in a family with a seemingly atypical phenotype

K. Lohmann[1], *I. Braenne*[1], *L. Bertram*[2], *K. Wiegers*[1], *T. Anderson*[3], *R. Wilcox*[4], *C. Klein*[1];
[1]*University of Luebeck, Luebeck, Germany,* [2]*Max Planck Institute for Molecular Genetics, Berlin, Germany,* [3]*Canterbury District Health Board Hospital, Christchurch, New Zealand,* [4]*Flinders Medical Centre, Adelaide, Australia.*

Mutations in ATP1A3 have been reported in rapid-onset dystonia-parkinsonism (RDP). Dystonia in RDP has a characteristic sudden onset, typically in adolescence in response to physical or mental stress. Dystonic symptoms usually involve the bulbar region and are accompanied by symptoms of parkinsonism. More recently, mutations in ATP1A3 have been linked to alternating hemiplegia of childhood (AHC) and CAPOS syndrome, respectively.
We investigated a family with dystonia from New Zealand with ten affected members. Interestingly, only females were affected. After exclusion of mutations in TOR1A and THAP1, we performed genome sequencing in two affected cousins. For filtering, we used the KnomeDiscovery Data Filtering Software. Since re-sequencing of 20 candidate variants did not elucidate the genetic cause, we performed exome sequencing in another affected individual. Analysis of the raw data using an in-house bioinformatics pipeline revealed a previously unreported three base-pair deletion (c.443_445delGAG, p.148_149delSer) in ATP1A3 in all three genome/exome sequenced patients. Segregation analysis showed the mutation in all patients and in one unaffected male. The mutation was not found in 200 controls. Subsequent clinical re-examination, revealed sudden onset of dystonic symptoms after stressful events. None of the patients reported any history of AHC or CAPOS syndrome.
In conclusion, our study identifies a novel mutation in ATP1A3 as cause of RDP and highlights two important challenges when using next generation sequencing: 1) The importance of detailed clinical information. In our family, we have initially missed the characteristic sudden onset. 2) The difficulties with the annotation of deletions/insertions in the used software package.

P09.063-S
Very late onset Friedreich ataxia: a case report

R. Selvatici[1], *A. Armaroli*[1], *A. Ravani*[2], *M. Caniatti*[3], *E. Groppo*[3], *M. Tola*[3], *A. Ferlini*[1], *F. Gualandi*[2];
[1]*Dip. Scienze Mediche e Dip. Riproduzione e Accrescimento, Ferrara, Italy,* [2]*Dip. Riproduzione e Accrescimento, Ferrara, Italy,* [3]*Dip. Neuroscience e Riabilitazione, Azienda Ospedaliero-Universitaria S. Anna, Ferrara, Italy.*

Friedreich ataxia (FRDA) is a rare autosomal recessive hereditary disorder caused by expansion of a GAA repeats in the first intron of the X25 gene. It typically begins before the age of 25, but up to 25% of patients may be considered atypical with respect to the established diagnostic criteria, showing delayed age at onset with mild clinical impairment, slower progression of disease, and fewer secondary complications. These patients are arbitrarily subdivided into late-onset FRDA [LOFA; 25-39 years] and very late-onset FRDA [VLOFA; ≥40 years], show retained deep tendon reflexes and unusually gradual disease progression. Here we describe a 63-year-old white woman showing lower limb spasticity with ataxia and preserved ankle and knee jerks. The progression was slowly during the past 6 years, family history was negative for neurological diseases and no consanguinity was reported. Cerebellar dysartria, axonal neuropathy and reduced glucose tolerance were also present. Brain NMR showed cerebellar and cortical atrophy. Molecular analysis revealed a pathologic GAA expansion in the gene encoding frataxin, carrying expanded alleles in the low-range size, corresponding to 110 and 180 GAA repeats. VLOFA is an infrequent subtype of the disease with onset ranging between 40 and 67 years. Nevertheless, considering the frequency of FRDA mutations carriers in the general population (1/60), and the associated risk of recurrence, this condition deserve to be considered in atypical ataxic patients, even when the full clinical criteria for a classical form are not satisfied.

P09.064-M
Correlation between genotype, phenotype, and effect of mutant protein in REEP1-associated motoneuron degeneration

C. Beetz, *A. Beindorf, J. Falk, C. Hübner;*
Jena University Hospital, Jena, Germany.

Mutations in REEP1 have classically been associated with a pure form of the neurodegenerative condition hereditary spastic paraplegia (HSP type SPG31), i.e. a phenotype resulting from exclusive involvement of upper motoneurons. We recently reported on a unique REEP1 alteration which results in complete skipping of the in-frame exon 5 and is associated with distal hereditary motor neuropathy (dHMN type V), i.e. an exclusive lower motoneuron phenotype. Using minigene constructs we found that additional exon 5 mutations, apparently representing non-sense or silent variants, confer partial missplicing of this exon. Interestingly, these mutations are associated with complicated forms of HSP in which both upper and lower motoneurons seem to be involved. A meta-analysis of published reports reveals that lower motoneuron involvement in SPG31 is significantly associated with mutations that truncate the protein after the first ~100 residues. This border co-incites with the C-terminus of the REEP homology domain which mediates hetero- and homomeric interactions. By overexpression we show that such truncated polypeptides resemble the previously reported exon 5 deletion variant in localizing to large peri-nuclear "clumps". Moreover, we observed that these structures indeed depend on presence of the REEP homology domain, and that their number and size increases over time. This indicates that they represent aggregates rather than intact cellular structures. We thus suggest that N-terminal mutations act via haploinsufficiency which causes pure HSP, while for more C-terminal mutations there is an additional, aggregate-mediated toxic gain-of-function effect which results in complex phenotypes due to lower motoneuron involvement.

Diseases, Department of Molecular Biology, Khartoum, Sudan.

Hereditary spastic paraplegia (HSP) constitutes a heterogeneous group of syndromes with core features of progressive lower limb spasticity and weakness, without or with other manifestations (pure / complex HSP). All modes of inheritance have been described.
HSP with thin corpus callosum (TCC) represents a distinct entity for which mutations in SPG11 are the most frequent causes.
As a part of a larger study to elucidate the molecular basis and the phenotypic patterns of HSP in Sudan, we report 2 extended Sudanese families with complex HSP and multiple consanguinity loops. Ten patients were clinically phenotyped and DNA was obtained from blood and saliva samples.
The age at onset in the first family ranged from 12 to 17 years. Patients presented with ataxia, mental impairment and skeletal deformities in addition to spasticity. Exome sequencing performed in 3 patients identified a homozygous deletion (c.6709del/p.Ala2237Gln*7) in exon 36 of SPG11.
In the second family, the age at onset extended from 11 to 24. The phenotype was more complex, with psychiatric symptoms, dysphagia and peripheral motor involvement with distal muscle atrophy of both limbs. Direct sequencing of SPG11 identified a stop mutation (c.6349G>T/p.Glu2117*) in exon 34 that segregated with the disease within the family.
MRI of 3 cases from both families revealed TCC, cerebellar and cortical atrophy and WMLs.
Both mutations are novel and lead to premature truncation of spatacsin protein. These families are the first described Sudanese families carrying SPG11 mutations. This study illustrates the wide range of clinical presentations associated with SPG11.

Assessing an anaplerotic therapy on the brain metabolic profile in Huntington disease

I. M. Adanyeguh[1], *D. Rinaldi*[1], *P. Henry*[2], *R. Valabregue*[3], *A. Durr*[1,4], *F. Mochel*[1,4];
[1]Institut du Cerveau et de la Moelle épinière; INSERM U1127; CNRS UMR7225; UPMC Paris VI UMR_S975, Paris, France, [2]Center for Magnetic Resonance Research, University of Minnesota, Minneapolis, MN, United States, [3]Center for NeuroImaging Research, Institut du Cerveau et de la Moelle épinière, Paris, France, [4]Assistance Publique-Hôpitaux de Paris, Fédération de Génétique, Salpêtrière University Hospital, Paris, France.

Objective: To obtain a proof-of-concept for an anaplerotic therapy in Huntington disease (HD) using a validated functional biomarker of brain energy metabolism.
Background: Energy deficit has been greatly implicated in the pathophysiology of HD. Our previous work has indicated a need to refill the Krebs cycle which can be achieved using anaplerotic therapy.
Methods: 31P brain magnetic resonance spectroscopy (MRS) was coupled with the activation of the occipital cortex to measure the levels of PCr and Pi before (rest), during (activation) and after (recovery) a visual stimulus. At visit 1, we performed 31P brain MRS in 10 patients at the early stage of HD and 10 controls. HD patients were then treated at home for one month with triheptanoin and came back for a second visit during which we performed 31P brain MRS.
Results: At visit 1, we confirmed a significant increase in Pi/PCr ratio ($p=0.022$) during brain activation in controls - reflecting increased ATP synthesis - followed by a significant return to baseline levels during recovery ($p=0.008$). In HD patients, we confirmed an abnormal brain energy profile with decreased Pi/PCr ratio before treatment. After one month of triheptanoin therapy, the MRS profile was greatly improved in HD patients with increased Pi/PCr ratio during visual stimulation ($p=0.004$).
Conclusion: This study suggests that triheptanoin is able to correct the bioenergetic profile in HD patients' brain at an early stage of the disease. The administration of triheptanoin over a longer period of time is now required to assess its clinical benefit.

P09.067-S

PMCA, SERCA and VEGF as potential patogenetic factors in Huntington's disease and as biomarkers of onset and progression

F. Cesca[1], *G. Dubsky de Wittenau*[1], *A. Poz*[1], *G. Damante*[1,2], *B. Peterlin*[3], *M. Zadel*[4], *G. Siciliano*[5], *F. Curcio*[1,6], *R. Lonigro*[1,6];
[1]Dipartimento di Scienze Mediche e Biologiche,Università di Udine, Udine, Italy, [2]Istituto di Genetica, AOU di Udine, Udine, Italy, [3]Institute of Medical Genetics, Division of Obstetrics and Gynecology, University Medical Center, Ljubljana, Slovenia, [4]Institute of Medical Genetics, Division of Obstetrics and Gynecology, University Medical Center,, Ljubljana, Slovenia, [5]Dipartimento di Medicina Clinica e Sperimentale,Università di Pisa, Pisa, Italy, [6]Istituto di Patologia Clinica, AOU di Udine, Udine, Italy.

To study calcium homeostasis deregulation in Huntington's disease (HD) ethiology we investigated calcium pumps expression level in HD cellular models and in peripheral blood of pre-symptomatic and symptomatic HD patients. We compared the steady-state level of cellular membrane associated PMCA1-4 and endoplasmic reticulum associated SERCA2,3 pumps in wild-type STHdh(Q7)/Hdh(Q7) and mutant STHdh(Q111)/Hdh(Q111) cell lines derived from the murine embryonic striatum. We observed a significant reduction of PMCA1 protein in glial differentiated mutant cells ($p<0.05$) and SERCA2 protein in undifferentiated mutant cells ($p<0.001$). Using doxycicline-inducible rat striatal cell lines (Hd19 and HD43 Sipione et al. 2002) we confirmed the reduction of SERCA2 as a mutant huntingtin expression dependent event.
To evaluate the role of PMCA1 and SERCA2 gene expression as biomarkers of disease onset or/and progression we compared their mRNA levels in the peripheral blood mononuclear cells (PBMC) of 20 pre-symptomatic and 90 symptomatic HD subjects and in sex and age matched healthy subjects. We observed a reduction of SERCA2 mRNA both in pre-symptomatic and symptomatic HD patients compared with healthy subjects. Our data highlight SERCA2 gene down-regulation as a biomarker of HD having a role in early cellular dysfunction.
Finally, in PBMC we studied the neuroprotective angiogenic factor vascular endothelial growth factor (VEGF) mRNA level. VEGF transcript level resulted significantly lower in pre-symptomatic HD compared to healthy subjects ($p<0.01$) and even lower in late-symptomatic compared to pre-symptomatic group ($p<0.05$). This finding suggests VEGF transcript as a peripheral biomarker useful for monitoring disease onset and progression.

Rossi, Verona, Italy, [6]Department of Paediatrics, Faculty of Medicine, University of Szeged, Szeged, Hungary, [7]Department of Neurosurgery, Faculty of Medicine, University of Szeged, Szeged, Hungary, [8]Department of Medicine and Surgery, University of Salerno, Salerno, Italy.

Joubert syndrome (JS) is a congenital disorder diagnosed by the presence of a peculiar mid-hindbrain malformation (the "molar tooth sign"), that consists of cerebellar vermian hypodysplasia, thickened mal-oriented superior cerebellar peduncles and a deepened interpeduncular fossa. The typical neurological features of pure JS include hypotonia, ataxia, psychomotor delay, abnormal ocular movements and intellectual impairment. This phenotype may be complicated by defects of the kidneys, eyes, liver, skeleton and orofacial defects, resulting in wide clinical variability. JS is recessively inherited and genetically heterogeneous, with 24 known genes. All genes encode for proteins of the primary cilium, and indeed there is clinical and genetic overlap with other ciliopathies. In particular, JS shares 13 genes with Meckel syndrome (MS), a lethal condition characterized by cystic kidneys, bile duct proliferation of the liver, encephalocele and polydactyly. As part of a large screening of ciliopathy genes in 260 JS patients, we identified novel pathogenic mutations in two genes not previously implicated in this condition. Two patients carried mutations in the *MKS1* gene, a 44-year-old man with JS and retinal dystrophy, and a two-year-old child with a pure JS phenotype. Mutations in the *B9D1* gene were identified in two other patients, a 9-year-old boy and a 6-year-old girl both presenting with pure JS. All identified mutations were inherited from heterozygous healthy parents, were not reported in public databases, and affected highly conserved residues. Missense mutations were predicted as pathogenic by prediction web tools.

P09.069-S

Pseudo-dominant inheritance of a novel CTSF mutation associated with type B Kufs disease

F. Moro[1], *R. Di Fabio*[2], *M. Meschini*[1], *S. Doccini*[1], *F. Pierelli*[2], *A. Simonati*[3], *F. Santorelli*[1];
[1]Fondazione Stella Maris, Calambrone, Pisa, Italy, [2]Department of Medical-Surgical Sciences and Biotechnologies, Sapienza University of Rome, Latina, Italy, [3]Department of Neurological and Movement Sciences, University of Verona, Verona, Italy.

Kufs disease (KD) is the rare adult form of neuronal ceroid lipofuscinosis (NCL). Mutations in the cathepsin F gene (CTSF) (MIM 603539) have recently been discovered in autosomal recessive Type B KD families characterized by movement and behavioral abnormalities and dementia. We present a family in which pseudo-dominant transmission of Type B KD was explained by a novel homozygous splice site mutation in CTSF leading to the lost of exon 1.
Three affected individuals showed similar neurological pictures characterized by generalized seizures, cerebellar dysarthria and cognitive decline, evolving into frank dementia. The presence of three additional relatives with a neurological syndrome compatible with KD and two instances of parent-

to-child transmission proposed an initial hypothesis of a dominant form of dementia representing a confounding factor for genetic testing. A more detailed clinical assessment of the patients, meticulous collection of family history and recognition of the high degree of inbreeding in the isolated community where this family lives, were crucial in disclosing an autosomal recessive pattern of inheritance, prompting investigation of CTSF.
In vitro experiments in cultured skin cells from the proposita and her aunt demonstrated a dysregulated autophagy and aggresome-like structures, confirmed by ultrastructural studies in skin biopsies. These data put forward the hypothesis of a cytoplasmic toxicity of pathological cathepsin F in KD type B.

Lymphoblastoid cell lines (LCLs), obtained through the immortalization of B lymphocytes by Epstein-Barr virus, can provide a virtually unlimited source of DNA, mRNA and protein for research studies and have been used as a replacement for molecular and functional analyses of diseases including those affecting central nervous system (CNS). Autosomal dominant adult-onset leukodystrophy (ADLD) is a demyelinating disease of the CNS associated with duplication of the lamin B1 gene (LMNB1). Studying LCLs compared to fibroblasts from a survey of patients affected by ADLD, we showed a wide variability in LMNB1 levels both at mRNA and protein levels. Lamin B1 expression was inversely proportional to miR-23, a known LMNB1 regulator. Linear regression analysis showed that there was a significant inverse correlation between the mean miR-23 levels and lamin B1 expression in patients' LCLs, whereas no correlation was observed in fibroblasts. We speculate that the immortalization of LCLs randomly deregulates miR-23 expression that, in turn, alters lamin B1 levels. This work further demonstrates the importance of miR-23 in the regulation of lamin B1 expression, and suggests caution when using LCLs as the only source of mRNA in the contest of in vitro research and of lamin B1 as Western blots loading control for nuclear extracts.

P09.071-S
Molecular analysis of EIF2B genes in adult-onset leukodystrophy with vanishing white matter

F. Taroni, *S. Caldarazzo, M. Savoiardo, L. Farina, C. Lamperti, R. Mantegazza, D. Pareyson, E. Salsano, D. Di Bella;*
Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy.

Leukodystrophy with vanishing white matter (LVWM) is a rare autosomal recessive white matter disease due to mutations in one of the five eukaryotic initiation factor 2B genes (EIF2B1-5). Onset is typically in late infancy or early childhood, but later onset is also reported. The adult-onset form is usually associated with EIF2B5 Arg113His mutation while, thus far, there are only 3 reports of mutations in EIF2B3. Genetic analysis of EIF2B5 and EIF2B3 genes was performed in 6 adult-onset Italian patients from 5 families, for whom LVWM was suggested by MRI pattern. We identified 5 different EIF2B5 missense mutation (2 novel), in 4 patients (2M, 2F) and 2 different EIF2B3 missense mutations (1 novel) in 2 female patients. The clinical presentation of mutated patients is heterogeneous and nonspecific, ranging from nearly-isolated neurogenic bladder or ovarian failure to stroke-like episodes or various psychiatric disturbances. Overall, the clinical course was slowly progressing over years or decades, although rapid motor or cognitive deterioration was observed in one case. In all cases, brain MRI was characterized by diffuse leukoencephalopathy associated with a varying burden of areas of rarefaction/cavitation. This study provides further evidence that not only EIF2B5, but also EIF2B3 mutations can be associated with a wide clinical spectrum of adult-onset LVWM, whereas the neuroradiological pattern - characterized by areas of white matter rarefaction/cavitation - unequivocally guides the clinician to request the proper diagnostic molecular test. [Partly supported by Italian Ministry of Health grant RF-2009-1539841 to FT]

Combined analysis of linkage and exome sequencing identifies a novel SYNE1 mutation in a consanguineous family from Turkey with a rare form of recessive cerebellar ataxia

E. Yucesan[1], *B. Bilgic*[2], *H. Hanagasi*[2], *B. Bakir Gungor*[3,4], *Z. Gormez*[4], *A. Sarac*[4], *M. Sagiroglu*[4], *H. Gurvit*[2], *S. Ugur Iseri*[1], *U. Ozbek*[1];
[1]*Institute for Experimental Medicine, Istanbul, Turkey,* [2]*Istanbul Faculty of Medicine, Istanbul, Turkey,* [3]*Faculty of Engineering and Natural Sciences, Abdullah Gul University, Kayseri, Turkey,* [4]*The Scientific and Technological Research Council of Turkey (TUBITAK), Kocaeli, Turkey.*

Cerebellar ataxias are characterized by incoordination and unsteadiness of movement due to cerebellar dysfunction. In this study, we analyzed a consanguineous family with 4 affected individuals presenting very slowly progressive cerebellar symptoms including dysartria, dysmetria and gait ataxia. All 4 affected and 3 unaffected members from this family were genotyped using Illumina Human HumanCytoSNP-12 BeadChip kit. The genotyping data obtained were further analyzed in terms of copy number variation (CNV) and linkage using Illumina proprietary software cnvPartition and easyLinkagePlus interface, respectively. The patients were negative for a common CNV, while a single linkage peak on chromosome 6q25 was obtained with a maximum LOD score of 3.42.
Whole exome sequencing (WES) was performed in two affected sibs from the family in parallel to linkage analysis. Genetic variants of the affected individuals within the linkage interval were filtered against novel variants with harmful effect. This approach has led to identification of a novel mutation in gene SYNE1 (c.13086delC; p.His4362Glnfs*2) segregating with the condition in the family as confirmed by Sanger sequencing. SYNE1 has 147 exons encoding 8797 amino acids. This mutation is predicted to truncate almost half of the protein.
SYNE1 encodes a nuclear envelope protein, which is expressed in various tissues, particularly in the cerebellum. Mutations in SYNE1 have previously been implicated in a rare form of recessive spinocerebellar ataxia observed especially in French-Canadian population.
Our study presents the combined analysis of linkage and WES as a powerful and precise tool to diagnose a clinically unknown condition at the molecular level.

P09.073-S
Screening the LRRK2-3'UTR region on a Spanish cohort of PD-patients and controls and mRNA relative quantification in brain

L. F. Cardo, *E. Coto, V. Álvarez;*
Hospital Universitario Central de Asturias, Oviedo, Spain.

Mutations in LRRK2 are recognized as the most common genetic determinant of sporadic and familial Parkinson's disease (PD). Recently, several studies of exonic variants in large populations were published; however, none of them was focused in the 3'UTR region. Our aim was to screening the 3'UTR of LRRK2 looking for risk variants, modifying factors, disrupted targets for microRNA binding and a possible effect of this region in mRNA expression.
Our cohort consisted of 743 PD patients (67±10 years; 52% male) and 523 healthy controls (67±12 years; 50% male). The human post-mortem tissues were obtained from three different brain regions of 9 PD and 5 healthy donors.
Patients were genotyped for the LRRK2 mutations G2019S and R1441G/C/H resulting in 16 G2019S carriers and 15 R1441G carriers. None of the tissue donors was mutation carrier. We identified a total of 12 variants; 2 of them new (c.*130_131del and c.*1382C>A) in the 3'UTR region. We found rs66737902 T>C as a possible variant related with PD risk being the C allele overrepresented in patients; p= 0.01 OR=1.37 CI=1.07-1.74. To tested if rs66737902 had an effect in the gene expression through the binding of miRNAs, we study miR-138-2* as candidate miRNA (TargetScan, microRNA.org) and miR-205 as control miRNA. We did not find any effect of miR-138-2*. In the mRNA expression study we found significant differences between TT and TC rs66737902 genotypes in the SN of PDs, with a minor expression level in the TC group (p=0.011). No differences between patients and control were found.

P09.074-M
Variation in the promoter of the autophagic beclin-1 gene (BECN1) and its impact on expression levels: a study in Machado-Joseph disease (MJD/SCA3) patients

N. I. Kazachkova[1,2], *M. Raposo*[1,2], *R. Montiel*[3], *A. Ramos*[1,2], *M. Lima*[1,2];
[1]*Center of Research in Natural Resources (CIRN), University of the Azores, Ponta Delgada, Portugal,* [2]*Institute for Molecular and Cell Biology (IBMC), University of Porto,*

Porto, Portugal, [3]Laboratorio Nacional de Genómica para la Biodiversidad (LANGEBIO), Unidad de Genómica Avanzada, CINVESTAV-IPN, Irapuato, Mexico.

Background and Objectives: Autophagy, as a process of intracellular components degradation, is especially important in disorders where accumulation of the mutant protein is a hallmark, such as MJD, a late onset polyglutamine ataxia. We documented the variation in the promoter of the BECN1 gene whose overexpression has been reported to exert neuroprotective effects in MJD. The relation between BECN1 promoter variation and expression levels were studied, as well as its impact on disease onset.
Methods: The BECN1 promoter was sequenced in 95 MJD patients and 120 controls. In silico analysis (PROMO) were performed to detect differences in putative transcription factor binding sites (TFBS). BECN1 expression level was quantified by Real-time PCR in 29 MJD patients and 27 controls, for which cDNA from peripheral blood was available.
Results: Two previously described variants (rs60221525 and rs116943570) were found in MJD patients and controls. In silico analysis predicted the existence of less putative TFBS for rs60221525 and of more TFBS for rs116943570. BECN1 expression levels were in agreement with the in silico predictions, showing decreased and increased expression for rs60221525 and rs116943570, respectively. CAG number explained 60.5% of the variance in onset; when rs60221525 and rs116943570 were added to the multiple regression model, there was a tendency for the increase in the explanation.
Conclusions: Variation found in the BECN1 promoter modulates expression and has a potential to modify onset of MJD. The analysis of further patients should increase the power of the study and confirm the role of BCN1 as modifier of MJD.

