Case I: 9 years-old female, birth: weight 3,400gr, height 53cm. Between 5-6 years-old displayed flesh-colored papules on face. Showed clinical and hystopathological features indicating trichoepithelioma, with keratinizing cystic spaces.

Case II: 42 years-old female showed, flesh-colored-papules on scalp, face and trunk. Three biopsies were reviewed, 1) right preauricular region revealed trichoepithelioma, 2) scalp region conclusive cylindroma, 3) third lumbar región conclusive ecrine spiradenoma. Given cryotherapy treatment and cosmetic surgery with good results.

Discussion:

Brooke-Spiegler syndrome, sex ratio of F:3: M:1. include skin appendage tumors such cylindromas, thichoepitheliomas and spiradenomas, share a common genetic basis. May be associated with other skin disorders such, basal cell adenomas/carcinomas. Treatment included dermabrasion, cryotherapy and some cases radiotherapy. We present a Mexican family, mother and daugther similar affected, with the clinical features of the disease. Is the first mexican case reported with this entity. Molecular studies are needed to understand the genetic bases of the disease.

First molecular analysis of Ehlers-Danlos kyphoscoliotic type in Slavic population

A. Junkiert-Czarnecka[1], *M. Pilarska*[1], *O. Haus*[1,2];

[1]Department of Clinical Genetics Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Toruń, Bydgoszcz, Poland, [2]Department of Hematology, Blood Malignancies and Bone Marrow Transplantation, Medical University, Wrocław, Poland, Wrocław, Poland.

The kyphoscoliotic type of Ehlers-Danlos syndrome (EDS) is a heritable connective tissue disorder characterized by a deficiency of collagen lysyl hydroxylase 1 (LH1) due to mutations in PLOD1 gene. According to Villefranche criteria this type of EDS is characterized by kyphoscoliosis and hypotonia at birth, severe joint hypermobility as well as skin extensibility and fragility. 2-year old girl examined by us was born by caesarean section because of pelvic longitudinal position (situs longitudinalis pelvicus). Directly after the birth, kyphosis, hypotonia, joint hypermobility and unilateral hip dislocation were observed. Parents of investigated child did not present any clinical features of EDS. The gDNA of affected patient was obtained by isolation from peripheral white blood cells. Direct sequencing of all PLOD1 exons was carried out, revealing the presence of two mutations. The first one, substitution of cytosine by thymine in position 1095 (c.1095C>T), was localized in the exon 10. It was a splice site mutation, described earlier. The second one, which turned out to be a missense mutation that had never been described earlier in patients with kyphoscoliotic type of EDS, was localized in exon 17.
Our investigations of genetic background of kyphoscoliotic type of Ehlers-Danlos syndrome were the first ones in East-Central Europe.

Atypical Fibrodysplasia Ossificans Progressiva (FOP) phenotype in a girl carrying uncommon missense mutation (p.G356D) in ACVR1

A. Poluha[1], *A. Sobczynska-Tomaszewska*[2], *J. Postepski*[3], *M. Babicz*[4], *M. Holweg*[4], *I. Jaszczuk*[1], *M. Lejman*[4], *B. Styka*[4], *D. Winnicka*[4], *J. Kowalczyk*[5];
[1]Division of Medical Genetics, Department of Pediatric Hematology, Oncology and Transplantology, Childrens University Hospital, Lublin, Poland, [2]Medgen, Warsaw, Poland, [3]Department of Pediatric Pulmonology and Rheumatology, Medical University, Lublin, Poland, [4]Cytogenetic Laboratory, Childrens University Hospital, Lublin, Poland, [5]Department of Pediatric Hematology, Oncology and Transplantology, Medical University, Lublin, Poland.

Fibrodysplasia ossificans progressiva (FOP, MIM #135100) is a rare genetic condition characterized by progressive transformation of soft tissue into bone. There are approximately 3 000 individuals living worldwide with this severely disabling disease, for which there is still no definitive treatment. Heterozygous mutations in ACVR1 (MIM# 102576) has been identified as a cause of this condition. All reported patients of various ethnic backgrounds with classic clinical presentation of FOP have previously been found with the identical heterozygous activating mutation 617G>A(R206H). Recently other types of mutations in ACVR1 gene have been described in patients with variant FOP.
We present a course of FOP in 3,5 years old girl carrying uncommon missense mutation 1067G>A(G356D) in the protein kinase domain of ACVR1. Identical mutation has been identified in several patients with atypical FOP among which at least in two with mild clinical symptoms. On contrary, our patient experiences a severe course of FOP with already significant restriction of movement. Though it should be emphasized, that retrospectively analyzing evolution of intense heterotopic ossification in our patient, we have discovered, that most of the lesions were directly triggered by soft tissue injuries resulting from diagnostic procedures and inadequate rehabilitation that she underwent prior to recognition of her genetic disease.
Our presentation may add to the understanding of the variability of clinical FOP presentation in patients with atypical ACVR1 mutations, as well as help spreading knowledge of this disease among health care professionals, in hope for the earliest possible diagnosis established in each newly affected child.

J04.11
Genetic characterization of a Portuguese patient with fibrodysplasia ossificans progressiva

S. Sousa[1], *C. Corzo*[2], *I. Alonso*[1,3], *J. Silva*[1], *J. Sequeiros*[1,3,4];
[1]CGPP, Instituto de Biologia Molecular e Celular (IBMC) Univ. Porto, Porto, Portugal, [2]Hospital do Espírito Santo - Évora, Unidade de AVC, Évora, Portugal, [3]UnIGENe, IBMC, Univ. Porto, Porto, Portugal, [4]ICBAS, Univ. Porto, Porto, Portugal.

Fibrodysplasia ossificans progressiva (FOP) is a rare autosomal dominant disease with a prevalence of approximately 1 in 2 million worldwide. FOP is characterized by the presence of malformations of the big toes and of postnatal progressive heterotopic endochondral osteogenesis, especially in the presence of exacerbating factors such as trauma, surgical intervention, lesion biopsy, and intramuscular injection. FOP has been associated with a specific mutation on ACVR1 (c.617G>A; p.Arg206His), which encodes a receptor for bone morphogenetic proteins (BMPs). Our aim was to establish the molecular diagnosis by mutation screening of ACVR1. We report a male patient with progressive ossificans since childhood, showing calcification of the axial line with inability to perform flexion and extension of the scapular and pelvic girdle with neck stiffness. Surgical intervention in adolescence resulted in disease progression. At the moment, patient is bedridden and with partial jaw fixation. Mutation screening was performed by PCR amplification of all coding and flanking regions, followed by bidirectional direct sequencing. We have found one missense mutation in exon 6 (c.617G>A; p.Arg206His), previously described as a FOP disease-causing mutation. The codon 206 is at the end of the highly conserved glycine-serine rich (GS) activation domain at the junction with the kinase domain. To our knowledge, this is the first genetic study of FOP in a Portuguese patient. The mutation screening of ACVR1 distinguishing FOP from other disorders allows the correct clinical management of the patient. Molecular diagnosis will also allow appropriate genetic counseling to this patient and at-risk relatives.

J04.12
First Italian case of Crouzon-like Craniosynostosis and Dental Anomalies (CRSDA, #614188) with severe scoliosis

G. Gai[1], *P. Nieminen*[2], *V. G. Naretto*[1], *F. Sirchia*[1], *A. Zonta*[1], *C. Arduino*[1], *P. Bibbò*[1], *E. Grosso*[1];
[1]S.C. Genetica Medica - U. - AOU Città della Salute e della Scienza, Torino, Italy, [2]Institute of Dentistry - University of Helsinki, Helsinki, Finland.

Crouzon-like craniosynostosis and dental anomalies (CRSDA, #614188) is an autosomal recessive disorder due to homozygous mutations of the IL11-RA gene.
Our patient (a 16-years-old boy) was referred to our Clinic for oxycephaly with frontal bossing and biparietal narrowing. By the age of 4 years he underwent a surgical correction because of raised intracranial pressure with optic nerve atrophy. He had maxillary hypoplasia with malocclusion, persisting deciduous teeth and supernumerary teeth (1.3, 2.3, 3.1, 4.2) treated by surgical correction, severe dorsal scoliosis with right convexity and thorax asymmetry. Encephalus and spine MRI showed a Chiari I malformation, and enlarged dural sac.
His parents were first cousins hailing from Southern Italy (Naples); his father underwent scoliosis surgical correction by the age of 19 years.
Molecular analysis of IL11RA gene in the proband identified a homozygous mutation c.598C>A (p.Pro200Thr) in exon 6; bioinformatic analyses by PolyPhen2 and SIFT suggested that this mutation is harmful for the protein function.
The mutation has been previously described by Keupp et al. (2013) in a non-consanguineous Turkish family in two siblings compound heterozygous c.598C>A /c.710G>C. It is also present in the databases as a rare variant
To our best knowledge, this is the first description of an Italian patient affected by CRSDA. We speculate that severe scoliosis, not previously described in affected patients, could be included in the clinical spectrum of the syndrome.

J04.13
The role of polymorphisms of inflammatory mediators genes in pyoinflammatory diseases of maxillofacial area

I. R. Minniakhmetov[1], *A. Suleimanov*[2], *I. Gizzatullin*[2], *E. Shut*[1], *R. Latypov*[1], *E. Khusnutdinova*[1];
[1]Institute of Biochemistry and Genetics, Ufa, Russian Federation, [2]Bashkir State Medical University, Ufa, Russian Federation.

Despite advances in the treatment of pyoinflammatory diseases of maxillofacial area, the number of diseases is increasing from year to year. In this connection, the study of the pathogenesis of pyoinflammatory diseases is one of the most pressing issues in maxillofacial surgery. The purpose of this study was to investigate the role of the cytokines genes in the development of odontogenic inflammatory processes.
To estimate the role of polymorphisms of inflammatory mediator genes in genetic predisposition to pyoinflammatory diseases, the allele and the genotype frequencies distributions of IL1β, IL1RA, TNFα, TNFβ and IL10 genes were investigated. The studied groups included 189 patients with pyoinflammatory diseases of maxillofacial area divided into two groups: odontogenic phlegmon (141) and osteomyelitis (48) and 105 healthy controls. Genomic DNA was extracted from peripheral blood leukocytes by standard phenol/chloroform method. Genotyping was performed by the PCR-RFLP technique.
Studies have revealed that the C*A* genotype (OR = 1,83; 95% CI 1,08-3,10) of IL10 polymorphic locus 627C>A is associated with increased risk of odontogenic phlegmon, while the G*A* genotype (OR = 0,29; 95% CI 0,08-1,04) of TNFα polymorphic locus 308 G>A is associated with lower risk of osteomyelitis of maxillofacial area. It is possible to suggest that genotype C*A* of IL10 polymorphism (627C>A) and genotype G*A* of TNFα polymorphism (308 G>A) may be genetic predictor of odontogenic inflammatory processes. No significant differences were found between the groups of patients and

healthy control concerning the genotype frequencies of the polymorphisms IL1β (3953 C>T), IL1RA (VNTR) and TNFβ (1069 C>T).

Icthyiosis, the XXI century pandemy of Ecuador

A. E. Toapanta Ortiz, *M. Cartelle Gestal, R. Velez;*
Faculty of Public Health. ESPOCH, Riobamba, Ecuador.

Ichthyosis is a group of inherited keratinizing disorders. There are five different types described. This type of genetic disorder can be autosomal recessive or x-link. This disorder has been related with inbreeding and new mutations. More than 16000 babies are born each year with some form of ichthyosis. In Manabí province, Ecuador (population 1,369,780) there are more than 230 cases, compared with rates of other countries this is very high. But when put into context, Ecuador is a developing country, in more isolated areas marriage between closely related family members is still common place. We are presenting a case of twin brothers that suffer from ichthyosis.
Case report: Mother and father are first cousins. They are parents of three children, one girl and two tween brothers. The boys present the typical fish scales, alopecia, constant conjunctivitis and skin infections. We found isolates of different microrganisms in all samples taken from eyes, skin and wounds. They present constant weeping of the eyes and intense itching. They do not eat pork due metabolic disorders associated with this dissease. After living in several places in Ecuador, they moved to Banos a small city in the Andes (1,815 m) because the moderate climate (moisture and temperature) is more favorable to their condition. Their treatment is: Rocutan (isotretinoin) for 2 weeks and after that Neotigason (retinoids, 25 mg every day or two). Their pathology has improved a lot since then. They do not show signs of hyperactivity or any mental problems.

J04.15
Lacrimo-auriculo-dento-digital syndrome, case report

A. Mitroi, *A. Apostol, M. Aschie, G. Cozaru;*
Emergency Clinical County Hospital of Constanta, Constanta, Romania.

Lacrimo-auriculo-dento-digital syndrome (Levy-Hollister syndrome) (MIM:149730), is a extremly rare genetic disorder (prevalence < 1/1 000 000) characterised by abnormalities affecting the lacrimal and salivary glands and ducts, ears, teeth and fingers. Levy-Hollister syndrome may occur sporadicaly or be inherited as an autosomal dominant trait. We present a 16 years old index male patient clinicaly diagnosed with this syndrome. Our patient present recurrent obstruction of nasal lacrimal ducts and bilateral agenesia of parotid glands. The auricular feature was cup-shaped pinnas. The dental features were represented by hypodontia, microdontia, spaced teeth, enamel dysplasis and early onset caries. The limb defects were fifth finger clinodactily, hipoplasia of thenar eminence and absence of thumb flexion creases. No family history was found in our case. Due to agenesia of parotid glands is possible that our case shuold be the result of FGF10 de novo mutation. We compare the phenotype and findings of our case to previuosly published cases.

A Novel mutation in SHOX gene in four members with Langer Mesomelic Dysplasia and in three members with Leri-Weil Dyschondrosteosis of a family

F. Hazan[1], *A. Aykut*[2], *H. A. Korkmaz*[3], *B. Ozkan*[3], *F. Ozkinay*[2], *H. Onay*[2], *O. Cogulu*[2];
[1]*Department of Medical Genetics, Dr. Behcet Uz Children's Hospital, izmir, Turkey,*
[2]*Department of Medical Genetics, Ege University Faculty of Medicine, izmir, Turkey,*
[3]*Department of Pediatric Endocrinology, Dr. Behcet Uz Children's Hospital, izmir, Turkey.*

Leri-Weill dyschondrosteosis (LWD; #MIM 127300) is an autosomal dominant hereditary disease, which is characterized by short stature, mesomelic shortening of the limbs, and characteristic bilateral abnormality of the wrists known as Madelung deformity. LWD is caused by mutations in the Short Stature Homeobox gene (*SHOX).* The other diseases which are associated with *SHOX* gene mutations are Langer Mesomelic Dysplasia (LMD, MIM #249700) and Turner syndrome as well as nonsyndromic idiopathic short stature (ISS). The *SHOX* gene is localized within the pseudoautosomal region 1 (PAR1) of the X and Y chromosomes. Both alleles of *SHOX* gene must be functional for normal growth. While heterozygous mutations of *SHOX* gene or its enhancer regions are responsible for both LWD and ISS syndromes, LMD is caused by homozygous or compound heterozygous mutations in this gene. Herein, four LMD and one LWD siblings and their consanguineous parents with LWD are presented. Mutation analysis revealed that the parents and one sibling were heterozygous, and the other 4 siblings were homozygous for the c.42delG (p.Q14QfsX15) in the *SHOX* gene.

A novel mutation in LEMD3 gene in a Turkish family with Buschke-Ollendorf syndrome

S. Ulusal[1], *H. Gürkan*[2], *M. Çiftdemir*[3], *H. Tozkir*[1], *K. Sarıdoğan*[4];
[1]*Trakya University Faculty of Medicine, Department of Medical Genetics, Edirne, Turkey,*
[2]*Trakya University, Faculty of Medicine, Department of Medical Genetics, Edirne, Turkey,*
[3]*Trakya University, Faculty of Medicine, Department of Orthopedics and Traumatology, Edirne, Turkey,* [4]*Trakya University Faculty of Medicine, Department of Orthopedics and Traumatology, Edirne, Turkey.*

Buschke-Ollendorff Syndrome (BOS, OMIM#166700) is an autosomal dominant disorder of connective tissue with an incidence of 1/20000. Although It is characterized by multiple subcutaneous nevi or nodules and osteopoikilosis (OPK), some patients may also have melorheostosis. Expressivity of bone and skin manifestations differs between the cases. Mutations in LEM Domain-Containig Protein-3 (*LEMD3*, OMIM *607844, chromosome 12q14.3) have been implicated in BOS. 14-year-old girl was directed to our department for an incidentally realised osteopoikilosis in the X-Ray exploration. She also has yelowish plaques on her anterolateral thigh. Complete X-Ray study revealed multiple osteoclastic foci around the bones as implicated in te BOS. 35-year-old mother has been X-Ray examined and she also has ospteopoikilosis but she has no skin plaques. *LEMD3* gene was sequenced from the DNA of the patient and the mother. Both of them have a heterozygous c.2405_2406insAGTG mutation in the 12th exon of LEMD3 gene.This mutation results in a premature stop codon at the 802th position of the MAN1 protein encoded by *LEMD3* gene. The remaining parts of the gene were also sequenced and confirmed that there was not another mutation. We submit the mutation to MutationTaster and see that it causes loss of Interaction with SMAD1, SMAD2, SMAD3 and SMAD5. To our knowledge, this is the first study implicating the c.2405_2406insAGTG mutation in the cases of BOS.

J04.18
HRM scanning of mutations in human structural proteins

R. Blatny[1], *L. Homolova*[1], *J. Vasak*[1], *V. Krivjansky*[1], *V. Filimonenko*[2], *L. Jarolimova*[2], *I. Novakova*[2], *P. Hozak*[2], *M. Krivjanska*[1];
[1]*KRD molecular technologies Ltd., Prague, Czech Republic,* [2]*Institute of Molecular Genetics, Prague, Czech Republic.*

Background: This project aims at the development of assays for detection of mutations in structural proteins. Both intracellular (cytoskeleton and nucleoskeleton) and extracellular proteins (extracellular matrix) are considered, as well as non-structural proteins which are closely functionally associated with these structural proteins. Mutations in the selected proteins are known to cause rare diseases (RD). The project resonates with current clinical need to improve diagnostics and prognostics of rare diseases as formulated in many running national and European programs (e.g. Czech National Action Plan for Rare Diseases, COST NANONET, ORPHANET, EURORDIS, ERNDIM, EUROCAT, ICBDSR, E-rare ERA). **Methods:** The main detection method chosen is the scanning high-resolution melting analysis. The primers were designed for 65 subselected genes. The amplicons are succesively optimized to fit maximally two major PCR/HRM conditions for each gene. The following assays have been technically finalized on control DNA and both major tested platforms (LightScanner 96 and LightCycler 480): LMNA, MYH7, DMD, ACTC1, MYH6, MYL2, MYL3, DES, MYLK2, MYH14, MYH9 and MYO6. LMNA, MYH7 and DMD is currently undergoing testing on positive patient and synthetic DNA samples. **Results:** Female patient, 35 years old, with suspected Emery-Dreifuss muscular dystrophy was scanned using the LMNA scHRM assay. The scanning revealed putative mutation in the exon 6 of the LMNA gene which was confirme by the Sanger sequencing. Additional reported cases with mutations in the DMD and MYH7 genes will follow. This work is supported by the FR-TI3-588 grant from the Ministry of Industry and Trade of the Czech Republic.

J04.19
A novel homozygote p.Met540Ile LMNA mutation causes mandibuloacral dysplasia type A

V. R. Yassaee[1,2], *A. Khojasteh*[3], **F. Hashemi-Gorji**[1], *P. Toossi*[4], *S. M. Poorhosseini*[2], *S. R. Mazhari*[2];
[1]*Genomic Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Dept. of Medical Genetics, Faculty of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*Dept. of Craniofacial Surgery, Faculty of Dentistry , Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [4]*Dept. of Dermatology, Skin Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Mandibuloacral dysplasia with type A lipodystrophy (MADA) is a rare genetic disorder inherited in an autosomal recessive fashion characterized by hypoplasia of the mandible and clavicles, acro-osteolysis and lipodystrophy due to mutations in LMNA or ZMPSTE24 gene. Very few families have been studied for the above genes alteration so far. We have investigated a consan-

guineous family with an affected boy for LMNA alteration. Isolated genomic DNA derived from subjects was amplified using intronic primers. The entire sequence of the LMNA gene, including coding regions and exon-intron boundaries were analyzed by PCR and Sanger sequencing. Molecular analysis ascertained a homozygote mutation c.1620 G>A (p.M540I) in the proband and heterozygote alteration in the rest of the family. We have also applied several online tools including PolyPhen2, Pmut, SIFT, Mutation Taster and phyre2 to predict the p.Met540Ile substitution effects. All these tools showed reduction the stability of the protein structure. We conclude that M540I mutation may causes disease in homozygous state.

J04.20
Atrophic skin patches with abnormal elastic fibers, as a presenting sign of MASS phenotype associated with mutation in the Fibrillin-1 gene

E. Reinstein, *J. Nevet, H. Shoshany, R. Bergman;*
Rambam Medical Center, Haifa, Israel.

Marfan syndrome (MFS) is a dominantly inherited disorder of connective tissue caused by mutations in the Fibrillin-1 (FBN1) gene. The most common skin finding in MFS is striae distensae. Particular individuals referred for suspicion of MFS whom do not completely fulfill the MFS diagnostic criteria are classified as having a MASS phenotype. The acronym represents the phenotype's apparent manifestations: a prolapsed Mitral valve, Myopia, Aortic root enlargement, Skeletal and Skin manifestations. Mutations in FBN1 have been shown to be associated in a few cases with MASS phenotype. Skin manifestations may be an important clue to the diagnosis of these disorders. We studied a case referred for unusual atrophic skin patches on the buttocks. Histopathology and electron microscopy demonstrated markedly abnormal elastic fibers. Consequent medical genetics evaluation led ultimately to the diagnosis of MASS phenotype, and to the discovery of an underlying FBN1 mutation.
Though the clinical suspicion and diagnosis of MFS and related disorders are usually established by its main associated clinical features including the eye, skeletal and vascular involvement, clinicians should be aware of the associated skin manifestations, including unusual atrophic patches with abnormal elastic fibers that can sometimes be the first noted sign of the genetic disorder.

J04.21
Novel *COL9A3* mutation in a family diagnosed with multiple epiphyseal dysplasia

A. Kwon[1], *J. Kim*[1], *H. Choi*[1], *H. Park*[2], *P. Kim*[3], *Y. Lee*[3], *J. Jung*[3], *H. Chea*[2], *M. Kim*[2];
[1]*College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,* [2]*Department of Laboratory Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,* [3]*Syntekabio Inc., Seoul, Korea, Republic of.*

Background : The clinical and radiographic phenotypes of multiple epiphyseal dysplasia(MED) are heterogenous according to the genetic mutation. Mutations *COMP*, *MATN3*, *COL9A1*, *COL9A2* and *COL9A3* result in autosomal dominant MED, and mutations in the *DTDST* gene is associated with an autosomal recessive MED. Here in, we present a family with novel *COL9A3* gene mutation.
Case : The proband was a 12-year-old boy born from non-consanguineous parents. He was referred to the pediatric orthopedic clinic for the evaluation of intermittent knee pain that occurred from a few months. The radiographic phenotype of COL9-MED is that the epiphysis of the distal tibia, distal radius and distal ulnae showed lateral shortening, wedge shape and small, respectively. Direct sequencing of COL9-MED associated genes was performed and identified a novel mutation c.104G>A in exon 2 of *COL9A3*, which resulted in p.Gly35Asp. The same mutation was observed in the proband's father. The molecular dynamics (MD) simulation of wild type and mutant model structure were performed using AMBER11 program and demonstrated that the mutant type collagen was aggregated by themselves while wild type structure formed hydrogen bonds with its neighboring strand. In addition, the distances between the mutation site of the wild type and the mutant collagen are almost twice. The calculated energy state of the mutant is much lower, causing a self aggregation.
Conclusion : We report a family of MED with novel *COL9A3* mutation and propose that major structural change caused by the mutation of COL9A3 gene induce the malfunction of the type IX collagen.

J04.22
Neurofibromatosis-Noonan Syndrome - clinical and molecular studies of 4 patients

A. Kutkowska-Kaźmierczak[1], *M. Gos*[1], *S. Fahiminiya*[2], *A. Abramowicz*[1], *J. Klapecki*[1], *J. Majewski*[2], *J. Bal*[1], *E. Obersztyn*[1];
[1]*Department of Medical Genetic, Institute of the Mother and Child, Warsaw, Poland,* [2]*Department of Human Genetics, McGill University and Genome Quebec Innovation Centre, Montreal, QC, Canada.*

Neurofibromatosis-Noonan syndrome (NFNS) (OMIM 601321) combines the variable clinical signs of both entities – Neurofibromatosis type I (NF1) (OMIM 162200) and Noonan syndrome (NS) (OMIM 163950). All these clinical disorders belong to the RASopathies caused by the dysregulation of the RAS/MAPK pathway. The phenotype of NS includes short stature, heart defects (particularly pulmonary stenosis), chest deformities, ptosis, bleeding abnormalities and dysmorphic features. The clinical features of NF1 are: café-au-lait (CAL) spots, neurofibromas, Lisch nodules, axillary and inguinal freckling, optic glioma and skeletal defects. In the majority of patients with NFNS the mutation in *NF1* gene is found. In few patients also the mutation in *PTPN11* was identified.
We present 4 patients with clinical features of NFNS with multiple CAL spots (all patients), relative macrocephaly consistent with NF1 (2 patients) and patchy depigmentation of skin (1 patient). None of them had neurofibromas. Dysmorphic features and heart defects (mitral or aortic valve prolaps, descrete pulmonary stenosis) specific for NS were present in all patients. The short stature and myopia were observed in 2 patients, speech delay, ptosis, occipital region cyst, submucous cleft palate, pectus deformity, unilateral cryptorchidism and bleeding abnormalities in 1 patient. The mutations in *NF1* gene were identified in all patients. No mutation was found in the *PTPN11* gene. This and previous studies indicate that there are significant phenotypic differences between NFNS and NF1 or NS. Detailed comparison of NFNS clinical symptoms in described group of patients with data from publications as well as genotype-phenotype correlation will be presented.

J04.23
Expression of the genes that are indicators of young bone growth and histological analysis in evaluation of osteogenic process

M. Vukelic[1], *S. Najman*[1], *P. Vasiljevic*[2], *T. Jevtovic-Stoimenov*[1];
[1]*Medical Faculty, University of Nish, Nish, Serbia,* [2]*Faculty of Science and Mathematics, University of Nish, Nish, Serbia.*

Osteoreparation is a complex, dynamic and still incompletely revealed process. There are different approaches in evaluation of osteogenic process. The purpose of our research is evaluation weather and to what extent relative expression of genes that are indicators of young bone growth are in correlation with histological findings, as commonly used methods for evaluation of osteogenic process. In our research, subcutaneous implantation model on Balb/c mice was used. The implants were composed from deproteinized bone mineral matrix and bone marrow and/or different components of blood. The animals were sacrificed after 1, 2, 4, and 8 weeks after implantation. Analysis of implants included comparison of relative expression profiles of the gene for alkaline phosphatase, osteocalcin, osteonectin, osteopontin and collagen type I (RealTime PCR) and histological analysis of implants after staining with hematoxylin-eosin and Masson's trichrome method. Our results show: the most informative genetics markers are profiles of expression of genes for osteocalcin and alkaline phosphatase, as indicators of stimulation of young bone growth; histological picture was lagging in comparison to the findings of gene expression in all terms of sacrifice; valid assessment of osteogenic process requires a combination of different methods, because neither gene expression nor histological analysis are sufficient for complete evaluation of osteogenic process.
Key words: RealTime PCR, histology, ectopic osteogenesis

Bone mineral accrual and fracture outcomes in children with osteogenesis imperfecta treated by pamidronate

M. M. Kostik[1], *I. A. Chikova*[1], *N. V. Buchinskaya*[1], *O. V. Kalashnikova*[1], *L. A. Scheplyagina*[2], *V. I. Larionova*[3];
[1]*State Pediatric Medical University, Saint-Petersburg, Russian Federation,* [2]*Moscow scientific and research clinical institute named M.F. Vladimirskiy, Moscow, Russian Federation,* [3]*Turner's Scientific and Research Institute for Children's Orthopedics, Saint-Petersburg, Russian Federation.*

The purpose of this study was to evaluate the bone mineral accrual and fracture outcomes in children with osteogenesis imperfecta (OI) treated by pamidronate (PAM). Material and Methods: in our retrospective study 21 children with different types of OI were included: 7 boys and 14 girls. According to clinical OI classification proposed by D. Sillence, patients were divided in 3 types: I type - 11, III type - 7, IV type - 3. We divided patients in 2 groups: mild to moderate (OI I type) and moderate-to severe (III and IV types). The standard protocol with cyclic PAM infusions (3 consequent days 3-4 times in a year) was applied in annual cumulative 9-12 mg/kg. All children received vitamin D and calcium supplementation in physiological doses. Observation period was 36 months. Bone mineralization parameters were detected by dual-energy X-ray absorptiometry of lumbar spine L1-L4. Results: There were no differences in bone mineral accrual between types

of OI. The maximum efficacy in bone mineral accrual was observed in first year (+32.9%) and second year (+22.1%) and no real improvement in BMD in third year. Reduction of fractures in OI I types was from 0.87 (0.64; 1.08) to 0 (0.0; 0.5) fractures per year (p=0.09). In severe OI group fracture reduction was more impressive: from 28.5 (4.6; 56.2) to 1.1 (0.86; 2.6) fractures per year (p=0.02). Conclusion: PAM treatment was effective in bone mineral accrual and fracture reduction. The maximum efficacy in bone mineral accrual was observed in first two years.

Medical approach in a severe case of osteogenesis imperfecta

D. Stoicanescu[1], *M. Ceveī*[2];
[1]*University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania,* [2]*University of Oradea, Faculty of Medicine and Pharmacy, Oradea, Romania.*

Osteogenesis imperfecta is one of the most common skeletal dysplasias and comprises a group of genetic disorders that are characterized by increased bone fragility, low bone mass and increased susceptibility to bone fractures. The inheritance is autosomal dominant, but it may also results from new dominant mutations. We present the case of a young woman, 27 years old, retired, diagnosed with osteogenesis imperfecta in early childhood. She has negative family history, thus, it was considered to be due to a new mutation. The first fractures, double fracture of tibia and femur occured during infancy, after minor trauma. Until now more than twenty bone surgical treatments were needed. The patient has very short stature, severe scoliosis, deformed thorax, dorsal kyphosis, muscular and bone pain, poor muscle tone, osteoporosis, dentinogenesis imperfecta, white sclera, signs that led to the clinical diagnosis of osteogenesis imperfecta type III. Functional independence is affected due to low muscle strength, especially in the lower extremities, with a tendency to fall, due to reduced joint mobility and not least because of the pain. Complex therapies include not only surgery, but also medication, secondary prophylaxis with healthy lifestyle and diet, and application of early rehabilitation programs. Management of subjects with osteogenesis imperfecta, especially severe forms, by a multidisciplinary team, increase psychomotor development, improve quality of life and prevent fractures with major vital risk.

J04.26
LRP5 gene polymorphism V667M (rs4988321) in man with osteoporosis and Polish population - a pilot study

M. Kaczmarek-Ryś[1], *M. Ignaszak-Szczepaniak*[2], *J. Hoppe-Gołębiewska*[1], *S. T. Hryhorowicz*[3], *A. Pławski*[1], *R. Słomski*[1,4];
[1]*Institut of Human Genetics, Polish Academy of Sciences, Poznań, Poland,* [2]*Department of Familly Medicine, University of Medical Sciences, Poznań, Poland,* [3]*Nanobiomedical Center, Adam Mickiewicz University, Poznań, Poland,* [4]*Department of Biochemistry and Biotechnology, University of Life Sciences, Poznań, Poland.*

Many recent reports confirmed, in the disease onset, both genetic and environmental factors, may be different in osteoporosis for women and men. Mutations in the low-density lipoprotein receptor-related protein 5 (LRP5) gene cause rare syndromes characterized by altered bone mineral density (BMD). LRP-5 is a transmembrane protein encoded by gene located in 6q25.1. LRP-5 protein takes part in a proliferation and differentiation of osteoblasts via Wnt signaling. The Wnt/b-catenin signaling pathway stimulates bone formation through a number of mechanisms such as stimulation of preosteoblast replication, induction of osteoblastogenesis, and inhibition of osteoblast and osteocyte apoptosis. LRP-5 is widely expressed in most human tissues, with greater amounts in the liver and pancreas. In bone, it is mainly expressed by the bone-forming cells as osteoblasts, in the endosteal and trabecular bone surfaces. Common LRP5 variants were associated with the osteoporosis risk in males. The aim of this pilot study was to analyze occurrence of polymorphic variant c.2074G>A (p.V667M, rs4988321) in a group of 187 male patients with osteoporosis and 203 individuals from Polish population. Genotyping was performed by pyrosequencing technique. Hardy-Weinberg equilibrium (HWE) were examined for subjected groups by chi-square distribution and Fisher exact tests. The odds ratios (ORs), 95% confidence intervals (CIs), and p-values were calculated. Statistical significance was set at $p<0.05$. We observed statistically relevant higher frequency of minor allele c.2074A in male osteoporosis patients with p=0.01401 (OR=2.162, CI=[1.154-4.050). In conclusion we state that c.2074A in LRP5 gene variant may be one of the risk factor for osteoporosis in males.

Association of gene variants in TLR4, TNF-α, IL-3 and IL-6 genes with Perthes disease

S. Srzentic[1], *V. Spasovski*[1], *D. Spasovski*[2,3], *Z. Zivkovic*[4], *D. Matanovic*[2,5], *Z. Bascarevic*[2,3], *Z. Terzic Supic*[2], *M. Stojiljkovic*[1], *T. Karan-Djurasevic*[1], *B. Stankovic*[1], *S. Pavlovic*[1], *G. Nikcevic*[1], *Z. Vukasinovic*[2,3];
[1]*Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia,* [2]*Faculty of Medicine, University of Belgrade, Belgrade, Serbia,* [3]*Institute for Orthopaedic Surgery „Banjica", Belgrade, Serbia,* [4]*Clinical Center „Dr Dragisa Misovic", Belgrade, Serbia,* [5]*Clinic for Physical Medicine and Rehabilitation, Clinical Center of Serbia, Belgrade, Serbia.*

Background: Perthes disease is idiopathic avascular osteonecrosis of the hip in children, with unknown etiology. Inflammation is present during development of Perthes disease and it is known that this process influences bone remodeling. Since genetic studies related to inflammation haven't been performed in Perthes disease so far, the aim of this study was to analyze the association of frequencies of genetic variants of immune response genes: toll-like receptor 4 (*TLR4*), tumor necrosis factor alpha (*TNF-α*), interleukin-3 (*IL-3*) and interleukin-6 (*IL-6*) with this disease.
Methods: The study cohort consisted of 37 patients with Perthes disease and 50 healthy controls from Serbia. Polymorphisms of *TLR4* (Asp299Gly, Thr399Ile), *TNF-α* (G-308A) and *IL-6* (G-597A, G-174C) genes were determined by polymerase chain reaction restriction fragment length polymorphism method, while *IL-3* gene polymorphisms (C-16T, C132T) were determined by direct sequencing of PCR product.
Results: *TLR4* polymorphisms (Asp299Gly, Thr399Ile) were in complete, while *IL-3* (C-16T, C132T), as well as *IL-6* (G-597A, G-174C) polymorphisms were in perfect linkage disequilibrium. A statistically significant increase of heterozygote subjects for *IL-6* G-174C/G-597A was found in controls in comparison to Perthes patient group (P=0.047, OR=2.49, 95% CI=1.00-6.21). Also, the patient group for *IL-6* G-174C/G-597A polymorphisms wasn't in Hardy-Weinberg equilibrium. No statistically significant differences were found between patient and control groups for *TLR4* , *TNF-α* or *IL-3* analyzed polymorphisms.
Conclusion: Our results suggest that children who are heterozygous for the *IL-6* G-174C/G-597A polymorphisms have a lower chance of developing Perthes disease than carriers of both homozygote genotypes.

J04.28
Medical Management in Pierre-Robin Sequence

M. Puiu, *A. Chirita-Emandi, S. Talpos, G. Doros;*
Victor Babes University of Medicine and Pharmacy, Timisoara, Romania.

Background: Dysregulation of the genes SOX9 and KCNJ2 may be involved in Pierre-Robin Sequence, evidenced by a familial translocation with a breakpoint located in the gene empty region between SOX9 and KCNJ2, and by reduced expression of SOX9 and KCNJ2 in non-translocated patients. Pierre-Robin Sequence congenital craniofacial malformations associated with obstructive sleep apnoea, results in decreased pharyngeal airway, which, in severe cases, may lead to tracheostomy dependence. We aim to highlight management difficulties in such a case. Material and method: An 11 year old male diagnosed with Pierre-Robin sequence presented to our clinic for multidisciplinary management. Results: The child presents craniofacial anomalies associated with severe microretrognathia, protruding ears, hypotelorism, malocclusion, bilateral simian crease and sandal gap sigh, short stature, failure to thrive, severe difficulties in feeding and sleep apnoea. Blood work was unremarkable. Head CT revealed: severe microretrognatia and crowding of teeth (Angle type I- neutrocclusion). Sleep studies have demonstrated obstructive sleep apnoea. He did not require tracheostomy, but will undergo mandibular distraction in an attempt to relieve the severe upper airway obstruction and improve his sleep pattern and food ingestion and chewing. Conclusions: Infants with Pierre-Robin Sequence should be evaluated by a multidisciplinary team to assess the anatomic findings, delineate the source of airway obstruction, and address airway and feeding issues, but also genetic counceling for the family.

J04.29
First molecular-genetic analysis of Rothmund-Thomson syndrome in Serbia

I. Novakovic[1], *M. Ristanovic*[1], *V. Dobricic*[2], *M. Nikolic*[1,3];
[1]*Faculty of Medicine, Belgrade, Serbia,* [2]*Neurology Clinic CCS, Belgrade, Serbia,* [3]*Dermatology Clinic CCS, Belgrade, Serbia.*

Rothmund-Thomson syndrome (RTS) is an autosomal recessive genodermatosis presenting with a characteristic facial rash (poikiloderma) associated with short stature, sparse scalp hair, sparse or absent eyelashes and/or eyebrows, juvenile cataracts, skeletal abnormalities, radial ray defects, premature aging and a predisposition to cancer. The prevalence is unknown but several hundred cases have been reported in the literature so far. Two clinical subforms of RTS have been defined: RTSI characterised by poikiloderma, ectodermal dysplasia and juvenile cataracts, and RTSII characterised by poikiloderma, congenital bone defects and an increased risk of osteosarcoma in childhood and skin cancer later in life. RTS is genetically heterogeneous: RTSII is caused by homozygous or compound heterozygous mutations in the RECQL4 helicase gene (detected in 60-65% of RTS patients), whereas the

aetiology in RTSI remains unknown. According to literature data missense mutations are rare, while frameshift, nonsense mutations and splice-site mutations prevail. We describe 5 years old girl with typical signs of RTSII and indication for molecular genetic testing of RECQL4 mutations. After extraction of genomic DNA from peripheral blood we performed direct sequencing of mutation prone exons of RECQL4 gene. Two different mutations have been detected in exon 9: c.1568G>C (p.Ser523Thr) and c.1573delT (p.Cys525AlafsX33). The observed frame shifting deletion is the most common RECQL4 mutation, while substitution is rarely described. This is the first case of RTSII from Serbia confirmed by genetic testing. Genetic testing of RTSII is important in the context of differential diagnosis and genetic counseling for patients and their families.

J04.30
A family with proximal symphalangism (SYM1)

M. Smerdel[1], *M. Joergensen*[2];
[1]*Vejle Hospital, Department of Clinical Genetics, Vejle, Denmark,* [2]*Vejle Hospital, Department of Clinical Genetics and Faculty of Health Sciences, University of Southern Denmark, Vejle, Denmark.*

Background: A 33 year old woman was referred to genetic counselling with a family history of congenital stiffness of the digits. Absence of the proximal interphalangeal joints of all fingers except the pollex, and fusion of the calcaneus naviculare and calcaneus cuboideum had previously been diagnosed radiographically. At the physical examination, stiff digits and poorly discernable skin crease was found along with severe pes planus. The pedigree demonstrated autosomal dominant inheritance with four generations of affected family members presenting with stiff fingers, fusion of foot bones and at least one sister with impaired hearing as a result of stapes fixation. A review of the literature revealed that hereditary fusion of the proximal interphalangeal joints was first described by Harvey Cushing in 1916, followed by other case reports. This is - to the best of our knowledge - the first family to be reported in Denmark. The *NOG* gene (17q22) encodes noggin, a secreted polypeptide important for regulating multiple signaling pathways, particularly in cartilage and bone. A mutation herein is believed to cause Proximal Symphalangism (SYM1) which conforms to the above condition. **Methods**: Sequence analysis of *NOG1*. **Results**: Test results of *NOG1* mutation screening are pending.

J04.31
Investigation of Interleukin-10 (IL-10) family cytokines polymorphisms in patients with psoriasis

E. Galimova[1,2], *V. Akhmetova*[1], *S. Kõks*[3], *E. Khusnutdinova*[1];
[1]*Institute of Biochemistry ang Genetics, Ufa Scientific Center of Russian Academy of Sciences, Ufa, Russian Federation,* [2]*Department of Physiology, University of Tartu, Tartu, Estonia,* [3]*Department of Pathophysiology, University of Tartu, Tartu, Estonia.*

Background: Interleukin (IL)-10 family cytokines IL-10, IL-19, IL-20, and IL-24 have been implicated in autoimmune diseases and we have previously reported that genetic variants in IL10 gene cluster were associated with psoriasis. Objective: To analyze the relationship of genetic polymorphisms in the IL10 gene cluster with psoriasis for Russian population. This study also explores whether there are gene-gene interactions among these genetic polymorphisms. Methods: A total of 273 patients with psoriasis and 298 matched healthy controls were enrolled to carry out a case-control study for 48 SNPs of IL10 gene cluster. Genotyping for the SNPs was conducted on the Applied Biosystems 3730 DNA Analyzer using SNPlex™ technology. Results: The results showed that the genotype distributions of IL20 T/T (rs1518108) and IL20 A/G (2232363) are significantly different between case and control groups (P = 0.034 and P = 0.047, respectively). Carriers of IL20 A (2232363) allele conferred risk to psoriasis (OR = 2.26, 95% CI = 1.05-4.88) while those of IL10 T (rs1554286) and of IL20 T (1400986) alleles conferred protection to psoriasis (OR = 0.71, 95% CI = 0.53- 0.94; OR = 0.69, 95% CI = 0.49-0.97). Conclusions: Our preliminary data suggest that four polymorphisms (rs1554286, 1400986, rs2232363, rs1518108) located in IL10 gene cluster related to inflammatory and immunity processes showed an association with protection or development of psoriasis in Russians.

Mutations in COL2A1 in a Brazilian cohort of 15 patients with SEDC phenotype

K. C. Silveira[1], *L. C. Bonadia*[1], *C. A. Moreno*[1], *M. T. Sanseverino*[2], *E. Mattos*[2], *D. R. Bertola*[3], *G. Yamamoto*[3], *A. A. L. Jorge*[3], *C. Mellado*[4], *T. Felix*[2], *J. C. Llerena Jr*[5], *D. P. Cavalcanti*[1];
[1]*Universidade de Campinas, Campinas, Brazil,* [2]*Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil,* [3]*Universidade de São Paulo, São Paulo, Brazil,* [4]*Pontificia Universidade Católica do Chile, Santiago, Chile,* [5]*Fundação Oswaldo Cruz, Rio de Janeiro, Brazil.*

Type II collagenopathies are characterized by a spectrum of different conditions among which the most common phenotype is the spondyloepiphyseal dysplasia congenita - SEDC. More than 30 missense mutations, usually private and involving the change of a glycine, have been described in patients with SEDC. Unfortunately, little is known about severity and follow up of the patients with known mutations. Here we present the molecular results of 15 new patients with SEDC. The molecular analysis was performed by direct sequencing of the COL2A1. Thirteen mutations have been found until now, and the majority is located at the center of the triple-helical domain between exons 23-27. Among the 13 mutations, eight are novel (p.G516S, p.G528A, p.G570D, p.G708R, p.G498D, p.G687R, p.G1149R, and p.G1080V), and result in the glycine substitution by a bulkier amino acid. Two mutations were recurrent and previously described, p. R989C and p.G594E. In two patients with no mutations the sequencing of COL2A1 is still ongoing. Severe phenotype was associated with the following mutations: p.R989C, p.G570D and p.G687R. The patients with the following mutations G549E and G516S, all died in the first months of life. The mutations p.G1149R and p.G1080V were seen in less severe phenotypes. The remains mutations could not to be associated with severity because children are still very young. In conclusion, p.R989C mutation seems to produce a constant and severe phenotype. The two less severe phenotype were associated with mutations in the extremity of the triple-helical domain.

J04.33
Homozygous shox gene deletion detected by array CGH in a girl with langer mesomelic dysplasia

B. Karaman, *N. Satkin, U. Altunoglu, G. Toksoy, H. Kayserili, O. Uyguner, S. Basaran;*
Medical Genetics Department of Istanbul Medical Faculty, Istanbul University, Istanbul, Turkey.

Langer mesomelic dysplasia (LMD) is characterized by hypomelia with severe hypoplasia of ulnae and fibulae, and bowed, thickened radii and tibiae, causing deformities of the hands and feet. LMD is caused by homozygous mutations in the SHOX/SHOXY (short stature homoebox) gene, of which heterozygous mutations or deletions cause Leri-Weil Dysplasia (LWD). Phenotype of LWD can be incomplete between and within families. We present a 13 year old female with LMD, the second child of healthy first cousin parents. She had micrognathia, disproportionate short stature with various musculoskeletal findings (absence of the distal flexion creases of the 3rd, 4th, 5th fingers on the right, camptodactyly of the 3rd, 4th, 5th fingers on the left, tibial bowing). X-rays revealed hypoplasia of ulnae, fibulae and the mandible. Chromosome analysis and FISH investigation by using SHOX gene probe revealed normal results. Sequence analysis failed due to unsuccessful PCR amplifications. Array comparative genomic hybridization (a-CGH) study showed a 174 kb homozygous deletion, encompassing the SHOX gene. Proband's parents were heterozygous for the same deletion by a-CGH. FISH was uninformative, because there was no difference between the intensity of the signals on both chromosomes. Since the primers used were located within the deleted region, molecular studies could not be performed. A-CGH proved to be the most powerful diagnostic tool in this case.

J04.34
Papillon-Lefevre syndrome and an autosomal dominant form of palmoplantar keratoderma in the same Indian family: mutation screening and in-depth bioinformatic analyses of the cathepsin C gene

M. Bhavika[1], *U. Ratnamala*[2], *T. Y. Mehta*[3], *M. Raveendrababu*[4], *J. Banwait*[5], *D. Bastola*[5], *U. Radhakrishna*[2];
[1]*Sree Dattha Institute of Engineering and Science, Hyderabad, India,* [2]*Green Cross Pathology & Molecular Laboratory, Ahmedabad, India,* [3]*Samarpan Centre for skin, Sexually transmitted diseases and Research Center, Modasa, India,* [4]*Department of Zoology, School of Sciences, Gujarat University, Ahmedabad, India,* [5]*School for Interdisciplinary Informatics, University of Nebraska at Omaha, Omaha, NE, United States.*

Papillon-Lefevre Syndrome (PALS, MIM 245000) is a rare autosomal recessive disorder characterized by palmoplantar keratoderma and early onset severe periodontitis affecting both deciduous and permanent dentition. Several recessive families and sporadic cases with variable clinical presentation have been reported. Several loss-of-function mutations have been identified in the lysosomal protease cathepsin C gene (*CTSC*) in PALS individuals from various ethnic groups. We describe Papillon-Lefevre syndrome and an autosomal dominant form of palmoplantar keratoderma in the same Indian family (UR075) and present the mutation analysis of the cathepsin C gene. Sequence analysis of known exons and splice junctions revealed a homozygous nucleotide substitution G to A at nucleotide position 901, resulting in a change from glycine (GGC) to serine (AGC) at amino acid position 301 (G301S) was observed in homozygous condition in an affected individual, and excluded other affecteds with severe palmoplantar keratoderma from the same family. We re-evaluated family UR075 and excluded chromosome 11q14-q21 region by linkage analysis. This mutation was found to be at a

highly conserved residue in of *CTSC* gene. Structure prediction and energetic analysis of wild-type *CTSC*, comparison with mutant (G301S) revealed that this change in amino acid does not imply any secondary structural change. However, prediction of functional effect(s) of this mutation is possibly damaging the protein structure and/or function. Additionally, based on the energy calculation and the modeled protein structure of the mutant is expected to be energetically unstable.