P09.075-S

Study of the genetic architecture behind mood disorders by whole exome sequencing on a large Italian pedigree

E. Giacopuzzi[1], *C. Magri*[1], *A. Minelli*[1], *P. Valsecchi*[2,3], *S. Monchieri*[4], *G. Borsani*[1], *E. Sacchetti*[2,3], *M. Gennarelli*[1,5];
[1]*Division of Biology and Genetics, Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy,* [2]*Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy,* [3]*Department of Mental Health, Brescia Spedali Civili, Brescia, Italy,* [4]*Fondazione Poliambulanza, Brescia, Italy,* [5]*Genetics Unit, IRCCS San Giovanni di Dio, Fatebenefratelli, Brescia, Italy.*

Major depressive disorders (MDD) and bipolar disorder (BD) are mood disorders with a lifetime prevalence in the adult population of approximately 16% and 4%, respectively. Estimated heritability is about 37% for MDD and 75% for BD and the two disorders have a genetic correlation of about 43%. As of today their genetic architecture remains unclear and no major genetic risk factors or causative genes have been identified yet. With the aim of identifying susceptibility loci responsible for the MDD/BD phenotype, we studied a IV generation Italian pedigree composed of 20 subjects, 7 of whom are affected by mood disorders (5 MDD, 2 BD). Linkage analysis identified 5 regions that were inherited by all the affected members, extending for 222 Mb overall. Exome sequencing performed on the 7 affected subjects and 2 unaffected relatives identified ~1930 genetic variants within linkage regions, 222 of which are functional variants (missense, LoF, splicing) shared by all affected subjects. These latter variants affect several genes already associated to MDD/BD and other relevant biological pathways, such as synaptic development and neurodevelopment. We also identified 28 rare variants (MAF<1 % in dbSNP, 1000G and ESP6500), 8 in the linkage regions, present only in the affected subjects. Among the genes affected by these variants, we selected 4 candidates that could differentiate affected from unaffected subjects in the family. In conclusion, our data suggest that MDD/BD arise from the combination of a shared mutational burden on risk genes together with a few rare variants triggering the observed phenotype.

P09.076-M

Spectrum of Mutations in a New Cohort of Pakistani Families with Primary Microcephaly

I. Ahmad[1], *M. S. Hussain*[2], *S. M. Baig*[3], *P. Nürnberg*[1];
[1]*Cologne Ceneter for Genomics, Cologne, Germany,* [2]*Institute of Biochemistry I, Cologne, Germany,* [3]*National Institute of Biotechnology and Genetic Engineering (NIBGE), Faisalabad, Pakistan.*

Autosomal Recessive Primary Microcephaly (MCPH) is a neurodevelopmental disorder resulting in diminution of brain growth in utero. The noticeable features are reduced head circumference at birth, and varying degree of intellectual impairment without other neurologic findings. To date, twelve genes have been reported to be associated with MCPH, including *MCPH1, WDR62, CDK5RAP2, CASC5, ASPM, CENPJ, STIL, CEP135, CEP152, ZNF335, PHC1, and CDK6.* Among these, *ASPM* has been found to be most frequently mutated in the Pakistani population. In the current study, 30 new families were ascertained from different regions of Pakistan. We performed SNP array-based homozygosity mapping and revealed linkage to at least one of the known MCPH gene loci in 23 families. In seven families all known MCPH loci could be excluded. Subsequently, we analyzed DNA samples from members of the "linked" families by Sanger sequencing of the corresponding known MCPH gene. We found 10 mutations in *ASPM*, five of them are novel and 9 families carry the already reported founder mutation p.W1326*. Among the remaining five families, two showed novel overlapping microdeletions of 580.8 kb and 164.2kb in *MCPH1*, two other showed novel mutations in *CDK5PAP2*, and the last one showed a previously reported mutation in *WDR62.* This study adds to the mutational spectra of known MCPH-associated genes. The observed high frequency of the *ASPM* mutation p.W1326* underscores its prominent role as a founder mutation in the Pakistani population.

P09.077-S

The metabolism of GABA and glutamate is affected in the brain of the Mecp2-deficient mouse, a model for Rett syndrome.

R. El Khoury[1,2], *N. Panayotis*[1,2], *A. Ghata*[1,2], *V. Matagne*[1,2], *G. Alcaraz*[1,2], *L. VILLARD*[1,2], **J. Roux**[1,2];
[1]*Inserm UMR_S 910, Marseille, France,* [2]*Aix Marseille Université, Marseille, France.*

Rett syndrome (RTT) is a severe neurological disorder affecting females. Most RTT cases are caused by mutations in the X-linked methyl-CpG binding protein 2 (MECP2) gene. RTT patients develop normally until 6-18 months of age, before the onset of deficits in autonomic, cognitive and motor functions. Studies on Mecp2-deficient mouse models have revealed severe neurotransmission dysregulations, including deficits in bioamine levels and dysfunction of the GABAergic and glutamatergic systems leading to an imbalance between excitation and inhibition in the brain of the mutant animals. However, published results are divergent due to differences in age, model used and/or brain areas studied. Here, we have used real-time PCR, western blotting and HPLC dosage to compare the GABA and glutamate metabolism in eight different brain areas of the Mecp2-deficient mouse brain at two developmental stages (early and late symptomatic). Several key enzymes of GABA and glutamate metabolism have been studied (Kcc2, Nkcc1, Vglut1/2, Gad1/2). Our results show : 1- a progressive reduction of the GABA and glutamate contents; 2- a spatial and temporal deregulation of the GABAergic and glutamatergic key enzymes. We have used that information to assess a pharmacological stimulation of the GABAergic system in vivo and we showed that such a treatment increases the lifespan of Mecp2-deficient mice.

P09.078-M

MEF2C haploinsufficiency is a recurrent finding in patients with autism spectrum disorders

A. Ziegler[1,2], *R. Delorme*[3,2,4], *P. Amati-Bonneau*[1,5], *A. Guilmatre*[2,4], *T. Bourgeron*[2,4,6], *D. Bonneau*[1,5];
[1]*Department of Biochemistry and Genetics, CHU Angers, Angers, France,* [2]*Human Genetics and Cognitive Functions, Institut Pasteur, Paris, France,* [3]*Assistance Publique-Hôpitaux de Paris, Robert Debré Hospital, Department of Child and Adolescent Psychiatry, Paris, France,* [4]*CNRS URA 2182 "Genes, synapses and cognition," Institut Pasteur, Paris, France,* [5]*UMR CNRS 6214 INSERM 1083, Angers, France,* [6]*University Denis Diderot Paris 7, Paris, France.*

Since the first description of MEF2C haploinsufficiency syndrome in 2009, 42 patients have been reported either with deletion or point mutation of this gene. Intellectual disability (ID) is the core disorder of this syndrome but autistic features such as stereotypic movements and lack of social communications are commonly reported. To further assess the role of MEF2C in autism spectrum disorder (ASD), we looked for MEF2C point mutations by Sanger sequencing and for MEF2C copy number variations by SNP-array in a cohort of 195 patients with ASD and mild to severe ID.
We identified a de novo frameshift mutation leading to a premature stop codon in 2 siblings with ASD and severe ID. A maternal germinal mosaicism was confirmed based on the haplotype. A de novo MEF2C deletion was also found in a patient with ASD and a mild ID. In this study, we observed MEF2C haploinsufficiency in 1,5% (95% confidence interval: 0-3.2%) of patients with ASD. This is the first study to look specifically at MEF2C in ASD. Of note, a mutation in MEF2C was also found once by whole-exome sequencing in another cohort of 175 trios with ASD. According to this notable MEF2C haploinsufficiency frequency in ASD, we strongly recommend to pay specific attention to this gene when performing non-targeted genetic screening in ASD with a comorbid ID even for patients without severe ID.

P09.080-M

Importance of genotype-phenotype correlation in genetic diagnosis of microcephaly

F. M. Nedelea[1,2], *A. Pavel*[2], *L. Dimos*[2], *V. Plaiasu*[3,2], *D. Ochiana*[3], *M. Bari*[1,4], *D. Stambouli*[2], *G. Peltecu*[1,4];
[1]*Clinical Hospital Filantropia, Bucharest, Romania,* [2]*Cytogenomic Medical Laboratory, Bucharest, Romania,* [3]*Mother and Child Hospital, Alfred Rusescu, Bucharest, Romania,*

[4]University of Medicine "Carol Davila", Bucharest, Romania.

New genetic tools for the investigation of cases with neurodevelopmental delay increased continuously the knowledge concerning the underline causes of genetic syndromes.
Array CGH is a highly sensitive method for diagnosis of pathological CNVs responsible for malformative syndromes.
We report a case of a 5y.o girl, who was referred to Medical Genetics Department for evaluation due to microcephaly, mild dysmorphic features and developmental delay. From her medical history, severe and frequent urinary infections, in the absence of any malformation present in the urinary system, are noticeable.
Conventional karyotype from peripheral blood revealed a 12p terminal deletion. Discrepancies between clinical findings and karyotype results required additional investigation using comparative genomic hybridization method. Array CGH revealed a 5Mb terminal deletion on the long arm of chromosome 10, result that matches with the clinical findings of our patient. The molecular result was verified by FISH analysis .This finding is consistent with a complex chromosomal rearrangement involving insertion of genetic material from chromosome 12p to chromosome 10 and consequent deletion of terminal region on the long arm of chromosome 10.
Parental karyotypes are normal, suggestive of a "de novo" rearrangement and consequence low recurrence risk for other siblings.
This case report illustrates the importance of considering genotype-phenotype correlation for each patient and the advantages and the limits of genetic diagnostic techniques in our practice.
In conclusion, clinical judgment complementary to genetic tests provides an accurate diagnosis, prognosis and recurrence risk evaluation.

P09.082-M
New deletion in exon 32 and 33 in MLL2 gene causes Kabuki Syndrome in a spanish patient

G. Pi, M. Ortiz, I. Aleixandre, **A. Zuñiga***;*
HOSPITAL DE LA RIBERA, Alzira (Valencia), Spain.

Kabuki syndrome (KS; OMIM# 147920) is a rare congenital disorder, characterized by typical facial features including: long palpebral fissures, eversion of the lateral third of lower eyelids, arched and broad eyebrows with lateral sparseness, short columella and prominent ears. Point mutations and large intragenic deletions and duplications of the histone methyl transferase *MLL2* gene are the main causes of KS. *MLL2* encodes a large protein that belongs to the SET1 family of human SET-domain protein methyltransferase superfamily. Recently, *de novo* partial or complete deletions and point mutations of *KDM6A gene*, have been identified as additional causes of KS. Case report: We report the molecular and phenotype studies of a Spanish patient who have typical features of KS. The patient is a 9 y.o. girl with mental retardation, a peculiar facies characterized by long palpebral fissures, a broad and depressed nasal tip, large prominent earlobes, a cleft palate, scoliosis, radiographic abnormalities of the vertebrae, hands, and hip joints, and recurrent otitis media. Genomic DNA was extracted from the patient and parents and mutation screening of coding exons and intron-exon junctions of the *MLL2* gene was performed by direct sequence analysis using a 3130XL Genetic Analyzer. All found changes were *in silico* analyzed (Polyphen 2.0) to estimate a possible damaging effect in the protein. We identified a deletion in exon 32 that expands to the first portion of exon 33 (c.20711-c.21014 NG_027827). This deletion is absent in both parents and it has not been previously described.

P09.083-S
SGK223, a novel candidate gene for an autosomal recessive form of dHMN

E. Gregianin[1], *A. Vettori*[1], *E. Tognon*[1], *D. Tessarolo*[2], *M. Mostacciuolo*[1], *G. Vazza*[1];
[1]*University of Padova, Padova, Italy,* [2]*San Camillo Forlanini Hospital, Roma, Italy.*

Distal hereditary motor neuropathies (dHMN) are a subgroup of Hereditary Motor Sensory Neuropathies characterized by a predominant motor involvement of the peripheral nervous system. In the present study a family affected by an autosomal recessive form of dHMN was examined by using a combined strategy of linkage analysis and whole-exome sequencing (WES) in two patients. WES variants in the known disease-related genes associated with similar phenotypes, and copy-number variants shared by the affected subjects were excluded. Considering the presence of two consanguineous marriages in the family, the homozygosity mapping approach was performed and a candidate autozygous region shared exclusively by the affected subjects was highlighted on chromosome 8p23.1-p22. The candidate region contains 120 genes and is characterized by a high number of pseudogenes and paralogs which led to many false positive calls due to multiple-mapping reads. No evident mutations were identified in the also poorly-covered exons of the linkage region but the prioritization analysis of the about 230 WES variants within the candidate region pinpointed a novel missense substitution in the SGK223 gene (c.1529T>C). In silico predictions strongly suggested an alteration of a cryptic splice site in presence of this variant. Interestingly, SGK223 codes for the pragmin protein involved in the reorganization of cytoskeleton, which is a pathway already involved in the dHMN pathogenesis. Despite this functional consistency, further studies are warranted to confirm these findings.

P09.084-M
In search of a new vascular dementia: An exome sequencing approach to a Swedish multi-infarct family

M. Siitonen[1], *A. Börjesson-Hanson*[2], *M. Pöyhönen*[3], *P. Pasanen*[1], *S. Kern*[2], *J. Kern*[2], *C. Sundal*[4], *O. Andersen*[4], *M. Baumann*[5], *R. Kalaria*[6], *H. Kalimo*[7], *J. Hardy*[8,9], *M. Viitanen*[10,11], *L. Myllykangas*[7], *R. Guerreiro*[8];
[1]*Department of Medical Biochemistry and Genetics, University of Turku, Turku, Finland,* [2]*Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden,* [3]*Department of Clinical Genetics, Helsinki University Central Hospital, Helsinki, Finland,* [4]*Department of Neurology, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden,* [5]*Protein Chemistry Unit, Institute of Biomedicine/Anatomy, University of Helsinki, Helsinki, Finland,* [6]*Institute for Ageing Health, Newcastle University, Newcastle upon Tyne, United Kingdom,* [7]*Department of Pathology, Haartman Institute, University of Helsinki, Helsinki, Finland,* [8]*Department of Molecular Neuroscience, Institute of Neurology, University College London, London, United Kingdom,* [9]*Reta Lila Weston Institute, UCL Institute of Neurology, London, United Kingdom,* [10]*Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden,* [11]*Department of Geriatrics, University of Turku, Turku, Finland.*

In 1977, Sourander and Wålinder described a case of hereditary multi-infarct dementia (MID) in a Swedish family. Later their disease was suggested to be cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL). The clinical picture of recurrent strokes resembles CADASIL, but we did not detect any pathogenic mutations in the entire 8091 bp reading frame of *NOTCH3* nor found evidence for the *NOTCH3* gene linkage. Neither did we find any evidence of the CADASIL-typical granular osmiophilic material (GOM) in skin biopsies. These multiple approaches suggest that in this Swedish family the hereditary MID suspected to be CADASIL is a different disorder with dissimilar pathological features, and belongs to the growing group of genetically uncharacterized familial small vessel diseases (SVDs).
In order to search for the pathogenic mutation behind the disease, we did a whole-exome sequencing for two healthy and three affected family members. The exon targeting was done with NimbleGen's sequence capture (Roche Inc. USA) and the sequencing with Illumina's sequencing platform (Illumina Inc. USA).
After sequencing the results were filtered against public SNP databases in order to identify the sequence variants that have not been published previously as polymorphisms. Subsequently, we concentrated on the variants that are shared by all the three patients and excluded the variants that are also shared by the healthy controls. Since the disease is dominant we narrowed our search by excluding the variants that are homozygous in all patients. Detailed results of our studies will be presented at the congress.

P09.085-S
Multiple sclerosis risk variant at the ch12q14.1b locus affect the expression of the CYP27B1 gene in activated monocytes

M. Karaky[1], *M. Fedetz*[1], *C. Barrionuevo*[1], *Ó. Fernández*[2], *C. Delgado*[3], *G. Izquierdo*[4], *M. Lucas*[5], *M. Torrecillas*[6], *F. Matesanz*[1], *A. Alcina*[1];
[1]*Instituto de Parasitología y Biomedicina 'López Neyra', Granada, Spain,* [2]*Servicio de Neurología, Instituto de Neurociencias Clínicas, Hospital Regional Universitario Carlos Haya, Málaga, Spain,* [3]*Centro Regional de Transfusión Sanguínea Granada-Almería, Granada, Spain,* [4]*Unidad de Esclerosis Múltiple, Hospital Virgen Macarena, Sevilla, Spain,* [5]*Servicio de Biología Molecular, Hospital Virgen Macarena, Sevilla, Spain,* [6]*Centro de Salud, Armilla, Granada, Spain.*

Background: The region ch12q14.1 was shown to be associated with several autoimmune diseases in different Genome Wide Association Studies. We have determined that a variant which alters the enhancer activity of a regulatory element explains the association of the locus with multiple sclerosis (MS). This region contains the *CYP27B1* gene encoding the enzyme 1-alpha-hydroxylase which catalyses the conversion of 25(OH)D to 1,25$(OH)_2$D, the active form of vitamin D. Since the vitamin D is a key regulator of the immune response and plays a role in MS susceptibility, we want to determine the effect of the variant on the expression of the *CYP27B1* gene in specific population of immune cells. **Methods :** The monocytes CD14 cells were purified from 111 healthy individuals. They were activated with Interferon-gamma (IFNγ) and lipopolysaccharide (LPS). The *CYP27B1* expression was then measured by quantitative real time PCR and correlated with the genotype of the variant. **Results:** We observed that the MS risk allele of the polymorphism rs10877013 was significantly associated with a low expression of the

CYP27B1 gene (p=0,007) in activated monocytes. **Conclusion:** In this work we demonstrate that the causal variant of MS association at the ch12q14.1 locus, alters the transcription of *CYP27B1* gene suggesting that the intracellular vitamin D levels could be affected. Our data point to lower production of $1,25(OH)_2D$ is the functional cause of the genetic association with MS.

P09.086-M
Alterations of gene expression at the peak level in the experimental allergic encephalomyelitis

A. Sen, *G. Celik, O. Ozgun, S. Arslan;*
Pamukkale University, Denizli, Turkey.

Experimental allergic encephalomyelitis (EAE) is the widely used model for studying multiple sclerosis (MS). MS is a chronic disease where the inflammation throughout the brain and spinal cord cause demyelinated plaques of gliotic scar tissue. We have studied the alterations in gene transcription in the EAE induced in the C57/BL6 mouse using real-time PCR. We have studied the genes mediating MS progression, such as cytokines and chemokines, inflammatory and immune response genes, as well as genes involved in cell adhesion, cellular stress and apoptosis whose expressions correlated across multiple analyses. For this purpose female C57/BL6 mice weighing between 18-20 gr were immunized s.c. with 250 µg of MOG peptide (the 35-55 sequence) emulsified in complete Freund's adjuvant (CFA) supplemented with 4 mg/ml killed *M. tuberculosis*. Pertussis toxin (PT, 500 ng/mouse) was injected *i.p.* immediately and 48 hours later. Control mice were received only CFA and further PT. Clinical assessment was performed on the general clinical scales. The average score of EAE group was 3.5. Expression of amyloid beta precursor protein, complement component 1s, chemokine (CC motif) ligand 5, CXC ligand 9, CXC ligand 10, CD4 antigen, G protein alpha inhibiting 2, histocompatibility 2 class II antigen Eβ, IL6, IL13, MBP, NFκB light polypeptide gene, proteolipid protein 1, and TNF are found to be significantly different in the brain at about the peak of disease than control animals. Our data revealed strong transcriptional regulation of genes involved in inflammatory processes, such as antigen presentation and processing, complement activation and chemotaxis.

P09.087-S
Target resequencing of regions associated with Multiple Sclerosis in the Italian population

N. Barizzone[1], *M. Sorosina*[2], *F. Clarelli*[2], *S. Anand*[3,4], *E. Mangano*[3], *R. Bordoni*[3], *F. Esposito*[2], *PROGEMUS, PROGRESSO, IMSGC, O. Raymkulova*[5], *G. Predebon*[1], *V. Martinelli*[2], *G. Comi*[2], *M. Leone*[5], *G. De Bellis*[*3], *F. Martinelli-Boneschi*[*6], *S. D'Alfonso*[*1];*
[1]*A. Avogadro University, Novara, Italy,* [2]*San Raffaele Scientific Institute, Milano, Italy,* [3]*National Research Council of Italy, Institute for Biomedical Technologies, Segrate, Milano, Italy,* [4]*Department of Science and Technology, University of Sannio, Benevento, Italy,* [5]*MS Centre, SCDU Neurology, AOU Maggiore della Carità, Novara, Italy,* [6]*San Raffaele Scientific Institute, Italy., Milano, Italy.*

Multiple Sclerosis (MS) is a multifactorial autoimmune demyelinating disease of the CNS. Several large international association studies detected over 100 MS loci. However, for the majority of them the causal variant is not yet identified and, generally, only common variants have been studied. The aim of this study was to follow-up the MS loci in the Italian population, searching for the primarily associated variants, focusing also on rare variants. After an association study in 1750 Italian MS cases and 2272 matched controls (Illumina 660-Q, and Immunochip), we selected for target resequencing 32 MS associated regions showing a significant association in the Italian population. The selected regions (1.9 Mb), either including the whole genomic segment (N=17 regions, 45 genes) or only the coding sequences (further 48 genes), were captured (Agilent SureSelect) and sequenced (GAIIx Illumina) in 600 Italian MS patients and 400 matched controls pooled in groups of 12 individuals.We used the variant caller CRISP to call the variants, ANNOVAR to annotate them, and custom R-scripts to calculate allele frequency. Validation of a subset of variants by individual genotyping demonstrate a high correlation with allele frequency in the pools.After QC, results in the MS patients showed that among the 23065 detected variants, 67% were absent in public databases, including 1061 variants with a predicted functional consequence on the gene product (missense, nonsense, splice variants), thus potentially directly involved in the MS susceptibility. The comparison with the data of the controls and the replication in independent cohorts is ongoing

P09.088-M
Modulation of Protein Kinase C Alpha (PRKCA) mRNA expression and alternative splicing by functional polymorphisms contribute to multiple sclerosis susceptibility

E. M. Paraboschi[1], *V. Rimoldi*[1], *C. Dall'Osso*[1], *E. Saba*[1], *T. Tabaglio*[1], *L. Clario*[1], *M. D. Benedetti*[2], *S. D'Alfonso*[3], *M. Leone*[4], *D. Gemmati*[5], *S. Duga*[1], *G. Soldà*[1], **R. Asselta**[1];
[1]*Department of Medical Biotechnologies and Translational Medicine, University of Milan, Milan, Italy,* [2]*Department of Neurosciences, University Hospital, Verona, Italy,* [3]*Department of Health Sciences and IRCAD, Eastern Piedmont University, Novara, Italy,* [4]*MS Centre, SCDU Neurology, AOU Maggiore della Carità, Novara, Italy,* [5]*Center Hemostasis & Thrombosis, University of Ferrara, Ferrara, Italy.*

The Protein Kinase C Alpha (PRKCA) gene, encoding the Th17-cell-selective PKCα kinase, was repeatedly associated with multiple sclerosis (MS), but the underlying biological mechanism remains unknown.
We replicated this genetic association in an Italian population (409 cases, 723 controls), identifying a protective signal, corresponding to a GCC microsatellite in the PRKCA promoter (P=0.033, OR=0.12, 95%CI=0.015-0.94), and a risk haplotype in intron 3 (P=7.7*10-4; OR=1.57, 95%CI=1.24-1.99, meta-analysis P=1.1*10-12). Expression experiments demonstrated that the protective signal is associated with PRKCA promoter variants conferring higher expression levels of the gene. Minigene-based transfection experiments proved that the risk signal is driven by an ins/del polymorphism (rs35476409/rs61762387) influencing, with an hnRNP-H-dependent mechanism, the skipping of a PRKCA alternative exon.
Studies performed on RNA extracted from different cell lines and human tissues evidenced a complex pattern of alternatively-spliced (AS) PRKCA isoforms, which are modulated by the nonsense-mediated mRNA decay (NMD) and display a preferential association with the use of alternative polyadenilation sites.
MS patients showed significantly decreased PRKCA levels (49 cases, 61 controls; P<1*10-4) in peripheral blood mononuclear cells, with a concomitant unbalance in the relative abundance of its mRNA variants. One of these alternative transcripts is predicted to encode a truncated PKCα that, when overexpressed, aberrantly localizes to the plasma membrane and/or in cytoplasmic clusters.
Our data suggest that AS-NMD coupling, in the presence of specific genotypes, modulates PRKCA expression and isoform diversity, and point to a dysregulation of PRKCA splicing in MS, with possible implications in Th17-cell-mediated immune responses.

P09.089-S
A novel mutation in SCN4A gene, in a patient with an unusual clinical presentation of Myotonia Permanents: Expanding the clinical and molecular spectrum of SCN4A mutations

C. Vinkler[1], *E. Leshinsky Silvers*[2], *T. Sagie Lerman*[3], *M. Ginzberg*[4], *F. Lehmann-Horn*[5];
[1]*Institute of Clinical Genetics, Holon, Israel,* [2]*Molecular-Genetic Laboratory Wolfson Medical Center, Holon, Israel,* [3]*Pediatric Neurology Unit, Wolfson Medical Center, Holon, Israel,* [4]*Pediatric Neuromuscular Service, pediatric neurological Unit, Holon, Israel,* [5]*Department of Applied Physiology, University of Ulm, Ulm, Germany.*

Congenital myotonias are a group of hereditary muscle disorders that present in infancy and childhood, characterized by impaired muscle relaxation following a voluntary forceful contraction. The core symptoms either relate to myotonia or to periodic weakness. These disorders are caused by mutations in genes encoding the skeletal muscle chlorides, sodium and calcium channels.
We report a 7-years old boy with a severe early onset unique phenotype of myotonia permanents. He had neonatal respiratory failure and as well as severe recurrent episodes of laryngospasm during infancy. Massive general muscle hypertrophy, eye lid myotonia and prolonged hand grip relaxation, were present since early childhood. An unusual complication of tongue hypertrophy was noted during infancy and reoccurred again after surgical resection.
A novel V717G mutation in SCN4A was identified in the proband, but not in his parents.
This is the first case of myotonia permanens reporting recurrent tongue hypertrophy as a major clinical feature in this case. Tongue hypertrophy resulted most probably from continued tongue contraction caused by his permanent myotonia .
The novel mutation found in SCN4A in this boy, has not been found in his parents. It has been suggested to be pathological by a number of in silico prediction programs. It is located in a well conserved area of the gene in the transmembrane helical part of the Sodium channel protein subunit. This mutation has not been describes previously in SCN4A related disorders.
This case further expands the genetic and clinical spectrum of myotonia permanents.