J04.35

PROGINS progesterone receptor polymorphism in Systemic Lupus Erythematosus

D. Tanev[1], *S. Andonova*[2], *A. Savov*[2], *R. Robeva*[3], *M. Nikolova*[4], *A. Tomova*[3], *P. Kumanov*[3], *R. Rashkov*[1], *Z. Kolarov*[1];

[1]*Clinic of Rheumatology, Medical University – Sofia, Sofia, Bulgaria,* [2]*National genetic laboratory, Medical University - Sofia, Sofia, Bulgaria,* [3]*Clinical Center of Endocrinology and Gerontology, Medical University – Sofia, Sofia, Bulgaria,* [4]*Clinic of Nephrology, Medical University – Sofia, Sofia, Bulgaria.*

Background: Systemic lupus erythematosus (SLE) is a chronic inflammatory autoimmune disease with an unexplained etiology. Several studies have investigated the role of steroid hormones and their receptor polymorphisms for the development of the disease. However, the clinical significance of the PROGINS receptor polymorphism of the progesterone receptor gene has not been studied yet, despite the known immunosuppressive actions of the progesterone. Therefore, the present study aimed to investigate the potential influence of the PROGINS haplotype on the SLE onset and clinical manifestations. Materials and methods: The PROGINS Alu insertion polymorphism was investigated in 122 Caucasian lupus patients and 105 healthy controls by PCR-RFLP analysis. Results: PROGINS variant allele (Alu ins) was found in 15.20% of the participants. No significant differences in the genotype frequencies of progesterone receptor PROGINS polymorphism in patients and controls were observed, although the prevalence of Alu ins/Alu ins genotype was more common in controls than in patients (4.76% vs. 0.82%, p=0.182). The progesterone receptor polymorphism did not influence the clinical manifestation, severity of the disease or the age of SLE onset (p>0.05). Conclusions: PROGINS polymorphism is not associated with a specific clinical phenotype in Bulgarian SLE patients. Further studies in other ethnic groups are needed to establish the influence of the PROGINS polymorphism on the SLE development as well as on the autoimmune disease susceptibility. The present study was financially supported by the Medical University Sofia (Grant 26/2010, Grant 55/2012).

Detection of rs2073618 polymorphism in the Osteoprotegerin gene in Slovak post-menopausal women

I. Boronova[1], *J. Bernasovska*[1], *J. Kloc*[2], *Z. Tomkova*[2], *S. Macekova*[1], *E. Petrejcikova*[1], *D. Gabrikova*[1];

[1]*University of Prešov, Presov, Slovakia,* [2]*Osteocentre, Presov, Slovakia.*

Osteoporosis is a common complex disease in post-menopausal women, which is characterized by decreased of bone mineral density (BMD) and detoration of skeletal microarchitecture leading to increased bone fragility and fracture. Several studies proved that genetic factors play an importatnt role in the pathogenesis of osteoporosis. Osteoprotegerin (OPG) is a recently discovered member of the TNF receptor superfamily that acts as important paracrine regulator of bone remodeling. In the present study, we screened rs2073618 polymorphism in the OPG exon 1. Study group included 200 post-menopausal women diagnosed as osteoporotic by clinicians based on clinical features and radiological evidence. Control group included 200 post-menopausal non osteoporotic women. Genotyping for the presence of rs2073618 polymorphism was performed using the Custom Taqman®SNP Genotyping assays. The frequencies of investigated genotypes for rs2073618 polymorphism in the group of patients with osteoporosis were as follows: GG (21.0%), GA (56.5%), CC (22.5%), the distribution in control groups was: GG (24.0%), GA (56.0%), CC (20.0%). Hardy-Weinberg equilibrium was tested for each group of participants using $\chi 2$ test. All statistical analyses were performed with SPSS 16.0. No differences in genotype or allele frequencies in OPG gene rs2073618 polymorphism between patients with osteoporosis and control subjects were found ($\chi 2=0.69$, p=0.405; $\chi 2=0.61$, p=0.436). Further studies are necessary for obtaining of more reliable results on the larger population for clarification molecular mechanisms with practical use in everyday practice.

This work was supported by project APVV-0716-10 and projects ITMS 2622120023 and ITMS 26220120041.

Severe osteosclerosis in a patient with trichothiodystrophy

E. Sukarova-Angelovska[1], *N. Jaspers*[2], *M. Kocova*[1], *I. Stefanovska*[3], *V. Anastasovska*[1], *G. Ilievska*[1];

[1]*Pediatric Clinic, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Department of Genetics, Erasmus Medical Center, Rotterdam, Netherlands,* [3]*Remedica Hospital, Skopje, Macedonia, The Former Yugoslav Republic of.*

Trichothiodystrophy (TTD) is rare autosomal recessive disease that affects DNA repair mechanism. TTD demonstrate great variability in severity and clinical involvement of different tissues and organs - skin and hair, bones, gonads, brain. Several attempts are made to classify TTD, according photosensitivity, age of onset and, more recently, genetic findings.

We report on a female patient with severe form of TTD. She is the first child in a family. The baby was delivered in 33 week of pregnancy and had low birthweight and poor accommodation during perinatal period due to the breeding and swallowing difficulties. Ichtiosis was present from the beginning, ranging from dry skin, scaling to freckling in different parts of the body. Photosensitivity was not clinically evident. Trichorexis and dystrophic nails were present, as well as typical facial appearance. Short stature and developmental milestones were noticed after the second year. Axial osteosclerosis started from her fifth year initially discovered with X-ray and densitometry, afterwards progressing rapidly and at the age of 9 year she experienced profound walking difficulties. DNA repair synthesis was moderately affected. A heterozygous mutation in ERCC2 gene was found - Y339X, 1017C>G and R722W, 2164C>T.

Patients with TTD have altered production of transcription factor II, due to the mutation in one of the three subunits: ERCC2, ERCC3 and GTF2H5. Osseous anomalies were seen in 20% of TTD cases and are often undescribed. Although reported to give a severe clinical presentation, disease specific causative allele R722W was rarely associated with the appearance of osteosclerosis.

J04.38

Association between vitamin D receptor gene polymorphisms and chronic periodontitis among Libyans

M. M. ElJilani[1], *A. A. Mohmed*[2], *I. M. Alhudiri*[2], *H. Ben-zeglam*[2], *A. M. Ramadan*[2], *S. S. Saleh*[2], *N. Ashammakhi*[2], **N. S. Enattah**[1,2];

[1]*School of Engineering and Applied Science, Department of Biomedical Engineering, Division of Genetic Engineering, Libyan Academy, Tripoli, Libyan Arab Jamahiriya,* [2]*Department of genetic engineering, Biotechnology Research Center (BTRC), Twisha, Tripoli, Libyan Arab Jamahiriya.*

Background: Chronic periodontitis (CP) is an oral disease resulting in inflammation within the supporting tissue of the teeth "the periodontium", progressive attachment loss, and alveolar bone loss, it has a microbial aetiology. Recent findings suggest that the genetic factors, such as vitamin D receptor gene polymorphisms have been also involved in the inflammatory disease aetiology of CP. **Aim of the research:** Investigation of the relationship between vitamin D receptor gene polymorphisms and CP among Libyans. **Materials and Methods:** In this study, we examined 196 unrelated Libyans between the ages of 25 and 65 years, including 99 patients and 97 controls. An oral examination based on Ramjford Index was performed at different dental clinics in Tripoli, and information's were obtained using a self-reported questionnaire. DNA was extracted from buccal swabs, the VDR ApaI, BsmI, and FokI polymorphisms were genotyped by using polymerase chain reaction (PCR), and were sequenced to read the nitrogen bases by using Sanger Method. **Results:** A significant association between ApaI SNP C/T rs#731236 and CP was found (P value = 0.022), while no significant associations were found between ApaI SNP G/T rs#7975232 , BsmI SNP A/G rs#1544410, and FokI SNP rs#2228570 and CP (P value = 0.939, 0.466, 0.239) respectively. **Conclusion:** Vitamin D receptor ApaI SNP C/T rs#731236 may be related to the risk of CP in the Libyan population.

Frequent mutation Ala597Glu in Alox12B gene at autosomal recessive congenital ichthyosis in patients from Russian Federation

N. N. Vasserman, *V. A. Galkina, E. G. Okuneva, G. E. Rudenskaya, A. V. Polyakov; Research Center for Medical Genetics, Moscow, Russian Federation.*

Autosomal recessive congenital ichthyosis (ARCI) is a heterogeneous group of disorders of keratinization. It divides on several types the main of which are lamellar ichthyosis (LI) and nonbullous congenital ichthyosiform erythroderma (NCIE), although phenotypic overlap within the same patient or among patients from the same family. Mutation in several genes can lead to both LI and NCIE. We analyzed DNA samples from 11 patients with LI and 8 patients with NCIE on mutations in Alox12B gene. We found mutations in DNA from 11 patients (6 with LI and 5 with NCIE). One mutation Ala597Glu in exon 14 occurs on 11 chromosomes in 8 families: 3 in homozygous state and 5 in heterozygous state. So this mutation is responsible for 72% ARCI with mutations in Alox12B gene.

J04.40

Molecular-genetic analysis in patients with autosomal recessive osteogenesis imperfecta from Russia

D. Nadyrshina[1,2], *R. Khusainova*[2], *A. Nurgalieva*[1], *E. Khusnutdinova*[1,2];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics RAS, Ufa, Russian Federation.*

Osteogenesis imperfecta (OI) is a clinically and genetically heterogeneous brittle bone disorder. Whereas dominant OI is mostly due to heterozygous mutations in either COL1A1 or COL1A2 encoding type I procollagen, recessive OI is caused by mutations in genes encoding proteins involved in type I procollagen processing or chaperoning. We aimed to study mutations in CRTAP, LEPRE1, PPIB and SERPINF1 genes in OI patients. We examined 78 patients with OI and 100 healthy controls corresponding by age, gender, ethnicity and place of residence. We sequenced the coding and exon-flanking regions of CRTAP, LEPRE1, PPIB and SERPINF1 genes. We identified two distinct heterozygous mutations, undescribed before. For the first time previously unreported splicing mutation c.1724+4G>A in LEPRE1 gene was identified in one patient from Tatar population and the c.913C>G (p.Leu305Val) mutation in SERPINF1 gene was observed in patient from Bashkir population. We observed 12 SNPs: rs4234239 and rs586178547 in CRTAP, rs2307247, rs2253557 and rs4904 in PPIB, rs3738499, rs3738498 and rs3738497 in LEPRE1, rs58697961, rs2071022, rs1136287 and rs11658342 in SERPINF1 previously described; whereas, the c.1153-78G>A in intron 6 of CRTAP gene was novel identified in two patients from one family. Interestingly, rs4904 in PPIB gene was identified in a patient with c.1081C>T (p.Arg361X) in COL1A1; one patient with OI was characterized by rs2307247 in PPIB gene and c.579delT (p.Gly194ValfsX71) in COL1A1. Accordingly, for the first time two novel unreported mutations in LEPRE1 and SERPINF1 genes and one novel SNP in CRTAP gene was observed in Russian patients with OI.

A clinical report on congenital joint dislocations: A new association

P. O. Simsek-Kiper[1], *E. Dikoglu*[2], *B. Campos-Xavier*[2], *A. C. Ceylan*[1], *G. E. Utine*[1], *S. Unger*[3], *L. Bonafe*[2], *K. Boduroglu*[1], *A. Superti-Furga*[2];
[1]*Hacettepe University School of Medicine Pediatric Genetics Unit, Ankara, Turkey,* [2]*Center for Molecular Diseases, Department of Pediatrics, Lausanne University, Lausanne, Switzerland,* [3]*Medical Genetics Unit, Lausanne University, Lausanne, Switzerland.*

Congenital joint dislocations are caused by structural abnormalities in joint development. The differential diagnosis is broad and involves recessive Larsen syndrome, diastrophic dysplasia, gPAPP deficieny and some others. Molecular studies have revealed several gene defects in proteoglycan biosynthetic pathway and have highlighted the importance of proteoglycans in the joint development. Loss of function mutations have been identified in the chondroitin sulfate synthase 1 (*CHSY1*; MIM 608183) gene which encodes a key protein in glycosaminoglycans biosynthesis and a secreted FRINGE enzyme required for NOTCH signalling to cause Temtamy Preaxial Brachydactyly syndrome (TPBS, MIM 605282). Congenital joint dislocations have not been reported in association with *CHSY1* gene mutations so far. We here present the first clinical report on two siblings with TPBS carrying a novel homozygous *CHSY1* mutation in whom one of the sibs had bilateral complete anterior knee and unilateral hip dislocations in addition. The *CHSY1* deficiency is yet another disorder of proteoglycan biosynthesis that can present at birth with congenital joint dislocations.

J04.42

Autosomal recessive congenital ichthyosis: identification of a Spanish family with a new PNPLA1 mutation

L. Fachal[1], *L. Rodríguez-Pazos*[2], *M. Ginarte*[3], *Á. Carracedo*[1], *J. Toribio*[3], **A. Vega**[1];
[1]*Fundación Pública Galega de Medicina Xenómica-SERGAS. Grupo de Medicina Xenómica-USC, CIBERER, IDIS, Santiago de Compostela, Spain,* [2]*Dermatology Service, University Hospital Complex of Ferrol, SERGAS, Ferrol, Spain,* [3]*Department of Dermatology, University Hospital Complex of Santiago de Compostela, SERGAS, Santiago de Compostela, Spain.*

PNPLA1 has recently been identified as one of the eight genes (ALOX12B, ALOXE3, CERS3, CYP4F22, NIPAL4 or TGM1) in which mutations can cause autosomal recessive congenital ichthyosis (ARCI), although only two families harbouring such mutations (both of North African origin) have been identified.
In a study of ALOX12B, ALOXE3, CYP4F22, NIPAL4 and TGM1 performed in 17 ARCI families in Galicia (NW Spain), about 80% of these families had mutant TGM1 or ALOXE3, while no mutations of NIPAL4, CYP4F22 or ALOX12B were found.
In 2012 a new locus of ARCI mutations, in PNPLA1, was published and we accordingly investigated the prevalence of PNPLA1 mutations in our series of 18 ARCI families, which constitute 95% of the 19 Galician ARCI families identified to date. Four Galician families known to have no deleterious mutations of ALOX12B, ALOXE3, CYP4F22, NIPAL4 or TGM1 were studied. The potential pathogenic effect of the variant identified was evaluated using the programs Align-GVGD, MAPP, PolyPhen and SIFT. One consanguineous family was found to harbour the missense substitution c.100G>A (p.Ala34Thr), located in the catalytic domain of PNPLA1. Cosegregation analysis indicating the deleterious nature of this variant was supported by the bioinformatic predictions.
We have identified the third known ARCI family with PNPLA1 mutations, and the first of European ancestry. Although mutant PNPLA1 was found in about 6% of our Galician ARCI series, the small number of Galician ARCI families prevents us from generalizing this figure.
This work was funded by a grant from the Ramon Areces Foundation awarded to AV.

Simvastatin affects ABCA1 expression and cholesterol efflux in THP-1 macrophages by a ROR-Alpha-dependent pathway

N. Coban, *B. Ozsait-Selcuk, C. Gulec, N. Erginel-Unaltuna;*
Institute for Experimental Medical Research, Department of Genetics, Istanbul, Turkey.

The ATP-binding cassette transporter A1, ABCA1, is a ROR-Alpha target gene that participates in the removal of cholesterol from lipid-laden macrophages, a crucial anti-atherogenic mechanism. Statins are currently the most efficacious therapy for the treatment of hypercholesterolemia and cardiovascular diseases. Some studies have shown that statins decrease ABCA1 expression and choleterol efflux from human macrophages. However, other studies have reported no change, or even a modest increase in this variables. In this study our aim was to investigate the ABCA1 expression and apolipoprotein AI (apoAI)-mediated cholesterol efflux after simvastatin treatment in THP-1 macrophages. Cholesterol is one known ligand of ROR-Alpha and is important in cardiovascular diseases like atherosclerosis. Thus, we further explored the effect of simvastatin on activation of the ROR-Alpha in human macrophages by studying the influence of cellular cholesterol efflux. We observed that simvastatin repressed the expression of ABCA1 gene, and that this repression was partially prevented by ROR-Alpha ligands (especially by SR1001). Furthermore, ligand induced activation of ROR-Alpha by CPG 52608 and SR 1001 increased apoAI-mediated cholesterol efflux in THP-1 macrophages. In conclusion, activation of ROR-Alpha not only increased ABCA1 expression and cholesterol efflux in the absence of simvastatin, but also restored these functions in the presence of simvastatin. With the demonstration of the ABCA1 that involve in the pathogenesis of atherosclerosis might be controlled by an inducible transcription factor, this study offers a potential therapeutic treatment for the disease.

J05.02

Expression of two ABCG1 transporter isoforms in macrophages of patients with atherosclerosis

V. Miroshnikova[1,2], *E. Demina*[1], *A. Panteleeva*[1], *N. Mayorov*[2], *V. Davydenko*[2], *A. Schwarzman*[1,3];
[1]*Petersburg nuclear physics institute, Gatchina, Russian Federation,* [2]*Saint-Retersburg Pavlov State Medical University, Saint-Retersburg, Russian Federation,* [3]*Institute of Experimental Medicine, Saint-Retersburg, Russian Federation.*

The ABCG1 transporter plays an important role in reverse cholesterol transport by mediating the efflux of cholesterol from macrophage foam cells to high density lipoproteins. Two major ABCG1 isoforms exist in humans, which differ by the presence or absence of twelve amino acids between the ATP cassette and the transmembrane domains (ABCG1(+12) and ABCG1(-12)). We have reported earlier that expression of the ABCG1 gene was reduced in macrophages of patients with atherosclerosis. However the role of the ABCG1 isoforms in human atherosclerosis is still undiscovered. The aim of this study was to evaluate the expression of the ABCG1 isoforms in macrophages of patients with atherosclerosis and in the control group. Human peripheral blood monocytes were obtained from 10 patients with angiographically proved atherosclerosis and 10 healthy blood donors. Monocytes were cultured with macrophage colony-stimulating factor (M-CSF) for 5 days to get monocyte-derived macrophages. Real time PCR system designed for this study was used for simultaneous detection of ABCG1(+12) and ABCG1(-12) mRNA levels. Mann-Whitney U-test was used for statistical analysis of the data. ABCG1(-12) mRNA levels were significantly reduced in group of patients when compared with the control group: medians were 0.70 (0.15 - 2.02) and 1.61 (0.51 - 2.98) ($p<0.05$). There were no differences in ABCG1(+12)/ABCG1(-12) mRNA ratio between patients and controls. ABCG1(+12)/ABCG1(-12) mRNA ratio tends to be 0.55 in human macrophages. In conclusion, while expression of the ABCG1 gene is reduced in macrophages of patients with atherosclerosis, the ratio of two main ABCG1 isoforms doesn't change during atherosclerosis.

J05.03

Chromosomal deletion in abdominal aortic aneurysms

F. Sangiuolo[1,2], *A. Luchetti*[1], *R. Mango*[1,2], *A. Nardone*[1,2], *D. Postorivo*[2], *A. Ippoliti*[1,2], *G. Novelli*[1,2];
[1]*Tor Vergata University, Rome, Italy,* [2]*Medical Genetics, Policlinico Tor Vergata, Rome, Italy.*

Abdominal aortic aneurysm (AAA) is an irreversible and progressive dilatation of the abdominal aorta. Known risk factors for AAA include smoking, male sex, increasing age, and family history, but no genetic markers have clearly been shown to be responsible for this pathology.
In order to assess the potential role of genetic rearrangements in the pathogenesis of AAA, we analyzed a cohort of 50 patients who had undergone surgical repair of AAA. DNA from peripheral blood and AAA wall specimens of each patient was analyzed by CGH array. A common deletion region on chromosome Xp22 was found in about half of AAA wall specimens and never in the corresponding peripheral blood. In order to demarcate the boundaries of the identified deleted region, a real time PCR was performed on some genes located within the deleted region: SHOX, CRFL2 and DHRSX. Specifically, samples deleted for SHOX, CLRF2 and DHRSX genes represented 41.8, 28 and 32.5% respectively.
These results allowed us to identify for the first time a common deletion region on chromosome Xp22 link to abdominal aortic aneurysm using CGH array technology. Future characterization of the involved genes within the deleted region may contribute to define the molecular mechanisms involved in the structural alteration of vascular wall tissue and predisposing to abdominal aortic dilatation.

J05.04

Mutations in ACTA2 are not a common cause of Bicuspid Aortic Valve associated with Thoracic Aortic Aneurysm

G. Tortora[1], *D. Pacini*[2], *C. Marconi*[1], *A. Pantaleo*[2], *P. Beretta*[2], *R. Di Bartolomeo*[2], *M. Seri*[1], *A. Wischmeijer*[1,3];
[1]*Medical Genetics Unit, Policlinico S.Orsola-Malpighi, Bologna, Italy,* [2]*Department of Cardiac Surgery, Policlinico Sant'Orsola-Malpighi, Bologna, Italy,* [3]*Clinical Genetics Unit, Arcispedale S. Maria Nuova - Istituto di Ricovero e Cura a Carattere Scientifico, Reggio Emilia, Italy.*

Bicuspid aortic valve (BAV) is a common congenital heart defect, occurring in 0,5% to 2% of the population. Its clinical presentation is heterogeneous, but associated dilatation of the ascending aorta is often present. Familial studies showed that BAV with or without thoracic aortic aneurysm (TAA) segregates in an autosomal dominant manner with incomplete penetrance and variable expression, likely underlying a single common gene defect. Even if mutations in NOTCH1 and rarely in GATA5 and TGFBR2 have been linked to BAV+/-TAA, its molecular basis in most families remains unknown. Mutations in ACTA2 have been reported as major cause of familiar TAA (up to 14%), with associated BAV in some individuals.
We recruited 20 patients who underwent surgery for BAV and TAA to investigate the possible role of ACTA2 mutations in their phenotype, to evaluate possible common clinical signs correlating with the cardiovascular pathology, to determine the prevalence of familiarity of BAV+/-TAA (performing echocardiography in first degree relatives).
We did not identify ACTA2 mutations in our probands, nor common clinical signs possibly related to their heart disease. Furthermore, we found that the phenotype BAV+/-TAA segregates in 25% of our families, in accordance to literature data. Although our cohort is small, we conclude that ACTA2 does not seem to contribute significantly to the common phenotype of BAV+/-TAA, and that cardiac ultrasound screening is important in probands' relatives.

J05.05

Dysmorphic features and genetic counselling goals of germline Braf mutated patients: Two unrelated Tunisian children

N. B. Abdelmoula[1], *R. Louati*[1], *D. Abid*[1], *S. Kammoun*[1], *M. Zenker*[2], *T. Rebai*[1];
[1]*Medical University, Sfax, Tunisia,* [2]*Institute of Human Genetics, Erlangen, Germany.*

Germline heterozygous gain-of-function mutations of the BRAF gene that encode a downstream molecule of RAS in the RAS-MAPK signaling pathway have been identified in noonan syndrome and other RASopathy, essentially cardiofaciocutaneous (CFC) syndrome. Distribution of BRAF mutations in this syndrome was specific and nonrandom. Here, we report dysmorphic features of two unrelated Tunisian; BRAF mutated children and discuss difficulties of genetic counselling in our environment. The first case (P1) and second case are 7-years-old girls born to distant consanguineous parents from Bir Ali Ben Khalifa and no consanguineous parents from Sidi Bouzid, respectively. Pregnancies were complicated by hydroamniosis. P1 had a congenital severe valvular pulmonic stenosis detected immediately after birth, treated 4 years later but with a failed valve repair. P2 had hypertrophic cardiomyopathy detected 6 months after birth without any familial history of congenital heart diseases. Molecular analysis of genes involved in the RASopathies genes (PTPN11, KRAS, HRAS, NRAS, BRAF, RAF1, SOS1, MAP2K1, MAP2K2, SHOC2, and CBL) by HRM and direct sequencing revealed heterozygous mutations of the BRAF gene: 736G-C transversion in exon 6 (A246P) for P1 and 1501G-A transition in exon 12 (E501K) for P2. Cognitive impairment, speech delay and ectodermal abnormalities as well as a distinctive facial appearance similar for P1 and P2 were consistent with CFC syndrome characteristics. At the genetic counselling level, the management of the risk for haematological malignancies must be discussed with parents and clinical team. Furthermore, regarding the theoretic possibility of germline mosaicism, prenatal diagnosis must be offered.