P09.090-M
PANK2 and C19orf12 mutations in neurodegeneration with brain iron accumulation (NBIA)

G. Annesi[1], *P. Tarantino*[1], *M. Gagliardi*[1,2], *G. Lesca*[3,4], *E. Broussolle*[5,6], *G. Iannello*[1,7], *A. Quattrone*[1,8];

Lyon, France, [5]Universitè Lyon I, Centre de Neurosciences Cognitives,CNRS UMR5229, Lyon, France, [6]Service de Neurologie C, Hopital Neurologique Pierre Wertheimer, Lyon, France, [7]University of Magna Graecia, Germaneto (CZ), Italy, [8]Institute of Neurology, University Magna Graecia, Germaneto (CZ), Italy.

Neurodegeneration with brain iron accumulation (NBIA) defines a group of neurodegeneration diseases that share prominent extrapyramidal features, dementia and radiographic evidence of iron deposition in the basal ganglia. Different forms of early onset NBIA with autosomal recessive transmission are associated with mutations in specific genes as (1) pantothenate kinase-associated neurodegeneration (PKAN); (2) phospholipase-associated neurodegeneration (PLAN); and (3) fatty acid hydroxylase-associated neurodegeneration (FAHN). Mutations in PANK2 are the most common cause of these disorders. C19orf12 was recently reported as another causative gene. In this study we recruited 20 subjects with NBIA that include clinical data and associated DNA samples. DNA and clinical information were collected and used after partecipants gave written informed consent. The 8 exons of PANK2 and 3 exons of C19orf12 were amplified by PCR and sequenced on an ABI PRISM 3130 XL-AVANT Genetic Analyzer. Phenotypic data were obtained by neurologic examination and magnetic resonance imaging. Mutation screening of PANK2 and C19orf12 were found in 3 and 5 patients, respectively. In conclusion mutations in both PANK2 and C19orf12 contributed significantly to NBIA in the our patients.

P09.091-S
Identification of the genetic factors involved in neural tube development and defects

V. Massa[1], G. Soldà[2], L. Avagliano[1], A. Gallina[1], G. Bulfamante[1], A. Marozzi[2], F. Cotelli[3], **A. Pistocchi**[2];
[1]University of Milan-Department of Health Sciences, Milano, Italy, [2]University of Milan-Department of Medical Biotechnology and Translational Medicine, Milano, Italy, [3]University of Milan-Department of Biosciences, Milano, Italy.

Neural tube is the embryonic precursor of brain and spinal cord, and forms as a consequence of closure of the developing neuroepithelium. If closure events fail, the embryo will manifest a neural tube defect (NTD: spina bifida or exencephaly). Despite significative advances in the field, the elucidation of genetic factors associated to NTD has remained elusive and NTDs are the second most common congenital defects affecting human pregnancies. This project aims at investigating two different aspect of NTDs: on one side the analysis of the transcription factor Sax-1, that was found to be down-regulated in a microarray screening in murine NTDs model (Zic2Ku). Sax-1 expression correlates remarkably closely with the progression of posterior closure of the neuroepithelium, overlapping with Zic2 expression. Functional studies of Sax1 and Zic2 in zebrafish will be flanked to mouse embryos and in vitro analyses. On the other side, this project investigates the role of miRNAs in neural tube development on human samples. From a database of 534 fetal autopsies, we selected 9 fetuses with NTDs (7 myelomeningocele, 2 anencephaly). Using a combination of bioinformatics tools (MirWalk, CO-ME-TA, DAVID), we have identified 4 candidate miRNAs whose predicted targets are significantly enriched for functional pathways related to neurulation, that are now under functional evaluation.

P09.092-M
Mutations in RNA kinase CLP1 cause neurodegeneration

V. R. C. Eggens, J. L. Cazemier, P. R. Kasher, M. A. J. Weterman, **F. Baas**;
Academic Medical Centre Amsterdam, Amsterdam, Netherlands.

Cleavage and polyadenylation factor I subunit (*Clp1*) is an important kinase in RNA metabolism. It is involved in processes as tRNA maturation and mRNA 3' end processing. Recently, a missense mutation in the *CLP1* gene has been identified in patients with atrophy of the cerebellum, pons and corpus callosum. We have isolated an ENU induced zebrafish mutant, harbouring a p.R44X nonsense mutation in the *Clp1* gene. Using *in situ* hybridization and morpholino knockdown of p53 we examined the phenotype of homozygous p.R44X zebrafish embryos. We show that *Clp1* knockout zebrafish do not survive beyond 4 days post fertilisation (dpf), have a reduced head size and show an S-curved body. At 2dpf, *Clp1* knockout fish show reduced expression of midbrain marker *otx2*, increased cell death in the brain and a disturbed organisation of motor neurons. The phenotype can be partly rescued by injecting human wild type, but not by mutant p.R140H *CLP1* mRNA. Morpholino knock down of p53 partially rescues the phenotype as well. We show that *Clp1* is an essential gene in both the central and peripheral nervous system. Similar to the human situation, *clp1* mutations cause neurodegeneration and motor neuron problems in zebrafish. We show that the neurodegeneration is mediated by the p53 apoptosis pathway. Our data supports the hypothesis that amongst other RNA processing genes, *CLP1* plays a crucial role in neurodevelopment.

P09.093-S
Familial case of NBIA

K. Radic, *N. Lojo-Kadric, J. Ramic, K. Bajrovic, L. Kapur-Pojskic;*
Institute for Genetic Engineering and Biotechnology, Sarajevo, Bosnia and Herzegovina.

Neurodegenerative brain iron accumulation (NBIA) is a group of inherited disorders with various symptoms and genetic aetiology. Common feature of all NBIA forms is accumulation of iron in basal ganglia and progressive movement disorder.
NBIA belongs to rare genetic conditions affecting 1-3 per million individuals which makes it insufficiently studied and understood. Nevertheless, new mutations and genes implicated in different NBIA types are being discovered. One of them is C19ORF12 mutation, which causes MPAN - *mitochondrial membrane protein-associated neurodegeneration*, characterized by childhood/early adulthood onset, dystonia, spacity, optic atrophy and neuropsychiatric changes. The disorder is progressive and symptomatic therapy is the only currently available option.
Parents of affected child came to our institution for genetic counselling and testing for previously detected mutation on exon 3 (C19ORF12) of MMIN gene, c.204-214del11bp homo, in the index patient (daughter, aged 17). Family members (mother, father, daughter-proband and son-aged 5, asymptomatic) were tested using specifically designed amplification primers. Agilent 2100 bioanalyzer was used for analysis of PCR products.
Deletion in sample of affected patient was confirmed as basis for linkage analysis. Both parents and son are heterozygous carriers for described mutation. Since MPAN is autosomal-recessive, risk of affecting future offspring is 25 % in this case. Risk for asymptomatic carriers is 50 %, so genetic counselling is highly recommended.
Discovering new mutations associated with NBIA is significant process as it could elucidate mechanisms underlying this group of disorders and create new possibilites in terms of gene therapy and effective therapeutic options in the future.

P09.094-M
A cell reprogramming-based approach to study 7q11.23 gene dosage imbalances in Williams Beuren syndrome and autism spectrum disorder

S. Atashpaz[1], *A. Adamo[1], P. Germain[1], J. Chenoweth[2], G. D'Agostino[1], M. Zanella[1], P. Prontera[3], C. Unger[4], P. W. Andrews[4], G. Pruneri[1], B. Hamilton[5], G. Merla[6], R. D. McKay[2], G. Testa[1];*
[1]European Institute of Oncology, Milan, Italy, [2]Lieber Institute for Brain Development, Baltimore, MD, United States, [3]Department of Experimental Medicine and Biochemical Sciences, University of Perugia, Perugia, Italy, [4]Centre for Stem Cell Biology, Department of Biomedical Science, University of Sheffield, Sheffield, United Kingdom, [5]Stemgent, Cambridge, MA, United States, [6]Medical Genetics Unit, Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy.

Symmetrical gene dosage imbalances at 7q11.23 cause two neurodevelopmental diseases, Williams Beuren Syndrome (WBS) and the 7q11.23 microduplication associated to autistic spectrum disorder (7dup-ASD). Besides intellectual disability and craniofacial dysmorphisms, WBS patients display hypersociality and comparatively well-preserved language skills while 7dup-ASD is associated with impairments of varying severity across the autistic spectrum. The striking symmetry in genotype and phenotype between the two conditions points to the 7q11.23 cluster as a surprisingly small subset of dosage-sensitive genes affecting social behavior and cognition. The molecular phenotypes of these syndromes in disease-relevant cell-types remain to be elucidated however, due to scarce availability of primary diseased tissues. Convergent evidence both from human studies and mouse models, points to transcriptional dysregulation as a critical aspect of both conditions, consistent with the presence of several transcription factors in the 7q11.23 interval.
Here we present the first analysis of transcriptional dysregulation in human physiopathologically relevant cell types carrying 7q11.23 dosage imbalances. We selected a large and unique panel of WBS and 7dup-ASD patients and derived induced pluripotent stem cells (iPSC) with the most advanced reprogramming technology based on synthetic mRNAs. These were then differentiated into relevant lineages to establish experimentally tractable models of these conditions. Next, we integrated high-throughput sequencing for transcriptional and chromatin analysis and present here a functional dissection of these symmetric conditions that uncovers the principles of dosage-dependent transcriptional dysregulation in disease-relevant human cells types.

P09.095-S
Next-generation sequencing in the diagnosis of neurodevelopmental disorders

N. Okamoto[1], *F. Miya[2], T. Tsunoda[2], M. Kato[3], S. Saitoh[4], M. Yamasaki[5], Y. Kanemura[6,7], K. Kosaki* [8];

[1]Department of Medical Genetics, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan, [2]Laboratory for Medical Science Mathematics, Center for Integrative Medical Sciences, RIKEN, Yokohama, Japan, [3]Department of Pediatrics, Yamagata University Faculty of Medicine, Yamagata, Japan, [4]Department of Pediatrics and Neonatology, Nagoya City University Graduate School of Medical Sciences, Nagaoya, Japan, [5]Department of Pediatric Neurosurgery, Takatsuki General Hospital, Osaka, Japan, [6]Division of Regenerative Medicine, Institute for Clinical Research, Osaka National Hospital, National Hospital Organization, Osaka, Japan, [7]Department of Neurosurgery, Osaka National Hospital, National Hospital Organization, Osaka, Japan, [8]Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan.

Introduction

Recently, genetic bases of neurodevelopmental diseases including CNS anomalies, intellectual disability (ID), and epilepsy have been significantly elucidated, but are still largely unknown. We have developed a target and whole exome sequencing (WES) based mutation screening strategy. The target sequencing system enabled us to screen 284 genes associated with neurodevelopmental disorders. Unresolved patients were studied by proband-parent trio approach using WES.

Materials and Methods

Forty seven patients were included in the study. Fourteen patients were studied by WES. They were analyzed under the approval by our institutional ethics committee. To capture the exonic DNAs, we used SureSelectXT Custom capture library for neuronal genes capture. We performed sequencing using Illumina HiSeq 2000 sequencer and obtained paired-end sequence reads. We excluded known variants found in dbSNP, 1000 Genomes Project, ESP6500 and our control samples, and narrowed the candidates to missense, nonsense SNVs and frameshift indels.

Results

Fourteen mutations including *FOXG1, AHI1, PTPN11, DYRK1A, ACTB, CASK, GABRD* were identified by target screening and conventional sequencing. WES revealed de novo mutations in *CREBBP, KIF1A, GRIN2A* and *ALDH18A1. HNRNPH2* and *AMMECR1* mutations were noted in X-linked pattern. None of these mutations were recorded in database. Some other mutations have unknown pathogenic significance.

Discussion

NGS method could clarify a consistent percentage of patients with neurodevelopmental disorders. NGS method would be an alternative to current technologies for identifying the multiple genetic causes of neurodevelopmental disorders.

P09.096-M

Seven novel neurofibromatosis 1 (NF1) gene mutations identified in Spanish pediatric patients

P. Santibañez[1], *C. Cervera-Acedo[1], M. Lopez[1], J. Aguirre-Lamban[1], A. Garcia-Oguiza[2], M. Poch-Olive[2], J. Revorio-Gonzalez[2], E. Dominguez-Garrido[1];*
[1]Fundacion Rioja Salud - CIBIR, Logroño, Spain, [2]Hospital San Pedro, Logroño, Spain.

Introduction: Neurofibromatosis type 1 (NF1) is one of the most common human autosomal dominant disorder with an estimated incidence of 1:3500. This is a neurodermal dysplasia characterized by café-au-lait spots, axillary freckling, dermal neurofibromas, and Lisch nodules of the iris. The condition is fully penetrant and has a highly variable expression. It is caused by mutations in the neurofibromin gene (*NF1*) located on chromosome 17q11.2. **Subjects and Methods:** Seven children suspected of having NF1 were tested for mutations in the *NF1* gene. Some of them only have café-au-lait spots and two presented other clinical features. Single and multiexon deletion/duplication were tested by MLPA assay. PCR and sequencing analysis in RNA was performed. Segregation of the mutations was checked in 3 cases. **Results:** Seven pathogenic not previously reported mutations in NF1 gene were identified in heterozygous (Table 1). Only 1 sample showed a deletion of the exon 23 by MLPA. In one case the mutation was considered to be *de novo.* **Discussion:** Mutational NF1 analysis is considered to be a difficult task owing to the size of the gene, the absence of clear mutational hot spots and the presence of pseudogenes. RNA and MLPA-based techniques should be used in conjunction to provided reliable and accurate molecular genetic testing.

P09.097-S

Genetic diagnosis of neurological diseases using NGS: first year of experience

M. Climent[1], *A. Romera-López[1], D. Valero-Hervás[1], V. Volpini[2], A. Matilla[3], C. Collado[1], R. Rodríguez-De Pablos[1], Á. Arilla-Codoñer[1], J. Triviño[1], S. Zúñiga-Trejos[1], G. Marco[1], D. Cantalapiedra[1], L. Pérez-Cabornero[1], C. Buades[1], C. Camprubí[3], R. Miñambres[1], S. Santillán[1];*
[1]Sistemas Genómicos, Paterna, Spain, [2]Instituto de Investigación Biomédica de Bellvitge, Barcelona, Spain, [3]Hospital Germans Trias i Pujol, Barcelona, Spain.

The diagnosis of neurological diseases is not straightforward, mainly due to the presence of nonspecific overlapping clinical symptoms and of genetic heterogeneity. A global approach using high throughput technologies such as NGS could be of great help to improve their diagnosis.

We present our experience in the analysis of Neurological diseases using a 200-gene NGS targeted re-sequencing panel. Samples from 48 patients were submitted to our laboratory for genetic testing. Clinical diagnosis included Spastic Paraplegia (17), Motor/Sensitive Hereditary Neuropathy (12), Ataxia (6), Parkinson (4), Miastenia (3), Joubert Syndrome (2), Frontotemporal Dementia (2), Hyperkalemic Periodic Paralysis (1) and SMA (1). Coding exons and splice-site regions of the genes associated with each pathology were analysed. Enrichment and sequencing were carried out using SureSelect Enrichment System (Agilent) and SOLiD 5500/MiSeq (Life Technologies/Illumina). Mean depth was established at 200x.

In 7 out of 48 samples (14%), a genetic cause that justifies the clinical diagnosis was found. Taking into account all the samples, 63 variants (confirmed by Sanger sequencing) were identified and classified into pathogenic (7), probably pathogenic (2), Unknown (53) and probably benign (1). According to their effect, missense (29), synonymous (21), splice-site (8), frameshift (3) and nonsense (2) mutations were found. In 21 out of 48 samples, no variants (pathogenic/unknown) were identified. Despite being moderate, 14% of genetically diagnosed patients suggests that NGS is effective for the diagnosis of neurological diseases. A better understanding of unknown variants, that allow classifying them into SNPs or pathogenic mutations, could significantly increase the diagnosis rate.

P09.098-M

Individual cMRI based genetic testing algorithms for neuronal migration disorders increase mutation detection rates

U. Hehr[1], *T. Geis[2], J. Proepper[1], G. von Gersdorff[3], B. Propf[3], G. Schuierer[4], S. M. Herbst[1];*
[1]Zentrum und Institut für Humangenetik, Universität Regensburg, Regensburg, Germany, [2]Klinik und Poliklinik für Kinder- und Jugendmedizin, Regensburg, Germany, [3]LISS – Anlaufstelle für Eltern und Angehörige an Lissenzephalie leidender Kinder e.V., Hamburg, Germany, [4]Zentrum für Neuroradiologie, Universitätsklinikum Regensburg, Regensburg, Germany.

Background

Neuronal migration disorders are an important cause of severe psychomotor retardation and seizures, frequently resistant to antiepileptic medication. Based on cerebral MR imaging (cMRI) neuronal migration disorders (NMD) can be subdivided into various radiological forms including classic and cobblestone lissencephaly.

Method

Genetic testing was performed for 1034 index patients either (1) individually after in-house cMRI reevaluation (n=214) or (2) as assigned by the referring doctor (n=820). Individual testing strategies included MLPA analysis, Sanger sequencing and massive parallel sequencing. In an ongoing study we assess long-term development and genotype dependent response to antiepileptic and supportive therapies.

Results

119 NMD patients of study arm 1 were genetically analyzed leading to the identification of the underlying genetic alterations in 35.3% of the analyzed samples incl. classic lissencephaly 65.4%, subcortical band heterotopia 83.3%, polymicrogyria 10.0%, cobblestone lissencephaly 14.3%, periventricular nodular heterotopia 37.5% and complex cortical malformations 20.0%. In comparison, the overall mutation detection rate in study arm 2 without in-house cMRI reevaluation was only 18.5% (p<0.0005).

Overall, pathogenic mutations were identified in 18.9% of independent patients incl. *LIS1* (34), *DCX* (47), *ARX* (10), *TUBA1A* (4), *TUBB2B* (4), *GPR56* (10), *FLNA* (30), *POMT1* (22), *POMGnT1* (15), *FKTN* (3), *FKRP* (9), *ISPD* (1), *LARGE* (2) and *DAG* (1). Our preliminary data suggest a genotype dependant antiepileptic response in *LIS1* associated classic lissencephaly.

Conclusion

Genome wide genetic testing strategies will further improve the number of identified genes and genetic alterations, but continue to require their critical interpretation in the context of clinical findings and cerebral imaging.

P09.099-S

In a consanguineous family with two patients showing a novel autosomal recessive inherited syndrome another patient with an unlinked autosomal nonsyndromic form of mental retardation was identified

P. M. Kroisel[1], *V. Rupp*[1], *R. Birnbacher*[2], *C. Liechtenstein*[2], *E. Petek*[1], *K. Wagner*[1], *M. R. Speicher*[1], *C. Windpassinger*[1];
[1]*Institute of Human Genetics, Graz, Austria,* [2]*Department of Pediatrics, Regional Hospital Villach, Villach, Austria.*

We previously characterized in a large family of Turkish origin a male and a female patient showing a new syndrome, that includes following symptoms: severe mental retardation, corpus callosum agenesis, ataxia, moderate microcephaly, square face, hypertelorism, bilateral ptosis, arched eyebrows, epicanthal folds, downslanting palpebral fissures, strabismus, amblyopia, broad nasal bridge, low set ears, short philtrum and downturned corners of the mouth. Since mothers of both patients are first degree cousins and both fathers are second degree cousins, pedigree analysis makes an autosomal recessive mode of inheritance of this particular syndromic disorder very likely. Homozygosity mapping by 250 k Affymetrixs SNP array analysis allowed reducing homozygous genomic regions shared by both patients to only 4 segments ranging from 3.05 Mb to 8.84 Mb in size. Recently a brother of the male patient was diagnosed with nonsyndromic mental retardation (NSMR). Affymetrix CytoScan ® HD analysis of his DNA was performed, indicating his NSMR is not linked to the new syndrome. Because the number of potential candidate genes in these genomic regions according to obtained RS-loci on chromosome 1 (1p36.22), 2 (2q22.3), 3 (3p14.1) and 9 (9q21.13) is considerable, whole exome next generation sequencing will be applied to search for homozygous mutations in both patients especially in those segments. Although the phenotype of our patients shows similarities with Toriello-Carey syndrome and Charlevoix disease, it clearly does not resemble these syndromes, so we think that our patients exhibit a new syndromic disorder and another NSMR form could be mapped in this family as well.<br

P09.100-M

Next-generation analysis of the amyotrophic lateral sclerosis / Parkinsonism-dementia complex of Guam

I. Guella[1], *C. Thompson*[1], *C. Szu-Tu*[1], *D. M. Evans*[1], *F. T. Pishotta*[1], *H. E. Sherman*[1], *C. Vilarino-Guell*[1], *P. McGeer*[2], *H. Morris*[3], *K. Gwinn*[4], *T. Siddique*[5], *D. W. Dickson*[6], *J. Steele*[7], *M. J. Farrer*[1];

The amyotrophic lateral sclerosis (ALS)/ Parkinsonism-dementia complex (PDC) is a progressive, age-associated neurodegenerative disorder described in Guam, Western Papua and the Kii peninsula of Japan. Despite decades of research the excess incidence and pathogenesis of ALS-PDC on Guam remains enigmatic and mutations underlying disease have yet to be elucidated by genome-wide linkage analysis of multi-incident pedigrees. In this study we have used next-generation targeted resequencing to evaluate the contribution of genetic variability in the pathogenesis of Guamanian neurodegeneration. A target-capture panel covering the exonic regions of 116 major genes previously linked and/or associated with parkinsonism, dementia, ALS and related syndromes has been developed. Ninety-three indigenous Chamorro Islanders, including patients with ALS, parkinsonism and/or dementia, as well as neurologically normal subjects, were longitudinally examined and comprehensively assessed. We report putatively pathogenic variants in HTT, PINK1, DCTN1, CHMP2B, DNAJC13, FUS, GRN and ALS2, identified in patients with parkinsonism and/or dementia, that explain multi-incident disease in several pedigrees.

P09.101-S

Multiple sclerosis and NF1: it's time to think about it

G. Melloni[1], *C. Cesaretti*[1], *M. De Riz*[2], *L. Ghezzi*[2], *M. Sciacco*[3], *F. Lalatta*[1], *E. A. Scarpini*[2], *F. Natacci*[1];

Neurofibromatosis type 1 (NF1) is a rare genetic condition, with a frequency of 1/2500-1/3000, caused by mutations in the NF1 gene (OMIM * 613 113). Since the first description in the literature, knowledge about the clinical picture and the possible associated conditions is gradually increased. In the past, cases of multiple sclerosis (MS) in patients with NF1 have been sporadically described . The association between these two diseases is rare, but probably not accidental, because intron 27b of the the NF1 gene contains OMGP gene (OMIM * 164 345), which acts in myelination processes and seems to be involved in immunopathogenesis of MS. Moreover, NF-1 and MS may share a common influence from genes on chromosome 17 affecting cell proliferation and inflammation processes. We report our 12 years experience in the follow up of NF1 adult patients. The cohort is composed by 301 patients, with an age range of 18-72 years, and Males/Females ratio of 111/190. A multidisciplinary equipe evaluates patients yearly, thus allowing a precise knowledge about the natural history of the condition. Over the years, MS has been diagnosed in four of our patients (3 women and 1 man). This observational study enables us to define for the first time MS prevalence in a large cohort of NF1 adult patients (1.3%). Detailed clinical features of each MS-NF1 patient, together with review of literature and current aetiopathogenetic hypothesis will be provided.