Sudden infant death syndrome and unexplained intrauterine fetal demise: role of calmodulin

A. Ghidoni[1,2], *P. Cox*[3], *M. Torchio*[1,2], *I. Scheimberg*[4], *R. Insolia*[1], *I. Cetin*[5], *F. Facchinetti*[6], *L. Crotti*[1,7,8], *M. Cohen*[9], *R. Coombs*[10], *P. J. Schwartz*[7];
[1]*Department of Molecular Medicine, University of Pavia, Pavia, Italy,* [2]*Laboratory of Cardiovascular Genetics, IRCCS Istituto Auxologico Italiano, Milan, Italy,* [3]*Birmingham Women's Hospital, Birmingham, United Kingdom,* [4]*The Royal London Hospital, London, United Kingdom,* [5]*Department of Clinical Sciences Luigi Sacco, University of Milan, Milan, Italy,* [6]*Department of Obstetrics and Gynaecology, University of Modena and Reggio Emilia, Modena, Italy,* [7]*IRCCS Istituto Auxologico Italiano, Center for Cardiac Arrhythmias of Genetic Origin and Laboratory of Cardiovascular Genetics, Milan, Italy,* [8]*Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany,* [9]*Sheffield Children's Hospital, Sheffield, United Kingdom,* [10]*Sheffield Teaching Hospitals, Sheffield, United Kingdom.*

Background: Cardiac channelopathies are responsible for approximately 15% of sudden infant death syndrome (SIDS) and 9% of intrauterine fetal demise (IUFD). Recently, mutations in two genes encoding the calcium-binding protein calmodulin (CALM1 and 2), have been associated with recurrent cardiac arrest in infants with Long QT Syndrome, Catecholaminergic Polymorphic Ventricular Tachycardia and Idiopathic Ventricular Fibrillation. Calmodulin mutations disrupt Ca2+ signalling in the heart, affecting membrane ion channels' function and kinase-mediated signal transduction. Given the life-threatening arrhythmias described in infants, it seemed logical to expect that calmodulin could play a role in SIDS and in IUFD.
Methods: Genomic DNA was extracted from frozen tissue. All three genes encoding calmodulin (CALM1-2-3) were analysed with Sanger sequencing in a cohort of SIDS cases (n=46) and in a population of IUFD (n=44; gestational age at death >=20 weeks) classified as "unexplained" after a post-mortem evaluation.
Results: Mutational analysis of the 3 CALM genes did not identify any pathogenic variant. In addition, the CALM3-rs115265989 polymorphism (NM_005184.2:c.267G>A) was identified in one Black IUFD case, and is present in 1% of subjects of the Exome Sequencing Project Black population.
Conclusions: Surprisingly, even though calmodulin mutations have been described in severe and early-onset cardiac arrhythmic syndromes, no genetic variants were identified in our SIDS and IUFD populations. These data suggest that calmodulin mutations are not a major cause of SIDS and IUFD. Possible explanations include a combination of rarity of calmodulin mutations and small sample size of the population analysed.

J05.07

Beware at the Cardiac Genetic Clinic: things are not always what they may seem

R. McGowan[1], *I. Findlay*[2], *V. Murday*[1];
[1]*West of Scotland Clinical Genetics Service, Glasgow, United Kingdom,* [2]*Royal Alexandra Hospital, Paisley, United Kingdom.*

We report on two families seen at our Regional Cardiac Genetic Service in Glasgow. Both demonstrate clinical variability as well as the potential for incorrect or delayed diagnosis.
Family 1 was originally reviewed at another centre. The post mortem of a 19 year old male demonstrated features suggestive of arrhythmogenic right ventricular cardiomyopathy (ARVC). Subsequently, his 56 year old mother who has dilated cardiomyopathy (DCM) and had recently developed muscle weakness, was investigated locally. Her phenotype was consistent with a myofibrillar myopathy. A missense DES mutation (c.338A>C) was identified, confirmed in her deceased son (PM tissue sample) and her daughter who has conduction abnormalities. The mutation occurs at the 1A alpha helical domain. Similar mutations have been associated with ARVC.
Family 2 presented in 2008. A 26 year old mother and her 7 month old son were diagnosed with DCM. He had probable endocardial fibroelastosis. Investigations for Barth syndrome were negative. Subsequently, a 45 year old distant cousin was investigated for hypertrophic cardiomyopathy and found to have an MYH7 missense mutation (c.2441T>G). The mutation segregated across all affected family members, including another 1st cousin with left

ventricular non-compaction.
Clinical heterogeneity is an important feature of DES and MYH7 related inherited cardiac disorders. There is a need for careful assessment of individuals at the Cardiac Genetic Clinic to ensure recognition of these conditions, early diagnosis, appropriate treatment, cascade testing and surveillance for unaffected, at risk relatives.

J05.08
Chromosome 9p21 rs564398 variant is associated with the internal carotid artery stenosis severity

B. Bayoglu[1], *C. Arslan*[2], *S. Gode*[2], *B. Arapi*[2], *S. B. Deser*[2], *M. Cengiz*[1];
[1]*Istanbul University, Cerrahpasa Medical Faculty, Department of Medical Biology, Istanbul, Turkey,* [2]*Istanbul University, Cerrahpasa Medical Faculty, Department of Heart and Vessel Surgery, Istanbul, Turkey.*

Carotid atherosclerosis is atherosclerotic stenosis of proximal internal carotid artery (ICA), and is one of the main causes of stroke. Recent genome-wide association studies (GWAS) revealed chromosome 9p21 INK4b-ARF-INK4a is a novel locus for susceptibility to type-2 diabetes and coronary artery disease. INK4/ARF transcript, p16INK4a, arrests cell cycle progression by inhibiting the activities of CDK4/CDK6. Cell cycle regulation may be an important mechanism in vascular smooth muscle cells for atherosclerosis progression. Thus, we aimed to examine the frequency of the single nucleotide polymorphisms (SNPs) on chromosome 9p21 in carotid atherosclerosis (CA).
The study is composed of 50 symptomatic and asymptomatic CA patients and 53 healthy controls. Genomic DNA extraction was performed from peripheral blood leukocytes. Real-time polymerase chain reaction (RT-PCR) was used to analyze 4 SNPs (rs564398 A/G, rs10757274 A/G, rs2383207 A/G, rs10757278 A/G) in CA patients and controls.
Analysis of 4 SNPs revealed a significant difference in the genotype distribution for rs564398 and rs10757278 between CA patients and controls (p=0.027 and p=0.01). However no significant relationship was found in genotype frequencies of rs10757274 and rs2383207 when CA patients and controls were compared (p>0.05). There was also a significant relation in allele frequencies of rs564398, rs2383207 and rs10757278 polymorphisms between CA patients and controls (p=0.016, p=0.049, p=0.001). ICA stenosis severity was found to be associated with the AA variant of rs564398 polymorphism in CA patients (p=0.01).
These results indicate that, chromosome 9p21 rs564398 and rs10757278 polymorphisms may be associated with CA. These findings need to be confirmed by further studies.

J05.09
ADIPOQ variants in patients with coronary artery disease in Turkish population

D. Erkoc Kaya[1], *H. Arikoglu*[1], **A. Asik**[1], *S. E. Unal*[1], *F. Iscioglu*[2];
[1]*Selcuk University, Faculty of Medicine, Department of Medical Biology, Konya, Turkey,* [2]*Ege University, Science Faculty, Department of Statistics, Izmir, Turkey.*

Adiponectin, a hormone produced predominantly by adipocytes, is an essential modulator of insulin sensitivity and has anti-atherogenic and anti-inflammatory properties. Several studies have been performed to investigate the association of genetic variations in the adiponectin with obesity, insulin resistance, and type 2 diabetes (T2D), but few studies were performed in association with coronary artery disease (CAD). Adiponectin is coded by ADIPOQ gene located on chromosome 3q27, consisting of 3 exons and 2 introns spanning a 17-kb region. Among the variations of the ADIPOQ gene reported, rs17300539 (−11391G>A), rs2241766 (+45T>G), rs1501299 (+276G>T), and rs2241767 (+349A>G) have been most extensively studied and are thought to be linked to CAD. In our study, the effects of these polymorphisms in ADIPOQ on CAD were investigated and 125 patients and 123 healthy controls were included. Polymorphisms were screened by PCR-RFLP technique. Genotyping data and demographic characteristics were analyzed by the SPSS18.0 program. p<0.05 was considered statistically significant. No effect of these polymorphisms on CAD was detected in association analysis under additive, dominant and recessive models (p>0.05). While Genotype distributions were in Hardy-Weinberg equilibrium (p>0.05) in patient and control groups, except a deviation observed in both groups for +276G>T (p<0.05). ADIPOQ and its variants, shown having role in common genetic background of insulin resistance, T2D and CAD in several populations, had no effect on CAD in our society. We note that this study was based on a relatively small sample size, which limits the power to detect association. These results need to be interpreted with caution.

J05.10
Investigation of association between Leu125Val polymorphism of PECAM-1 gene and coronary heart disease in the Iranian population

M. Bidmeshki, *S. M. Seifati;*
Department of biology, Ashkezar branch, Islamic Azad University, Ashkezar, Islamic Republic of Iran.

Coronary heart disease (CHD) is a major cause of death in Iran and many other countries. CHD is a multifactorial disease, which is probably influenced by a combination of environmental and genetic factors. Several studies indicate that conditions leading to myocardial infraction and death can be prevented by controlling environmental factors and screening for genetic risk factors. Atherosclerosis is the most predominant coronary artery pathology and it seems that Platelet Endothelial Cell Adhesion Molecule-1 (PECAM-1) plays a role in creation of atherosclerotic plaques. In this study, we have investigated the association between Leu125Val polymorphism of PECAM-1 gene and coronary artery disease in Iranian population. Blood samples were collected from 85 healthy controls and 126 angiographically confirmed CAD patients with stenosis in at least one coronary artery. After DNA extraction, the PECAM-1 Leu125Val polymorphism detection was carried out by PCR-RFLP method. Frequencies of GG, CC, GC genotypes were 17%, 35%, and 48% in patients and 20%, 35% and 45% in healthy controls, respectively. Data analysis (p-value= 0.815) revealed no association between Leu125Val polymorphism of PECAM-1 gene and coronary artery disease. Preliminary results do not reveal an association between Leu125Val polymorphism and coronary artery disease. This study is continuing.

J05.11
Association of rs7903146 polymorphism in TCF7L2 gene with myocardial infarction in T2DM patients in Uzbekistan

Y. Kapralova[1], *G. N. Rakhimova*[2], *F. A. Takhirova*[3], *Z. S. Akbarov*[3], *S. H. Turdikulova*[1];
[1]*Institute of Bioorganic Chemistry, Academy of Sciences Republic of Uzbekistan, Tashkent, Uzbekistan,* [2]*Tashkent Institute of Postgraduate Medical Education, Tashkent, Uzbekistan,* [3]*Scientific-Research Institute of Endocrinology, Uzbekistan Public Health Ministry, Tashkent, Uzbekistan.*

The Coronary Heart Disease (CHD) has the similar risk factors with type 2 Diabetes Mellitus (T2DM). A polymorphism in the TCF7L2 gene has been found to be associated with type 2 diabetes in several ethnic groups. Possible relationship between the genetic polymorphism of the TCF7L2 gene and CHD was not clear.
We aimed to determine the association between rs7903146 (C/T) polymorphism in TCF7L2 gene with the development of myocardial infarction (MI) in patients with T2DM in Uzbek population. We genotyped 108 patients divided into 3 groups: I - patients without CHD (n = 26, control); II - patients with CHD without MI (n = 42); III - patients with MI (n = 40). All patients were unrelated, aged over 45 years, and had disease duration over 10 years.
Results of genotyping showed that the CC genotype frequency in I group was 15.4% and the CC genotype was present in 70% patients of III group. The frequency of the T allele (83,8%) in patients with MI was significantly higher compared to the group without CHD (65,4%, P <0.05, control). At the same, we found significantly lower prevalence of allele C (16,3 ± 4,1%) in patients with MI compared with the control group (34,6 ± 6,6%, P <0.05)
The results of our study suggest that TCF7L2 rs7903146 polymorphism is significantly associated with development of MI in patients with T2DM. TT genotype of TCF7L2 gene may be a predictor of the risk of myocardial infarction in patients with T2DM.

J05.12
GLA nonsense mutation (W162X) and cardiac involvement in heterozygous females

G. Sarca[1], *C. Dragomir*[2], *A. Stan*[2], *E. Severin*[3];
[1]*Prof.Dr.C.Angelescu Hospital, Bucharest, Romania,* [2]*Genetic Lab, Bucharest, Romania,* [3]*Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.*

Background. In the past, medical literature stated that Fabry disease affects only male. Based on X-linked pattern of inheritance the heterozygous females are usually asymptomatic. Recent studies describe Fabry disease in heterozygous females but manifestations tend to occur at a later age than in males and are often less severe. Objectives. The aim of our study was to detect the presence of GLA mutation in females of a family with Fabry disease and corelate with the severity of clinical phenotype. Subjects and methods. Five related females of the same family were enrolled and clinically assessed. Enzyme activity levels were evaluated too. Genetic testing included isolated DNA from blood samples and sequence analysis of all coding exons and all intron-exon boundaries of the GLA gene. Results. All five females were found to be heterozygous for a familial pathogenic GLA mutation (c.485G>A). The mutation caused different low levels of enzyme activity in grandmother, mother, daughter and the two fraternal nieces of the grandmother. None of

these females received enzyme replacement therapy prior to the study. Age-related variable phenotypic expression was noticed. Grandmother, now 62 year-old presented mild angiokeratoma and mild left ventricular hypertrophy. Her daughter, 31 year-old, presented mitral valve thickened with mild regurgitation. The granddaughter, 5 year-old, had no clinical manifestation. Both fraternal nieces of the grandmother, 20 year-old and respectively 22 year-old, presented dry skin and mild angiokeratoma but no cardiac involvement. Conclusion. Early genetic testing should be considered in younger female with a family history of Fabry disease.

J05.13
Polymorphisms in FII, FV and PAI-1 genes in Ukrainian patients with atherothrombotic and cardioembolic ischemic stroke

M. Burlova-Vasylieva, *N. Kravchenko, O. Savchuk;*
Educational and Scientific Centre "Institute of Biology" of Taras Shevchenko National University of Kyiv, Kyiv, Ukraine.

Background and aim: Imbalance between coagulation and fibrinolysis factors is known to be a predictor of thrombosis and cardiovascular events. The aim of our study was to compare the genotype distribution of the coagulation factors FII and FV and fibrinolysis factor PAI-1 functional polymorphisms in patients with atherothrombotic ischemic stroke and patients with cardioembolic ischemic stroke with atrial fibrillation (AF).
Methods: 54 patients with cardioembolic ischemic stroke with AF and 60 patients with atherothrombotic ischemic stroke from Ukraine were included in this study. The genotypes of FII G20210A, FV G1691A (Leiden) and PAI-1 5G/4G polymorphisms were determined by PCR analysis based on the banding pattern on gel electrophoresis.
Results: No individuals with FII and FV homozygous mutations were found in both study groups. In cardioembolic stroke patients with AF, 1 (2%) FII and 3 (6%) FV heterozygous mutations were found. In patients with atherothrombotic stroke, 5 (8%) FII and 0 (0%) FV heterozygous mutations were found. Among patients with cardioembolic ischemic stroke with AF, PAI-1 5G/5G, 5G/4G and 4G/4G genotypes were observed in 9 (17%), 23 (43%) and 21 (40%), and in atherothrombotic stroke in 14 (24%), 19 (32%) and 26 (44%) patients respectively.
Conclusion: Our findings suggest that there is a tendency toward a higher frequency of FII G20210A heterozygotes in atherothrombotic ischemic stroke patients compared with cardioembolic ischemic stroke patients with AF. We also observed that FV Leiden heterozygotes are more frequent in cardioembolic stroke with AF. PAI-1 homozygous state is equivalent between the two study groups.

J05.14
The importance of genetic profile for thrombophilia detection in patients with pulmonary venous thromboembolism after operation for anomalous pulmonary vein return malformations

G. S. Doros, *A. V. Popoiu, M. Puiu, A. But, M. Gafencu;*
Victor Babes University of Medicine and Pharmacy, Timisoara, Romania, Timisoara, Romania.

Aim: To present two rare cases of pulmonary thromboembolism in vital vessels, after surgery for cardiac malformations, late discovered with positive genetic profile for thrombophilia.
Material and methods: A 3 mo old girl presented with signs of cardiogenic shock and myocardial iskaemia due to totally anomalous pulmonary venous return (TAPVR) in coronary sinus. The second case was a 2 yo girl, with recurrent wheezing, discovered with right pulmonary veins draining in superior vena cava, a partial anomalous pulmonary veins return (PAPVR). Both patients were operated.
Results: First case, two years after cardiac surgery presented with discrete bluish discoloration of the skin, but with normal O2Sat. The pulmonary venous return was redirected to the left atrium. Angio CT detected superior vena cava thrombosis, with reverse flow into azygos system, and complete thrombosis of the right venous brachiocephalic trunk. Second case, was operated, redirecting the right pulmonary vein collector to left atrium. After two years she presented with haemoptisia. Angio CT detected right pulmonary venous trunk embolism, with pulmonary edema in the right lung. She was treated with heparin. In both patients we detected positive genetic predisposition to thrombophylia, that changed the recommendation for aticoagulant therapy, for life long.
Conclusions: Patients with operated TAPVR and PAPVR have the risk for pulmonary thromboembolism, which is vital when the collector is redirected to left atrium.
Genetic profile for thrombophilia is important to be searched in this type of cardiac malformations. If positive, anticoagulant therapy is life long mandatory, to prevent thromboembolism and even death.

Investigation on Mitochondrial DNA deletions in Iranian Dilated Cardiomyopathy and Hypertrophic Cardiomyopathy patients

F. Montazeri[1], *M. Houshmand*[2], *M. Montazeri*[3];
[1]*Asia hospital, Tehran, Islamic Republic of Iran,* [2]*National Institute for Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran,* [3]*Department of Medical Biotechnology, Faculty of Advanced Medical Science, Tabriz University of Medical Sciences, Tabriz, Iran, Tabriz, Iran, Islamic Republic, Tabriz, Islamic Republic of Iran.*

Hypertrophic cardiomyopathy is a genetic disorder with autosomal dominant inheritance. The disorder has been estimated to occur in 0.05%-0.2% of population. Recently mitochondrial DNA mutations have been associated with cardiomyopathies. Mitochondria are the major site of energy production in the cell. Thus it is reasonable to assume that energy dependant tissues such as heart, brain, skeletal muscle and endocrine system are affected by mitochondrial dysfunction. Many mitochondrial diseases arise form defects of the mitochondrial respiratory chain. mitochondrial disorders have maternal inheritance pattern. The mtDNA mutation rate is much higher than nuclear DNA due to lack of a repair mechanism and also having no intron. Recent studies have reported maternally inherited, non-x linked HCMs are associated with defects in mitochondrial oxidative metabolism. Methods: In this study we screened 52 Iranian hypertrophic cardiomyopathy's patients for mitochondrial DNA deletions. Results: Mitochondrial DNA deletions were detected by PCR using 6 paired primers. Five different deletions were found in 29 patients (55.8%). Eighteen patients (34.4%) showed 8.5 kb deletion. Twelve (23%) patients had 9 kb deletion. Seven patients (13.4%) had a 7.3 kb deletion. Eight patients (15.5%) had 4977 bp common deletion between nt8161-nt13640, and 11 patients had 7.4 kb deletion. Multiple deletions have been found in 11 patients (21.1%). Conclusion: Mitochondrial DNA deletions may occur as a result of aging; on the other hand mt deletions may affect myocardium and lead to secondary hypertrophy. However, the question regarding primary or secondary role of mtDNA deletions in hypertrophic cardiomyopathy remains unanswered.

J05.16
Novel SMAD4 mutation causing juvenile polyposis (JP) and hereditary haemorrhagic teleangiectasia (HHT)

T. K. Kadiyska[1], *M. Hachmeriyan*[2], *A. Nossikoff*[3], *L. Angelova*[2];
[1]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [2]*University Hospital "St. Marina", Varna, Bulgaria,* [3]*University Hospital Lozenets, Sofia, Bulgaria.*

HHT is a genetic disorder with autosomal dominant inheritance pattern, causing abnormal blood vessel formation - multifocal vascular telangiectases and/or arteriovenous malformations(AVMs). The majority of patients harbor mutations in members of the transforming growth factor (TGF)-β pathway - either the endoglin (ENG) or activin receptor-like kinase 1 (ALK1) genes. Mutations in SMAD4 gene, encoding an intracellular mediator of TGF-β signals, are known to cause JP. Both HHT and JP are uncommon, but a combined syndrome JPHHT has been reported.
We present three generations of HHT family with three affected members. All of them were anaemic, and have been diagnosed with multiple pulmonary AVMs, cerebral cavernous haemangioma was documented in one of them. The proband had a history of gastrointestinal (GI) bleeding and few colon polyps documented at 9 year age. No GI bleeding/polyps were documented in remaining family members. No mutations were found in ENG/ALK1 genes on direct sequencing. We performed SMAD4 direct sequencing on the proband and found a novel frameshift mutation (p.R531GfsX536) in exon 11, leading to stop codon and synthesis of truncated protein.
The clinical importance of SMAD4 mutation finding in HHT has been widely discussed as these patients are likely to be at risk of JPHHT and developing gastrointestinal cancer. Based on our findings, ENG and ALK1 mutation negative HHT patients might benefit from SMAD4 genetic testing. We suggest that HHT patients with SMAD4 mutations should be regularly screened for colonic and gastric polyps associated with JP.

Next generation sequencing - useful tool in molecular diagnosis of inherited cardiomyopathy

J. Kadlecova[1], *L. Durcova*[1], *D. Grochova*[1], *M. Hiemerova*[1], *I. Grochova*[1,2,3], *L. Skutkova*[3], *P. Vlasin*[2,1];
[1]*Cytogenetic laboratory Brno, Brno, Czech Republic,* [2]*Center of prenatal diagnosis, Brno, Czech Republic,* [3]*International Clinical Research Center, St.Anne's University Hospital Brno, Brno, Czech Republic.*

Cardiomyopathy is characterized by mechanical or electrical dysfunction of cardiac muscle and it is a known risk factor of sudden cardiac death. More than hundreds of variant in 84 genes have been associated with inherited cardiomyopathy. A high number and variability of involved genes complicate diagnosis of cardiomyopathy. However, existence and availability of new

modern method - next generation sequencing enables analysis of high number of genes at the same time- in massively parallel approach. Sequencing DNA libraries in this fashion significantly shortens time and reduces costs of analysis, and makes previously cost prohibitive experiments possible.
Here we present our diagnostic NGS workflow for the analysis of 46 genes involved in pathogenesis of the inherited cardiomyopathy by the using TrueSight Enrichment technology (Illumina) followed by sequencing on the MiSeq (Illumina). This pilot study comprised group of 40 unrelated patients with DCM, ARVC and ventricular fibrillation. We detected several different variants, some of these variants were common and already published with proven association with development of cardiomyopathy and some of them were classified as new variants, where co-segregation analysis in pedigrees has to be performed. All detected variants classified as pathological, likely pathological and variants of unknown clinical significance (VOUS) have been confirmed by classical Sanger sequencing.
Our results demonstrate that this is a sensitive and robust assay with an average of 95 % of target regions consistently covered to x20 depth. This diagnostics approach can be a powerful tool for identifying presymptomatic individuals in families.

J05.18
The relationship between PIA1/PIA2 Glycoprotein IIIa genetic polymorphism and ischaemic stroke in Northern Romania

F. M. Petrisor[1], *R. A. Popp*[1], *A. Catana*[1], *M. D. Porojan*[2], *Z. Cuzmici*[1], *I. V. Pop*[1];
[1]Department of Medical Genetics U.M.F "Iuliu Hatieganu", Cluj-Napoca, Romania, Cluj-Napoca, Romania, [2]Department Internal Medicine U.M.F "Iuliu Hatieganu", Cluj-Napoca, Romania, Cluj-Napoca, Romania.

Introduction: Ischaemic stroke is one of the leading causes of disability and death in Romania. Platelets play a key role in generating the protective hemostatic plug that prevents blood loss at sites of vascular injury. The identification of functional prothrombotic polymorphisms during the past decade encouraged the study of common polymorphisms affecting platelet glycoproteins (GP) in stroke. The aim of the present study is to evaluate the relationship between PIA/PIA2 Glycoprotein IIIa gene polymorphism and ischemic stroke in a Northern Romanian population group and to determine whether it has an influence on the risk of cerebral events. This is a cross-sectional, randomized, case-control study for the evaluation of PIA/PIA2 Glycoprotein IIIa gene polymorphism alleles frequency among patients with ischemic stroke.
Material and method: The study included 131 patients diagnosed with ischemic stroke (neurological and CT scan examination), and 110 healthy unrelated controls. PIA/PIA2 Glycoprotein IIIa genotyping was carried out using PCR-RFLP technique. The amplification of the relevant gene fragment was subjected to restriction enzyme digestion, followed by gel electrophoresis.
Results: Molecular analysis did not reveal an increased frequency of A1A2 mutant genotype in the study group compared to the control group (p = 1.000, OR = 0,951, CI = 0.504- 1.797).
Conclusions: We found no significant differences in distribution of the PIA/PIA2 Glycoprotein IIIa gene polymorphism between ischemic stroke patients and controls.

J05.19
Noninmune hydrops fetalis atypical presentation of Milroy disease

I. Valenzuela;
Hospital Vall d'Hebron, Barcelona, Spain.

Milroy disease, is an autosomal dominant disorder characterized by typical phenotype of infantile onset lower-limb lymphedema accompanied by variable expression of recurrent episodes of cellulites, toenail changes, and papillomatosis. Mutations in the vascular endothelial growth factor receptor 3 (VEGFR3) have been identified as a genetic cause of Milroy disease.
We report a case of 22 week old foetus with bilateral pleural effusion, that although in uterus thoracocentesis, oedema progressed and ended in severe polyhydramnios and massive hydrothorax. Fetal karyotyping and array-CGH after amniocentesis were normal. Anatomopathological examination identified bilateral pedal lymphedema with pretibial extension.
The mother reported a personal history of bilateral lymphedema of the feet from birth, which improved during the first year of life. No lymphedema in other first degree family members. A paternal cousin of the patient had a child with bilateral lymphedema of the feet from birth. The diagnosis of Milroy disease was considered highly likely in view of the family history of lower limb lymphedema of congenital onset. Genetic analysis revealed novel missense mutation in VEGFR3 that cosegregates with the disorder in the family.
Clinical presentation ranges from asymptomatic individuals through classic features to rare prenatal life-threatening conditions, even in patients bearing the same mutation. Although in utero hydrothorax and hydrops fetalis is a rare manifestation of Milroy syndrome, should be taking into account when facing a case of in utero noninmune hydrops fetalis. A detailed family history could be the clue to reach de diagnosis, although de novo cases have been described.

J05.20
MTHFR and NNMT gene polymorphisms and conotruncal heart diseases

D. Sayin Kocakap[1], *C. Şanlı*[2], *F. Çabuk*[1,3], *M. Koç*[4], *A. Kutsal*[4];
[1]Kirikkale University Faculty of Medicine Department of Medical Genetics, Kirikkale, Turkey, [2]Kirikkale University Faculty of Medicine Department of Pediatric Cardiology, Kirikkale, Turkey, [3]Eli Lilly Company, İstanbul, Turkey, [4]Dr. Sami Ulus Maternity and Children's Training and Research Hospital, Department of Cardiovascular Surgery, Ankara, Turkey.

Congenital Heart Defects are the most common congenital anomalies with a worldwide 1 % prevalence and are a big part of childhood mortality and morbidity. The etiology of conotruncal heart diseases is complex, with both environmental and genetic causes. Hyperhomocysteinemia which is greatly accompanied with the defects of folic acid metabolism, is known to cause conotruncal heart anomalies. In this study we have evaluated three polymorphisms in two hyperhomocysteinemia related genes, such as Methylene Tetrahydrofolate Reductase (*MTHFR* C677T and A1298C) and Nicotinamide N-methyl Transferase (*NNMT* rs694539) in 79 children with conotruncal heart disease (CHD) and 99 children without CHD. We found no association in case and control groups for *MTHFR* C677T and *NNMT* rs694539 polymorphisms, while for *MTHFR* A1298C polymorphism we found a significantly higher frequency of C allele, suggesting that C allele might be a risk factor for CHD.

J05.21
Mutation analyses of PTPN11 and SOS1 genes in Belarusian patients with clinical features of Noonan/LEOPARD syndrome

T. Asadchuk[1], *N. Rumiantsava*[1], *O. Zobikova*[1], *S. Pauli*[2], *M. Möschner*[2], *P. Burfeind*[2], *W. Engel*[2];
[1]National Center of Research and Applied Medicine «Mother and Child», Minsk, Belarus, [2]Institute for Human Genetics, University Medical Center, Göttingen, Germany.

Noonan syndrome (NS) and LEOPARD syndrome are genetically heterogeneous autosomal dominant disorders associated with gain-of-function mutations in various genes encoding proteins of the RAS/MAPK signaling pathway, mainly in PTPN11, SOS1 and RAF1 genes.
8 Belarusian patients with Noonan/LEOPARD syndrome were screened for mutations in PTPN11 gene: 6 patients with clinical features of NS (2 family cases with mother-daughter pair, 2 sporadic cases) and 2 patients with clinical features of LEOPARD syndrome (a family with father-daughter transmission). All of the patients had cardiac diseases (pulmonary valve stenosis, septal defect, cardiomyopathy) and characteristic minor abnormalities.
Leukocyte genomic DNA was amplified for the 15 exons and flanking intronic sequences of PTPN11 gene by PCR. The PCR products were sequenced from both directions on an ABI3500xl autosequencer.
Four different PTPN11 mutations were identified in 7 out of 8 patients with clinical features of Noonan/LEOPARD syndrome (4 probands, 3 relatives available for testing). All mutations were heterozygous missense mutations: Asn58Lys (new genetic variant c.174C>A), Asp61Gly, Asn308Asp, Thr468-Met, and clustered either in exon 3 encoding the N-SH2 domain or in exons 8 and 12 encoding the PTP domain.
One out of 8 patients does not carry mutation in PTPN11 gene. Therefore, we searched for mutations in the second frequently mutated gene SOS1 - undescribed heterozygous mutation (c.797_798delCAinsAAGTA) was found in exon 6 of SOS1 gene encoding the DH-domain. At the age of 1.6 years old patient showed typical NS phenotype without ectodermal abnormalities. Detection of new mutation is important for further delineation of genotype-phenotype correlations.

J05.22
IL-6 gene polymorphism (-174G/C) in Romanian patients with ischemic stroke -results from a pilot study

L. Cherciu[1], *A. Ciobanu*[2], *R. Caisan*[3], *C. Bara*[1], *S. Tuta*[2], *I. Popescu*[2], *R. Sfrent-Cornateanu*[1];
[1]Department of Immunology and Pathophysiology, Faculty of Medicine, University "Carol Davila", Bucharest, Romania, [2]University "Carol Davila", Bucharest, Romania, [3]"Prof. Dr. C. T. Nicolau" National Institute of Blood Transfusion, Bucharest, Romania.

Stroke, mostly of ischemic origin, is considered a major cause of mortality worldwide. Interleukin-6 (IL-6) is demonstrated to be associated with atherosclerotic disease, also is considered a key mediator of inflammation in cerebral ischemia. IL-6 single nucleotide polymorphism (SNP) -174G/C was found to be associated with several atherosclerotic diseases; its relation to ischemic stroke is conflicting.
We aimed to investigate the role of -174G/C IL-6 SNP in ischemic stroke sus-

ceptibility in Romanian population. To our knowledge, this is the first study of IL-6 polymorphisms in Romanian patients with stroke.
We genotyped 208 subjects (60 patients, 148 unrelated controls) by Real-Time PCR technique (Taqman_SNP_Genotyping Assays_ rs1800795, Applied-Biosystems, USA) for the -174G/C IL-6 polymorphism. Statistical analysis was performed by using the SNPStats program for genetic association studies [1]; p-values ≤0.05 were considered significant.
All studied groups were in Hardy-Weinberg equilibrium (HWE) for -174G/C IL-6 polymorphism. The frequencies of minor allele -174C were similar in stroke patients and controls (0.28/0.25). There was no significant difference in SNP distribution regarding the genotype frequency between stroke and control subjects before (CC/GC/GG: 0.08/0.35/053 and 0.09/0.41/0.51, respectively) and after adjustments by age, sex and body mass index.
The present study shows no association of -174G/C polymorphism with the susceptibility to ischemic stroke in patients from Romania. In order to improve the statistical power of this study, a larger number of patients may be required to verify this conclusion.

Allelic variants of IL8 and IL10 genes influence ischemic stroke risk and prognosis

A. Kucherenko[1,2], *D. Shulzhenko*[3], *S. Kuznetsova*[3], *L. Livshits*[1];
[1]*Institute of Molecular Biology and Genetics of NASU, Kyiv, Ukraine,* [2]*Taras Shevchenko National University of Kyiv, Kyiv, Ukraine,* [3]*SI „Institute of Gerontology" of NAMS of Ukraine, Kyiv, Ukraine.*

Ischemia-related inflammatory signaling is involved in all stages of ischemic cascade. Pro- and anti-inflammatory cytokine balance is altered by changes in gene expression due to polymorphisms in promoter and intron regions. This study aimed to evaluate the role of IL8 gene C-781T, and IL10 gene C-592A polymorphisms as genetic markers of acute ischemic stroke (AIS) risk. Case group included 183 AIS patients. Control group - 88 individuals older 65 years without AIS history. Genotyping was performed using PCR followed by RFLP analysis. Significantly (P<0,05) higher frequency of IL8 -781T allele carriers in case group (81,6%) comparing to control (70,1%) was revealed. -781C allele carriers have 2-fold increased AIS development risk (OR=1,886; 95% CI: 1,041-3,417). Significantly (P<0,05) higher frequency of IL10 gene -592C allele carriers was observed in patients with AIS (98,2%) comparing to control (90,7%). AIS development risk in such individuals is 5-fold increased (OR=5,71; 95% CI: 1.48-22.11). These genotypes may result in aberrant initial inflammatory ischemia response. Genotype role in post-stroke improvement (state severity assessed using RANKIN scale on 3rd and 14th treatment day) was evaluated. -592C allele homozygotes have more than 2-fold higher improvement chances during the first fortnight of treatment (OR=2,76; 95% CI: 1.26-6.07). Pro-inflammatory cytokines induce expression of inflammation-specific molecules, and cerebral infarction zone expands. High levels of anti-inflammatory IL-10 may prevent from this outspread. Concluding, IL8 gene -781C and IL10 gene -592C variants may be considered the genetic markers of AIS development risk. Unlikely IL10 gene -592CC genotype is associated with better post-stroke improvement prognosis.

J05.25
Identification of Plasminogen as a pleiotropic susceptibility factor of coronary artery disease and periodontitis

A. S. Schaefer[1], *G. Bochenek*[1], *A. Jochens*[2], *European Periodontitis Genetics Consortium, W. Lieb*[3], *C. Wijmenga*[4], *B. Loos*[5], *I. König*[6], *S. Jepsen*[7], *S. Schreiber*[1];
[1]*Institute of Clinical Molecular Biology, Christian-Albrechts-University, Kiel, Germany,* [2]*Institute of Medical Informatics and Statistics, Kiel, Germany,* [3]*Biobank popgen, University Medical Center Schleswig-Holstein, Kiel, Germany,* [4]*Department of Genetics, University Medical Center Groningen, Groningen, Netherlands,* [5]*Department of Periodontology and Oral Biochemistry, Academic Centre for Dentistry Amsterdam (ACTA), University of Amsterdam and VU University Amsterdam, Amsterdam, Netherlands,* [6]*Institute for Medical Biometry and Statistics, University of Lübeck, University Medical Hospital Schleswig-Holstein, Lübeck, Germany,* [7]*Department of Periodontology, Operative and Preventive Dentistry, University of Bonn, Bonn, Germany.*

Periodontitis (PD) is a chronic inflammatory disease of the oral cavity, which affects human populations worldwide at prevalence rates of 11% for the severe forms. PD and coronary artery disease (CAD) share several risk factors such as obesity, smoking and sex, and there is consent of an association between both diseases, but a causative relationship is not supported. In the past, we identified several shared genetic risk alleles in the genetic regions of ANRIL and CAMTA1/VAMP3, which indicate a link of glucose and fatty acid metabolism and immune response in the shared etiology of both diseases. We aimed to identify further shared genetic risk factors to better understand conjoint disease mechanisms and genotyped all 46 published CAD risk loci of genome-wide significance in a large case-control sample of aggressive periodontitis (AgP), with the Illumina genotyping array Immunochip and Affymetrix 500K Arrays. We identified and replicated the same CAD risk allele within plasminogen (PLG) to be significantly associated with AgP upon correction for multiple testing, independent of smoking and sex (rs6923419, Ppooled =2x10-5, odds ratio (OR)=1.28, 95% confidence interval (95%CI)=1.1-1.4, 858 cases, 3,597 controls). A subsequent combined analysis of several genome-wide data sets of CAD and AgP suggested TGFBRAP1 to be associated with CAD (rs2679895, Ppooled=0.00003, OR=0.86, 95%CI=0.8-0.9, 4,117 cases, 5,824 controls) and AgP (rs2679895, Ppooled=0.00021, OR=1.29, 95%CI=1.2-1.5, 703 cases, 2,143 controls). We also give molecular biological evidence that in addition to PLG, and TGFBRAP1, all currently known shared susceptibility loci of CAD and PD, are members of TGF-β signaling.

Detection of a new silent mutation, antitrhombin Ala382Ala, in the analysis of antithrombin Cambridge mutations type I and II

I. Tirado, *N. Vilalta, I. Coll, D. Llobet, C. Vallvé, E. Martínez-Sanchez, J. Mateo, J. Fontcuberta;*
Hospital Sant Pau. Hematologia. Unitat d'Hemostàsia i Trombosi, Barcelona, Spain.

Background: Antithrombin (AT) is a serine protease inhibitor that inactivates Factor IIa and Factor Xa. Patients with AT deficiency are at an increased risk for venous thromboembolism (VTE) and pregnancy loss. Our unit is developing a study to determine risk factors in healthy women who are taking contraceptive hormone therapy. The case that we present is a 26 years old healthy woman without a history of thrombosis. *Methods:* We performed a genetic analysis of AT Cambridge II (*SERPINC1 G13268T*; p.Ala384Ser) using PCR and digestion with *PvuII* (Biolabs) and was confirmed by sequencing to distinguish it from the AT Cambridge I (*G13268C;* p.Ala384Pro). AT plasma levels were normal (108%). Protein C, Protein S, antiphospholipid antibodies, lupus anticoagulant, Factor V Leiden mutation, *F2G20210A* and *F12C46T* were normal. *Results:* The results showed a heterozygous pattern of AT Cambridge mutation. However, sequencing analysis revealed a new genetic variant within exon 6 of the *SERPINC1* gene, A*13264T.* This variant is a synonymous mutation and causes a codon change (GCA à GCT) but does not alter the sequence of the gene product of residue Ala382. *Conclusions:* This new synonymous mutation Ala382Ala was not detected in 100 healthy control subjects, suggesting that it is a rare nucleotide variation. Although the prevalence of this new polymorphism *(A13264T*) is low, its position adjacent to the *G13268* implies a possible interference with the genetic diagnosis of AT Cambridge II (*G13268T*) and AT Cambridge I (*G13268C*).

DNA methylation patterns in coronary heart disease

A. V. Markov[1], *M. S. Nazarenko*[1,2], *I. N. Lebedev*[1,2], *A. V. Frolov*[3], *V. A. Popov*[3], *O. L. Barbarash*[3], *V. P. Puzyrev*[1,2];
[1]*Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Siberian State Medical University, Tomsk, Russian Federation,* [3]*Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation.*

Epigenetic heterogeneity of arteries can contribute to regional vascular bed differences concerning susceptibility to atherosclerosis. We analyzed DNA methylation in atherosclerotic lesions of right coronary artery (AL-RCA) and plaque-free samples of internal mammary artery (IMA) harvested from coronary heart disease patients during surgical treatment. The first step included genome-wide DNA methylation comparison of more than 27K CpG-sites in AL-RCA (n=6) and matched IMA (n=6) samples in order to avoid the effect of interindividual variation. We identified 178 CpG-sites of 156 genes to be hypomethylated and 201 CpG-sites of 190 genes to be hypermethylated significantly (pFDR-adjusted < 0.05) in AL-RCA group compared to IMA, respectively, with the difference in methylation level of as minimum as 20%. Gene-annotation enrichment analysis revealed hypomethylated gene set implicated in immune processes (GO:0002376), response to stimuli (GO:0050896) and embryonic skeletal system development (GO:0048706). The next step was to validate and replicate results concerning DNA methylation of some relevant loci from received list in a larger cohort of vascular tissue samples (n=42). We confirmed frequent hypomethylation at the homeobox gene *HOXD4* and imprinted gene *MEST* by bisulfite pyrosequencing in AL-RCA compared to IMA tissues. Our observations suggest an atherosclerosis-related reduction in DNA methylation around genes that associated with inflammation in response to stimuli and related to developmental processes. This research was supported by President Grant for the Leading Scientific Schools of Russian Federation (5096.2014.4).

Prevalence of copy number changes and loss of heterozygosity in atherosclerosis

A. A. Sleptcov[1], *M. S. Nazarenko*[1,2], *I. N. Lebedev*[1,2], *N. A. Skryabin*[1], *A. A. Kashevarova*[1], *A. V. Frolov*[3], *V. A. Popov*[3], *O. L. Barbarash*[3], *V. P. Puzyrev*[1,2];
[1]*Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Siberian State Medical University, Tomsk, Russian Federation,* [3]*Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation.*

Numerous studies have relied on the idea that atherogenesis has molecular similarities with cancer. It is possible that genomic microstructural alterations, characteristic of various
neoplasms, are also present in atherosclerotic lesions. In this study we used, for the first time, array-CGH for detection of DNA copy number variations (CNVs) and copy-neutral loss of heterozygosity (cnLOH) patterns in patients with coronary heart disease undergoing coronary artery bypass graft surgery. The SurePrint G3 Human CGH+SNP 2×400K microarrays were used for DNA testing from patients' white blood cells (WBC, n=5), right coronary arteries in the area of atherosclerotic plaques (CAP, n=5), and internal mammary arteries (IMA, n=5). Polyploidy was observed in CAP of one patient. We detected the multiple CNVs and cn-LOH in all analyzed tissues from patients with atherosclerosis. Right coronary arteries in the area of atherosclerotic plaques presented a higher average CNVs length and number of genes located in their vicinity in comparison with other tissues that may support the notion of higher genomic instability. The majority of CNVs (68-91%) were identified in disease affected tissues, suggesting that some variations might represent somatic events. The gains in 3p21.31 (*CACNA2D2*), 7q32.1 (*FLNC*), 19p13.3 (*PIP5K1C*), and 21q22.3 (*COL6A1*) were detected in the vascular tissues but not in WBC. We identified gain 7p15.2 (*SKAP2*) in all tissues that not overlapping with any CNV regions currently reported in the Database of Genomic Variants. CnLOH were detected in 12 out of 13 chromosomal regions involving tumor-suppressor genes, such as *SFRP1, CEBPD, RB1CC1, DIRAS3, TUSC3* and *ZDHHC2.*

The effect of endogenous opioids on apoptosis of cardiomyocytes in a rat model of cirrhotic cardiomyopathy

I. Jahanzad[1], *A. Abbasi*[1], *N. Faramarzi*[2], *M. Khosravi*[3], **F. Yazarlou**[4], *M. Abbasi*[5], *A. Dehpour*[3];
[1]*Department of Pathology, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Department of Cardiology, Tehran Heart center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*Department of Pharmacology, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [4]*Department of Medical Genetics, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [5]*Department of Internal Medicine, Shahid Beheshti Medical University, Tehran, Islamic Republic of Iran.*

Background: Cirrhosis is known to be associated with various manifestation of cardiovascular dysfunction (cirrhotic cardiomyopathy). Some possible pathogenic mechanisms has been reported and still more details should be explored.
Aim: To explore the contribution of endogenous opioids in the apoptosis process in a rat model of cirrhotic cardiomyopathy.
Material and Methods: Cirrhosis was induced in rats by bile duct ligation (BDL) and resection. Cardiomyopathy was confirmed using trichrome staining for fibrosis. Naltrexone, an opioid antagonist was administered for 29 ± 1days. Apoptosis was detected using TUNEL assay. For molecular analysis, expression of BCL2, Caspase3, Fas and FasL was explored using reverse transcriptase real-time PCR.
Results: Left ventricular (LV) wall thickness was significantly ($p<0.001$) lower in the BDL group than the sham group, either receiving naltrexone or saline. Apoptosis density was significantly increased in BDL-saline group ($P<0.001$) vs. sham-saline group. Cardiomyocyte apoptosis was significantly decreased in the BDL-naltrexone group compared to BDL-saline group ($P<0.001$). There was no significant change in apoptosis density in sham groups receiving either naltrexone or saline. BDL-saline group showed significant over-expression of BCL2 and FAS and down regulation of caspase3 by a factor of 1.44 ($p<0.001$) compared to sham-saline group, 1.3 ($p< 0.001$) compared to BDL-naltrexone group and 0.77 ($p< 0.001$) compared to sham-naltrexone group, respectively. No significant change was observed in the other 4 analysis for BCL2, caspase3 and FAS. **Conclusion:** Apoptosis occurs during cirrhotic cardiomyopathy through both intrinsic and extrinsic pathways activation and endogenous opioid receptors blockade using naltrexone decreases its amount.

Association of CELSR2 gene with Coronary artery disease, replication in Tehran Lipid and Glucose Study (TLGS)

M. Fallah[1,2], *M. Daneshpour*[1], *A. Ebrahimi*[1], *D. Khalili*[3], *S. Matoo*[4], *R. Mousavi*[4], *F. Azizi*[5];
[1]*Cellular and Molecular Endocrine Research Center, Obesity research center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Kawsar Human Genetics Research Center (KHGRC), Tehran, Islamic Republic of Iran,* [3]*Prevention of Metabolic Disorders Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran., Tehran, Islamic Republic of Iran,* [4]*Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [5]*Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran., Tehran, Islamic Republic of Iran.*

Background: Coronary artery disease (CAD), is a leading cause of death worldwide and also have high health care cost in Iran. However environment and lifestyle are major risk factors of CAD, genetic susceptibility plays a major role in its pathogenesis. As association of cadherin, EGF LAG seven-pass G-type receptor 2 gene (CELSR2) and CAD was reported in other population including European and Asian-Indians, here we report a replication study to determine association of rs646776 polymorphisms (near CELSR2 gene) and CAD in Iranian population using samples from the Tehran lipid and glucose study (TLGS), a large population-based cohort study.
Methods: 600 cases with coronary artery disease and 1050 age and sex matched healthy control was selected from participant of TLGS cohort and enrolled in the study and rs646776 has been genotyped using the Centaurus (Nanogen) platform in DeCODE genetics. Association of G-allele with coronary artery disease, lipid related variables (e.g. triglyceride, cholesterol, HDL and LDL) and anthropometric index was tested using plink software after age and sex adjustment.
Results: G-allele of rs646776 was associated with higher HDL levels ($p <10–4$), lower waist circumference (WC) levels ($p < 0.029$) and lower prevalence of coronary artery disease ($p < 0.018$) (OR: 0.841).
Conclusion: Our findings showed the association between the presence of G allele in rs646776 and coronary artery disease and related traits among Iranian population and confirmed previous result in other ethnicity.