P09.102-M

An NGS gene panel for the genetic diagnosis of rare autosomal recessive cerebellar ataxias

S. Magri[1], *D. Di Bella*[1], *E. Sarto*[1], *S. M. Caldarazzo*[1], *L. Nanetti*[1], *C. Mariotti*[1], *C. Gellera*[1], *M. Koenig*[2], *M. Schulze*[3], *P. Bauer*[3], *F. Taroni*[1];
[1]*Unit of Genetics of Neurodegenerative and Metabolic Disease, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy,* [2]*Laboratoire de Génétique Moléculaire et Unité INSERM UMR_S 827, IURC, Montpellier, France,* [3]*Institute of Medical Genetics, University of Tübingen, Tübingen, Germany.*

Autosomal recessive cerebellar ataxias (ARCA) are a genetically highly heterogeneous group of neurological disorders involving both central and peripheral nervous system. One of the goal of the E-Rare EUROSCAR project is to establish an NGS-based targeted genotyping for the diagnosis of known ARCA genes. One-hundred-forty-two ataxic patients referred from different European partners were analyzed using a HaloPlex-based gene panel targeting the coding regions of 127 genes involved in recessive and dominant ataxia. Patient inclusion criteria for analysis were: progressive ataxia, exclusion of nongenetic causes, family history suggestive of autosomal recessive ataxia (AR) or sporadic (S) patients with onset before age 40. We contributed with 34 Italian patients (14AR and 20S) previoulsy tested for FRDA, AVED, or APTX, as appropriate. This approach allowed us to identify homozygous or compound heterozygous pathogenic mutations in ADCK3 and 2 challenging genes (SYNE1 and SACS) in 6 patients (4S and 2AR). Moreover, different missense variants of uncertain pathogenicity were identified in genes responsible for dominant ataxia (PDYN, SPTBN2, CACNA1A). Finally, several heterozygous mutations were identified in recessive genes. For 6 patients, analysis revealed no candidate variants in screened genes. All high-quality variants were confirmed by Sanger sequencing indicating reliability of this approach. Further analyses are required for the validation of uncertain variants and the evaluation of large in/del mutations in recessive genes in which heterozygous mutations have been identified. In conclusion, NGS gene panel represents a necessary tool for genetic diagnosis of highly heterogeneous diseases such as ataxia. (E-Rare grant to MK, PB, and FT)

P09.103-S

Complete recovery from psychosis upon miglustat treatment in a juvenile Niemann-Pick C patient

K. Szakszon, *I. Szegedi, Á. Magyar, É. Oláh, M. Andrejkovics, P. Balla, A. Lengyel, E. Berényi, I. Balogh;*
University of Debrecen, Debrecen, Hungary.

Niemann-Pick disease type C (NPC) is a rare recessive lipid trafficking disorder characterized by the accumulation of unesterified cholesterol and glycosphingolipids in the brain and viscera. In the juvenile form, patients in their early years are symptom free, but present with neurodegeneration later in their lives. These include clumsiness, seizures, ataxia, and motor and intellectual decline. Psychiatric manifestations (schizophrenia, presenile dementia, psychosis or depression) may occur at any stage of the disease. Recently, miglustat was approved for the therapy of NPC. We present a case of a patient with juvenile NPC disease whose psychosis was reversed completely by miglustat treatment. At age 14 of the patient, slurred speech and coordination problems, frequent falls and loss of balance were observed. Later, dyslexia and dysgraphia developed. Fine motor skills started to decline more rapidly at age 17, and dysphagia developed. Vertical supranuclear gaze palsy when looking downwards, a hallmark of NPC was observed. Laboratory diagnosis of NPC was established by sequencing of the NPC1 gene. Genotype of the patient was [c.3019C>G] + [c.3182T>C] . Both pathogenic mutations were described previously in the literature. Brain MRI was performed at age 17, 20.5, and 23. At age 17 no signs of atrophy could be detected. Moderate degree atrophy developed between ages 17 and 20.5 years. Miglustat therapy was introduced at age 20.5. Between ages 20.5 and 23, atrophy showed no progress. In conclusion, the introduction of miglustat in NPC patients even in the most advanced cases, with respect to psychiatric

illness might be beneficial.

P09.104-M
VEGF-mediated sphingosine kinase activity decreases in Niemann-Pick Type C neurons and contributes to pathology in NP-C mice

H. Jin[1], *J. Bae*[2,3];
[1]*College of Veterinary Medicine, Kyungpook National University, Daegu, Korea, Republic of,* [2]*School of Medicine, Kyungpook National University, Daegu, Korea, Republic of,* [3]*BK21 Plus KNU Biomedical Convergence Program, Daegu, Korea, Republic of.*

Sphingosine is a major storage compound in Niemann-Pick type C disease (NP-C), although the pathological role(s) of this accumulation have not been fully characterized. Here we show that sphingosine kinase (SphK) activity is reduced in NP-C patient fibroblasts and NP-C mouse Purkinje neurons (PNs) due to defective VEGF levels related to deficiency of NPC1. VEGF released from bone marrow mesenchymal stem cells also activated SphK by binding to VEGFR2, resulting in decreased sphingosine storage as well as improved PN survival and clinical outcomes in NP-C cells and mice. Similar effects were noted after genetic and pharmacologic replenishment of VEGF in NP-C mice. Further, iPSC-derived human NP-C neurons were generated for the first time and the sphingosine accumulation caused by SphK inactivity in these cells was corrected by replenishment of VEGF. Overall, these results reveal a novel pathogenic mechanism in NP-C PNs where defective SphK activity is due to impaired VEGF.

P09.105-S
The role of the NR2A and NR2B subunits of the NMDA receptor in epileptogenesis

J. Lemke[1], *K. Geider*[2], *B. Laube*[2], *D. Lal*[3], *E. M. Reinthaler*[4], *S. Weckhuysen*[5], *S. Biskup*[6], *EuroEPINOMICS-RES Consortium, S. von Spiczak*[7];
[1]*Institute of Human Genetics, University of Leipzig, Leipzig, Germany,* [2]*Department of Neurophysiology and Neurosensory Systems, Technical University Darmstadt, Darmstadt, Germany,* [3]*Cologne Center for Genomics, University of Cologne, Cologne, Germany,* [4]*Department of Neurology, Medical University of Vienna, Vienna, Austria,* [5]*Neurogenetics Group, Department of Molecular Genetics, VIB, Antwerp, Belgium,* [6]*CeGaT GmbH, Tübingen, Germany,* [7]*Department of Neuropediatrics, University Medical Center Schleswig-Holstein and Christian-Albrecht University Kiel, Kiel, Germany.*

NMDA receptors are tetrameric ligand-gated ion channels composed of two glycine-binding NR1 subunits and two glutamate-binding NR2 subunits (NR2A, NR2B, NR2C, NR2D) regulating synaptic plasticity. Mutations in the NR2A and NR2B subunits encoded by the genes *GRIN2A* and *GRIN2B* have been associated with different phenotypes of intellectual disability (ID). Mutations in *GRIN2A* were known to cause unspecific ID and epilepsy as well as other neurodevelopmental disorders, whereas mutations in *GRIN2B* have mainly been associated with autism spectrum disorders (ASD) but not seizures. We show for the first time that mutations of NR2 subunits of the NMDA receptor cause different and specific epilepsy phenotypes. NR2 mutations are involved in benign Rolandic epilepsy, the most frequent childhood epilepsy as well as in a variety of rare infantile epileptic encephalopathies, such as Landau-Kleffner and West syndrome. Furthermore, we demonstrate distinct genotype-phenotype correlations. Severe encephalopathic phenotypes are significantly more often caused by truncating mutations in *GRIN2A*, whereas missense mutations are by far more common in benign Rolandic epilepsy patients. For *GRIN2B*, the majority of ASD individuals present with truncating mutations, whereas all epilepsy cases appear to have gain-of-function mutations. The severity of phenotypes depends on the affected domain and the extent of receptor activation. Our observations highlight the so far underestimated role of dysregulated NMDA signalling in both frequent and rare epilepsy disorders and reveal promising pharmacologic targets for novel therapeutic approaches.

No evidence for a role of NOL3 gene in Italian families with familial adult myoclonic epilepsy or essential tremor

P. Tarantino[1], *M. Gagliardi*[1,2], *G. Iannello*[1,2], *A. Labate*[3], *E. Ferlazzo*[4,5], *U. Aguglia*[4,5], *A. Quattrone*[1,4], *A. Gambardella*[4], *G. Annesi*[1];
[1]*Institute of Molecular Bioimaging and Physiology, Section of Neuroimaging, National Research Council, Germaneto, Catanzaro, Italy,* [2]*University of Magna Graecia, Catanzaro, Italy,* [3]*Institute of Neurology University Magna Graecia, Catanzaro, Italy,* [4]*Institute of Neurology, University Magna Graecia, Catanzaro, Italy,* [5]*Epilepsy Center, Ospedale Riuniti, Reggio Calabria, Italy.*

Cortical tremor (CT) is characterized by fast, small-amplitude, focal or multifocal jerks. It is commonly induced by movement or somatosensory stimulation. CT may have different etiologies: metabolic abnormalities, various neurodegenerative disorders and posthypoxic myoclonus. CT may also be present in familial adult myoclonic epilepsy (FAME) defined by an autosomal dominant inheritance, but despite the locus has been mapped to chromosomes 8, 2 and 5, no causative mutations have been identified to date. A recent study, however, illustrated that FAME may be caused by mutation in NOL3 gene.
Here we wished to screen families with FAME for mutations of NOL3. Since there is growing evidence of an overlap between FAME and essential tremor (ET), we also included families with ET to screen for mutations of NOL3.
We analyzed 10 probands of families that originated from Southern of Italy. Four families had FAME, and six ET. After obtaining the informed consent, the DNA was extracted according to standard procedures and analyzed by direct sequencing with the Sanger method.
No causative mutations have been identified in all patients analyzed for NOL3 gene. However, three polymorphic rare variants have been identified: one in the encoded region, one in 5' UTR region and one in 3' UTR region of NOL3 gene in three different patients.
Exclusion of mutations in NOL3 gene in our families further illustrates the great genetic heterogeneity of FAME/ET and suggests the involvement of other genes. Role of the polymorphic variants in our population remains to be clarified.

P09.107-S
Analysis of RIT1, a novel gene for Noonan syndrome, in patients with suspected Noonan syndrome and negative for other known Noonan syndrome gene mutations

S. Chahrokh-Zadeh, **I. Vogl**, *S. H. Eck, S. Datter, S. Küçük, S. Scherer, M. Scholz, I. Rost; Zentrum fuer Humangenetik und Laboratoriumsdiagnostik, Martinsried, Germany.*

Noonan syndrome (NS) is an autosomal dominant multisystem disorder (1/2,000 live births) caused by mutations in genes dysregulating the RAS-MAPK pathway. The syndrome belongs to the RASopathies that includes Costello syndrome (CS), Cardio-facio-cutaneous syndrome (CFC), Neurofibromatosis type 1 (NF1) and other syndromes sharing a common pattern of congenital anomalies. Recently the RIT1 gene encoding for a new member of the RAS subfamily was functionally characterized. Moreover, gain-of-function mutations in RIT1 gene were found in 9% of the individuals with Noonan syndrome or a related condition without detectable mutations in known Noonan-related genes. In order to confirm these findings, we examined 11 patients suspicious of Noonan syndrome/RASopathies including one abortion with Hydrops fetalis and one prenatal case presenting with nuchal translucency > 97th pct and a normal karyotype. In an initial study, all 11 patients were screened for mutations in the known genes for Noonan syndrome or RASopathies using a panel of 12 genes (PTPN11, SOS1, RAF1, KRAS, BRAF, NRAS, MAP2K1, CBL, SHOC2, MAP2K2, HRAS, NF1). DNA sequence analysis was carried out on the Illumina MiSeq Next-Generation Sequencing platform. Data analysis was performed using the CLCbio workbench (v6.5) and custom developed Perl scripts. Target regions with a coverage of less than 20X were reanalyzed by Sanger sequencing in order to ensure complete coverage of all coding regions and adjacent splice sites (-20/+10). No causal mutations could be identified using the 12 gene panel. In a second step all patients were screened for mutations in RIT1 gene using Sanger sequencing.

P09.108-M
Novel sequence variations in the human NPC1 gene

M. L. Saraiva-Pereira[1,2,3], *M. Polese-Bonatto*[1,4], *H. Bock*[1,4], *M. C. Matte*[1], *R. Mergener*[1], *M. S. Gil*[1], *F. T. S. Souza*[2,3], *R. Gus*[2], *R. Giugliani*[1,2];
[1]*Laboratório de Identificação Genética – Centro de Pesquisa Experimental – Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil,* [2]*Serviço de Genética Médica – Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil,* [3]*Depto. de Bioquímica – Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil,* [4]*PPG em Ciências Biológicas: Bioquímica – Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.*

The NPC1 gene spans more than 47 kb, located at locus 18q11, and encodes for an 1278-amino-acid protein located primarily into late endosomes. Mutations in this gene are associated to Niemann-Pick type C (NP-C) disease, which is a fatal autosomal recessive lysosomal disorder characterized by storage of unesterified glycolipids and cholesterol that leads to progressive neurodegeneration. The aim of this work was to define pathogenic variations in patients with clinical suspicion of NP-C. In total, 244 DNA samples were included. DNA was isolated from peripheral blood by standard methods. The whole coding region of the gene was amplified by PCR and sequenced by Sanger sequencing followed by electrophoresis in the genetic analyzer ABI3130xl. Sequence variations were compared to data in the NP-C database (http://npc.fzk.de/) and in silico analyses were performed when necessary. Fourteen new variations were identified in 20 DNA samples that were classified as pathogenic. From those, 4 (28,57%) mutations (p.P434S, p.S667L, p.G911S, p.V1115F) are responsible for change in amino acid polarity, and two of those are located within transmembrane regions. Additional changes were observed in other functional domains, such as in disulfide bond (p.C238R), and in cholesterol binding and transfer (p.A183T) regions. Same of them (p.C238R, p.P434S, p.R615H, p.S667L) were shown to be loca-

ted in conserved regions based on gene alignment among different species. We can predict that alterations reported here can affect protein conformation structure and/or protein function. These findings can contribute to the understanding of important functional domains in the human NPC1 gene.

P09.109-S
PARK2 deletions in patients with Autism Spectrum Disorder (ASD) and other neurodevelopmental pathologies

I. C. Conceição[1,2,3], *M. M. Rama*[1], *B. Oliveira*[1,2,3], *C. Café*[4], *J. Almeida*[4], *S. Mouga*[4], *G. Oliveira*[4,5,6], *A. M. Vicente*[1,2,3];
[1]*Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisbon, Portugal,* [2]*Center for Biodiversity, Functional & Integrative Genomics, Lisbon, Portugal,* [3]*Instituto Gulbenkian de Ciência, Oeiras, Portugal,* [4]*Unidade Neurodesenvolvimento e Autismo, Centro de Desenvolvimento, Hospital Pediátrico (HP), Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, Portugal,* [5]*Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal,* [6]*Centro de Investigação e Formação Clinica do HP-CHUC, Coimbra, Portugal.*

The PARK2 gene encodes Parkin, a component of a multiprotein E3 ubiquitin ligase complex that targets misfolded proteins for proteasomal degradation, such as dopamine transporters, synaptotagmin and ?-synuclein. PARK2 genetic mutations are associated with Parkinson Disease, while Copy Number Variants (CNV) have been found in patients with developmental delay (DD), Attention Deficit Hyperactivity Disorder (ADHD) and ASD.
We identified 5 male patients with inherited PARK2 deletions in 342 ASD individuals, screened for CNVs using Illumina 1M SNP arrays (frequency=1.5%). Three patients had a 45Kb deletion of intron 9, and two patients had a deletion of either 29Kb in intron 6 or 266Kb encompassing exons 5 and 6. Clinical presentation was heterogeneous in these ASD patients. A literature search showed recurrent deletions of introns 2 and 3 (N=15 ADHD, N=7 ASD), as well as exons 1 (N=1 ASD) and 2 (N=2 ASD and DD), while DECIPHER reported one ASD individual with an exon 5-6 deletion. In available control databases, deletions of segments from exons 1 to intron 4 as well as intron 9 were recurrent, but only 1/4139 controls had a CNV overlapping exon 6, suggesting a pathogenic role of deletions in this region. The smaller exon 6 CNVs deleted a functional domain SYT11 binding site, compromising the attachment of synaptotagmin and ubiquitination.
These results support a role of PARK2 structural variants in ASD. However, certain PARK2 regions are also frequently deleted in control subjects, and therefore rigorous analysis is mandatory before assuming a pathogenic role for identified CNVs.

P09.110-M
GBA mutations are a major genetic risk factor for Parkinson Disease and Dementia with Lewy Bodies in the Italian population.

R. Asselta[1], *V. Rimoldi*[1], *C. Siri*[2], *I. Guella*[1], *G. Soldà*[1], *C. Baccin*[1], *R. Cilia*[2], *N. Meucci*[2], *G. Pezzoli*[2], *S. Duga*[1], **S. Goldwurm**[2];
[1]*Dipartimento di Biotecnologie Mediche e Medicina Traslazionale, Università degli Studi di Milano, Milan, Italy,* [2]*Parkinson Institute, Istituti Clinici di Perfezionamento, Milan, Italy.*

Mutations in the glucocerebrosidase (GBA) gene increase risk of Parkinson Disease (PD). We determined the frequency and relative risk of the two most frequent GBA mutations in a large series of Italian patients with PD or other parkinsonisms. We studied 2,766 unrelated consecutive patients with diagnosis of primary degenerative parkinsonism (including 2,350 PD), and 1,111 controls, who contributed to the Parkinson Institute Biobank (www.parkinsonbiobank.com). The entire cohort was screened for mutations in GBA exons 9 (containing p.N370S) and 10 (containing p.L444P), covering approximately 50% of GBA mutations. Five mutations were identified in the heterozygous state: 4 missense (p.N370S, p.L444P, p.E388K, p.D443N), and the splicing mutation IVS10+1G>T, which we showed to result in the in-frame exon-10 skipping. GBA mutations were significantly more frequent in PD (4.5%, RR=7.2) and Dementia with Lewy Bodies (DLB) (13.8%, RR= 21.9), compared to controls (0.63%), but not in the other form of parkinsonisms, such as Progressive Supranuclear Palsy (PSP)(2%), Corticobasal Degeneration (CBD)(0%), and Multiple System Atrophy (MSA)(0.85%). Considering only the PD group (2,350), GBA carriers had an earlier onset (51±10 vs. 56±10, p<0.0001) and were more likely to have a positive family history for PD (34% vs. 20%, p<0.001). GBA mutations in the Italian population resulted one of the major genetic factor predisposing to synucleinopathies (parkinsonisms due to alpha-synuclein deposition: PD and DLB), but not to tauopathies (parkinsonisms due to tau deposition, PSP and CBD), with the exception of MSA, another synucleinopathy. This suggests a different pathogenic mechanism for MSA compared to PD.

P09.111-S
Polymorphisms and mutations in a specific population of Central Europe (South-Eastern Moravia, Czech Republic) with autosomal-dominant Parkinsonism

R. Vodicka[1], *K. Mensikova*[2], *P. Kanovsky*[2], *I. Sakmaryova*[3], *R. Vrtel*[1], *M. Godava*[1], *P. Otruba*[2], *L. Mikulicova*[2], *M. Kaiserova*[2], *M. Vastik*[2], *S. Kurcova*[2], *T. Bartonikova*[2], *P. Dudova*[2];
[1]*Dept of Medical Genetics and Fetal Medicine University Hospital and Palacky University Olomouc, Olomouc, Czech Republic,* [2]*Department of Neurology University Hospital and Palacky University Olomouc, Olomouc, Czech Republic,* [3]*The Institute for Nanomaterials, Advanced Technology and Innovation Technical University of Liberec, Liberec, Czech Republic.*

Background: In an epidemiological study carried out in an isolated population of South-Eastern Moravia in the Czech Republic, a surprisingly high prevalence of parkinsonism was found, differing from the published prevalence rates in other European countries. Objective: To determine the type of mutation in families with autosomal-dominant parkinsonism with dementia. Methods: On the basis of a detailed genealogical examination of all the individuals with confirmed parkinsonism, the pedigrees were compiled and a DNA analysis of probands from each pedigree was subsequently initiated. A massive parallel sequencing method using Ion Torrent technology was used; the DNA sequence analysis was focused on the gene loci in which the causal mutations related to Parkinson's disease (PD) have been described. Results: Three large pedigrees with an autosomal-dominant inheritance pattern with reduced penetration of parkinsonism were identified. None of the previously described pathogenic mutations associated with PD were found; rare variants or yet-undescribed mutations were also found. In 5 of 10 examined probands, a novel missense Q230H mutation of the MAPT gene was detected. Polyphene and SIFT in silico predictors indicate this mutation as "probably damaging". Conclusion: Confirmation sequencing using an independent method is underway to examine the targeted MAPT mutation in other individuals from all three pedigrees and to compare it with healthy controls. Supported by grants: IGA MZ ČR NT - 14407-3/2013 and IGA LFUP 2013-024

P09.112-M
HOMER1 promoter analysis in Parkinson's disease: association with levo-dopa dosage

V. De Luca[1], *G. Annesi*[2], *A. Quattrone*[2];
[1]*CAMH, Department of Psychiatry, University of Toronto, Toronto, ON, Canada,* [2]*Istituto di Scienze Neurologiche, CNR, Cosenza, Italy.*

AIMS: HOMER1 gene expression has been linked to abnormal movements in animals receiving chronic administration of antipsychotics. The continuing neurodegeneration of Parkinson's disease (PD) and the prolonged use of L-dopa are associated with motor complications, such as dyskinesia, and psychotic side effects, including hallucinations and paranoid delusions. Approximately 25-40% of patients with idiopathic PD experience hallucinations. Genetic variability within different candidate genes has been implicated in the clinical severity of sporadic PD in many populations.
METHODS: We investigated 3 polymorphisms located in the 5' flanking region of the HOMER1 gene within a sample of 131 sporadic PD patients from southern Italy, using a 3-SNP genotype and haplotype combination (rs4704559, rs10942891, rs4704560). RESULTS: Our study implicates the effects of allele A of the rs4704559 marker in high dosage levo-dopa treatment in PD (p <0.05). CONCLUSION: Even though our results are preliminary, this HOMER1 gene variant may represent a genetic variant for personalized treatment in PD patients.

P09.114-M
PCDH19 mutations in girls with infantil epilepsy: four novel mutations and prediction of their functional impact

E. Leonardi[1], *L. De Palma*[2], *M. Vecchi*[2], *E. Bettella*[1], *S. Sartori*[3], *C. Boniver*[2], *A. Murgia*[1];
[1]*Laboratory of molecular genetics of neurodevelopment, Department of Women's and Children's Health, University of Padua, Padua, Italy,* [2]*Pediatric Neurophysiology Unit, Department of Women's and Children's Health,University of Padua, Padua, Italy,* [3]*Pediatric Neurology Unit, Department of Women's and Children's Health, University of Padua, Padua, Italy.*

The *PCDH19* gene encodes for protocadherin 19, a transmembrane protein with six extracellular cadherin (EC) domains containing adhesive interfaces involved in neuronal connection. Over a hundred mutations in PCDH19 gene have been identified in girls with epilepsy, with or without cognitive impairment. While some mutations are recurrent, many new variants remain private. Furthermore, transmitting hemizygous males are devoid of seizures or cognitive impairment, making it difficult to establish the pathogenic nature of newly identified variants.
Here, we propose an approach to evaluate the pathogenicity of four novel PCDH19 mutations found in girls with epilepsy and variable degree of de-

velopmental delay. Segregation analysis is complemented with an *in silico* analysis of mutation effects on the protein structure and function. Using sequence information, we compared different computational prediction methods. We also used homology modelling to build structural models of two PCDH19 EC-domains containing the novel missense mutations. Wild-type and mutant models were compared to identify the differences in the presence and type of residue interactions or in the biochemical properties (conservation, electrostatic charge, hydrophobicity) of the model surfaces. This analysis revealed that these novel mutations exert their pathogenic role using different molecular mechanisms. Two of them interfere with or alter functional residues predicted to mediate ligand or protein binding, another alters the EC-domain folding stability, and the frame-shift mutation produces a truncated protein lacking the intracellular domain.
We also observed that the two girls with severe neurological impairment carry mutations predicted to have the worst effects on the protein structure.

P09.115-S
Molecular genetic background of patients with PEHO-like features

A. Laari[1,2,3], *M. Muona*[4,1], *A. Anttonen*[5,1,6], *M. Somer*[7], *A. Palotie*[4,8], *A. Lehesjoki*[1,2,3];
[1]*Folkhälsan Institute of Genetics, University of Helsinki, Helsinki, Finland,* [2]*Research Programs unit, Molecular Neurology, University of Helsinki, Helsinki, Finland,* [3]*Neuroscience Center, University of Helsinki, Helsinki, Finland,* [4]*Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland,* [5]*Department of Clinical Genetics, University of Helsinki, Helsinki, Finland,* [6]*Department of Medical Genetics, University of Helsinki, Helsinki, Finland,* [7]*Norio Centre, Rinnekoti Foundation, Helsinki, Finland,* [8]*Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA, United States.*

PEHO syndrome (Progressive encephalopathy with Edema, Hypsarrhythmia and Optic atrophy; MIM 260565) is an autosomal recessive inherited progressive infantile encephalopathy. The main features of PEHO syndrome are hypotonia, infantile spasms and/or hypsarrhythmia, psychomotor retardation, absence or early loss of visual fixation, edema of the face and limbs, and typical dysmorphic features. Brain atrophy is progressive and most prominent in the cerebellum, where the molecular layer is strongly reduced, Purkinje cells are deformed and misaligned, and the cells of the granule cell layer are significantly reduced in number. In addition, the optic nerves show varying degrees of loss of myelinated axons and gliosis, and the retinal nerve fiber and ganglion cell layers are atrophic. A number of patients present with many of these clinical features, but lack typical neuroradiological and neuropathological findings or progression of brain atrophy and do not have the PEHO founder mutation. These patients are classified as having PEHO-like syndrome. This group is clinically heterogeneous and therefore it is likely that there are multiple underlying genes. To characterize the genetic background of patients showing PEHO-like features, we performed exome sequencing of 33 Finnish patients, and parents of six of them. We identified likely pathogenic mutations in known disease genes (CDKL5, ABAT, SPTAN1, SCN2A, MT-CYB, WDR45 and KCNQ2) in nine individuals. Analysis of mutations in novel disease genes is ongoing. Our preliminary findings imply that patients with PEHO-like features are genetically highly heterogeneous and that the entity overlaps with early-infantile epileptic encephalopathies.