DNA methylation profile of coronary artery bypass grafts

M. S. Nazarenko[1,2], *A. V. Markov*[1], *I. N. Lebedev*[1,2], *A. V. Frolov*[3], *V. A. Popov*[3], *O. L. Barbarash*[3], *V. P. Puzyrev*[1,2];
[1]*Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Siberian State Medical University, Tomsk, Russian Federation,* [3]*Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation.*

Human blood vessels vary in their predisposition to develop atherosclerosis. The internal mammary arteries (IMA) are commonly used as the conduit to bypass major coronary artery stenosis, and have shown greater long-term resistance to atherosclerosis as compared to saphenous vein (SV) grafts. To explore differential DNA methylation profile in IMA and SV will help to further elucidate the mechanism of graft atherosclerosis. Vascular tissues were obtained from six patients undergoing coronary artery bypass grafting. Genome-wide DNA methylation analysis in IMA versus matched SV was performed using the Illumina HumanMethylation 27K BeadChip, which contains 27,578 probes within 14,475 genes. Using our criteria of pFDR-adjusted < 0.05 and a minimum median β-value difference of 20%, we identified 337 probes (290 genes) that were significantly differentially methylated. Gene ontology analysis revealed enrichment of biological processes associated with the development. There were four genes (*ALDH1A3, DAB2IP, DLX5, WT1*) with significant differences in methylation levels of three and more CpG-sites located inside CpG-islands. In conclusion our analysis lays the groundwork for further molecular studies of graft atherosclerosis by identifying novel pathways and genes potentially involved in pathology.
This research was supported by President Grant for the Leading Scientific Schools of Russian Federation (5096.2014.4).

Link of the PPAR gamma and Omentin-1 gene expression in visceral adipose tissue

M. Nikolaev[1], *T. Usenko*[1,2], *E. Bazhenova*[2], *X. Zhu*[2], *A. Neimark*[2], *P. Bogdanov*[2], *E. Baranova*[2], *S. Pchelina*[1,2];
[1]*Petersburg Nuclear Physics Institute, St.Petersburg, Russia, St-Petersburg, Russian Federation,* [2]*Pavlov's State Medical University of Saint-Petersburg, St-Petersburg, Russian Federation.*

Adipose tissue is the source of soluble mediators (adipokines), secreted mainly by adipocytes. The adipokines could play a central role in the development of insulin resistance and type 2 diabetes (DM2), and the increased risk of cardiovascular disease associated with obesity. Omentin-1 is one of the adipokines that is down-regulated in association with obesity-linked metabolic disorders including insulin resistance, glucose intolerance and DM2. The nuclear receptor peroxisome proliferator-activated receptor γ (PPARγ) is a ligand-dependent transcription factor that acts as primary regulator of adipogenesis, adipocytes metabolism, insulin action. The link between PPARγ and Omentin-1 is unclear today. The aim of our work was to estimate

the Omentin-1 gene, PPARγ mRNA levels in visceral fat of individuals without DM2 and cardiovascular dysfunction as well as serum Omentin-1 levels. We generated the visceral fat of 30 individuals without DM2 and cardiovascular dysfunction (mean age 45±9, 9 males, mean BMI 32±9). Visceral fat was received from gastrocolic omentum during laparoscopic cholecystectomy in non-acute period of gall-stone disease. PPARγ, Omentin-1 mRNA levels were estimated by RT-PCR with TagMan Probes. G protein mRNA levels (GNB2L1) was used as internal control. Serum Omentin-1 levels were determined by ELISA. Using Spearman correlation analysis positive correlation between PPARγ mRNA levels and Omentin-1 mRNA levels (r= 0,443; p=0,044) and PPARγ mRNA levels and serum Omentin-1 levels (r = 0,493, p=0,027) were found. This is first the report about the link between gene expression PPARγ and Omentin-1gene in visceral adipose tissue of individuals without DM2 and cardiovascular dysfunction.

Molecular analysis in X-linked adrenoleukodystrophy patients: Identification of a novel mutation

A. Durmaz[1], *T. Atik*[2], *H. Onay*[1], *E. E. Canda*[3], *S. K. Ucar*[3], *F. Bademkiran*[4], *M. Coker*[3], *O. Cogulu*[1], *F. Ozkinay*[1];
[1]*Ege University Medical Faculty Department of Medical Genetics, Izmir, Turkey,* [2]*Ege University Medical Faculty Department of Pediatrics, Subdivision of Genetics, Izmir, Turkey,* [3]*Ege University Medical Faculty Department of Pediatrics, Subdivision of Metabolic Diseases, Izmir, Turkey,* [4]*Ege University Medical Faculty Department of Neurology, Izmir, Turkey.*

X linked adrenoleukodystrophy (X-ALD) is a neurodegenerative disease characterized by progressive demyelination of the central nervous system, adrenocortical insufficiency and elevated levels of very long chain fatty acids (VLCFAs). It is caused by mutations in ABCD1 gene located at Xq28. More than 1300 mutations have been identified to date without any genotype-phenotype correlation. In this study we report the mutational analysis of 3 X-ALD patients (1 male and 2 females) showing variable clinical spectrum. In one of the female patients previously reported heterozygous p.W132X mutation was detected. In the other female patient showed IVS5-6delC (c.1489-6delC) and p.P543L variations in compound heterozygous state. The male patient was found to be hemizygous p.R104P mutation that was not reported previously. In conclusion the cases presented in this paper may contribute to the mutation and clinical spectrum of X-ALD while defining a novel mutation and a female case presenting cerebral symptoms.

Nutritional variations in pcu children

W. Aizel, *D. Azouaoui, L. Chamberlain, A. Berhoune;*
CHU Mustapha Bacha, Alger, Algeria.

We have invested in the biological diagnosis of Phenylketonuria (PKU) for many years.
We performed nutritional blood tests on 30 children with PKU, who had been placed on a diet poor in Phenylalanine for at least 12 months. The age of these children was between 15 months and 10 years old.
Following our nutritional study, which included determination of the calcium phosphate product, determination of iron balance and the dosage of vitamins B9, B12 and D parallel to a determination of phenylalanine concentration in serum, we concluded that in the patients that presented consistently a high concentration of phenylalanine in serum there was a direct correlation to a nutritional imbalance.

J06.04
Rare association between thyroid tumor and Anderson-Fabry disease

N. V. Buchinskaya[1], *M. M. Kostik*[1], *E. R. Dosovitskaya*[2], *O. V. Kalashnikova*[1], *V. G. Chasnyk*[1];
[1]*State Pediatric Medical University, Saint-Petersburg, Russian Federation,* [2]*Children Hospital of Rauhfuss #19, Saint-Petersburg, Russian Federation.*

Background: Anderson-Fabry disease (AFD) is a rare, X-linked, inborn error of glycosphingolipid catabolism, resulting from mutations in the alpha-galactosidase A gene (GLA) at Xq22.1. The disease usually starts in early childhood with acroparesthesia and angiokeratomas. Untreated patients have poor prognosis and usually die in their third or fourth decade of life from stroke or uremia. Associations between AFD and some kinds of neoplasm are known. Data about AFD and neoplasm in children are absent for our experience. **Methods:** 15 year old boy with positive family history of AFD has low limbs acroparesthesias since 11 years. Presence of mutation R301L in the GLA gene confirmed the diagnosis. Family members are affected by AFD: mother has acroparesthesias, hypertrophic cardiomyopathy (HCMP) and angiokeratomas, uncle from mother side has HCMP and end stage renal disease. Also 2 family member (men) died early through unknown reason. No neoplasm in the affected family members known. Later patient developed spread acroparesthesias, pain in legs, fever and erythrocyte sedimentation rate elevation. Enzyme replacement therapy with Fabrazyme started in 15.5 years. **Results:** At the age of 15 years old boy presented the clinical signs suspected to hypothyroidism. Ultrasound has revealed a single nodule in thyroid. Follicular adenoma was diagnosed on ultrasound-guided needle biopsy and also confirmed after successful hemythyroidectomy. Currently he receives hormonal replacement therapy. Interestingly, the boy's grandmother had the same adenoma of thyroid gland. **Conclusion:** in our case we report about rare association between thyroid tumor and AFD in childhood age.

J06.05
Study of EPCR gene A1 and A3 haplotypes' in Iranian patients affected with combined hyperlipidemia

N. Janani[1], *P. Mohammadynejad*[1], *H. Delshad Siahaki*[2], *M. Safarpour*[3], *M. Abbaspour*[3], *T. Fazeli Gargari*[1], *R. Asadi*[1], *A. Ebrahimi*[3];
[1]*Islamic azad university of shahr kord, shahr kord, Islamic Republic of Iran,* [2]*Endocrine Center, Tehran, Islamic Republic of Iran,* [3]*Parse, Tehran, Islamic Republic of Iran.*

Disorder of lipid metabolism, especially hyperlipidemia is among the major human health problems. Hyperlipidemia is a disorder of lipid metabolism leading to abnormal rise in fatty substance in circulating blood lipids. The studies that have been done in our country in the recent decade indicate a high prevalence of hyperlipidemia and resulting clinical complications including cardiovascular diseases. Hyperlipidemia broadly occurs for two reasons; genetic disorders and different environmental factors. Today, various genes have been identified in which mutation can cause hyperlipidemia disease among which reference can be made to clotting-factor genes such as EPCR. EPCR gene, as one of the major factors in the control path of thrombosis, is considered as a receptor of protein C in endothelial cells, and its connection with cardiovascular diseases has made us embark on the possible survey of EPCR in hyperlipidemia diseases given the relationship between hyperlipidemia and cardiovascular diseases. The samples includes 100 infected and 100 normal individuals from among the patients who have come to the Center for Endocrine Research of Shahid Beheshti Medical University of Tehran. After genetic counseling, samples are taken from the individuals in question and the samples are sent to the laboratory. Primer design is performed to determine the genotype of the samples based on the molecular methods study of ARMS PCR. The results indicated significant difference between the infected and control groups in A1 Haplotype and in A3 Haplotype($p<0.05$). Therefore, EPCR gene polymorphisms is irrelevant with susceptibility to family combined hyperlipidemia in the Iranian population.

Distribution of I172N missense mutation in Macedonian and Serbian simple virilizing 21-hydroxylase deficiency patients

V. Anastasovska[1], *M. Kocova*[1], *T. Milenkovic*[2], *E. Sukarova-Angelovska*[1];
[1]*Genetic Laboratory, University Children's Clinic, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Institute for Mother and Child Health, Belgrade, Serbia.*

Background: Steroid 21-hydroxylase deficiency is an autosomal recessive disorder, present in 90-95% of all cases with congenital adrenal hyperplasia (CAH). Its classical simple virilizing (SV) form leads to virilization of external genitalia in newborn females and pseudoprecocious puberty in both sexes, due to reactive androgen overproduction. Mainly associated with SV CAH is I172N missense mutation at codon 4 of the CYP21A2 gene that produce enzyme retaining 1-2 % of normal activity.
Method: In 16 Macedonian and 5 Serbian patients suffering from SV CAH, we have performed molecular detection of the I172N mutation, using the PCR/ACRS method. Patients were diagnosed according to standard clinical criteria at the Department of Endocrinology and Genetics, University Children's Clinic, Skopje, Republic of Macedonia and Institute for Mother and Child Health, Belgrade, Serbia.
Results: The I172N mutation was observed in 25% (4/16) of Macedonian SV patients on 18.8% (6/32) of the alleles. Two of them were homozygotes for I172N, one compound heterozygote with P30L on the second allele and one was heterozygote without observed other mutation among tested nine most common point CYP21A2 mutations. The I172N mutation was detected in only one Serbian SV patient (20%) in homozygous state.
Conclusion: The I172N mutation distribution in Macedonian and Serbian SV patients was slightly lower than reported in the European population of the simple virilizing patients. However, our findings suggesting that this mutation indeed acts as a simple virilizing deficiency allele.
Key words: Congenital adrenal hyperplasia, CYP21A2 gene, I172N mutation.

The effect of Sodium Butyrate on the expression of liver specific urea cycle genes (CPS 1, OTC) in human lymphocytes

G. Kazemi sefat[1], *Z. Noormohammadi*[1], *M. Keramatipour*[2], *F. Ghaemi manesh*[3], *S. Talebi*[2], *N. Mohajer*[2];
[1]*Department of Biology, Science and Research Branch, Islamic Azad University, Tehran, Islamic Republic of Iran,* [2]*Department of Genetics, Tehran University of Medical sciences, Tehran, Islamic Republic of Iran,* [3]*Monoclonal Antibody Research Center, Avicenna Research Institute, ACECR, Tehran, Islamic Republic of Iran.*

Introduction: At present the only method for enzyme assay and confirmation of mutations that causing splicing error in CPS 1 and OTC urea cycle genes is liver biopsy. Therefore developing a noninvasive method for evaluation of gene expression in lymphocytes can be an efficacious method in diagnosis of urea cycle disorders. Induction of gene expression using Histone deacetylase inhibitors is a usual method. we have assessed the OTC and CPS 1 expression level after treatment of human lymphocyte cell line with sodium butyrate.
Material and Methods: MTT assay was done to check cell cytotoxicity. Then Quantitative assessment of gene expression was done at non-cytotoxic time-concentrations using SYBR-GreenI Real-time RT-PCR method.
Results: After 48 hours, treatments more than 10 mM, lead to cell injury in human lymphocyte cell line by increasing cell granulation and decreasing cell adhesion. MTT assay also confirmed that 1 and 5 mM concentrations are not cytotoxic. Sodium butyrate significantly increased CPS 1 gene expression (p-value <0.05). This increment was near the expression level in Hep-G2 cell line specifically at 5 mM concentration after 48 hours. In addition sodium butyrate treatment induced OTC gene expression in human lymphocyte cell line.
Conclusion: This study showed that sodium butyrate can induce and or increase expression of two urea cycle specific genes (OTC and CPS 1). The most induction effect occurred in 5 mM treatment after 48 hours. Key words: CPS 1, OTC, Sodium Butyrate
Key words: CPS 1, OTC, Sodium Butyrate, HDACi

Cystic fibrosis liver disease-ultrasound evaluation

I. M. Ciuca[1], *L. Pop*[2], *L. Tamas*[3], *O. Fufezan*[4], *Z. Popa*[5];
[1]*Pediatric II Department, University of Medicine and Pharmacy, Timisoara, Romania,* [2]*Pediatric II Department, University of Medicine and Pharmacy „ Victor Babes", Timisoara, Romania,* [3]*Biochemistry Department, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania,* [4]*Radiology Department, University of Medicine and Pharmacy, Cluj Napoca, Romania,* [5]*National CF Centre, Timisoara, Romania.*

Objectives: Cystic fibrosis (CF) is characterized by clinical polymorphism impressive , whether manifested by chronic obstructive pulmonary disease and pancreatic insufficiency or chronic liver disease that is associated with secondary diabetes . Early diagnosis and proper monitoring of all diseases and aims to extend the quality of life of these children. Ultrasound is a very useful method for the diagnosis neivazivă these complications.
The purpose of this paper is to evaluate hepatopathy associated with cystic fibrosis using ultrasonography .
Methods: 158 patients who were registered with the National Center for Mucoviscidoza (Cystic Fibrosis) Timisoara were evaluated by ultrasound in addition to clinical examination and biological assessment .Ultrasonography Williams score has been used for the assessment of liver and in some cases hepatic transient elastography .
Results: The prevalence of liver disease was 32.27 % (51 patients) . Most patients 62.74 % (32 patients) had moderate liver disease , a rate of 9.8% associated multilobular cirrhosis.There was a good correlation between Williams ultrasound score and the detection of fibrosis by transient elastography , with a better sensibility of the last method.
Conclusion: The frequency of cystic fibrosis associated liver disease is significant. Ultrasound is an extremely effective method for the diagnosis and monitoring of hepatobiliary disease in cystic fibrosis . Early detection of the disease allows the establishment of an appropriate treatment options with improved life expectancy of these patients.

Cystic fibrosis and cow`s milk allergy

L. L. Pop[1], *I. CIUCA*[1], *Z. L. Popa*[2], *B. Almajan Guta*[3], *L. Tamas*[4];
[1]*Pediatric II Department, University of Medicine and Pharmacy, Timisoara, Romania,* [2]*Gynecology Department, University of Medicine and Pharmacy, Timisoara, Romania,* [3]*Department of Physical Education and Sports, Politehnica University, Timisoara, Romania,* [4]*Biochemistry Department, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania.*

Background: In cystic fibrosis an important feature is the pancreatic insufficiency expressed by steatorheea; in some cases, despite enzyme supplementation the chronic diarrhea is poorly controlled. Aim study was to evaluated the presence of cow`s milk allergy among cystic fibrosis children.
Methods: In one year, sixty seven children with cystic fibrosis, aged 1month -3 years (19 infants), followed in our center were observed for CMPA. Cow`s milk allergy was suspected in the presence of specific clinical manifestation(gastrointestinal symptoms, cutaneous signs, respiratory features), in cases with a suggestive medical history(failure to thrive, colics etc). In addition CMPA-specific IgE(α andβ lactoglobulin, casein) and diagnostic elimination test + food challenge test.
Results: Among infants, CMPA was diagnosed in 47.36% (9 patients) of children, predominantly in pancreatic insufficient children (77% -CF infant with pancreatic insufficiency). Toddlers (1-3 years) were diagnosed in a smaller percent, only 16.6 %(8 children) proved to have CMPA, although in more than 35% of toddlers, a positive history for CMPA diagnosis was found. Cystic fibrosis patients with pancreatic insufficiency associated more frequently CMPA(88.23%) than cystic fibrosis patients pancreatic sufficient. The prevalence of cow`s milk allergy was important, cumulating a 25.37% of CF patients.
Conclusion: Cow`s milk allergy was frequently found in CF children, especially associated with pancreatic insufficiency. The „ combined" enteropathy could influence the disese`s outcome and should be considered especially in persistent diarrhea of CF children with correct enzyme supplementation.

J06.10

Heme oxygenase microsatellite polymorphism, oxidative stress, glycemic control in type 2 diabetes Iranian patients

S. Valizadegan[1], *G. Esmail Nia*[2], *K. Banihashemi*[3];
[1]*Biology department ,faculty of science , alzahra university ,tehran,Iran, Tehran, Islamic Republic of Iran,* [2]*Science and Research Azad University of Tehran, Tehran, Islamic Republic of Iran,* [3]*Member of Genetics Society of America, Academic Member, Department of Medical Sciences,IECF, Ministry of Science, Research and Technology, Iran, Tehran, Tehran, Islamic Republic of Iran.*

Heme oxygenase-1 (HMOX-1) is activated by oxidative stress, and gene responsiveness is reportedly determined by the number of dinucleotide (GT(n)) repeats in its highly polymorphic promoter region. „Short" (S; GT(n)<25) alleles reportedly associate with higher response, lower oxidative stress, lower risk of type 2 diabetes mellitus (type 2DM), and better glycemic control and outcome, but data are conflicting. We investigated GT(n) in type 2DM subjects (all ethnic Iranians) in relation to basal glycemic control, oxidative stress, and outcome during up to 3 years' follow-up. Fasting blood from 418 type 2 DM subjects was collected at entry for GT(n) genotyping, glycated hemoglobin, glucose, lipids, and biomarkers of oxidative stress and antioxidants. A subset (n=368) was followed for up to 3 years for incident complications or death. GT(n) genotype distribution was 128, 182, and 108 for, respectively, S/S, S/L, and L/L. No significant differences in glycemic control, lipids, or oxidative stress were seen across genotypes. During follow-up, 168/368 subjects developed complications. No association was seen with GT(n). Glycated hemoglobin and lymphocytic DNA damage was higher (p<0.05) at entry in the incident complications group. No other significant differences were seen in oxidative stress or antioxidants. Data do not support the postulated link between HMOX-1 microsatellite polymorphism and type 2 DM or the putative beneficial effect of the S allele on glycemic control, oxidative stress, or outcome in type 2 DM patients, at least in this particular population.

J06.11

Association study of 844ins68 CBS gene mutation in patients with PKU from Republic of Moldova

K. R. Boiciuc, *N. Usurelu, D. Badicean, V. Sacara;*
Institute of Mother and Child, Chisinau, Moldova, Republic of.

Inherited nonsyndromic sensorineural hearing loss (NSHL) is characterized by a high level of genetic heterogeneity, making extremely challenging to obtain a molecular diagnosis with traditional screening methods. Whole exome sequencing (WES) has been recently introduced as an alternative approach to search for alleles underlying Mendelian disorders and has been successfully applied for gene/mutation discovery. In this study, we used WES to identify the pathogenic mutations responsible for NSHL in three families (NSHL6, 11, and 12), with a recessive inheritance pattern and at least two affected siblings. A total of 9 individuals were subjected to WES using the SeqCapEZ Exome capture kit (Roche) and the HiSeq 2000 sequencer (Illumina). In particular, the NSHL6 patients were compound heterozygous for two novel mutations within the TMPRSS3 gene (DFNB8/10 locus). Both variants segregate with post-lingual, bilateral, high-frequency NSHL and affect evolutionary conserved amino acids located within the TMPRSS3 catalytic domain. In the NSHL11 family, two novel missense variants were found in the heterozygous state in OTOGL, a gene that was only recently associated with NSHL (otogelin-like protein, DFNB84 locus). Finally, in the consanguineous NSHL12 pedigree, WES coupled with homozygosity mapping analysis poin-

ted out a known missense variant (rs74315438) in the CLDN14 (DFNB29 locus) gene, coding for the claudin 14 protein. In conclusion, we provide evidence of the usefulness of WES for the diagnosis of NSHL and increase the knowledge on the genetic defects underlying this disease. This study was supported by: Italian Telethon Foundation (grant#GGP11177) and Fondazione Cariplo, grant N°2013-0825.

Adipocytes mitochondrial DNA copy number variations in metabolic syndrome patients

O. I. Mozhey[1], P. A. Zatolokin[2], L. S. Litvinova[1], **I. O. Mazunin**[1];
[1]Immanuel Kant Baltic Federal University, Kaliningrad, Russian Federation, [2]Kaliningrad Regional Hospital, Kaliningrad, Russian Federation.

Defects in mitochondrial functions play an important role in the metabolic syndrome pathogenesis. Using droplet digital PCR method we showed different fat tissue (greater omentum, hypodermic adipose tissue and mesostenium) mtDNA copy number variations in metabolic syndrome patient ranked by body mass index (BMI). One hundred subjects were recruited from Kaliningrad Regional Hospital, Kaliningrad, Russia during 2012-2013. This group consisted of 20 subjects without metabolic syndrome (BMI ≤ 24.9 kg/m^2) and 80 subjects with metabolic syndrome. The last one was ranked by BMI into four subgroups: pre-obese (BMI 26-30 kg/m^2), obesity first degree (BMI 31-35 kg/m^2), obesity second degree (BMI 36-39.9 kg/m^2), and obesity third degree (BMI ≥40 kg/m^2). The adipose tissue was taken from the patients during scheduled laparoscopic operations. We showed a tendency to reduce the mtDNA copy number, which was observed with increasing body mass index.

J06.13
Identification and functional analysis of a novel mutation in methylmalonyl CoA mutase gene (MUT gene) causing methylmalonic acidemia

M. Keramatipour, *S. Talebi, S. Ahmadlou;*
Tehran University of Medical Sciences, Department of Medical Genetics, Tehran, Islamic Republic of Iran.

Methylmalonic acidemia (MMA) is one of the inborn errors of metabolism, caused by either deficiency of the enzyme methylmalonyl CoA mutase, or a defect in the biosynthesis of its cofactor, adenosyl-cobalamin. At least 200 mutations in the methylmalonyl CoA mutase gene (MUT gene) have been identified in patients with methylmalonic acidemia. Here we present a novel mutation in the MUT gene of a 3 years Old Iranian girl with metabolic acidosis.
The patient had history of recurrent attacks of severe metabolic acidosis. Tandem mass spectroscopy showed elevated propionyl carnitine (C3) and the urine organic acid analysis confirmed the diagnosis of MMA. She was screened for mutations in the MUT gene. A novel C to G nucleotide change was found in position -3 of the acceptor splice site in intron 12. The heterozygosity of both parents was confirmed.
In order to demonstrate the possible effect of this nucleotide change, an Insilico analysis was done using CBS prediction site (http://www.cbs.dtu.dk/services/SignalP). This analysis suggested that the reported nucleotide change can create abnormal splicing pattern.
To confirm abnormal splicing from the mutant allele, total RNA was extracted from patients' father peripheral blood. cDNA synthesis was done. Appropriate primers were designed to amplify fragments from the region representing normal and aberrant variants of mRNA. Amplified products were sequenced. This experiment, clearly confirmed the retention of intron 12, caused by the reported nucleotide change, in sample obtained from patients' father, consistent with the role of reported change in causing MMA.