P09.116-M
De novo mutations in periventricular heterotopia: an exome sequencing study

A. C. O'Neill[1], *D. Markie*[1], *R. Newbury-Ecob*[2], *S. Robertson*[1];
[1]*University of Otago, Dunedin, New Zealand,* [2]*University Hospitals NHS Foundation Trust, Bristol, United Kingdom.*

Disorders involving neuron mispositioning encompass a heterogeneous group of phenotypes affecting neuronal development. Periventricular heterotopia (PH) is one such disorder characterised by failure of neurons to migrate to the outer cortex of the brain, resulting in ectopic positioning along their sites of origin – the lateral ventricles. Although mutations in *FLNA* account for an estimated 80% of familial PH cases, mutations at this locus account for only 25% of sporadic cases, leaving the vast majority with no genetic diagnosis. Here we describe a project intended to characterise the mutational heterogeneity underlying PH and gain insight into the molecular networks that when defective underpin this disorder. We describe an approach involving careful phenotyping of each proband and employ a trio design to exome sequence characterise causative mutations. This study will encompass both non-syndromic and syndromic cases of PH and seek to map candidate causative variants into gene interaction networks. Similar approaches have proved successful for other neurological disorders such as autism. Illustrating the legitimacy of our approach we describe an identified *de novo* mutation in a gene encoding a calmodulin isoform. The mutation resides in one of four highly conserved calcium binding pockets of this protein where it is predicted to alter function. Substantial evidence demonstrates direct binding between calmodulin and filaminA. Although the exact pathogenic status of this variant has yet to be corroborated by a second individual, this illustrative case demonstrates that functional genetic relationships can contribute to the implication of extremely heterogeneous disorders such as PH.

P09.117-S
PLA2G6-associated neurodegeneration (PLAN): long-term follow-up, genotype-phenotype correlates and identification of a founder mutation in a large North-African cohort

A. Micalizzi[1,2], *M. Romani*[1], *I. Kraoua*[3], *H. Klaa*[3], *H. Benrhouma*[3], *I. Turki*[3], *S. Castellana*[1], *T. Mazza*[1], *E. Valente*[1,4], *N. Gouider-Khouja*[3];
[1]*IRCCS Casa Sollievo della Sofferenza, Mendel Laboratory, San Giovanni Rotondo, San Giovanni Rotondo, Italy,* [2]*Department of Medical and Surgical Pediatric Sciences, University of Messina, Messina, Italy,* [3]*Research Unit 06/11 and Department of Child and Adolescent Neurology, National Institute Mongi Ben Hmida of Neurology, Tunis, Tunis, Tunisia,* [4]*Department of Medicine and Surgery, University of Salerno, Salerno, Italy.*

Mutations in the *PLA2G6* gene are causative of PLAN, a spectrum of neurodegenerative conditions including infantile, childhood and adult onset forms. Seventeen North African patients with a clinical suspicion of infantile-onset PLAN underwent clinical and instrumental examinations and *PLA2G6* sequencing. Haplotype analysis was performed to date the identified founder mutation. All patients carried pathogenic biallelic mutations in *PLA2G6*. Sixteen children had the commonest form of infantile-onset PLAN, with early onset of psychomotor regression, hypotonia, cerebellar signs and abnormal ocular movements. The phenotype was highly homogeneous, with rapid development of severe spastic tetraparesis, cognitive impairment, optic atrophy, and cerebellar atrophy at brain MRI. Motor neuropathy and EEG fast rhythms were also frequent. Nine patients from six families shared the same founder mutation (p.V691del) which likely arose in the late seventeenth century. Only one patient fits the diagnosis of the much rarer childhood-onset PLAN. Despite the early onset (18 months), progression of cerebellar and pyramidal signs was slower, with behavioral disturbances and dystonia. Typical features of infantile-onset PLAN such as hypotonia, nystagmus/strabismus, optic atrophy, EEG fast rhythms and motor neuropathy were absent. Besides cerebellar atrophy, MRI showed iron deposition in the basal ganglia. This patient carried a missense mutation predicted to be less deleterious.

P09.118-M
Identification and functional characterisation of a new KCNJ2 mutation

I. Rivolta[1], *L. Sala*[2], *M. Rocchetti*[3], *R. Giovannoni*[4], *C. M. Cornaggia*[4], **R. Combi**[4];
[1]*Dept. Health Sciences, University of Milano-Bicocca, Monza, Italy,* [2]*Dept. Biotechnology and biosciences, University of Milano-Bicocca, Milano, Italy,* [3]*Dept. Biotechnology and Biosciences, University of Milano-Bicocca, Milano, Italy,* [4]*Dept. Surgery and Translational Medicine, University of Milano-Bicocca, Monza, Italy.*

Autism is a genetic disorder, with an estimated heritability greater than 90%. Over the past years, the convergence of genomic technologies has led to the identification of several susceptibility loci by means of linkage studies. Autism is associated with epilepsy in early childhood and epilepsy occurs in 10-30% of autism patients. Recently, a role of potassium inward rectifying channels in the pathogenesis of autism disease has been postulated due to the identification in patients affected by autism and epilepsy of two mutations in the KCNJ10 gene. The gene encodes the Kir4.1 channel which is expressed in astrocytes and neurons.We then searched for mutation in the KNCJ10 gene, as well as in two genes (KCNJ2 and KCNJ16) coding for additional Kir channels with reported expression in astrocytes and neurons, in two unrelated patients. We detected a new mutation in the KCNJ2 gene in a boy affected by autism. The mutation has been detected also in the healthy father and in the paternal grandmother who reported a case of SIDS (Sudden Infant death Syndrome) in her family. A functional analysis of the mutation effects was performed using an electrophysiological approach based on whole cell patch clamp.

P09.119-S
A novel 2p21 deletion isolated to the *PREPL* gene

E. Mårtensson[1], *A. Mattsson*[1], *E. Danefur*[1], *M. Olsson Engman*[2], *M. Soller*[1], *T. Jonson*[1];
[1]*Department of Clinical Genetics, Region Skåne and Lund University, Lund, Sweden,* [2]*Department of Pediatrics, Blekinge Hospital, Karlskrona, Sweden.*

Hypotonia-cystinuria syndrome (HCS) is an autosomal recessive disease characterized by hypotonia at birth, failure to thrive, growth retardation, cystinuria type I and, in some cases, hypergonadotropic hypogonadism. These symptomes are attributed to a homozygous deletion on chromosome 2p21, encompassing the genes *SLC3A1* and *PREPL*. Since loss-of-function *SLC3A1* mutations cause isolated cystinuria, the other HCS symptoms have been considered to be caused by PREPL deficiency. Using a high-density whole genome array, we identified an 11 kb homozygous deletion in the *PREPL*

gene in a patient presenting with symptoms characteristic of HCS, but without cystinuria.
Immediately after birth, the patient presented with severe muscular hypotonia and feeding problems, followed by growth hormone deficiency and hypergonadotropic hypogonadism. Initial molecular analyses excluded a number of syndromes, including Prader-Willi (PWS). The homozygous deletion in *PREPL* identified by array analysis corresponded to heterozygous deletions in each of the nonconsanguineous parents. qPCR analysis confirmed these findings and pinpointed the extent of the deletion to exons 5-10. An isolated homozygous microdeletion involving only *PREPL* has not been previously described, however, Régal *et al*., (in press) recently identified a patient carrying a nonsense mutation in *PREPL* combined with a microdeletion involving *SLC3A1* and *PREPL*, resulting in a similar phenotype to the case presented here. These findings may contribute to further delineate the normal function of PREPL, as well as support the notion that homozygous *PREPL* inactivation should be considered in the diagnosis of patients with a PWS phenotype, but no PWS genotype (Maartens *et al*., Biol Chem 387;879-883,2006).

P09.121-S
Compound heterozygous mutations in two known MCPH genes in autosomal recssesive primary microcephaly

R. Kadir[1], *S. Shalev*[2], *J. Zlotogora*[3];
[1]*Human Genetics and the Genetics Institute, Soroka Medical Center, Ben-Gurion University, Beer Sheva, Israel,* [2]*Genetics Institute, HaEmek Medical Center, Afula, Israel,* [3]*Department of Community Genetics, Ministry of Health, Israel, Jerusalem, Israel.*

Autosomal recessive microcephaly with severe mental retardation with no dysmorphism or other anomalies was diagnosed in seven individuals of an Arab Israeli family. Brain CT scan of affected individuals showed no structural anomalies. Whole exome sequencing of an affected individual identified four mutations in two known MCPH genes: compound heterozygous mutations both in STIL and in ASPM. Of 100 ethnically matched controls, none had more than one of the 4 mutations, and only in a heterozygous state. Segregation analysis and functional assays are underway to unravel which of the above variations are the causative mutations for microcephaly in the affected individuals within this family.

P09.122-M
VPS53 compound novel mutations cause progressive cerebello-cerebral atrophy type 2 (PCCA2)

M. Feinstein[1], *H. Flusser*[2], *T. Lerman-Sagie*[3], *B. Ben-Zeev*[4], *D. Lev*[3], *I. Cohen*[1], *R. Kadir*[1], *E. Leshinsky-Silver*[3], *O. Agamy*[1], *B. Marcus*[1], *S. Sivan*[1], *O. S. Birk*[1,5];
[1]*Morris Kahn Laboratory of Human Genetics at Ben-Gurion university in the negev, Beer-sheva, Israel,* [2]*Zussman child development center, Soroka Medical Center, Faculty of Health Sciences, Ben-Gurzion University of the Negev, Beer-sheva, Israel,* [3]*Institute of Medical Genetics and Pediatric Neurology Unit, Wolfson Medical Center, Holon, Israel,* [4]*Pediatric Neurology Unit, Sheba Medical Center, Ramat-Gan, Israel,* [5]*Genetics Institute, Soroka Medical Center, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-sheva, Israel.*

Progressive cerebello-cerebral atrophy (PCCA) leading to profound mental retardation, progressive microcephaly, spasticity and early onset epilepsy, was diagnosed in four non-consanguineous apparently unrelated families of Jewish Moroccan ancestry. None of the known SepSecs (MIM613009) mutations were found in the investigated families. Common founder mutation(s) were assumed. Genome wide linkage analysis and whole exome sequencing were done, followed by realtime PCR and immunofluorescent microscopy. Genome wide linkage analysis mapped the disease-associated gene to 0.5Mb on chromosome 17p13.3. Whole exome sequencing identified two mutations within this locus, which were common to the affected individuals: compound heterozygous mutations in VPS53, segregating as expected for autosomal recessive heredity within all four families, and common in Moroccan Jews (~1:37 carrier rate). The Golgi-associated retrograde protein (GARP) complex is involved in the retrograde pathway recycling endocytic vesicles to Golgi. Both c.2084A>G and c.1556+5G>A VPS53 founder mutations are predicted to affect the C-terminal domain of VPS53, known to be critical to its role as part of the GARP complex. In fact, mRNA studies showed detrimental effects of the mutations on VPS53 transcripts, and immunofluorescent microscopy demonstrated swollen and abnormally numerous CD63 positive vesicular bodies, likely intermediate recycling endosomes, in fibroblasts of affected individuals. Thus, VPS53 mutations cause autosomal recessive PCCA type 2.

P09.123-S
Clinical and molecular characterization of progressive encephalopathies in children

D. Misceo[1], **T. H. Gamage**[1], *T. Barøy*[1], *C. Ramane*[1], *A. Holmgren*[1], *T. Hughes*[1], *M. D. Vigeland*[1], *S. Thirukeswaran*[1], *S. S. Amundsen*[1], *A. Torgersbråten*[1], *N. Skauli*[1], *E. Ø. Carlsen*[1], *R. Helle*[1], *M. Fannemel*[1], *P. Strømme*[2], *E. Frengen*[1];
[1]*Department of Medical Genetics, Oslo University Hospital and University of Oslo, Oslo, Norway,* [2]*Women and Children's Division, Department of Clinical Neurosciences for Children, Oslo University Hospital, Ullevål, Oslo, Norway.*

Progressive encephalopathies (PE) are defined as progressive diseases of the Central Nervous System often accompanied by decline of cognitive and/or motor functions and include a number of different disorders. PE can primarily be divided into neurodegenerative and metabolic, the latter defined by defects in subcellular organelles or in the intermediary metabolism of macromolecules. In the neurodegenerative disorders, progressive loss of neural tissue is often detected by cerebral MRI or markers in the cerebrospinal fluid. PE is associated with high morbidity and mortality rate, but treatment options are available for some PE disorders. Genetic explanations lack for about 20% of PE disorders, which are classified according to MRI findings and phenotype.
Our aim is to characterize novel mutations causing PE. We have collected more than 60 PE-patients in 45 families. In all patients, we ruled out CNS infection, trauma, vascular accidents and sequelae after prematurity. Evaluation of all patients by biochemical examinations and neuroimaging revealed cortical atrophy, cerebellar degeneration or basal ganglia abnormalities in the majority of the patients. Congenital anomalies, also those outside the nervous system, were evaluated using the London Medical Database for syndrome identification.
Karyotyping, aCGH and analysis of candidate genes by MLPA and/or sequencing revealed no relevant findings. We have initiated Whole Exome Sequencing (WES) on DNA from 43 family trios. Among the 16 trios finalized through the bioinformatics pipeline, a putative disease causing mutation has been identified in eight. Functional studies are currently being performed to characterize their clinical implications.

P09.124-M
OTX2, PRRX1 and PRRX2 gene: molecular characterization of two cases of agnathia-otocephaly foetus

A. Sanchis[1], *G. Pi*[2], *I. Aleixandre*[3], *M. Ortiz*[4], *A. Zuñiga*[4];
[1]*Servicio de pediatria. Hospital dr. Peset., Valencia, Spain,* [2]*Servicio de pediatria, Hospital Univ. De La Ribera, Alzira/Valencia, Spain,* [3]*Servicio de genética. Hospital Univ. De la Ribera, Alzira/Valencia, Spain,* [4]*Servicio de genética. Hospital univ. De la ribera, Alzira/Valencia, Spain.*

Agnathia-otocephaly is a rare, sporadic and lethal malformation with an estimated incidence of less than 1 in 70000 births. Otocephaly is considered a defect of blastogenesis and it can further result in the mal-development of the craniofacial midline, extracephalic and axial body structures. This malformation spectrum is usually lethal, because is associated severe respiratory distress.
We screened 2 agnathia cases for orthodenticle homeobox 2 (OTX2), paired related homeobox 1 (PRRX1) genes and for the homeobox 2 (PRRX2) gene by sequencing in a ABIPRISM 3130xl genetic analyzer.
In the first case, a full autopsy in the fetus proband of 12+6 weeks, revealed agnathia, holoprosencephaly, cyclopia, microstomia, malformed pinnae (misplaced toward the angle of the mandible), omphalocele and shortening of the long bones. The cytogenetic analysis showed a partial trisomy 13 and partial monosomy 18. Screening for the OTX2, PRRX1 and PRRX2 gene in foetal tissues, identified a heterozygous S144N in the exon 2 of PRRX2 gene. An analysis *in silico* with Polyphen v2.0 and Shift Mutation showed this mutation as a high probability of altering protein function.
In the second case, the proband was a foetus of 14+3 weeks. The autopsy revealed agnathia and omphalocele. Screening for these three genes identified a heterozygous P181L in the exon 3 of PRRX1 gene, mutation with a high probability of altering the protein function as analysis *in silico* shows.
In summary, we report novel mutations in PRRX1 and PRRX2 gene implicated in two case of agnathia.

P09.125-S
Study of *FOXG1* gene in Spanish patients: review of clinical presentation

J. Armstrong Morón[1], *M. O'Callaghan*[1], *N. Brandi*[1], *E. Gerotina*[2], *E. Quandt*[1], *M. Rabaza*[1], *C. Elisenda*[1], *A. Roche*[3], *À. Garcia-Cazorla*[1], *M. Pineda*[2];
[1]*Hospital Sant Joan de Déu, Esplugues de Llobregat, Spain,* [2]*Fundació Sant Joan de Déu, Esplugues de Llobregat, Spain,* [3]*Consorci Sanitari Parc Taulí, Sabadell, Spain.*

Introduction: Since ,mutations in *MECP2* gene were described as causing Rett syndrome (RTT, OMIM#312750) in 1999, other genes have also appeared to be responsible of RTT: X-linked cyclin-dependent kinase-like 5 (*CDKL5*) lying in Xp22 and forkhead box G1 (*FOXG1*) in 14q12. We present our experience in clinical and molecular diagnosis of congenital form of RTT.
Materials and methods: We have studied the *FOXG1* gene by direct sequencing and MLPA (Probemix-P075, MC-Holland) in patients RTT-without

MECP2 mutation and in patients with mental retardation and Rett-like clinical features.
Results: We analyzed 211 patients with clinical presentation likely to have mutations in *FOXG1* gene: 143 RTT (classic and congenital form *MECP2*-negative), 39 male patients with severe mental retardation and hypotonia and 29 patients with RTT like features. We detected 9 mutations: 5/23 girl patients with congenital form and 4/39 male patients with severe mental retardation.
None of classical form or girls with RTT-like clinical features carried mutation in *FOXG1.*
Conclusions: Genetic etiologies of variant Rett syndrome are heterogeneous; screening the *FOXG1* gene should be done not only in females, but also in male patients with severe hypotonia and acquired microcephaly since the first months of life.
FOXG1 is not an X-linked gene and therefore there can be a higher incidence of mutation detection in RTT-like males than in *MECP2* and *CDKL5* genes.

The spinocerebellar ataxia type 2 (SCA2) is caused by CAGn expansion at ATXN2 gene, which account for 50% of the variability in age at onset (AO). Previous reports pointed to CAGn variations and polymorphisms at other genes as responsible for the remaining AO variance. Aims: to address a confirmation study of other polyglutamine tracts and of a mitochondrial DNA polymorphism as modifiers of AO in SCA2 patients. Methods: symptomatic individuals with a molecular diagnosis of SCA2 were recruited from Brazil. Capillary electrophoresis was performed to detect CAG lengths at SCA1, SCA2, SCA3/MJD, SCA6, SCA7 and RAI1 associated genes; the mitochondrial complex I gene polymorphism (10398G) was determined by PCR followed by restriction endonuclease analysis. Pearson correlations with AO were tested against each CAGn for each individual; the 10398G polymorphism of one person per maternal lineage was analysed by t test; all followed by a step-wise linear regression. Results: 57 individuals (33 families and 42 maternal lineages) were studied. Mean (range) AO and CAGn at normal and expanded ATXN2 alleles were 32.9 (3-76) years and 23 (22-33) and 42 (34-67) repeats. At first, AO correlated with the large alleles at ATXN2 and ATXN3 genes, and with small allele at RAI1. 10398G was not associated with AO. On step-wise regression, the unique correlation maintained was with ATXN2 expanded allele ($r = -0.78$; $r2 = 0.61$; $p < 0.0001$). Discussion: our preliminary data did not support previous published results; they should be confirmed with an outlier sampling strategy, in the future.

P09.127-S
Heterozygous deletion of KLHL1/ATXN8OS at the SCA8 locus are likely not associated with cerebellar impairment in humans

G. Mandrile[1,2], E. Di Gregorio[3,4], H. Goel[5], **D. F. Giachino**[1,2]*, S. De Mercanti[1,6], M. Iudicello[6], S. Losa[7], M. Rolando[7], L. Ranum[8], M. De Marchi[1,2], A. Brusco[3,4];*
[1]University of Torino - Dept. Clinical and Biological Sciences, Orbassano (TO), Italy, [2]Medical Genetics - San Luigi University Hospital, Orbassano (TO), Italy, [3]University of Torino - Department of Medical Sciences, Torino, Italy, [4]S.C.D.U. Medical Genetics, Città della Salute e della Scienza, Torino, Italy, [5]Faculty of Health and Medicine, University of Newcastle, Callaghan, Australia, [6]Neurology Unit - San Luigi University Hospital, Orbassano (TO), Italy, [7]S.C. Neuropsichiatria Infantile - ASLTO3, Collegno-Pinerolo (TO), Italy, [8]Center for NeuroGenetics, Department of Molecular Genetics and Microbiology, Department of Neurology, and Genetics Institute, College of Medicine, University of Florida, Gainesville, FL, United States.

Spinocerebellar ataxia type 8 is a dominantly inherited ataxia, mainly occurring in adulthood, caused by a CTG.CAG tract expansion in the ATXN8OS gene, an untranslated antisense RNA partially overlapping the KLHL1 gene, and the complementary CAG repeat in the ATXN8 gene.
We report a father (59 years) and his daughter (10 years) carrying a genomic deletion (800 kb) completely overlapping ATXN8OS gene and part of KLHL1 (from 70,345,271 to 71,196,665 - NCBI Build 37/hg19 - Array-CGH 60K) and a 4 Mb duplication in 8q13.33q21.11 (72,268,801-76,311,849) segregating in an unaffected brother. The girl was evaluated for dysarthria, difficulties in sentence structuring, short attention span and mild intellectual deficit. No other neurological signs were reported. Brain MRI was normal. Neurological examination of the father revealed short attention span; coordination, sensitivity, reflexes and cranial nerves were normal; no abnormal gait or dysarthria. Brain MRI revealed several areas of gliosis in the frontal white matter.
Databases mining showed a partially overlapping 357 kb deletion involving only KLHL1 and ATXN8OS (chr 13:70,486,026-70,843,210) in a patient with mild speech delay (Decipher 278559), inherited from a healthy mother.
In contrast with the KLHL1/ATX8OS knockout mouse model, our data suggest that heterozygous deletion of KLHL1/ATX8OS is not associated with ataxia/cerebellar involvement in humans.

Genetics of Schizophrenia: preliminary results of an Italian multicenter study

G. Piluso[1]*, T. Giugliano[1], M. Savarese[1], C. Pisano[1], A. Torella[1], S. Galderisi[2], V. Nigro[1];*
[1]Dipartimento di Biochimica, Biofisica e Patologia Generale, Seconda Universita' degli Studi di Napoli, Napoli, Italy, [2]Dipartimento di Salute Mentale e Fisica e Medicina Preventiva, Seconda Universita' degli Studi di Napoli, Napoli, Italy.

Schizophrenia (SCZD) is a major psychiatric disease causing severe disability and with a prevalence of 1% worldwide. Genetic factors play a key role in the etiology of schizophrenia but its genetic bases are complex and not yet clarified. In the last few years, innovative technologies have been widely applied to the genetic study of schizophrenia. This multicenter study aims to apply aCGH and NGS technologies to investigate genetic risk factors for specific SCZD-related endophenotypes that greatly affect real-life functioning of people with schizophrenia or variables strongly associated with it. To investigate the contribution of *de novo* CNVs to schizophrenia vulnerability, we have used the Enhancer Chip (*PLoS One 2012;7(12):e52264*), a customized aCGH recently developed by our group, which is able to examine CNVs in the whole human genome as well as testing over 1,250 enhancers for their potential pathogenic role. Clinical research units have provided us DNAs from 60 sporadic SCZD patients and their parents (family trios). To date, we have identified two *de novo* partially-overlapping deletions at 7q31.2 in unrelated SCZD patients. Interestingly, both CNVs include *MET*. This proto-oncogene has been previously associated to schizophrenia (*Am J Psychiatry* 2010;167(4):436). Another SCZD patient presented a *de novo* duplication at 19p13.3. A similar rearrangement is reported in Decipher, possibly associated to intellectual disability. *De novo* protein-altering mutations will be also investigated by NGS-based exome sequencing of all family trios recruited (now in progress). These preliminary data may help to strengthen the role of *de novo* variants in the pathogenesis of schizophrenia.

Genome-wide methylation profiling of schizophrenia

B. B. Rukova[1]*, R. Staneva[1], S. Hadjidekova[1], G. Stamenov[2], V. Milanova[3], D. Toncheva[1];*
[1]Department of Medical Genetics, Medical University, Sofia, Sofia, Bulgaria, [2]Woman Health Hospital „Nadezhda", Sofia, Bulgaria, [3]Department of Psychiatry, Medical University, Sofia, Sofia, Bulgaria.

Background: Schizophrenia is one of the major psychiatric disorders. It is a disorder of complex inheritance, involving both heritable and environmental factors. DNA methylation is a fundamental inheritable epigenetic modification that stably alters the gene expression levels. We reasoned that genetic modifications, resulting from environmental stimuli could also make a contribution to the disease development.
Materials and Methods: We have performed 26 high-resolution genome-wide methylation array analyses to determine the methylation status of 27,627 CpG islands and compared the data between patients and healthy controls. Methylation profiles of DNAs were analyzed in six pools (220 schizophrenia patients; 220 age-matched healthy controls; 110 female schizophrenia patients; 110 age-matched healthy females; 110 male schizophrenia patients; 110 age-matched healthy males) and 20 individual patient DNA samples (7 females and 13 males).
Results: We find significant differences in the methylation profile between schizophrenia and control DNA pools. New candidate genes that principally

participate in apoptosis, synaptic transmission and nervous system development (*GABRA2, LIN7B, CASP3*) were discovered. Methylation profiles differed between the genders. Among females the most important genes participate in apoptosis and synaptic transmission (*XIAP, GABRD, OXT, KRT7*). Among males *DHX37, MAP2K2, FNDC4, GIPC1* genes represent the most significant candidate-genes.
Conclusion: Our data revealed substantial differences in methylation profiles between schizophrenia patients and controls and between male and female patients. Dysregulated activity of these candidate genes could play a role in schizophrenia pathogenesis.

Childhood Onset Schizophrenia (COS) is a severe neurodevelopmental disorder, for which the genetic etiology remains largely unknown. Recently, whole exome sequencing studies have identified severe rare *de novo* variants in sporadic cases of adult onset schizophrenia and autism. In this study, we performed exome sequencing of 17 COS trios with the aim of identifying *de novo* variants in the COS affected children. We identified 20 *de novo* mutations in 17 probands, which is consistent with the *de novo* mutation rate thus far identified in adult form of schizophrenia. Our findings also suggest that *de novo* missense variants identified in our study have a high likelihood for pathogenicity. In fact, the pool of genes we found to present *de novo* variants appears to be enriched for genes that are less likely to tolerate such alterations. Among the genes found to be disrupted in our study, there is evidence suggesting that some of them are involved in neuronal functions. Moreover some of these genes were previously reported to be associated with neurodevelopmental disorders. Hence this list of genes should be considered to represent genuine COS candidate genes. We believe that insights from the identification of COS genes may help to develop diagnostic tools, which in turn may help to intervene before the onset of symptoms. Eventually, knowing the genetic etiology may lead to the identification of therapeutic avenues for better treatment.

Schizophrenia (SCZ) is a severe neuropsychiatric disorder. SCZ genome-wide association studies (GWAS) have identified common single nucleotide polymorphisms (SNPs) and a large polygenic contribution to illness risk, but biological mechanisms remain unclear. The known role of microRNAs (miRNAs) as potent disease modifiers in neuropsychiatric disorders raises the question of whether genetic variation in miRNAs plays a critical role in SCZ etiology.
Therefore, we implemented a systematic set-based test for all miRNAs defined in the miRBase based on test statistics from GWAS data. Results from the largest SCZ meta-analyses to date [Ripke et al., 2013] provided the basis for this analysis. Alike the popular gene set testing tool VEGAS [Liu et al., 2010], SNPs in within miRNAs were grouped together, corrected for linkage disequilibrium and controlled for the number of SNPs within each miRNA to calculate a miRNA test statistic.
From all analyzed miRNAs, 2.76% were significantly associated with SCZ after correction for multiple testing; further 18.90% were nominal significant. As expected from the GWAS results, the strongest association was found for hsa-mir-137. Moreover, miRNAs involved in neural and synapse development such as mir-9 and let-7 as well as in miRNAs with yet unknown function were identified. Further evaluation of targets from significantly associated miRNAs as well as their presence in brain QTLs will be presented.
Overall, our results give the first unbiased screening of miRNA association based on large SCZ GWAS data and might lead to the discovery of key players suitable for further functional studies.

P09.132-M
Whole exome sequencing of schizophrenia patients with high level of autozygosity

C. Magri[1], *E. Giacopuzzi*[1], *P. Valsecchi*[2,3], *M. Traversa*[1], *R. Gardella*[1], *G. Borsani*[1], *S. Barlati*[1], *E. Sacchetti*[2,3], *M. Gennarelli*[1,4];

Schizophrenia (SZ) has a high heritability (about 80%), but the genetic architecture of the disease is still unclear. The numerous genome wide association studies and the recent next generation sequencing analyses indicated that about 32% of the genetic variability of SZ is due to the additive effect of a high number of susceptibility alleles with a modest effect size and/or to the presence of rare deleterious copy number variants (CNVs) or coding single nucleotide variants (SNVs). To evaluate the contribution of rare recessive homozygous SNVs in SZ, we initially identified, with SNP-array analysis of 180 unrelated SZ patients, the offspring of mates that are closely related (inbreeding) and therefore have an increased prior probability to carry potentially deleterious recessive mutations; subsequently, we performed whole exome sequencing analysis of these patients.
An average of 269 (min-max: 196-384) functional (frameshift, missense and nonsense) homozygous SNVs has been observed in the autozygous regions of the 7 sequenced patients. About 8 SNVs per individual are novel (not in dbSNP, 1000G and dbESP6500) and have a high phyloP conservation score. Among these, we identified, in three patients, three different SNVs representing good candidate SZ mutations, since they are predicted to be damaging and map in genes mainly expressed in brain and previously associated with SZ.
Our data suggest that rare homozygous SNVs could be involved in the clinical phenotype of SZ, at least in patients with high level of autozygosity.

P09.133-S
Copy number variants analysis and targeted resequencing of the schizophrenia candidate gene RB1CC1

F. Degenhardt[1,2], *M. Pfohl*[1,2], *J. Strohmaier*[3], *I. Giegling*[4], *D. Rujescu*[4], *F. Streit*[3], *A. Forstner*[1,5], *T. Schulze*[6], *P. Hoffmann*[1,2], *R. Mössner*[7], *M. Rietschel*[8], *M. Nöthen*[1,2];
[1]*Institute of Human Genetics, Bonn, Germany,* [2]*Department of Genomics, Life and Brain Center, University of Bonn, Bonn, Germany,* [3]*Department of Genetic Epidemiology in Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim / Heidelberg University, Mannheim, Germany,* [4]*Department of Psychiatry, University of Halle-Wittenberg, Halle, Germany,* [5]*Department of Genomics, Life and Brain Center, University of Bonn, Bonn, Austria,* [6]*Department of Psychiatry and Psychotherapy, Göttingen, Germany,* [7]*Department of Psychiatry, Bonn, Germany,* [8]*Department of Genetic Epidemiology in Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim / Heidelberg University, Bonn, Germany.*

Schizophrenia is a severe neuropsychiatric disorder with heritability estimates of ~80%. Xu et al. (2011) published the first exome-sequencing study focusing on de novo mutations in patients with schizophrenia. To provide additional genetic evidence for any of the genes suggested by the exome-sequencing study, we performed a follow-up study focusing on copy number variants (CNVs). We screened 1,637 patients and 1,627 controls for CNVs in any of the genes suggested by the exome-sequencing study. Duplications in RB1CC1 on chromosome 8 were overrepresented in patients. The duplications were followed-up in independent European samples. In the combined analysis, comprising of 8,461 patients and 112,871 controls, duplications in RB1CC1 were associated with schizophrenia (P = 1.29 x 10-5; odds ratio = 8.58). The aim of the present study was to further explore RB1CC1 as a candidate gene for schizophrenia. The gene consists of 24 exons. We focused our targeted resequencing on exon 15: (i) it contains >30% of the gene's total protein-coding sequence, and (ii) Xu et al. (2011) identified a de novo frameshift deletion in this exon. After quality control, the data from 1740 patients were available. Among 22 patients, a total of 17 different variants were identified and verified by sequencing the complementary strand. Of these, 10 were neither detected in the 1000 Genomes Project nor the Exome Variant Server. Currently, we are analyzing whether these variants co-segregate with a psychiatric diagnosis within the families of the affected probands. Furthermore, detailed phenotypic description of the mutation carriers are being assembled.

P09.134-M
Combination of whole-genome and whole-exome sequencing, to identify rare and de-novo variation in cases of schizophrenia and bipolar disorder from the Faroe Islands

F. Lescai[1], *T. Als*[1], *M. Nyegaard*[1], *A. McQuillin*[2], *D. Demontis*[1], *A. Fiorentino*[2], *N. O'Brien*[2], *A. Jarra*[2], *J. Grove*[1], *G. Andorsdottir*[3], *M. Biskopstø*[3], *A. G. Wang*[4], *O. Mors*[5], *J. Wang*[6], *A. Børglum*[1];
[1]*Aarhus University, Aarhus, Denmark,* [2]*University College London, London, United*

Kingdom, [3]Genetic Biobank of the Faroes, Faroe Islands, Denmark, [4]Mental Health Centre Amager, Capital Region of Denmark, Denmark, [5]Aarhus University Hospital, Risskov, Denmark, [6]BGI - Beijing Genomics Institute, Beijing, China.

Isolated populations represent an advantage to identify rare disease variants that may appear at higher frequencies compared to outbred populations. In this work, we use the Faroese population to test this hypothesis, and combine low-depth (6X) whole-genome (WGS) and high-depth (35X) whole exome (WES) sequencing approaches to describe genomic variation, de-novo mutations and perform association mapping in patients with schizophrenia (SZ) and bipolar disorder (BP).
Our sample consists of 106 SZ cases, 28 BP and 214 controls (344 total): together with unrelated individuals, it includes 54 complete trios.
A total of 17,345,307 and 259,904 variants have been called in WGS and WES respectively. We discovered 9,130 de-novo mutations in WGS and 417 in WES. Clear differences emerge between WGS and WES in identifying different types of variants. A specificity of this work is the combination of WGS and WES in the discovery of de-novo mutations: both approaches discover the same number of de-novo loss-of-function mutations but high-depth WES is clearly more powerful in calling coding variants, mostly because of depth filtering criteria. In the association mapping we identified 6 genome-wide significant loci, which are currently being replicated in 3,300 BP and controls from UCL. The results of this analysis, the concordance between WES and WGS, and their perspectives will be presented and discussed.

		Whole Exome (35X)		Whole Genome (6X)

Identification of a de novo 15q13.1-13.3 deletion in a reading and language impaired cohort

K. A. Pettigrew[1], *E. Reeves*[2], *R. Leavett*[2], *E. Hayiou-Thomas*[2], *N. H. Simpson*[3], *M. Snowling*[4], *D. F. Newbury*[3,4], *S. Paracchini*[1];
[1]*School of Medicine, University of St Andrews, St Andrews, United Kingdom,* [2]*Centre for Reading and Language, Department of Psychology, University of York, York, United Kingdom,* [3]*Wellcome Trust Centre for Human Genetics, Oxford University, Oxford, United Kingdom,* [4]*Department of Experimental Psychology & St John's College Oxford, Oxford, United Kingdom.*

Dyslexia and specific language impairment (SLI) are developmental disorders presenting deficits of written or spoken language respectively in individuals with normal intelligence and education, and without overt neurological abnormalities. Copy number variations (CNVs) have been implicated in neurodevelopmental and psychiatric conditions, such as autism and schizophrenia, but it is not clear to what extent they might contribute to reading and language abilities. Using data from a longitudinal study investigating the development of children between 3 and 7 years of age, we performed CNV analysis (n=94 children; 65% family risk of dyslexia, 23% language impaired, 12% typically developing) and identified a large deletion on chromosome 15q13.1-13.3 in an individual with an early age SLI diagnosis. This single copy deletion spanning BP3-BP5 (~3.2Mb) was validated by qPCR, and shown to be *de novo*. Both parents and a sibling are non-carriers of this deletion and do not display any reading or language deficits, suggesting this deletion may be directly involved in the phenotype of the proband. This is the first report of a BP3-BP5 deletion to be identified in an SLI cohort, in the absence of intellectual disability. The identification of a *de novo* chromosome 15q CNV in this cohort provides further support for the implication of this locus in contributing to a wide range of neurodevelopmental phenotypes.

P09.136-M
Gain-of-function $Na_v1.7$ and $Na_v1.8$ mutations in patients with idiopathic small fiber neuropathy

M. M. Gerrits[1], *C. G. Faber*[1], *J. G. J. Hoeijmakers*[1], *D. M. L. Merckx*[1], *L. K. M. Meekels*[1], *H. J. M. Smeets*[1], *S. D. Dib-Hajj*[2,3], *S. G. Waxman*[2,3], *I. S. J. Merkies*[1,4];
[1]*Maastricht University Medical Center, Maastricht, Netherlands,* [2]*Yale University School of Medicine, New Haven, CT, United States,* [3]*Center for Neuroscience and Regeneration Research, Veterans Affairs Medical Centre, West Haven, CT, United States,* [4]*Spaarne Hospital, Hoofddorp, Netherlands.*

Small fiber neuropathy (SFN) is a relatively common disorder of thinly myelinated and unmyelinated nerve fibers and is clinically characterized by burning pain and autonomic complaints. We have recently described the presence of gain-of-function variants in $Na_v1.7$ and $Na_v1.8$ (encoded by *SCN9A* and *SCN10A*) sodium channels in a small cohort of patients (n=92) meeting strict criteria for idiopathic small fiber neuropathy (I-SFN). In this study a cohort of 393 patients with I-SFN was tested for the presence of variants in *SCN9A*. Patients that did not harbor a *SCN9A* variant subsequently underwent *SCN10A* analyses. Electrophysiology was used to test functional effects of variant channels. In *SCN9A*, 17 different heterozygous variants classified as class 3 (unknown significance) or 4 (likely to be pathogenic) based on in silico prediction were found in 34 patients (~9%). For two $Na_v1.7$ variants, electrophysiology did not provide evidence for pathogenicity. In *SCN10A*, ten different heterozygous $Na_v1.8$ variants classified as class 3 (unknown significance) or 4 (likely to be pathogenic) based on in silico prediction were found in 15 patients (~4%). For one Nav1.8 variant no evidence for pathogenicity was provided by electrophysiology. In conclusion, heterozygous *SCN9A* or *SCN10A* variants are present in a substantial proportion (~12%; 49 of 393) of our cohort of I-SFN patients. For many variants electrophysiological analysis revealed gain-of-function attributes in mutant channels. This implies that functional variants in *SCN9A* and *SCN10A* may predispose carriers to the development of channelopathy-associated SFN. Analysis of *SCN9A* and *SCN10A* should be considered for patients with I-SFN.

P09.137-S
The CD45+ blood cells alpha-synuclein level in Parkinson's disease

A. K. Emelyanov[1,2], *P. Andoskin*[1,2], *A. Yakimovskii*[2], *A. Timofeeva*[2], *S. Pchelina*[1,2];
[1]*Petersburg Nuclear Physics Institute, Saint-Petersburg, Russian Federation,* [2]*Pavlov's State Medical University of Saint-Petersburg, Saint-Petersburg, Russian Federation.*

Impaired metabolism of alpha-synuclein and its aggregation are implicated in the pathogenesis of Parkinson's disease (PD). It was shown that L-DOPA treatment during the clinical course of the disease induces the alpha-synuclein oligomerization. Several studies estimated alpha-synuclein level in blood cells of PD patients. However the alpha-synuclein level in uncontaminated fraction of the peripheral blood lymphocytes remains unknown. Here we examined alterations in alpha-synuclein level in magneticaly separated CD45+ cells from the whole blood in 18 drug-naïve patients with sporadic PD and in 23 controls without neurological disorders by ELISA method (Human alpha-synuclein ELISA kit, Invitrogen, USA). CD45+ MicroBeads and MACS Columns (Miltenyi Biotec, USA) are used for positive selection lymphocytes after Ficoll-Paque PLUS peripheral blood separation. All subjects were residents of the North-Western region of Russia and ethnically matched. The level of a total alpha-synuclein in peripheral blood CD45+ cells was higher in patients with PD (median 9,59 (min - 2,23; max - 36,80), ng/ml) than in the control subjects (median 4,81 (min - 1,21; max - 28,1), ng/ml) (p=0,04). Taken together our findings suppose that the increased level of alpha-synuclein in blood CD45+ cells of PD patients can be used as diagnostic marker for PD.

P09.138-M
Linking amyotrophic lateral sclerosis and spinal muscular atrophy: analysis of the C9ORF72 gene in 162 SMA patients

L. Alías[1], *S. Bernal*[2], *M. J. Barceló*[1], *E. Martínez*[2], *R. Martínez-Hernández*[2], *M. Baiget*[1], *E. F. Tizzano*[1];
[1]*Hospital Sant Pau, CIBERER U-705, Barcelona, Barcelona, Spain,* [2]*Hospital Sant Pau, Barcelona, Barcelona, Spain.*

Spinal muscular atrophy (SMA) and amyotrophic lateral sclerosis (ALS) are both motor neuron disorders. Several studies have tried to establish a link between the two diseases but the subject is still under debate. It has been reported that large expansions of the hexanucleotide GGGGCC in intron 1 of the *C9ORF72* gene are often responsible for familial and sporadic ALS cases. On the other side, mutations in the SMN1 gene cause SMA and its highly homologous copy, *SMN2*, is a phenotypic modifier. **Objective:** We investigated whether the number of the hexanucleotide repeats in *C9ORF72* was associated with the phenotype and the number of *SMN2* copies in a group of 162 SMA patients. **Methods:** Conventional PCR was used to determine values within the normal range (less than 30 repeats), while Repeat Primed-PCR (RP-PCR) and Southern blot methods were used to exclude the existence of large expansions that are out of the range to be amplified by conventional methodology. **Results:** No pathological (> 30 repeats) or premutated alleles (20-30 repeats) were found. The allelic distribution of the *C9ORF72* gene in SMA patients overlapped with the data obtained in our control population discarding putative repeats that may be associated with the disease. No association was either observed with the SMA phenotype or the number of *SMN2* copies. **Conclusion:** The involvement of *C9ORF72* as a genetic marker in SMA is unlikely. Current investigation of modifier genes in SMA should consider other possible candidates (Supported by FIS 11-2606).

P09.139-S
Spinocerenellar ataxia type 6(SCA6): clinical pilot trial with medicinal herbs

T. Okabe;
University of Tokyo Hospital, Bunnkyo-ku, Japan.

Spinocerebellar ataxia 6 (SCA6) is an autosomal dominant cerebellar ataxia associated with small polyglutamine-dependent expansions in the alpha 1A-voltage calcium channel. At present, we have no effective therapeutic tools. We report here six cases of spinocerebellar ataxia 6(SCA6)with typical symptoms. Genetic tests revealed expanded allele of 22~25 CAG repeats at the spinocerebellar ataxia type 6 locus. Head MRI revealed a typical atrophic image in cerebellum. For the systems therapy with medicinal herbs, the differential diagnosis by traditional herbal medicine was made according to the guideline. Mixtures of 18~26 medicinal herbs were given according to the differential diagnosis in each patient. The remedies used for the cases consist of several different ingredients, which have well-established histories of use for treatment of vertigo, tremor, or ataxia and are expected to exert their specific effects. In 5 of 7 patients, ataxia of gait and stance was significantly improved in 30~ 60 days of the herbal treatment. 34~85% reductuion were obtained on the 100-point semiquantitative International Cooperative Ataxia Rating Scales (ICARS) scores. The results imply the therapeutic potential of herbal medicine for spinocerebellar ataxia 6. Further extensive investigations are required to clarify the mechanisms by which the remission induction of this genetic disease of CAG repeat expansion mutation has been attained with the medicinal herbs.

Mutant Ataxin-2 Induces Reactive Oxygen Species and Autophagy in transformed lymphoblastoid cells from patients with Spinocerebellar Ataxia Type 2

H. Tsai[1], *C. Wu*[2], *J. Huang*[2], *T. Yang*[2];
[1]*Chung Shan Medical University, Taichung, Taiwan,* [2]*CHUNG SHAN MEDICAL UNIVERSITY, Taichung, Taiwan.*

Spinocerebellar ataxia type 2 (SCA2), an autosomal dominant neurodegenerative disease, is caused by the expansion of a CAG triplet repeat located in the N-terminal coding region of the ATXN2 gene. Alleles of the ATXN2 gene that carry 13-31 CAG-trinucleotide repeats are present in normal individuals. Contrariwise, alleles with a CAG triplet repeat number of >31 and up to approximately 200 are present in patients with SCA2. Although the detail mechanism of pathogenesis is yet to be defined, neurotoxin, especially reactive oxygen species (ROS), released from aggregated mutant proteins, may play a role in the pathogenic process. In this study, the lymphoblastoid cell lines (LCLs) isolated from SCA2 patients were utilized to compare with the wild-type lymphoblastoid cells. We investigated the crucial relationship between the expression of p-ERK1/2 and autophagy. Results found the endogenous p-ERK1/2 and autophagy marker protein, Atg8 (LC3 class II) were higher in SCA2 patients. Electron micrographs showed that only the cells expressing expanded Ataxin-2 contained aggregated protein and autophagic vacuoles. Based on the above observations we hypothesized that the aggregated mutant Ataxin-2 proteins may generate ROS in mitochondria, which subsequently up-regulate Atg8 expression levels and ultimately lead to autophagy and cell death.

Intragenic deletions affecting two alternative *IMMP2L* transcripts in patients with Tourette syndrome

B. Bertelsen[1], *L. Melchior*[1], *L. R. Jensen*[2], *C. Groth*[3], *B. Y. Glenthøj*[4], *R. Rizzo*[5], *N. Mol Debes*[3], *L. Skov*[3], *K. Brøndum-Nielsen*[1], *P. Paschou*[6], *A. Silahtaroglu*[7], *Z. Tümer*[1];
[1]*Applied Human Molecular Genetics, Kennedy Center, Copenhagen University Hospital, Rigshospitalet, Glostrup, Denmark,* [2]*Institute for Human Genetics, Ernst-Moritz-Arndt-University Greifswald, Greifswald, Germany,* [3]*The Tourette Clinic, Department of Pediatrics, Herlev University Hospital, Herlev, Denmark,* [4]*Center for Neuropsychiatric Schizophrenia Research & Center for Clinical Intervention and Neuropsychiatric Schizophrenia Research, Copenhagen University Hospital, Psychiatric Center Glostrup, Glostrup, Denmark,* [5]*Section of Child Neuropsychiatry, Department of Pediatrics, University of Catania, Catania, Italy,* [6]*Department of Molecular Biology and Genetics, Democritus University of Thrace, Alexandroupoli, Greece,* [7]*Institute for Cellular and Molecular Medicine, University of Copenhagen, Copenhagen, Denmark.*

Tourette syndrome (TS) is a childhood onset neurodevelopmental disorder characterized by involuntary movements and vocalizations, known as tics. The etiology of TS is complex and largely unknown, but has a strong genetic component.
IMMP2L (inner mitochondrial membrane peptidase, subunit 2) is one of the few genes that have been suggested to increase susceptibility to TS, after identification of chromosomal rearrangements affecting *IMMP2L* in several families with TS or tics. However, to date only a single study has investigated the role of structural copy number variations (CNVs) of *IMMP2L* in a small cohort of TS patients without finding any deletions/duplications.
Through CNV screening of a cohort of 188 unrelated TS patients and 316 controls from Denmark, we identified seven patients (3.7%) and 3 controls (0.9%) with intragenic *IMMP2L* deletions, thus, the frequency of *IMMP2L* deletions was significantly higher in patients than in controls (P= 0.0447).
Four of the deletions identified in the patients did not include any known exons of *IMMP2L*, but were within intron 3. These deletions were found to affect a shorter *IMMP2L* mRNA species with two alternative 5'-exons, one of which included the ATG start codon. We showed that this short transcript and the previously published long transcript were expressed in several brain regions, with particularly high expression in cerebellum and hippocampus.
The current findings give further evidence for the role of *IMMP2L* as a susceptibility factor in TS and suggest that intronic changes in disease susceptibility genes should be investigated further for presence of alternatively spliced exons.

Molecular diagnosis of TTR gene mutations in Italy: the experience of the Molecular Genetics Laboratory of Ferrara

A. Ravani[1], *P. Rimessi*[1], **M. Taddei Masieri**[1], *B. Dolcini*[1], *A. Venturoli*[1], *C. Trabanelli*[1], *M. Fabris*[1], *A. Mazzeo*[2], *F. Salvi*[3], *C. Rapezzi*[4], *F. Gualandi*[1], *A. Ferlini*[1];
[1]*U.O. Genetica Medica, Ferrara, Italy,* [2]*U.O.C. Neuropatologia Azienda Ospedaliera Universitaria Policlinico "G. Martino", Messina, Italy,* [3]*U.O.C. di Neurologia - IRCCS Istituto delle Scienze Neurologiche - Ospedale Bellaria, Bologna, Italy,* [4]*Sezione di Cardiologia – Dipartimento di Medicina Specialistica, Diagnostica e Sperimentale – Università degli Studi, Bologna, Italy.*

Transthyretin (TTR), a plasma and cerebrospinal fluid protein secreted by the liver and choroid plexus, is mainly known as the physiological carrier of thyroxine (T(4)) and retinol. Under pathological conditions, various TTR missense mutations are known to destabilize the tetramer composed of mutant and wild type subunits, causing misfolding of the protein and fibril aggregation. This condition is associated with the amyloid diseases: senile systemic amyloidosis, familial amyloid polyneuropathy (FAP), familial amyloid cardiomyopathy (FAC). Direct sequencing of TTR gene detects more than 99% of disease-causing mutations.
In twelve years we analyzed 562 subjects, referred to our service by neurologists and cardiologists. About 47% of the exams were required for polyneuropathy, 33% for cardiac impairment and 20% for familiarity for TTR mutations.
We found the causative mutation (index cases) in 80/428 subjects with no familiarity for TTR-related diseases and in 78/134 subjects with a family history of the disorder.
The most frequent mutation in our cohort is Ile68Leu (31%), typically present in cases with cardiac involvement, followed by Phe64Leu (22%), Val30Met (15%) , Glu89Gln (14%) and Thr49Ala (5%). A novel mutation has been identified in exon 2: Val14Leu. The subject was affected by cardiac amyloidosis.
The Detection Rate achieved is good, keeping in mind the complexity of clinical diagnosis. The choice of the complete sequencing of TTR gene has proved successful, given the allelic heterogeneity of the disease. The molecular confirmation of the pathology is essential, also in order to offer an appropriate genetic counselling to the patient and his family.