J06.14
Study of nuclear gene POLG with mitochondrial function in mitochondrial diabetes

M. Fourati[1], *N. Mezghani[1], M. Mnif[2], M. Abid[2], F. Fakhfakh[1];*
[1]Laboratory of Human Molecular Genetics, Faculty of Medicine of Sfax University of Sfax, Sfax, Tunisia, [2]Department of Endocrinology, Hospital Hedi Chaker, Sfax, Sfax, Tunisia.

Mitochondrial diseases are highly variable; they can affect several organs such as the heart in cases of cardiomyopathy, ears deafness, brain in case of neurodegenerative diseases, and the pancreas in diabetes.... The common denominator of these diseases is the dysfunction of the respiratory chain, plays an essential role in the stimulation of insulin secretion and the regulation of blood glucose levels. This deficiency may be due to abnormalities related to mitochondrial DNA or nuclear DNA. Indeed, the mitochondrion is semiautonomous which 20 % of the proteins are encoded by the mitochondrial DNA, and 80% by nuclear DNA. We noted the nuclear gene *POLG*, involved in mitochondrial respiratory chain and responsible of mitochondrial DNA replication.
In this context, a Tunisian patient with mitochondrial DNA deletions, suffering from mitochondrial diabetes was studied: searching for mutations and polymorphisms in *POLG* gene, by PCR using specific primers followed by sequencing.
The results showed the complete absence of mutations in exons 13, 14, 19, 20 and 22, however, we note the presence of a heterozygous profile (10/ 11) of the CAG repeat different cases of normal control, insertion of four bases c.2734 +37-2734 +38 ins AGGT at intron 17 and a polymorphism described c.3708 G> T in the heterozygous state (rs3087374) at exon 23.
In this study we want to look if there is any correlation between mutations found at the nuclear POLG gene and mutations and deletions already found at the mitochondrial DNA of the patient.

J06.15
Mucolipidosis II presenting with rickets-like features in a newborn

B. G. Nur[1], *E. Mihci[1], Y. Erdogan[2], Y. Curek[3], N. Oygur[2], I. Bircan[3];*
[1]Akdeniz University School of Medicine, Department of Pediatrics, Division of Pediatric Genetics, Antalya, Turkey, [2]Akdeniz University School of Medicine, Department of Pediatrics, Division of Neonatology, Antalya, Turkey, [3]Akdeniz University School of Medicine, Department of Pediatrics, Division of Pediatric Endocrinology, Antalya, Turkey.

Mucolipidosis II (I-cell disease) is a progressive inborn error of metabolism with clinical onset at birth and fatal outcome most often in early childhood. The incidence is approximately 1 of 500,000. Urinary excretion of oligosaccharides are excessive, and high levels of lysosomal enzymes, such as β-hexosaminidase, β-galactosidase, α-mannosidase and arylsulfatase A, are detected in serum or cultured fibroblasts. GNPTAB is the only gene in which mutations are known to cause Mucolipidosis II. Here, we presented a female infant born as the second child of first degree cousin marriage. On her physical examination; course facies, craniotabes, long eyelashes and eyebrows, broad nasal bridge and tip, low set ears, gingival hyperplasia, short neck, rizomelic shortness of extremities, width of the wrists, pes cavus, hepatosplenomegaly, and abdomen distention were detected. Skeletal survey showed ovoid spine and scoliosis. Limb radiographies showed bilateral shortness of the humerus and femur, metaphysial dysplasia, wide metaphysis, osteopenia, sclerotic and lytic areas. Patent ductus arteriosus and secundum atrial septal defect were noted on echocardiography. Cranial magnetic resonance imaging revealed wide encephalomalasic areas on cerebral parenchyma and hydrocephaly. The urine tests for mucopolysaccharides detected elevated glucosaminoglycans (3.37mg/dl, normal ranges:0-3mg/dl). Plazma beta-hexosaminidaz A+B was 9223 umol/l/h (normal:600-3500, control: 922), alfa mannosidaz was 3069 umol/l/h (normal:20-100, control:43). This result was consistent with Mucolipidosis type II.
Although Mucolipidosis II is a rare disorder, it is important to consider in the differential diagnosis of newborns with Rickets-like radiological and biochemical features. Early diagnosis allows more effective medical management and genetic counseling.

Association study of ACE gen I/D polymorphism in Iranian affected patients with multiplex hyperlipidemia

T. Fazeli Gargari[1], *P. Mohammady nejad[1], A. Ebrahimi[2], M. Safarpour[2], M. Abbaspour[2], N. Janani[1], R. Asadi[1], H. Delshad Siahaki[3];*
[1]Islamic Azad University of Shahrekord, Shahrekord, Islamic Republic of Iran, [2]Parseh, Tehran, Islamic Republic of Iran, [3]Endocrine Center, Tehran, Islamic Republic of Iran.

Hyperlipidemia disease is the main causes of dangerous disease such as atherosclerosis, CVD, and ischemic heart disease. high cholesterol and other lipids in the blood is a susceptible Such disease in individuals patients hyperlipidemia. The main objective of this study is to Association study of ACE gene I/D polymorphism in Iranian affected patients with multiplex hyperlipidemia. This is a Case-control study based on population and 100 cases (56 men and 44 women) between 9-66 yearsold, in affected patients with multiplex hyperlipidemia Referred to the endocrinology clinic of Taleghani hospital and 100 healthy subjects have been implemented. All samples were measured cholesterol and triglycerides and completed questionnaires were obtained. Cholesterol above 200 mg/dl and triglycerides above 150 mg/dl, were classified as hyperlipidemia. Than we used GAP-PCR technique. Results showed that there is significant between patients and control group (P=0.004). So, ACE gene I/D polymorphism has association with hyperlipidemia disease in Iranian population.

Testing the impact of genetic and non-genetic factors on common forms of obesity from Romania

S. Spandole[1], *C. Cristescu[2], D. Cimponeriu[1], M. Toma[1], I. Radu[1], G. Mihaescu[3];*
[1]Department of Genetics, University of Bucharest, Bucharest, Romania, [2]Titu Maiorescu

University, School of Medicine and Pharmacy, Bucharest, Romania, [3]Department of Microbiology, University of Bucharest, Bucharest, Romania.

Obesity is one of the greatest medical challenges of the 21st century and its prevalence is continuously increasing. It has a complex determinism that involves genetic and non-genetic factors.
The aim of this study was to evaluate the impact of several genetic and non-genetic factors on common forms of obesity from Romania.
Unrelated obese patients (n=80) and healthy normoponderal subjects (n=80) were selected. Biological samples and clinical information was collected after informed consent was obtained. The genetic markers tested were Insulin -23Hph, IGF2 Apa I, SELL P213S, TGFb C-509T, HSPG BamH1 and IL6 G-174C.
Multiple linear regressions showed a relationship between obesity, cholesterol levels and triglyceridemia. The infection with Torque teno virus did not show a significant association with obesity. Genetic polymorphisms did not significantly alter the risk of obesity. However, statistical analysis showed an increased association between several genetic markers and teeth damage risk (HSPG BamH1, TGFb C-509T, SELL P213S, and IGF2 ApaI) and 2D/4D ratio (IGF2 ApaI) in our subjects.
The complex interplay between genetic and non-genetic factors plays an important role in modulating obesity risk. Nonetheless, further information is needed to accurately assess the impact of these factors on common forms of obesity.

The importance of NMR Spectroscopy in diagnosis of some inborn errors of metabolism: lessons from hyperammonemia condition, galactosemia, and alkaptonuria

R. Vulturar[1,2], *A. Nicolescu*[3,4], *C. Deleanu*[3,4];
[1]Univ. of Medicine and Pharmacy, Dept. of Cell and Molecular Biology, Cluj-Napoca, Romania, [2]Cognitive Neuroscience Laboratory, Babes-Bolyai University, Dept. of Psychology,, Cluj-Napoca, Romania, [3]"P.Poni" Institute of Macromolecular Chemistry of the Romanian Academy, Iasi, Romania, Iasi, Romania, [4]"C.D. Nenitescu" Institute of Organic Chemistry of the Romanian Academy, Bucharest, Romania, Bucharest, Romania.

Metabonomics is a powerful tool for identifying any disturbances in normal homeostasis of metabolic processes and this emerging fields, in which a large number of small-molecule metabolites are detected quantitatively in a single step, promises immense potential for early-diagnosis, monitoring, and understanding the pathogenesis of many diseases. In many errors of inborn metabolism, the relationship between disease state, metabolic biomarker and genetics is easily understood, but the clinical/ biochemical findings in some inborn errors of metabolism (IEM) are often nonspecific; an early differential diagnosis made in a single urinary sample it gives an important advantage. We present the spectrum of metabolites of urine from 1 year-old girl with stroke-like episode, elevated transaminases, coagulopathy, being first interpreted as encephalitis. Beside the clinical presentation and the hyperammonemia, the fast results gave by urinary NMR-spectrum showing a high concentration of orotic acid indicates the OTC (ornithine transcarbamilase) deficiency diagnosis. Beside this, we present our results and the utility of this method for rapid diagnosis and monitoring steps for galactosemia and alkaptonuria. The level of excretion of the metabolites in these three IEM has been well within the range of NMR detection. In the critical care setting, IEM that were not diagnosed through the neonatal screening should be considered as cause of acute neurologic, hepatic/ renal decline, rapid diagnosis being essential. We demonstrate the effective use of NMR-spectroscopic-profiles of urine in differential diagnosis for Urea Cycle Disorders and the possibility of management in other IEM.

A novel mutations in Iranian family with Phenylketonuria

Z. Soltani[1], *M. Miryounesi*[1], *V. R. Yassaee*[1,2];
[1]Genomic Research Center, Tehran, Islamic Republic of Iran, [2]Shaheed Beheshti Medical University, Tehran, Islamic Republic of Iran.

Phenylketonuria ((PKU; MIM# 261600) is an autosomal recessive inborn of metabolism resulting from a deficiency of PAH.
Since 2005, PKU screening program was performing in Iran. According to the national databases a number of mutation has been identified throughout the PAH gene.
We have investigated a consanguineous family referred to our center, as a center for national PKU screening program. Blood sample were collected after informed and written consent was obtain. Isolated genomic DNA derived from subjects was amplified using intronic primers. The entire sequencing of the PAH gene including coding region and exon-intron boundaries were analyzed by PCR and Sanger sequencing.
Molecular analysis revealed a heterozygote mutation (ex3 del. 4765) in parentsand homozygote mutation in the proband.This is the first report of this mutation in Iranian population.

J06.20
Phenylalanine hydroxylase (PAH) gene mutation spectrum in patients with PKU in Karachay-Cherkessia Republic, Russian Federation

A. Stepanova[1], *S. Amelina*[2], *R. Zinchenko*[1], *A. Polyakov*[1];
[1]Research Centre for Medical Genetics, Moscow, Russian Federation, [2]Scientific Research Institute of Biology „Southern Federal University", Rostov-on-Don, Russian Federation.

Phenylketonuria (PKU) is the most common inborn error of amino acid metabolism in Europeans. PKU is classified by the severity of hyperphenylalaninemia in patients. Phenylketonuria is caused by a high variety of mutations in the PAH gene (up to date more than 550 mutations is known).
We have studied 28 PKU-patients from Karachay-Cherkessia Republic, Russian Federation. For screening of 10 PAH gene mutations (IVS2+5G>A, IVS2+5G>C, p.L48S, p.E280K, p.R261X, p.R243X, p.R243Q, p.E390G, p.A403V, p.Y414C) the multiplex system for MLPA PCR-analysis was created. Using this method we detected mutation p.R261X on 45 (80,3%) chromosomes and mutation p.L48S on 1 (1,8%) chromosome. The remaining uncharacterized PKU chromosomes were analyzed by scanning the 2, 4, 5, 6, 7, 10, 12 exons and intron/exon junctions of PAH gene by automated sequencing. In addition three different mutations were found: p.R413P on 5 chromosomes (8,9%), p.F331S on 2 chromosomes (3,6%) and novel mutation p.P211L on one chromosome. Mutation p.P211L was not detected in 50 normal controls. A mutation detection rate 96,4% was achieved.
The p.R261X, p.R413P and p.F331S mutations account 92,8% PAH mutations detected in PKU patients from Karachay-Cherkessia Republic Russian Federation.

A Whole mitochondrial genome and POLG gene screening in a tunisian patient with mitochondrial myopathy and Diabetes

M. M. M. B. Maalej, **M. M. M. B. Maalej***;*
Laboratory of Molecular Human Genetics Faculty of Medicine of Sfax,, Sfax, Tunisia, Tunisia.

Inherited mitochondrial diseases can be caused by mutations of mitochondrial DNA or of nuclear genes that encode mitochondrial proteins. Although many mitochondrial disorders are multisystemic, some are tissue specific .Mitochondria-related myopathies (MM) are a complex and heterogeneous group of neuromuscular disorders defined by a varying degree of dysfunctions of the mitochondrial respiratory chain (OXPHOS). In the present study, we performed the clinical, genetic, and molecular characterization of a Tunisian patient with clinical features of mitochondrial myopathy associated with Diabetes. The analysis of the mtDNA extracted from the blood leucocytes in the studied patient revealed various reported polymorphisms in the D-loop region, the ribosomal and transfert RNAs but also the coding genes The detected missense substitutions, especially the 8701A>G(T59A),the 8860A>G (T112A) ,the 10086A>G(N10D),the 13105A>G(I257V) ,the 14766C>T(T7I) were reported in the literature in patients with LHON, Mitochondrial diabetes , Leigh syndrome, cardiomyopathy,muscle pathology and unaffected individuals .Indeed, we detect the 15940delT in the MT-ATT was previously described in association with Mitochondrial myopathy .In addition,we carried out a mutational analysis of POLG1 gene encoding the mtDNA polymerase gama ,to look for an evnetual implication of nuclear gene in the mitochondrial diseases .The results of direct sequencing of all the POLG exons show the presence of the known heterzygote variation c.2492A>G in exon16 which substitutes the conserved amino acid Tyrosine to Cysteine (Y831C) described in associtaion with mitochondrial myopathy The described proband suffers from multisystemic disorders affecting neuromuscular and endocrine organs which could be caused by the association of these variations.

Clinical complexity of Prader Willi Syndrome- genotype-phenotype correlations

A. Dobrescu[1], *A. Chirita-Emandi*[1], *N. Andreescu*[1], *N. Cucu*[2], *M. Puiu*[1];
[1]Victor Babes University of Medicine and Pharmacy, Timisoara, Romania, [2]University, Bucuresti, Romania.

Background: The genetic variability of Prader Willi Syndrome (PWS) has a high impact for the phenotypic features.
Aims:. We aim to evaluate the genotype-phenotype correlation of a Romanian PWS patients group.
Methods: The study group had 34 PWS patients, boys and girls: subgroup A- 21 patients with chromosome 15 deletion and subgroup B- 13 patients with positive methylation test. The mean age was 10.731±8.478 and 8.553± 5.458 years. We compared the PWS characteristic features between the two subgroups.
Results: The clinical score mean was 9.083±1.717 for subgroup A compared with 10,045±1.738 for subgroup B. All patients from deletion subgroup had facial dysmorphism. Hypogonadism and hair and skin hypopigmentation were

more frequent in subgroup A. Both groups presented sleep disorders (75%). The hyperphagia onset was almost the same for both groups (around the age of 2 years) with a similar fat mass distribution. All patients from subgroup B and 80.95% from subgroup A had small hands and feet; thick saliva and verbal coefficient were more frequent in subgroup B. Skin picking and ocular abnormalities had a higher prevalence in subgroup A. We didn't identify significant differences between the two groups regarding the spine and bone density.
Conclusions: The results highlight the clinical variability of PWS. The differences can be caused by qualitative change of paternal gene expression located outside the critical region and missing in patients with uniparental disomy. A reduced life expectancy is correlated with a severe phenotype.

J06.23
Familial hyperoxaluria and infertility: is there a correlation?

R. Frikha, *O. Trabelsi, S. Daoud, F. Turki, O. Kaabi, R. Louati, N. Abdellaoui, T. Rebai, N. Bouayed Abdelmoula;*
Laboratory of Histology, Faculty of Medicine, Sfax, Tunisia.

Hyperoxaluria (PH) is an autosomal-recessive disorder of endogenous oxalate synthesis characterized by accumulation of calcium oxalate primarily in the kidney; and leads to nephrocalcinosis and end-stage renal disease. A wide spectrum of associated anomalies may be present (cardiovascular; skeletal; neurological), and there are three forms of primary hyperoxaluria in which the underlying defects and clinical onset and severity have been identified.
It's about a 31-years-old man, with history of recurrent urolithiasis for who chromosomal investigation was carried out to explore a male infertility of 1 year and half related to azoospermic profile at the semen level, varicocele and microlithiasis on testicular ultrasound. Cytogenetic analysis carried out using RHG banding, disclose the presence of klinefelter syndrome (47,XXY) despite the normal morphotype. At the genetic counselling, the patient had non consanguineous parents and familial history showed similar recurrent lithiasis in his mother and brother, who was infertile since 2002.
To my knowledge; this is the first case of familial hyperoxaluria; especially the type IIII (HP3; OMIM #613616); a rare and middle entity with mitochondrial transmission, which is associated with klinefelter syndrome. The last is often associated with testicular microlithiasis; a rare entity; which may be the consequence of overproduction of oxalate and the cause of infertility. Thus, delineation of diagnostic both by genetic and histopathological screening is mandatory in order to clarify the genotype phenotype correlation.
Therefore; we insist in the comprehensive evaluation of infertility at cytogenetic (chromosomes abnormalities?) and molecular level (mosaicism?), since it's a heterogeneous and complex disease.

J06.24
Mutations of mitochondrial genome and atherosclerosis of coronary and carotid arteries.

L. Egorova, *A. Postnov, M. Ezhov, I. Sobenin;*
Cardiology Research Center, Moscow, Russian Federation.

Aim. To evaluate the association between the level of heteroplasmy for mitochondrial mutations C3256T, G13513A, G14846A, G12315A in human white blood cells and presence of atherosclerosis in coronary and carotid arteries.
Methods. We included 130 patients (mean age 55±9 years, 116 men) with coronary heart disease (CHD) verified by angiography. Control group consisted of 63 subjects without angiographic coronary artery disease. DNA samples were obtained from whole venous blood using commercially available kits for DNA extraction. For the amplification of fragments of mitochondrial DNA by polymerase chain reaction method followed by pyrosequencing, the corresponding primers and conditions were used. On the basis of pyrosequencing data analysis, the level of heteroplasmy for C3256T, G13513A, G14846A, G12315A mutations in DNA samples were calculated.
Results. The level of G13513A and C3256T heteroplasmy was significantly higher (p=0.03; p=0.01, respectively) and level of G12315A heteroplasmy was lower (p=0.004) in CHD patients versus control group. There was significant correlation of carotid atherosclerosis severity and levels of C3256T (r=0.49, p=0.0001), G14846A (r=0.48, p=0.0001) and G12315A heteroplasmy (r= -0.32, p=0.01). Level of G14846A heteroplasmy was higher in subjects older than 45 years. There was no any relation of mitochondrial genome mutations and smoking, hypertension, CHD family history. Presence of hyperlipidemia was positively related to C3256T heteroplasmy (r=0.18, p=0.01) and negatively associated with G12315A heteroplasmy (r= -0,2, p=0,005). There was positive significant correlation between lipoprotein(a) level and G14846A (r= 0,23, p=0,01).
Conclusion. We found independent positive correlation of mutations C3256T, G13513A and G14846A with both coronary and carotid atherosclerosis.

Assessing the implication of genetic and non-genetic factors in type one diabetes mellitus

C. Cristescu[1], *E. Rusu*[1], *V. Cristescu*[1], *S. Spandole*[2], *M. Toma*[2], *I. Radu*[2], *D. Cimponeriu*[2];
[1]*Titu Maiorescu University, School of Medicine and Pharmacy, Bucharest, Romania,*
[2]*Department of Genetics, University of Bucharest, Bucharest, Romania.*

Type 1 diabetes mellitus (T1DM) is a multifactorial disease with a high rate of incidence in the Romanian population. The purpose of this case-control study was to test the possible association of genetic and non-genetic factors with type 1 diabetes mellitus. For this study, eighty T1DM patients and eighty healthy subjects were selected. Blood samples along with clinical, anthropometric and lifestyle data were collected after informed consent. The genetic factors tested were polymorphisms of insulin, IGF2, SELL, TGFb, HSPG and IL6 genes. Total cholesterol levels were higher in T1DM group (p<0.0001), regardless of gender. Triglyceride levels were higher in diabetic women than in same sex controls (p=0.0003), and also in healthy men compared to healthy women (p=0.001). Men had fewer visits to the dentist in the last 12 months (p=0.001). Insulin -23Hph polymorphism was significantly associated with T1DM (OR AA = 4.26, p<0.0001). HSPG BamH1 polymorphism (OR TT = 0.22, p=0.0006), as well as the combination of IL6C allele and SELL CC genotype (OR=4.69, p=0.0004) were associated with dental damage. Our data showed that insulin -23Hph polymorphism is associated with T1DM in our patients. Dental damage risk may be modulated by genetic factors such as HSPG BamH1 polymorphism in our cohorts.

J06.26
Late-onset of Wilson's disease (case report)

A. Belengeanu[1], *M. Stoian*[2], *V. Belengeanu*[3], *C. L. Bohiltea*[4];
[1]*University of Medicine and Pharmacy "Victor Babes" of Timisoara, Department of Morphologic Microscopy, Discipline of Molecular and Cellular Biology, Timisoara, Romania,* [2]*Personal Genetics-Medical Genetics Center, Bucharest, Romania,* [3]*„Vasile Goldis" Western University of Arad, Department of Genetics, Timisoara, Romania,*
[4]*University of Medicine and Pharmacy "Carol Davila", Department of Medical Genetics, Bucharest, Romania.*

Wilson's disease is a rare inherited metabolic disease that leads to copper accumulation mainly in the liver and brain. The clinical symptoms and age at onset of Wilson's disease (WD) are highly variable.
Most patients with WD are diagnosed between the first and the fourth decade of life, although the age at presentation can vary from 3 to 70. Wilson's disease has many symptoms. The broad spectrum of clinical manifestations can be divided into neurological (brain-related) and non-neurological. The primary consequence in about 40 percent of patients with Wilson's is liver disease.
We report a case in which the diagnosis was made late in a man of 67 years. This patient suffered from macroglobulinemia Waldenstrom and had standard specific scheme with chemotherapy treatment. After a course of chemotherapy the patient had an acute attack of jaundice.
To establish the correct cause of jaundice more tests were done: MRI cholangiography, endoscopic retrograde cholangiography. Since these investigations were normal mechanical jaundice was excluded. Because jaundice progressed were performed and other tests, including ceruloplasmin, plasma copper and urine copper. Upon these determinations Wilson's disease was suspected because were found low level of serum ceruloplasmin (12 mg/dl), increased serum copper (187µg/dl), increased urinary copper excretion (97 µg/24 hours). FibroMax test revealed a moderate liver fibrosis denoted by F2. Comprehensive evaluations of clinical signs, liver biopsy and gene analysis are helpful for a correct diagnosis. Late-onset WD is a frequently overlooked condition.

J06.27
Increased level of oligomeric plasma alpha-synuclein in patients with different lysosomal storage diseases

E. Nuzhnyi[1], *A. Emelyanov*[1,2], *T. Boukina*[3], *G. Salogub*[1], *A. Yakimovskii*[1], *E. Zakharova*[3], *S. Pchelina*[1,2];
[1]*First Pavlov's State Medical University of Saint-Petersburg, Saint-Petersburg, Russian Federation,* [2]*Petersburg Nuclear Physics Institute, Saint-Petersburg, Russian Federation,*
[3]*Research Centre for Medical Genetics, Moscow, Russian Federation.*

Lysosomal storage diseases (LSD) are class of inherited disorders caused by mutations in genes, encoding proteins critical for lysosomal function. Alpha-synuclein is a presynaptic neuronal protein that can form neurotoxic oligomers and has been implicated in Parkinson's disease and other neurodegenerative diseases. Clearance of alpha-synuclein is mediated by ubiquitin-proteasome system and autophagy-lysosomal pathway so lysosomal dysfunction may play a role in accumulation and aggregation of alpha-synuclein.
The aim of our work was to estimate the level of oligomeric plasma alpha-synuclein in LSD patients.