P09.144-M
Tuberous sclerosis complex phenotypes suggestive of TSC1/TSC2 mosaicism

S. Boronat[1,2], *P. A. Caruso*[3], *E. A. Thiele*[1];
[1]*Pediatric Neurology. Massachusetts General Hospital, Boston, MA, United States,* [2]*Pediatric Neurology. Hospital Vall d´Hebron, Barcelona, Spain,* [3]*Neuroradiology. Massachusetts General Hospital, Boston, MA, United States.*

Tuberous sclerosis complex (TSC) is due to mutations in TSC1 or TSC2 but 15% of patients have no mutation identified (NMI). A recent study suggests that NMI patients are mosaic TSC. A TSC1/TSC2 mutation in a neural crest progenitor would explain NMI patients without tubers and subependymal nodules (SENs), because neural crest is the origin of the majority of extracranial lesions in TSC. We performed 2 studies aiming to support this hypothesis. First, a review of the MRIs of 220 TSC patients was performed to assess the phenotype-genotype of patients with tubers or SENs but not both lesions. In our cohort, 6/220 (2.7%) patients, all with NMI, had tubers without SENs, and five of the 6 patients had 3 or fewer tubers. Patients with SENs without tubers were not identified. This suggests that patients with NMI and absence of SENs had a first postzygotic mutation in neuroectoderm, which gives rise to neural crest progenitors harbouring the mutation. Second, we studied 19 patients with possible TSC who had brain MRI. Five of the 19 patients had TSC1/TSC2 mutational analysis, which was NMI. None of the 19 had tubers or SENs. None of the patients with NMI in our studies had any family member with TSC. These data suggest that patients with NMI

have a first postzygotic mutation in neuroectoderm or neural crest, explaining the negative mutational studies in leukocytes. They may present with 3 clinical recognizable phenotypes: a)possible TSC, b)TSC without tubers and SENs and c)TSC with tubers and without SENS.

P09.145-S

Novel compound heterozygous *UBE3B* mutations in two sisters with a craniofacial-intellectual disability syndrome

C. R. J. Pedurupillay[1], *A. Holmgren*[1], *T. Barøy*[1], *A. Blomhoff*[2], *M. D. Vigeland*[1], *Y. Sheng*[1], *E. Frengen*[1], *P. Strømme*[2,3], *D. Misceo*[1];
[1]*Department of Medical Genetics, Oslo University Hospital and University of Oslo, Oslo, Norway,* [2]*Women and Children's Division, Department of Clinical Neurosciences for Children, Oslo University Hospital, Ullevål, Oslo, Norway,* [3]*Faculty of Medicine, University of Oslo, Oslo, Norway.*

Ubiquitination is a fundamental post-translational modification pathway involved in a wide range of cellular activities. The substrate specificity of the Ubiquitination is mostly dependent on the E3 ubiquitin-protein ligase family. Homozygous and compound heterozygous mutations in the E3 ubiquitin-protein ligase UBE3B were found to cause Kaufman Oculocerebrofacial Syndrome (OMIM 244450) or Blepharophimosis-Ptosis-Intellectual Disability Syndrome (OMIM 615057) in six patients from five families.
We describe two affected sisters, carrying a compound heterozygous mutation *in trans* in *UBE3B*. They exhibited cranio-facial anomalies including microcephaly, microphthalmia, blepharophimosis, upslanting palpebral fissures, high-arched and interrupted eyebrows, and myopia. In addition, they had laryngomalacia, abnormal genitalia, severe intellectual disability, delayed motor development, hypotonia, failure to thrive, and growth delay. The younger sister had small kidneys and impaired hearing, and the older sister had corpus callosum hypoplasia. The facial dysmorphisms including arched and interrupted eyebrows and long eyelashes overlap with Blepharophimosis Ptosis and Epicanthus inversus Syndrome and Kabuki Syndrome.
By exome sequencing, followed by Sanger sequencing, we found in both sisters a *UBE3B* missense mutation in exon 1 (p.Met1Val) and a 1bp frameshift deletion (p.Phe591fs) in exon 17. The mutations were predicted to result in a truncated UBE3B protein and cause the disease.
We compared the findings in our patients with the previously described patients. Loss of *UBE3B* seems to result in a relatively homogeneous phenotype, recognizable by the distinct facial dysmorphisms of the ocular region in particular, and the severe psychomotor developmental delay.

P09.146-M

Exome Sequencing reveals a novel WDR45 Frameshift mutation and POLR3A compound heterozygous variants in a female with complex phenotype and mixed brain MRI findings

M. Khalifa[1,2], *L. Naffaa*[1];
[1]*Akron Children's Hospital, Akron, OH, United States,* [2]*Northeast Ohio Medical University, Rootstown, OH, United States.*

WDR45 and *POLR3A* are newly recognized genes; each is associated with a distinct neurodegenerative disease. *WDR45* is an X-linked gene associated with a dominant form of Neurodegeneration with Brain Iron Accumulation (NBIA), manifested by progressive disabilities, dystonia, cognitive decline, spastic paraplegia, neuropsychiatric abnormalities and iron deposition in the basal ganglia on brain imaging. *POLR3A* on the other hand is an autosomal gene and its mutations cause a recessive form of a hypomyelination with Leukodystrophy disease, also known as 4H syndrome, characterized by congenital Hypomyelination with thinning of corpus callosum, Hypodontia and Hypogonadotropic Hypogonadism. We report a female child with severe intellectual disability, aphasia, short stature, ataxia, failure to thrive and structural brain abnormalities. MRI of the brain obtained in late infancy showed hypomylelation involving the central periventricular white matter and corpus callosum with no evidence of iron accumulation. MRIs of the brain obtained in childhood showed stable hypomyelination, with progressive iron accumulation in the basal ganglia in particular in the globus pallidus and substania nigra. Whole Exome Sequencing (WES) identified a novel *WDR45* frameshift deleterious mutation in Exon 9 (c.587-588del). WES also revealed *POLR3A* 3 missence heterozygous variants. The first is a novel missence variant in exon 4 which is maternally inherited (c.346A>G). Exon13 carried 2 heterozygous missence variants; a maternally inherited variant (c.1724A>T) and a paternally inherited variant (1745G>A). These variants are considered likely damaging. The patient's complex clinical phenotype and mixed brain MRI findings might be attributed to the confounding effects of the expression of these 2 genes.

P09.147-S

Severe presentation of *WDR62* mutation: is there a role for modifying genetic factors?

C. J. Poulton[1,2], *R. Schot*[1], *K. Seufert*[3], *M. H. Lequin*[1], *A. Accogli*[4], *G. D`Annunzio*[5], *L. Villard*[6], *N. Phillips*[6], *R. de Coo*[1], *C. Catsman-Berrevoets*[1], *U. Grasshoff*[7], *A. Kattentidt-Mouravieva*[1], *H. Calf*[1], *E. de Vreugt-Gronloh*[1], *L. van Unen*[1], *F. W. Verhiejen*[1], *N. Galjart*[1], *D. J. Morris-Rosendahl*[8], *G. M. S. Mancini*[1];
[1]*Erasmus MC, Rotterdam, Netherlands,* [2]*Princess Margaret Hospital, Perth, Australia,* [3]*Albert-Ludwigs University, Freiburg, Germany,* [4]*Gaslini Institue, Genova, Italy,* [5]*Gaslini Institute, Genova, Italy,* [6]*Aix Marseille University, Marseille, France,* [7]*University Hospital Tuebingen, Tuebingen, Germany,* [8]*Imperial College, London, United Kingdom.*

Mutations in *WDR62* are associated with primary microcephaly; however they have been reported with wide phenotypic variability. We report six individuals with novel *WDR62* mutations who illustrate this variability and describe three in greater detail. Of the three one lacks neuromotor development and has severe pachygyria on MRI, another has only delayed speech and motor development and moderate polymicrogyria, and the third has an intermediate phenotype. We observed a rare copy number change of unknown significance, a 17q25qter duplication, in the first severely affected individual. The 17q25 duplication included an interesting candidate gene, tubulin cofactor D (*TBCD*), crucial in microtubule assembly and disassembly. Sequencing of the non-duplicated allele showed a *TBCD* missense mutation, predicted to cause a deleterious p.Phe1121Val substitution. Sequencing of a cohort of five individuals with *WDR62* mutations, including one with an identical mutation and different phenotype, plus twelve individuals with diagnosis of microlissencephaly and another individual with mild intellectual disability (ID) and a 17q25 duplication, did not reveal *TBCD* mutations. However, immunostaining with tubulin antibodies of cells from patients with both WDR62 and TBCD mutation showed abnormal tubulin network when compared to controls and cells with only the WDR62 mutation. Therefore we propose that genetic factors contribute to modify the severity of the WDR62 phenotype and, although based on suggestive evidence , TBCD could function as one of such factors.

Serotonergic signaling as modulator of Machado-Joseph disease pathogenesis

A. Jalles*[1,2], *A. Teixeira-Castro**[1,3], *A. Miranda*[1,2], *C. Bessa*[1,2], *R. Morimoto*[3], *P. Maciel*[1,2];
[1]*Life and Health Sciences Research Institute (ICVS), School of Health Sciences, University of Minho, Braga, Portugal,* [2]*ICVS/3B's - PT Government Associate Laboratory, Braga/Guimarães, Portugal,* [3]*Department of Biosciences, Northwestern University Institute for Neuroscience, Rice Institute for Biomedical Research, Northwestern University Evanston, Chicago, IL, United States.*

*these authors contribute equally for this work

Introduction: Machado-Joseph disease (MJD) is a neurodegenerative disorder caused by the expansion of a polyglutamine (polyQ) tract within the C-terminal of the ataxin-3 (ATXN3) protein. The lack of therapeutic strategies that effectively prevent neurodegeneration in MJD patients prompted us to search for compounds that modulate mutant ATXN3-related pathogenesis. Recent data from our lab have shown that many aspects of MJD can be properly modeled in the round worm *Caenorhabditis elegans*. This study is based on the idea that our *C. elegans* MJD model is amenable for large-scale drug screenings, in which the identification of effective drugs can be accomplished by looking simultaneously at protein aggregation in the live neuronal cells, and on its impact on neuron-regulated behavior of the whole-animal**. Methods:** We used our C. elegans MJD model to screen a library of ~1200 mainly FDA-approved compounds for their ability to prevent or delay the formation of mutant ATXN3 aggregates and neurological dysfunction. Results: We excluded the small molecules that were found to be toxic or cause developmental delay to the C. elegans at the concentrations tested. Of the remaining, ten percent of the compounds significantly reduced the locomotion deficits of the animals. **Discussion:** We found that one group of the newly identified compounds exert their function in *C. elegans* by increasing serotonin signaling. Rescue of MJD pathogenesis seems to be dependent on the serotonin receptors. We should be able to identify efficacious compounds that can be tested in higher organisms, including our transgenic mouse model, and eventually enter clinical development.

In vitro neurogenesis of human OPHN1 mutated iPS cells: morphological and biochemical analysis and phenotypic rescue with a ROCK inhibitor

C. Compagnucci[1], *S. Barresi*[1], *S. Petrini*[2], *E. Bertini*[1], **G. Zanni**[1];
[1]*Department of Neurosciences, Unit of Molecular Medicine for Neuromuscular and Neurodegenerative disorders, Bambino Gesù Childrens' Hospital IRCCS, Rome, Italy,* [2]*Confocal Microscopy Core facility, Research Laboratory, Bambino Gesù Childrens' Hospital IRCCS, Rome, Italy.*

The X-linked gene Oligophrenin-1 (OPHN1) encodes a RhoGTPase activating

protein (Rho-GAP) which is mutated in a syndromic form of intellectual disability associated with cerebellar hypoplasia. In vitro and in vivo studies on hippocampal neurons of ophn1 deficient mice have shown defects in synaptic morphology and function. The administration of Y-27632, an inhibitor of the ROCK signaling pathway, specifically hyperactivated in ophn1 loss of function, fully rescues the cellular and biochemical phenotype. We have developed a cellular model based on human induced pluripotent stem cells (iPSCs) technology and in vitro neurogenesis to analyze the morphological and biochemical properties of OPHN1 loss of function in patients cells. The neurogenic potential of the OPHN1-defective iPS cells has been assessed and compared with those of control iPS cells following the protocols for differentiation into different neuronal cell lineages. The results obtained show that human OPHN1-defective neurons have altered morphology, with shorter neurites and decreased branching level, when compared with control neurons. We also confirmed the hyperactivation of the ROCK signaling pathway in OPHN1-defective iPSCs through Western blot and immunofluorescence assays of the Myosin Phosphatase Target Subunit 1 (MYPT1) and its phosphorylated state on Thr-853. We treated control iPS cells with ROCK inhibitors and observed a phenotypic rescue in terms of ROCK activity and neuronal morphology. We are currently exploring the molecular mechanisms underlying these processes and analyzing in detail the phenotype of OPHN1 defective cells at different stages of neuronal differentiation, before and after treatment.

Rett syndrom:current situation in Algéria

B. Imessaoudene, **S. Hallal**, *Zahra Chami- Meriem Ghouali- Meriem Djeddou- Meriem Nebbache- Benchaib- Bennadji-Arezki Berhoune;*
Laboratory Of Biochemistry Chu Mustappha, Algiers, Algeria.

Rett syndrome is a progressive neurological disease that affects mainly girls. It is characterized by severe developmental disorder of the central nervous system. It is caused by mutations in the MECP2 (methyl CpG-binding protein 2) in Xq28, comprising four exons, the first of which is non-coding.
In this study, we analyzed the entire coding sequence of the MECP2 gene in 55 patients Algerians. 8 differents mutations were identified in exon 4, 2 missens mutations (p.E 394 K, p.K 135 E), 3 nonsense mutations (R255X, R294X), and 4 frameshift mutations (a deletion of one base pair: c.Del 806 G, c.Del 750 C).

P09.151-S
The association analysis of CDH10 gene (rs4307059 and rs4327572) with autism in a South African population

J. R. Sharma, *Z. Arieff, F. October;*
Department of Biotechnology, University of Western Cape, Bellville, South Africa.

Autism spectrum disorders encompass a group of childhood neurodevelopmental and neuropsychiatric disorders characterized by deficits in verbal communication and impairment of social interaction. Numerous researches have pointed out that strong genetics components are involved in susceptibility to autism. Genome wide association studies have revealed out strong association signal for *CDH10* gene with SNP rs4307059 and rs4327572. This gene had not been investigated for its association with Autism in South African population. Aim: In this study we aimed to investigate the association of two SNPs (rs4307059 and rs4327572) of *CDH10* gene of autism in the South African (SA) population. For SNPS rs4307059, the present study group was comprised of typed cases (188, unrelated autistic children) and typed controls (212, unrelated healthy children) where the respective figures for rs4327572 were 72 and 209 respectively. The Taqman ®Real-Time PCR and genotyping assay was utilized to determine the genotypes. Results: There was no significant association of SNP rs4307059 and4327572 with autism in the South African (SA) population. Conclusion: There might be a possible role of CDH10 in autism but we need to validate it with a larger sample number. The present study represents the first report on study of genetic association of *CDH10* gene in SA population.

P09.152-M
The Haplotype analysis to test for the association of three SNPs with autism in a South African Population

Z. Arieff[1], *J. R. Sharma*[1], *M. Davids*[1], *M. Kaur*[2];
[1]*Department of Biotechnology, University of Western Cape, Bellville, South Africa,*
[2]*Computational Bioscience Research Center, King Abdullah University of Science and Technology, Thuwal, Saudi Arabia.*

Autism spectrum disorder is a neuropsychiatric developmental disorder characterized by communication difficulties and impaired social interaction. The anhydrolase domain containing 11 gene (*ABHD11*) is located on 7q11.23 which is a hotspot region for autism and *ABCA13* maps to chromosome 7p12.3 in which multiple rare coding variants are observed. The aim of this study was to investigate the association of SNPs from genes *ABHD11* (rs2293484 and rs10279013) and *ABHD13* (rs17060) with haplotype analysis in South African autistic population. A total of 435 individuals were recruited including 197 autistic and 213 control subjects. The Taqman ®Real-Time PCR and genotyping assay was used to determine the genotypes. A significant association of SNP rs10279013 with autism in the South African population is observed. Haplotype analysis with three SNPs revealed that the frequency of CGC, TGT and TCT haplotypes is significantly higher in controls than cases ($p<0.05$). The haplotypes TGC and TCC presented a significantly higher frequency in cases and the odds documented nearly 3-3.47 fold higher risk to the disease in carriers of the haplotypes [OR=3.0 (1.16-7.79), OR=3.47 (0.95-12.63), respectively]. In conclusion there is a role of various haplotypes of these SNPs in increasing susceptibility to autism for South African populations. The present study represents the first report on haplotype analysis on these SNPs in a SA population.

P09.153-S
Mutations in *XRCC4* associated with a complex ataxic syndrome

D. Ghezzi[1], *L. Bee*[2], *A. Nasca*[1], *L. Melchionda*[1], *L. Celotti*[2], *R. Costa*[2], *C. Lamperti*[1], *M. Zeviani*[1,3];
[1]*The Foundation "Carlo Besta" Institute of Neurology, Milan, Italy,* [2]*University of Padua, Padua, Italy,* [3]*MRC Mitochondrial Biology Unit, Cambridge, United Kingdom.*

We studied two monozygotic twins (II-1 and II-2), born to first cousin parents (I-1 and I-2), affected by a multisystem disease. Since birth they presented with cryptorchidism, dysmorphism (short arms, hypotelorism) and short stature. In the adulthood they suffered of an ataxic syndrome with cognitive decline, pyramidal signs and depression; dilatative cardiomyopathy was also observed. We performed an exome-sequencing analysis on one proband (II-1) and his unaffected sister (II-3). First we filtered out common variants (>0.1% in public databases); then we selected non-synonymous variants that were homozygous only in II-1, based on a hypothesized recessive trait and on the known consanguinity of the parents. The remaining 28 gene variants were prioritized according to the predicted deleterious outcome of the corresponding amino acid substitutions. The most severe variant was the nucleotide change c.673C>T in the gene *XRCC4*, predicted to create a stop codon (p.R225*) causing the synthesis of a truncated protein; this variant segregated within the family. Quantitative PCR on cDNA extracted from patients' fibroblasts revealed that the *XRCC4* transcript level was strongly reduced, probably due to mRNA decay. Functional assays after gamma-ray irradiation demonstrated a reduction in DNA repair efficiency in mutant cells. These are the first patients reported with *XRCC4* mutations. XRCC4 protein has a role in double-strand DNA repair processes; mutations affecting other proteins with a role on DNA repair (SCAN1, AOA1, ATM) have been associated with peculiar forms of ataxia, suggesting an important role for DNA repair in the nervous system, in particular in the cerebellum.

P09.154-M
Screening for C9ORF72 repeat expansion in amyotrophic lateral sclerosis

L. Mosca, C. Tarlarini, C. Lunetta, V. Sansone, **S. Penco**;
Niguarda Ca' Granda Hospital, MIlano, Italy.

Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disorder characterized by a degeneration of upper and lower motor neurons, leading to a progressive muscle weakness, wasting and paralysis that results in death within a few years from disease onset. Moreover, evidences of ALS as a multisystem disorder also compromising frontotemporal functions in up to 50% of patients are reported. Recently, a hexanucleotide repeat expansion (GGGGCC) in the first intron of C9ORF72 gene was identified as the most common genetic cause of familial ALS, frontotemporal dementia and ALS-FTD. Aim of the present study was to determine the prevalence of C9ORF72 repeat expansion in our cohort of 753 ALS patients. C9ORF72 expansion was analyzed by using the repeat primed PCR: this method can detect repeat numbers of approximately maximum 60 and it is able to discriminate the repeat range detected in the normal population (0-20) from the higher mutated range (≥30). The expansion, in the pathogenic range (≥30), was identified in 34 ALS patients (4.5%); moreover, 4 cases (0.5%) resulted to be carriers of an intermediate number of reapets (20-30). Interestingly, 2 of the C9ORF72 expansion carriers also carried a causative mutations in one of other known causative genes of ALS (TARDBP and FUS). Our findings, in agreement with literature, suggest that C9ORF72 repeat expansion is the major genetic cause of ALS. Further efforts are needed to implement, in terms of intra- and inter-laboratory reproducibility, the method used for C9ORF72 analysis for using it in diagnostics.

P10.01-S
Analysis of the c9orf72 GC- rich low complexity sequence in ALS cases carrying GGGGCC expansion

L. Corrado[1], *A. Bagarotti[1], N. Barizzone[1], L. Mazzini[2], S. D'Alfonso[1];*
[1]University A.Avogadro, Dept of Health Sciences, Novara, Italy, [2]Department of Neurology, A. Avogadro University and Maggiore della Carita` Hospital, Novara, Italy.

Large expansions of a noncoding hexanucleotide G4C2 repeat in the C9orf72 gene have been identified as the main cause of Amyotrophic Lateral Sclerosis (ALS) accounting for about 40% of the familial and 7% of the sporadic cases. The c9orf72 G4C2 repeat is contiguous with another GC-rich region with imperfect repeats. A recent study observed heterozygous deletions of variable size (from 5 to 23 bp) in patients carrying a G4C2 expansion (about 37% in a Belgian cohort and 24% in an European cohort). These deletions are contiguous to the G4C2 repeat and create one long imperfect G4C2 repeat that could make this sequence prone to replication slippage. To confirm the role of these deletions, as a possible trigger event of the instability of G4C2 repeats, we sequenced the adjacent GC-rich region in 28 Italian ALS patients carrying c9orf72 expansion, , as described by the original study. We did not observe any deletion of the GC-rich region adjacent to G4C2 repeat in the Italian c9orf72 expanded cohort, although we expected at least 7 deleted cases since the deletion frequency in the European cohort was 24% (Fisher's exact test, two-tailed P value = 0.0102). We cannot exclude that our data could be population specific or due to technical artefacts. Further studies will be necessary to confirm the role of these deletions in c9orf72 genomic instability.

ANO5 mutations in Spanish LGMD patients

L. Gonzalez-Quereda[1], M. Rodriguez[1], R. Rojas[2], J. Díaz Manera[2], M. Ramos[3], N. Julià[4], J. Barcena[5], A. Lopez Arízteguí[6], M. Baiget[1], M. Olivé[7], **P. Gallano**[1];
[1]Genetics Dpt,CIBERER U705, Hospital Sant Pau, Barcelona, Spain, [2]Neurology Dpt CIBERNED, Hospital Sant Pau, Barcelona, Spain, [3]Clinical Genetics, Hospital V.Camino, Pamplona, Spain, [4]Neurology Dpt,Hospital Bellvitge, Hospitalet de Llobregat, Spain, [5]Clinical Genetics, Hospital de Cruces, Barcelona, Spain, [6]Clinical Genetics, Hospital de Cruces, Baracaldo, Spain, [7]Neuropathology Inst, Path Dpt, Neuromusc Unit, IDIBELL Hospital Bellvitge, Hospitalet de Llobregat, Spain.

Recessive mutations in *ANO5* gene have been reported in patients suffering from limb girdle muscular dystrophy (LGMD) 2L, distal myopathy resembling Miyoshi myopathy and patients manifesting with mialgia and high CK levels.
ANO5 gene, located on chromosome 11p14, is composed of 22 exons. To date, forty different mutations have been described in the literature, being c.191dupA the most frequent mutation. Interestingly, previous studies show considerable geographical differences regarding the prevalence of *ANO5* mutations. LGMD2L is the second most common form of LGMD in Northern Europe, in contrast to the low prevalence (2%) that has been reported in the Italian cohort of LGMD patients.
We present data from an *ANO5* gene molecular study in 27 Spanish patients manifesting the three different phenotypes: 1) LGMD 2L, 2) distal myopathy resembling Miyoshi myopathy, 3) mialgia and high CK levels. We identified six different mutations, two of them not previously described, in ten individuals (8 males and 2 females). Six patients presented 2 mutations and 4 only 1, suggesting symptomatic carrier status.
Among patients presenting two mutations, six of them carried the c.191dupA: three in homozygous state, 2 in compound heterozygous state and one as a single mutation. In our cohort of patients, c.191dupA is, as in the majority of populations, the most frequent *ANO5* mutation.
Our mutational screening reveals a higher prevalence of *ANO5* mutations in Spanish population compared to the Italy cohort of patients previously reported.

P10.03-S
Deletions involving the 17-22 repeats in the rod domain of dystrophin gene result in a late-onset Becker Dystrophinopathy

A. Taglia[1], E. Picillo[2], A. Torella[3], P. D'Ambrosio[1], R. Petillo[1], E. Manuela[1], L. Passamano[1], A. Palladino[1], V. Nigro[3], **L. Politano**[1];
[1]Second University of Naples, Naples, Italy, [2]Second University of Naples - Cardiomyology and medical Genetics, Naples, Italy, [3]Second University of Naples - Dept. of General Pathology, Naples, Italy.

Dystrophin, the protein product of DMD gene is a rod-shaped protein consisting of 3684 amino acids composed by four domains: actin binding domain; central rod domain; cysteine-rich domain and carboxy-terminal domain.
Mutations in DMD gene cause phenotypes ranging from severe (DMD) to mild (BMD) myopathic form or X-linked cardiomyopathy (XLCM). Mutations causing premature translation termination result in a total absence of the protein that leads to DMD, while mutations derived from in-frame deletions result in a reduced protein expression leading to BMD or XLCM.
We investigated the percentage of patients sharing mutations in the rod domain in a cohort of 160 BMD patients with gene deletions, followed at the Cardiomyology and Medical Genetics of Naples Second University. We found that 20 of them (12.5%) shared a deletion involving exons from 45 to 57, at the 17-22 repeats level.
From a clinical point of view, based on muscular, cardiac and respiratory assessment, 8 (40%) were asymptomatic, 11 (55%) had a mild phenotype and only 1 (5%) had dilated cardiomyopathy, as the first manifestation.
Compared with data reported by Kaspar et al. (2009), the percentage of asymptomatic patients in our cohort was higher (40 vs 8%) while that of patients with mild phenotype was lower (89 vs 11%). The difference probably lies in a younger mean age of our patients in both groups (30.5 vs 20.2 and 24.3 vs 30.5, respectively).
Data here reported confirm that mutations involving repeats 17-22 of the rod domain result in a late-onset mild Becker Dystrophinopathy.

P10.04-M
Mutations in the Charcot-Marie-Tooth disease–associated GDAP1 gene leads to calcium homeostasis dysfunction and endoplasmic reticulum stress

D. Pla-Martin, *E. L. Calpena, F. Palau;*
Centro de Investigación Príncipe Felipe and CIBERER, Valencia, Spain.

Charcot-Marie-Tooth (CMT) disease is the most common inherited neuromuscular disorder and is characterized by large locus heterogeneity. Mutations in the *GDAP1* gene show phenotypic and Mendelian heterogeneity in CMT patients. GDAP1 is a mitochondrial outer membrane protein related to mitochondrial dynamics network and different effects on the fission and fusion pathways have been reported for recessive and dominant mutations, respectively. Recently we have described the role of GDAP1 in the regulation of store-operated calcium entry (SOCE), a complex process needed to fill endoplasmic reticulum (ER) after Ca^{2+} release. Dysregulation of calcium processes and ER stress represent a common pathway in neurodegenerative diseases. Here we present how missense mutations of *GDAP1* expressed in the human neuroblastoma SH-SY5Y cells also affect calcium homeostasis depending of their mode of inheritance and its relative position in the protein. Recessive mutations within the protein interaction domain of GDAP1 blocks Ca^{2+} influx during SOCE avoiding ER-Ca^{2+} refilling, while dominant mutations show an exacerbated Ca^{2+} influx with high resting Ca^{2+} levels. These mechanisms may affect the proper function of ER, which produce ER stress that eventually could lead to neurodegeneration.

P10.05-S
Diagnostic time trend and genetic analysis of Charcot-Marie-Tooth Disease in Denmark

S. Vaeth[1], *H. Andersen[2], R. Christensen[1], M. Duno[3], U. B. Jensen[1];*
[1]Dept. Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark, [2]Dept. of Neurology, Aarhus University Hospital, Aarhus, Denmark, [3]Dept. Clinical Genetics, Copenhagen University Hospital, Copenhagen, Denmark.

Aim: To classify Danish patients diagnosed with CMT in the period 1977-2012 according to genetic analysis, sex, and age at diagnosis.
Background: Charcot-Marie-Tooth Disease (CMT) is the most common inherited neurological disease. More than 70 genes associate with a CMT phenotype, but mutations in only four genes accounts for the vast majority of cases. Little is known about the epidemiology of CMT in Denmark.
Material and Methods: Records with diagnostic codes ICD8 33009 (atrophia mm. neuropathica, Charcot-Marie-Tooth) and ICD10 G60.0 (hereditary motor sensory neuropathy) from 1977 to 2012 were retrieved from The Danish National Patient Register (DNPR). These data were linked with data on genetic analysis for CMT between 1990 and 2012 at Department of Clinical Genetics, Aarhus University Hospital and Copenhagen University Hospital.
Results: A total of 2084 patients with a CMT diagnosis were identified in DNPR. Of these 712 patients (34%) had genetic testing, a genetically confirmed CMT diagnosis was obtained in 50%. In total, 17% of the patients clinically diagnosed with CMT since 1977 had a genetically confirmed CMT diagnosis. This percentage was largest in the 0-9 years age group (35%). In the 2008-12 cohort, 573 patients received a CMT diagnosis, 246(43%) had a genetic analysis for CMT, of which 124 (50%) confirmed the diagnosis. The majority of confirmed CMT cases where caused by duplication of the PMP22 gene (58%).
Conclusion: Only half of the newly clinically diagnosed CMT patients have been genetically tested. Fifty percent of the tested patients had a genetically confirmed diagnosis.

Combined 12q24.3del and 17p12dup in a patient with truncal hypotonia and psychomotor delay

K. Kosma[1], *M. Tzetis*[1], *K. Kekou*[1], *A. Gika*[2], *V. Oikonomakis*[1], *S. Kitsiou-Tzeli*[1], *E. Kanavakis*[1];
[1]*Department of Medical Genetics, Medical School, University of Athens, Athens, Greece,* [2]*1st Department of Pediatrics, Medical School, University of Athens, Athens, Greece.*

The use of substantially improves the diagnosis of chromosomal abnormalities that are not evident by conventional karyotype. We report the clinical and molecular findings of a 2 year old boy presented with truncal hypotonia, absent deep tendon reflexes and psychomotor delay, but no major malformations or dysmorphic features. Cytogenetic analysis was normal and DNA analysis for SMA revealed a triplication of *SMN1*. Subsequently an array CGH analysis with high resolution 4X180K Agilent arrays (> 236.000 probes, average resolution of 8.9 Kb) showed a combination of the following: 1) 12q24.33 deletion [del12q24.33, 1.5 Mb; 132,302,325-133,733,528; hg19] containing the genes *FBRSL1, P2RX2, POLE, PXMP2, PGAM5, ANKLE2, GOLGA3, CHFR, ZNF605, ZNF26, ZNF84, ZNF140, ZNF10, ZNF268* 2) 17p12 duplication[dup 17p12,1.3Mb; 14,111,772-15,379,208; hg19] involving the Charcot Marie Tooth syndrome type 1A (CMT1A) critical region within which *PMP22* gene is contained. To our knowledge this is the first report of combined 12q24.3 deletion/ 17p12 duplication in a patient whose phenotype is not typical of either the described 12q24.3 deletion or CMT1A, perhaps the combination of dosage sensitive OMIM genes in the aberrant regions contribute to the specific phenotype. P10.07-S
Whole exome sequencing in patients with congenital myopathies

I. Zaharieva[1], *I. Colombo*[1,2], *M. Sframeli*[1], *J. Sigurðsson*[3], *L. Feng*[1], *R. Phadke*[1], *C. A. Sewry*[1], *J. E. Morgan*[1], *F. Muntoni*[1];
[1]*UCL, London, United Kingdom,* [2]*Neuromuscular and Rare Disorders Unit, Milan University, Milan, Italy,* [3]*deCODE genetics, Reykjavik, Iceland.*

Congenital myopathies (CM) are a group of disorders presenting at birth or early infancy, characterised by muscle weakness and specific changes in the muscle biopsy. During the recent decade a number of genes have been discovered, however, additional novel genes are yet to be identify as genetic diagnosis cannot be currently established in many CM patients. With the aim to reveal the genetic defect in 30 CM patients, in whom mutations in suspected genes have been previously excluded, we carried out whole exome sequencing. Recently, a homozygous missense mutation in STAC3 gene was identified in patients with Native American myopathy. Analysis of WES data in our cases identified a homozygous STAC3 mutation in a patient with King-Denborough syndrome and core-like changes on muscle biopsy. A second patient with a severe phenotype and muscle biopsy changes suggestive of nemaline myopathy, carried a homozygous missense mutation in KLHL40. Mutations in KLHL40 have been very recently identified as a frequent cause of severe nemaline myopathy. Two heterozygous truncating TTN mutations were detected in a patient with severe cardiomyopathy and muscle biopsy suggestive of a centronuclear myopathy (CNM), supporting the emerging data that TTN mutations should be investigated as causative in cases with unresolved CNM. The remaining cases carried mutations in potentially novel genes which are under investigation.

P10.08-M
Desmin mutations associated with myofibrillar myopathy in the Polish population.

J. P. Fichna[1], *J. Karolczak*[2], *M. Berdyński*[1], *A. Sikorska*[2], *M. J. Rędowicz*[2], *A. M. Kamińska*[3], *C. Żekanowski*[1];
[1]*Department of Neurodegenerative Disorders, Mossakowski Medical Research Centre, Warsaw, Poland,* [2]*Department of Biochemistry, Nencki Institute of Experimental Biology, Warsaw, Poland,* [3]*Department of Neurology, Medical University of Warsaw, Warsaw, Poland.*

Desmin is a muscle-specific intermediate filament protein, which forms a network connecting sarcomere, T tubules, sarcolemma, nuclear membrane, mitochondria and other organelles. DES mutations cause myofibrillar myopathies, cardiomyopathies and related phenotypes. Molecular mechanisms of the changes leading to the disease remain ambiguous. Here we describe DES mutations found in the Polish population.
The study group comprised 22 individuals representing 7 families with clinical diagnosis of desminopathy. DNA was extracted from peripheral blood using standard methods. Sanger sequencing identified one novel mutation (Q348P) and one previously described (A357_E359del) in the Polish population. Both mutations were predicted pathogenic using *PolyPhen-2*, *SIFT* and *PROVEAN* software. A common ancestry of A357_E359del found in the novel and previously reported families was confirmed. To test whether the mutations affect DES expression and intracellular distribution *in vitro* analyses of quadriceps muscle biopsies were performed. Western Blotting revealed elevated desmin level in the patients' muscles. The increased expression was confirmed using immunostaining. Abnormal localization of desmin with aggregates within the fibers was also observed. Additional staining for M-cadherin, α-actinin and MHCs confirmed severe disruption of myofibrillar organization. Abnormalities were more prominent for the Q348P muscle which additionally displays numerous centrally localized nuclei in the aberrant muscle fibers.
Based on the *in silico* and *ex vivo* analyses, Q348P and A357_E359del mutations may be assumed pathogenic. It could be speculated that abnormal structure of mutated desmin results in aberrant folding and aggregation, triggering myofibril disruption.

P10.09-S
Haplotype analysis and age of mutation in DMPK gene in Yakutia.

M. Swarovskaia[1,2], *S. Stepanova*[3], *A. Marusin*[1], *A. Suhomiasova*[3], *N. Maksimova*[3], *V. Stepanov*[1];
[1]*Institut of Medical Genetics, Tomsk, Russian Federation,* [2]*Siberian State Medical University, Tomsk, Russian Federation,* [3]*Yakut Scientific Center complex medical problems, Yakutsk, Russian Federation.*

We studied the genetic variability DMPK locus in patients with MD and healthy population of Yakutia. The objectives of the study included the estimate of age mutation in the Yakuts. In this work we used six SNP-markers in DMPK gene and six STR-markers which flanking DMPK locus.It was shown significant differences from patients MD and Yakut's population. The frequencies of alleles in three loci: rs572634, rs527221, rs915915 were significantly different. 29 haplotypes were found in patients with MD, and 37 haplotypes were found in Yakut's population. Major haplotype TTTCTC had 40% patients. Haplotype GTCCTT was typical only for patients Yakuts. The haplotype analysis by microsatellite markers of MD patients was identified 14 alleles and 114 haplotype (frequencies from 0.6 to 8.6%). It was found the founder haplotype. Average number of generations were found 158.95 ± 192.51. The age of mutation was estimated 3179 years. This period before the formation of ethnic Yakuts.

Mutational analysis of DMD gene reveals two novel small deletions in patients bearing no large deletions or duplications

Z. Fattahi[1,2], *G. Zamani*[3], *M. Fadaee*[1,2], *M. Akbari*[4], *H. Najmabadi*[1,2];
[1]*Genetics Research Centre, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Kariminejad - Najmabadi Pathology & Genetics Center, Tehran, Islamic Republic of Iran,* [3]*Department of Pediatric Neurology, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [4]*Women's College Research Institute, University of Toronto, Toronto, ON, Canada.*

Dystrinopathies are inherited muscular dystrophies with mutations in DMD gene which contains 79 exons and is the largest human gene. DMD encodes Dystrophin protein and is the only gene responsible for the spectrum of dystrinopathies.Genotype analysis has indicated that deletions of one or more exon account for ~65% of all cases, while 5-10% are in-frame or out-frame duplications and the remaining 30% of affected individuals may have point mutations, small deletions or insertions within the gene. In the present study, two patients diagnosed with Duchenne muscular dystrophy (DMD) are investigated. Multiple ligation-dependent probe amplification (MLPA) analysis which detects up to 98% of all deletions and duplications in DMD gene did not reveal any large rearrangement in these patients. Further investigation with application of two different techniques led to identification of two novel small deletions in DMD gene. In the first patient, all coding as well as flanking intronic regions of the dystrophin gene were PCR-amplified followed by sequencing and a hemizygous novel deletion, c.650-16_653del20 (p.D217V fs11X), was detected. Next, whole exome sequencing was applied to investigate the causative variant in the second patient that revealed another novel homozygous deletion defined as c.8297delT (p.Leu2766Arg fsX17). The identified variant was confirmed by Sanger sequencing in the proband as well as other family members. This result extends the mutational spectrum of the disease by introducing two novel mutations in DMD gene and is another indication that the advent of recent technologies such as whole exome sequencing has made the diagnostic approaches much easier.

Facioscapulohumeral muscular dystrophy has been associated with reduction of the number of D4Z4 repetitive elements at 4q35. FSHD is characterized by great clinical variability within families in which D4Z4 reduced allele (DRA) segregates. An increasing number of cases are sporadic with no other affected relatives and several findings suggest that additional factors (genetic modifiers) might modulate FSHD expression. Thus molecular diagnosis, prognosis and genetic counseling have become more challenging. To gain additional information on the complexity of FSHD, we tested 40 FSHD patients belonging to families with reduced penetrance by testing, a broad core panel of 93 genes involved in myopathies (Motorplex). This Next Generation Sequencing-based workflow permit the analysis of 2,544 exons. We studied 40 samples from FSHD patients belonging to families in which other DRA carries are healthy. In all subjects we found putative pathogenic variations in genes causing different myopathies. In addition to DRA, all patients carried at least one damaging variations in other disease genes. These variants, if they had been detected alone in the context of a single gene testing, would have been considered as causative. The high number of damaging mutations identified in each sample support the hypothesis of "multiple factors" leading to the FSHD phenotype. In conclusion, the use of a reliable, sensitive and specific method has been able to identify putative pathogenic mutations that can explain the variable penetrance of DRA. Importantly these large set of mutations observed in FSHD patients highlight the genetic complexity that might contribute to the disease expression.

P10.12-M
Clinical and molecular characterization of FSHD cases with 1-3 DRA :data from the Italian National Registry of FSHD

Besta" Institute Milan, Milan, Italy, [14]University of Messina, Messina, Italy, [15]University of Verona, Verona, Italy.

Facioscapulohumeral muscular dystrophy has been genetically linked to reduced numbers (≤8) of D4Z4 repeats at 4q35. Typically a rough inverse correlation between the number of repetitive elements and disease severity is accepted. Particularly severe FSHD cases have been associated with D4Z4 reduced alleles with 1-3 repeats (1-3 DRA) with some presenting ancillary features such as Coats-like retinopathy, facial diplegia, hypoacusia, epilepsy and cognitive impairment. Out of 110 probands from the INRF carrying 1-3 DRA, we identified 40 index cases carrying a de novo DRA and 26 with at least one relative carried the same DRA. In order to investigate the earliest signs of disease and access the information about addition clinical condition, we designed an Anamnestic Infantile Form (AIF). Thirty-six probands (54.6%) showed an early disease onset (within 10 years): among them, 26 cases (72.2%) were de novo and 10 (27.8%) were familial. Collectively our study reveals that congenital form is not present in the group of 1-3 DRA carriers and infantile disease onset is more common among de novo cases. Importantly we observed that earliest onset is not always associated with a more severe clinical progression of disease. Interestingly, out of 76 carriers of 1-3 DRA we detected complex phenotype with extramuscular features in only 14 subjects, 10 de novo and 4 familial cases.

P10.13-S
HPSE2, mutated in human urofacial syndrome (UFS), directs neuromuscular differentiation

N. A. Roberts[1], *H. M. Stuart[1], R. Thuret[2], E. A. McKenzie[2], W. G. Newman[1], E. N. Hilton[1], A. S. Woolf[1];*

[1]Faculty of Medical and Human Sciences, The University of Manchester, Manchester, United Kingdom, [2]Faculty of Life Sciences, The University of Manchester, Manchester, United Kingdom.

Background: Homozygous mutations in HPSE2, encoding heparanase 2, cause UFS, characterised by congenital bladder dysfunction, constipation, and inability to smile. We investigated the developmental roles of this gene in an animal model to further clarify UFS pathogenesis. **Methods:** Hpse2 transcripts were measured by qPCR during X. tropicalis development. Single cell embryos were injected with morpholinos to knockdown hpse2. Immunostaining was performed using an antibody raised to Xenopus heparanase 2 and imaged by laser confocal micrsoscopy, and protein levels were assessed by western blotting. **Results:** Frog embryos showed increased hpse2 soon after gastrulation, with expression maintained through organogenesis. Using hspe2 morpholinos caused a phenotype comprising a bent tail, proctodeal/cloacal protrusion and impaired swim response. In wildtypes heparanase 2 localised in nascent skeletal muscle, and morphants had impaired muscularisation. Heparanase 2 was also expressed in the neural tube and hindbrain, and morphants showed compromised neural outgrowths from these structures. Intruigingly heparanase 2 was found to co-localise with activated ERK (pERK) in the embryonic neural tube, and analysis of the morphants by western blot showed increased levels of pERK, suggesting altered regulation of key signalling pathways. **Conclusion:** Heparanase 2 plays a key role in vertebrate neuromuscular development. A role has been elucidated in ERK signalling, suggesting potential targets for experimental therapies.

P10.14-M
Exome sequencing as a highly efficient diagnostic approach in muscular weakness in newborns and early infancy

S. Papuc[1], *P. Josef[1], M. Zweier[1], L. Gogoll[1], M. Papik[1], A. Klein[2], B. Plecko[2], K. Steindl[1], A. Rauch[1];*

[1]Institute of Medical Genetics, University of Zurich, Zurich, Switzerland, [2]Division of Pediatric Neurology, University of Zurich, Zurich, Switzerland.

Muscular weakness in newborns and early infancy is a challenging clinical feature which may reflect either a neuromuscular disorder or only a secondary feature associated with a primary disorder for example of the central nervous system. Although the first signs may be present in first days of life, the full clinical picture might not be evident in newborns. An earlier and accurate diagnosis in those cases currently depends on a careful clinical assessment followed by the appropriate investigations. Recently developed research tools as next generation sequencing provide a distinct advantage over candidate gene sequencing to discover the underlying genetic defect in a timely manner. In this study, a clinical exome sequencing approach using the Illumina TruSight Rapid Capture Kit was used to investigate the disease-related mutations in 11 infants with unknown conditions presenting with muscle involvement. With a mean average coverage of 394 and at least 20-fold coverage in 98% of the targeted region, we have identified genetic defects in 3 of 7 patients analyzed so far (43%): a previously reported homozygous splice site mutation in the IGHMBP2 gene known to be altered in spinal muscular atrophy with respiratory distress 1, a novel compound heterozygous mutations in the MUSK gene recently associated with congenital myasthenic syndrome, and novel de novo missense mutation in the TPM3 gene involved in congenital fibre-type disproportion myopathy.
Our data suggest that clinical exome sequencing is an efficient tool for timely and accurate diagnosis of clinically and genetically heterogeneous disorders in infants with undiagnosed muscular weakness.

P10.15-S
Interaction among folat/homocysteine metabolism genes and endothelial nitric oxide synthase gene polymorphisms predicts the severity of Duchenne muscular dystrophy in Moldavian patients

V. C. Sacara[1], *V. Scurtu[1], E. Mocan[2], S. Groppa[2], M. Duca[3];*

[1]Institute of Mother and Child, Chisinau, Moldova, Republic of, [2]the State University of Medicine and Pharmacy "Nicolae Testemitanu", Chisinau, Moldova, Republic of, [3]University of AS RM, Chisinau, Moldova, Republic of.

Introduction. We try to modeling gene-gene interaction between 5 mutations in 4 genes, involved in folat/homocysteine metabolism (FHMG) and eNOS- play a pivotal role in vascular homeostasis and endothelial function, that may be alter the severity (in our case on the age at wheelchair dependency- 9 or 12 years) of this genetically simple disease.
Methods: A retrospective single institution long-term follow-up study was carried out in 148 corticosteroids-free DMD patients. The genotyping of

dystrophin gene were performed by the MPCR to detect the deletion in DMD gene and the PCR-RFLP to identify the MTHFRC677Tand A1298C, MTRA2756G, MTRRA66G, eNOS polymorphisms. Gene-gene interactions were analyzed using entropy-based multifactor dimensionality reduction (MDR).
Results: We evaluated single-site allelic and genotypic associations, genotype equilibrium and multilocus genotype associations, using MDR, which failed to show a genetic model of severity of myopathic process. Have been adopted the MDR method to explore the synergistic effects of the studied polymorphisms on modifying to myopathic process. We selected the best model, which included the. MTHFRC677T and A1298C, MTRA2756G, eNOS polymorphisms, cross-validation consistency is 9/10 ($\chi 2$ =54.22, p<0.0001) for case of wheelchair up to 12yrs). Since the selected polymorphisms were not associated with DMD there is evidence for the existence of epistasis between the two polymorphisms MTHFRC677T and eNOS (CVC10/10, $\chi 2$=5.3, p=0.02) in case of wheelchair up to 9yrs.
Conclusion: Our results indicate that the MTHFR, MTR and eNOS genes are modifying loci and presence of the high-risk alleles may associate with an increase in the severity of DMD.

P10.16-M
Limb girdle muscular dystrophy in the Czech Republic

K. Stehlikova[1,2], *D. Skalova*[1,2], *L. Fajkusova*[1,2];
[1]*The Central European Institute of Technology (CEITEC), Masaryk University, Brno, Czech Republic,* [2]*University Hospital, Brno, Czech Republic.*

Limb-girdle muscular dystrophy (LGMD) is defined as a muscular dystrophy with predominantly proximal distribution of muscle weakness. It includes a number of disorders with heterogeneous etiology. We determined the frequency of recessive LGMD subtypes (LGMD2A, LGMD2D, LGMD2I and LGMD2L) within a cohort of Czech LGMD2 patients using mutation analysis of the calpain3 (*CAPN3*), fukutin-related protein (*FKRP*), α-sarcoglycan (*SGCA*), and anoctamin5 (*ANO5*) genes. Last year we introduced next generation sequencing to accelerate patient diagnosis and to widen spectrum of analysed genes. We designed capture library to target the coding exons of genes responsible for all known types of LGMD and genes responsible for muscular dystrophy with similar phenotype to LGMD. We observed that mutations of the *CAPN3* gene are the most common cause of LGMD2. The frequency of particular forms of LGMD2 was 32.6% for LGMD2A, 4.1% for LGMD2I, 2.8% for LGMD2D, and 1.4% for LGMD2L. Using next-generation sequencing, we identified two patients with mutations in the gene encoding dysferlin (*DYSF*) - LGMD2B and a patient with mutations in the gene encoding β-sarcoglycan (*SGCB*) - LGMD2E. In total, we determined mutations in 41 % of Czech LGMD2 patients.

About one third of autosomal recessive limb-girdle muscular dystrophy patients show no mutations in the ARLGMD genes so far identified. The possible explanations are that several genetic cause of LGMD cannot be discovered by traditional DNA sequencing tests, or that the genetic heterogeneity is greater than expected with many other genes that should be analyzed. However, the present genetic testing is long, expensive and ineffective to cope with this second possibility. New powerful approaches for DNA analysis, like next-generation sequencing (NGS) and array CGH are revolutionizing the field, with the entire human genome that can be properly analyzed.
We combined SNP array-based linkage analysis and NGS technology to discover "orphan" LGMD mutations.
The patients to be studied were selected according to the following criteria: a) clinical diagnosis of LGMD; b) inconclusive molecular testing after the complete study of the known LGMD genes c) severity of disease.
A number of mutations were identified. In particular in a LGMD family with an autosomal recessive inheritance, we have recently identified a new homozygous mutation in the ACADVL gene, Acyl-CoA Dehydrogenase- Very Long Chain, that is shared by all the affected family members and by another patient from the same town. In other two family a heterozygous compound mutations and homozygous mutation in the *ACADVL* gene was also found.
This demonstrates that specific amino acid changes in the catalytic domain of the *ACADVL* Very gene may be associated with an LGMD-like phenotype and this should be considered in the differential diagnosis.