We generated plasma of 46 patients with different LSD: 41 - Gaucher disease (GD; median age 15, range 1-71, 17 males); 5 children with other LSD (2 - Niemann-Pick type C, 2 - Krabbe disease, 1 - Wolman disease; median age 4, range 1-18, 2 males) and two control groups: 41 healthy individuals (median age 16, range 3-70, 17 males) and 21 healthy children (median age 10, range 3-16, 9 males). Oligomeric alpha-synuclein plasma level was measured using sandwich ELISA (Human Synuclein OLIGO kit Roboscreen, Germany).
The level of alpha-synuclein oligomers was significantly elevated as in GD (patients: median 22,9 pg/ml, range 1,57-444,58 pg/ml; controls: median 6,08 pg/ml, range 1,05-439,43 pg/ml, p = 0.0001) so in others LSD (patients: median 126,35 pg/ml, range 5,42-378,50 pg/ml; controls: median 8,95 pg/ml, range 2,29-103,14 pg/ml, p = 0.021).
This is the first report of elevated oligomeric alpha-synuclein level in plasma of different LSD patients. Our results allow to suggest that mutations in lysosomal proteins genes promote alpha-synuclein aggregation in LSD.

Functional activity of lymphocytes mitochondria in children with genetically diagnosed gycogen storage disease of type I

O. Kurbatova, *A. Surkov, S. Polyakova, L. Miroshkina, T. Izmailova, I. Samokhina, E. Kapustina, K. Savostyanov, A. Pushkov, S. Petrichuk;*
Scientific Center of children's health Russian Academy of Medical Sciences, Moscow,, Russian Federation.

Introduction:Glycogen storage disease(GSD) is a metabolism disorder resulting in glycogen accumulation in hepatocytes and in development of the secondary mitochondrial disfunction.
Aim:to evaluate functional activity of lymphocytes mitochondria in children with genetically diagnosed GSD of Ia and Ib type.
Materials and methods:23 patients with GSD were examined,9 of them-with Ia type,14-with Ib type.34 nominally healthy children composed the control group.
The functional activity of mitochondria was estimated by succinatedehydrogenase(SDH) activity, which was identified in the general lymphocytes population,-in T-lymphocytes,B-lymphocytes and Nk-cells by flow cytometry method(FC500).
Results:In patients with GSD of Ia type there were determined mutations:c.247C>T, c.883C>T of G6PC gene. In patients with Ib GSD, mutations of the gene SLC37A4:c.1042_1043delCT , c.345insG, c.411G>A,c.413G>A,c.528delG, as well as mutations non-reported before:c.1016G>T(in 3 patients),c.817G>A(in 1 patient) were identified.
In all children with I type GSD,decrease of SDH activity in the general lymphocytes population in comparison with the norm was revealed(p<0,02,Kolmogorov-Smirnov test).
In patients with Ib type, characterized by more severe disease course, there was detected greater decrease of mitochondria functional activity than in children with Ia type(p<0,05).
SDH activity analysis in lymphocytes population showed 40% decrease in B-cells and 18 % in T-lf regarding the norm, with 20 % SDH activity increase in Nk-cells and NkT-lymphocytes compared with the norm.
Conclusions:Disfunctions of mitochondrial apparatus, more prominent in patients with Ib type, were revealed in patients with Ia and Ib GSD. SDH lymphocytes activity analysis may be used as additional diagnostic criterion for evaluation of the condition severity of children with GSD.

The Importance of Test Variability in Acute Myeloblastic Leukemia and the Comparison of Different Parameters in Follow-up of Minimal Residual Disease

A. Ozturk Kaymak, *Ç. Sönmez, S. Öztomurcuk, N. Talayhan, E. Özcan, M. Dinç, G. Güntaş;*
Department of Medical Genetics Ministry of Health, Dr. A.Y. Demetevler Oncology Training and Researc, Ankara, Turkey.

Acute myeloid leukemia (AML), phenotypically and genotypically is a quite heterogeneous disease. A patient who applied to hematology polyclinic of our hospital with various complaints was diagnosed with AML. Following this, in genetic analyses that were performed, t(8;21) and FLT3-ITD were found as positive. Additionally, in chromosome analysis trisomy 8 was observed. After remission was ensured in the patient, allogenic stem cell transplantation was made. By performing t(8;21), FLT3, and trisomy 8 analyses of the patient within regular intervals, it is aimed to provide prior information about relapse and minimal residual disease. In this patient, our follow-up parameter for minimal residual disease with RT-PCR was t(8;21). FLT3-ITD was our follow-up parameter with conventional PCR. Additionally in our patient, the chimerism follow-up was done in capillary electrophoresis by the analysis of short tandem repeats (STR). From the aspect of MRD follow-up, concordant results were obtained from both conventional PCR and RT-PCR and also from the capillary electrophoresis. From these three methods the one which has the highest sensitivity is RT-PCR, then in the second place capillary electrophoresis comes and after that conventional PCR comes. From the point of laboratory since the sensitivities of the methods are different, studying with several methods for the follow-up of minimal residual disease might be required. Additionally with this case, it is attempted to emphasize the importance of examination of all chromosomal anomalies along with known gene mutations in newly diagnosed AML patients from the aspect of diagnosis, follow-up and prognosis of the patients.

BIOMED-2 Protocols: The Best Diagnostic Tool for Suspicious Lymphoma Malignancies

S. Ghorbian[1], *E. Sakhinia*[2], *M. Asghari Estiar*[3];
[1]*Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [2]*Department of Medical Genetics, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [3]*Department of Medical Genetics, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

B cell non-Hodgkin lymphomas (B-NHL) are generally considered as aggressive malignancies which originate from of the transformed B cell. BIOMED-2 multiplex PCR has been suggested as a gold standard method for the detection of monoclonality in the immune cell system in hemato-malignancies and lymphoproliferative disorders. Molecular clonality (assays?) were performs based on the patterns of gene rearrangements in the immunoglobulin chains loci. During B cell malignancies, immunoglobulin recombinant constructions are produced exclusively, and are applied as diagnostic biomarkers in B-NHL. Here, we used the BIOMED-2 protocol to reveal the diagnostic value of immunoglobulin light chains (Igκ, Igλ) and incomplete IGH D-J monoclonal gene rearrangements on FFPE samples. The study was performed on 70 patients with B-NHL which were previously assessed for IGH monoclonality and failure to clarify rearrangements. Our results revealed positive clonality in 62 out of 70 (~89%) cases in the Igκ and Igλ analysis. The samples with positive clonality included 41.4% for Igλ and 47.2% for Igκ. However, our investigation on FFPE tissue revealed that EuroClonality BIOMED-2 protocols could be considered as a valuable and reliable method for clonality detection especially in failure of the IGH analysis. In general, clonal Ig gene rearrangement assays are applicable for the diagnosis of lymphoproliferative disorders and are a distinguishable method for differentiating between malignant and benign lymphoma disorders. Furthermore, we are able to implement the BIOMED-2 protocol as a routine diagnostic tool for hemato-malignancies.

J07.03
IGH Clonality Detection in Lymphoma Malignancies of an Iranian Population Using BIOMED-2 Protocols

G. Moharrame[1], *E. Sakhinia*[2], *M. Asghari Estiar*[3];
[1]*Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [2]*Department of Medical Genetics, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [3]*Department of Medical Genetics, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

The B-cell differentiation procedure is coordinated with the expression of particular cell surface antigen receptors, the so-called immunoglobulins. Lymphomas are mostly characterized as clonal prolif¬erations of specific tumour cells. Routinely, the detection of malignant lymphomas are largely evaluated by their morphological features, immunohistochemistry and flow-cytometric im¬munophenotyping. However, these conventional methods cannot be relied upon to distinguish between certain types of lymphomas. BIOMED-2 multiplex PCR has been suggested as a gold standard method for differentiating between malignant and benign lymphoma disorders. Here, we used BIOMED-2 protocols to determine the clonality of IGH gene arrangement in patients with lymphoma. PCR amplification was performed on FFPE of 50 patients with B-cell lymphoma, which consisted of 11 cases of with HLs, 25 cases of B-NHLs and 14 cases of B-LPD (lymphoproliferative disorders) with an unknown subtype. Positive clonality was detected in 76% of patients with B-NHLs, with 24% of the cases illustrating clonality showing a polyclonal pattern. In B-HLs, 63% of the cases showed clonality and 36% of the cases showed polyclonality. In addition, positive clonality was observed in 42.8% of cases with B-LPD, with clonality not observed in 57% of cases in any of the immunoglobulin gene family (FR1, FR2, FR3. In the DLBCL groups, clonality was detected 75% of the cases. Patients which were diagnosed with FL and MALTs showed 100% clonality for complete IGH. However, our investigation on FFPE tissue revealed that EuroClonality BIOMED-2 protocols could be considered as a valuable and reliable method for clonality detection, especially in IGH analysis.

Decreased IL-17A gene expression and decreased interleukin-17A on T-cells in children with Down Syndrome

A. Jakubiuk-Tomaszuk[1], *W. Sobaniec[1], A. Galicka[2], E. Poskrobko[3], M. Rusak[4], A. Nędzi[1];*
[1]Department of Pediatric Neurology and Rehabilitation, Bialystok, Poland, [2]Department of Medical Chemistry, Bialystok, Poland, [3]Laboratory Diagnostics, Bialystok, Poland, [4]Department of Hematological Diagnostics, Bialystok, Poland.

Down syndrome is by far the most common best known chromosomal disorders in human. It expresses multiple systemic complications with both structural and functional defects as a part of the clinical manifestation. Mechanism of immune changes occurring in Down Syndrome is complex and include extra gene copy of chromosome 21 and secondary dysregulation of numerous intercellular interactions. Recent studies suggest a role of IL-17 proinflammatory cytokine located on 6p12 chromosome in the pathogenesis of autoimmune diseases. Here we aimed to analyze IL17A gene expression in peripheral white cells and interleukin-17A intracellular expression on CD4+ T-cells. The research was carried out on the group of 58 children aged 6 to 12 including the group of 30 children with Down Syndrome (the simple trisomy of chromosome 21 only) and the reference group of 28 healthy children. We evaluated gene IL17A expression using real-time PCR and intracellular IL-17A analyzed by flow cytometry. We revealed significantly decreased gene expression on white cells and significantly decreased expression on IL-17A levels on CD4+ T-cells in Down Syndrome. Our data indicate that decreased IL-17A expression may play significant role in etiology of autoimmune diseases in Down Syndrome. Moreover, we demonstrated that in Down Syndrome the other gene located outside the extra chromosome 21 is also affected.

J07.05

Familial autoimmune Lymphoproliferative Syndrome caused by homozygous FAS Ligand (FASLG)mutation mimicking Familial Hemophagocytic Lymphohistiocytosis(FHL)

B. Ciambotti[1], *V. Cetica[1], E. Sieni[1], M. L. Coniglio[1], M. Da Ros[1], S. Santarone[2], G. Sindici[3], M. Aricò[4];*
[1]A.O.U. Meyer, Firenze, Italy, [2]Department of Hematology, Spirito Santo Hospital, Pescara, Italy, [3]U.O.C. Anatomia Patologica, P.O. Pescara, Pescara, Italy, [4]A.O.U. Meyer, Istituto Toscano Tumori (I.T.T), Firenze, Italy.

Familial Hemophagocytic Lymphohistiocytosis (FHL) is a fatal disease of children. Genetic defects have been identified in the majority but not all cases. Lack of a familial marker impairs counseling and appropriate treatment strategy, also allowing misdiagnosing.
We describe the example of a consanguineous family in which three children died of complications associated with FHL-directed therapies, which turned out to be undue in the light of the recently defined diagnosis.
Given the incomplete fitting of the clinical pictures with FHL diagnostic criteria, and lack of mutations in the FHL-related genes, whole exome sequencing of constitutional DNA of both consanguineous parents was performed. The novel c.A773G p.Y258C mutation was identified in both carrier parents and confirmed by Sanger sequencing, which showed it at the homozygous state in one affected child. The diagnosis of FHL, made elsewhere in the early '80s based on the clinical picture only, drove the decision to treat the child with an aggressive approach including chemotherapy. Recurrence of the disease and the fatal outcome of the initial case supported the choice of an aggressive therapeutic approach in this family. Identification of homozygous mutation of the FAS ligand gene allowed to redefine the diagnosis, from FHL with unknown genetic defect to FASLG. Definition of genetic diagnosis of congenital immune deficiencies may have not only counselling but also therapeutic implications and should be thus pursued, even retrospectively. Exome sequencing could be a valid tool to help defining genetic bases of difficult clinical pictures.

J07.06

Molecular analysis of Haemophilia A in a Colombian family with Haemophilia A and von Willebrand disease diagnosis

D. Polania Villanueva[1], *D. Narvaez Noguera[1], M. Duarte Romero[2], H. Groot de Restrepo[1];*
[1]Universidad de Los Andes, Bogota, Colombia, [2]Fundación Santa fe de Bogotá, Bogota, Colombia.

The von Willebrand factor circulates in plasma in a complex with coagulation factor VIII joined by noncovalent bonds. This interaction prevents enzymatic degradation of factor VIII (FVIII) and ensures its transport to the place of the fibrin clot formation. The factor VIII is transformed to factor VIIIa (activated) and acts as a co-factor for Factor IX activated (FIXa), which will continue activating next step in the blood clotting cascade. Because of their close relationship, decreasing activity of one or another factor may be affected, or they may also affect the other. The late generates a clinical diagnosis not very accurate, sometimes for Haemophilia A or von Willebrand disease. We report here a Colombian family that suffers the two diseases according to clinical diagnosis. However, the lack of a genetic study to verify and contrast the diagnosis made by health institutions which is based on phenotype only, can lead to a wrong classification of von Willebrand disease as a type of mild Haemophilia. The aim of this study was to confirm the clinical diagnosis in this family by molecular analysis. To achieve this, we identify the presence of the most common inversions of FVIII gene in introns 22 and 1 by LD - PCR and a general scan of the gene for frameshift mutations or stop codons through three family generations. The use of molecular techniques to confirm the clinical diagnosis for bleeding disorders will improve adequate treatment and patient prognosis in Colombia.

Association between vitamin D receptor gene polymorphisms and Hashimoto's thyroiditis in Serbian population: a pilot study based on FokI, ApaI and TaqI RFLP technique

J. Djurovic[1], *O. Stojkovic[1], C. Akurut[2], F. Silan[2], J. Todorovic[3], G. Stamenkovic[4], O. Ozdemir[2];*
[1]Institute of Forensic Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia, [2]Department of Medical Genetics, Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Turkey, [3]Private consulting room „Thyreomedicus", Belgrade, Serbia, [4]Institute of biological research „Sinisa Stankovic", University of Belgrade, Belgrade, Serbia.

Aim: Hashimoto's thyroiditis (HT) is the most prevalent autoimmune thyroid disorder caused by an interaction between genes and environmental triggers. Intra-thyroid lymphocytic infiltration may lead to progressive destruction of thyroid tissue and consequently hypothyroidism. Many studies in other populations have shown association between vitamin D receptor (VDR) gene polymorphisms and various autoimmune diseases, including HT. ***Methods:*** The study included 44 female patients (mean age ± standard deviation 38±5.4) with Hashimoto's thyroiditis and 32 healthy controls of age-, sex- and geographically matched adult without personal history of autoimmune and endocrine diseases. Genomic DNA was isolated from peripheral blood-EDTA, and target VDR gene was genotyped by PCR-RFLP technique after VDR-*Fok*I (rs2228570), VDR-*Taq*I (rs731236) and VDR-*Apa*I (rs7975232) restriction enzymes digestion. ***Results:*** We use Arlequin 3.5 integrated software for population genetics data analysis and found significant difference in the genotype distribution of VDR *Fok*I polymorphism between HT patients and controls (P=0,00465). For *Apa*I and *Taq*I we found the higher frequency of variant allele but not significantly different compared to control women (p>0,05), which is consistent with previous studies. ***Conclusion:*** The current first and preliminary results identified the association between VDR- *Fok*I gene polymorphism and Hashimoto's thyroiditis in the Serbian population. Results need to be supported by further investigations that define haplotypes patterns for VDR gene polymorphisms in a larger group of HT patients of both sexes.

J07.08

A Rare Alpha-Globin Mutation is Associated with Early-Onset Hemochromatosis with HFE C282Y Homozygosity, but not C282Y/H63D Compound Heterozygosity

A. Eaton[1,2], *D. Roberts[3], M. Thomas[1,2];*
[1]University of Calgary, Calgary, AB, Canada, [2]Department of Medical Genetics, Alberta Children's Hospital, Calgary, AB, Canada, [3]Genetic Outreach, Alberta Health Services, Drumheller, AB, Canada.

A 30 year-old Caucasian man presented with significant iron overload (ferritin 3287, transferrin saturation 87%) and was found to be homozygous for the C282Y HFE mutation. He concomitantly had mild microcytic anemia, and was found to have a missense mutation in HBA2 (c.242T>G). This mutation is known to produce an unstable hemoglobin (called Hemoglobin Ann Arbor) and cause mild, chronic hemolytic anemia in the heterozygous state.
The patient's mother also carries the Ann Arbor mutation. Interestingly, she is a C282Y/H63D HFE compound heterozygote. However, at age 55, she showed no signs of hemochromatosis (ferritin 197, transferrin saturation 40%,).
Severe iron overload has been reported as a complication of specific erythroid disorders (including sideroblastosis and porphyrias) in the context of HFE homozygosity (and questionably C282Y/H63D compound heterozygosity). However, to our knowledge, no cases of HFE mutations in combination with alpha-globin mutations or deletions have been reported.
We propose that the instablility of hemoglobin Ann Arbor leads to increased erythropoetic activity and enhanced iron absorption, which predisposed this C282Y HFE homozygote to atypically early-onset hemochromatosis. The mother's normal iron profile is consistent with the weakly-penetrant C282Y/H63D genotype, however it is noteworthy that in contrast to her C282Y homozygous son, HFE compound heterozygosity in combination with the Ann Arbor mutation did not result in early-onset hemochromatosis in this individual.

Large deletions of SERPING1/C1NH gene in Russian patients with hereditary angioedema

E. Bliznetz[1], *A. Dmitrieva*[2], *A. Polyakov*[1];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Scientific Center "Institute of Immunology of the Federal Medicobiologic Agency", Moscow, Russian Federation.*

Hereditary angioedema (HAE) is caused by defects in the C1 inhibitor gene (SERPING1/C1NH). Point mutations and large rearrangements have been found in HAE patients. Previously we have screened the entire C1 inhibitor coding region to identify point mutations in 53 Russian patients with HAE and have registered mutations in 29 patients. In this work, DNA samples from other 24 patients were examined by using MLPA MRC-Holland kit to detect large deletions/duplications in SERPING1/C1NH gene. Large deletions were revealed in 6 patients, in 25% of patients without point mutations, and have constituted 17% of all mutations in Russian HAE patients. Large deletions were including ex 1 del, two cases of ex 4 del, ex 7 del, ex 1-3 del and ex 3-7 del.

J07.10

Single nucleotide polymorphisms in cytokines genes promoters are associated with the susceptibility to HIV-1 infection in the Ukrainians

A. Piddubna;
Sumy State University, Sumy, Ukraine.

Background. Cytokines genes single nucleotide polymorphisms (SNPs) involved in the vulnerability to HIV infection in different population groups. We aimed to determine whether the carriage of cytokines genes allele variants influence the risk HIV-1 infection in Caucasian Ukrainians.
Methods. We examined promoter SNPs in IL-4 (rs 2243250), IL-10 (rs 1800872), TNF-α (rs 1800629) among 78 HIV-1 infected European Ukrainians (68 % male, 32 % female; age at diagnosis (33,35±0,76) years), 22 HIV-negative persons from the high risk infection group and 100 healthy controls using PCR-RFLP.
Results. The dominant cytokines genes variants among HIV-1 infected Ukrainians were major allele homozygotes that correspond to controls and the high risk infection group (C/C IL-4 - 62.82 %, C/C IL-10 - 53.85 %, G/G TNF-α - 62.82 %). T/T IL-4 and G/A TNF-α genotype variants significantly overrepresented in people with HIV-1 (p≤0.01-0.05); susceptibility to HIV-1 infection does not depend on gender. IL-10 minor allele distribution showed the difference among study groups: A/A variant was associated with the disease in men (p≤0.05). We found that carriage of IL-10 homozygous major allele genotype had protector effect on risk of HIV-1 infection among male population (p≤0.05).
Conclusions. The first report of cytokines genes allele frequencies in Ukrainian population shows their association with susceptibility to HIV-1 infection and suggests further research in the field of host genetic risk factors.

J07.11

Association between interleukin-1 type I receptor gene polymorphisms and the expression level of membrane-bound receptors

F. F. Vasilyev[1], *A. N. Silkov*[2], *S. V. Sennikov*[2];
[1]*North-Eastern Federal University (NEFU); Yakut Scientific Center of CMP SB RAMS, Yakutsk, Russian Federation,* [2]*Research Institute of Clinical Immunology SB RAMS, Novosibirsk, Russian Federation.*

Interleukin-1 (IL1) is a pro-inflammatory cytokine involved in a wide range of physiological processes, including a central role in the regulation of acute and chronic inflammation. The biological effects of IL1 (IL1α and IL1β) are realized upon binding of the cytokine to the membrane-bound IL1 type I receptor (IL1RI). The biological activity of IL1 is dependent on the expression level of its membrane-bound receptors. The aim of this study was to determine if there is an association between single nucleotide polymorphisms (SNPs) in the *IL1RI* receptor gene with the expression level of membrane-bound IL1RI on subpopulations of peripheral blood mononuclear cells (PBMC) and on serum levels of soluble IL1 receptors (sIL1RI) in healthy individuals. Serum levels of sIL1RI were determined via ELISA. Expression levels of membrane-bound IL1RI were determined by flow cytometry and genotyping was carried out using PCR-RFLP. This study did not reveal any association between the serum levels of sIL1RI and the SNPs examined. Healthy individuals with genotype GG in SNP rs3917225 and genotype CC in SNP rs2234650 in *IL1RI* displayed increased levels of membrane-bound IL1RI on intact $CD14^+$ cells. Individuals with genotype TT in SNP rs2234650 showed a lower percentage of cells expressing IL1RI in populations of intact $CD14^+$ monocytes and in a population of $CD14^+$ monocytes from mock-stimulated cultures of PBMCs. In summary, this study found that polymorphisms in the IL1 type I receptor gene can influence the expression level of membrane-bound receptors on immunocompetent cells.

J07.12

ITPA gene variant protects against combination treatment-induced anemia in Ukrainian patients with chronic hepatitis C

V. Pampukha[1], *A. Kucherenko*[1,2], *I. Bobrova*[3], *L. Moroz*[4], *L. Livshits*[1];
[1]*Institute of Molecular Biology and Genetics, Kyiv, Ukraine,* [2]*Taras Shevchenko National University of Kyiv, Kyiv, Ukraine,* [3]*Family Practice Center „ULDC", Kyiv, Ukraine,* [4]*National Pirogov Memorial Medical University, Vinnytsya, Ukraine.*

Standard chronic hepatitis C (CHC) antiviral treatment includes pegylated interferon-alfa (PEG-IFNα) and ribavirin (RBV) combination therapy. The most common RBV treatment side effect is hemolytic anemia - the major RBV dose reduction cause. The aim of this study was to clarify the association between the inosine triphosphate pyrophosphatase (ITPA) gene variants and PEG-IFNα/RBV combination treatment induced anemia in CHC Ukrainian patients. The data were collected from 80 CHC patients with HCV genotype 1 infection. All study participants received standard doses of PEG-IFNα and RBV. According to the Hb level changes patients were distributed into: case group - 42 patients with combination treatment induced anemia, and control group - 38 patients with no signs of anemia. Genotyping for ITPA gene rs1127354 and rs7270101 variants was performed using PCR followed by RFLP assay. Fisher's exact test was used to estimate the difference in genotype and allelic distribution. Distribution of rs7270101 genotypes was not significantly different between groups of CHC patients with RBV-induced anemia and without it. The frequency of rs1127354 A allele carriers was significantly higher (P<0,05) in group of CHC patients without anemia (23,7%) comparing to the group of patients with anemia (7,3%). The respective allele frequency in control group (13,2%) was almost 3-fold higher (P<0,05) comparing to the case group (4,9%). In conclusion, significant association of ITPA gene rs1127354 with protection against RBV-induced hemolytic anemia was found in Ukrainian patients with CHC infection. Rs1127354 variant may assist as a pharmacogenetic marker in HCV antiviral therapy correction for side effect avoidance.

J07.13

Combination gene therapy with Mcl-1 and survivin siRNA inhibits HL-60 malignant leukemia cell growth in vitro

H. Karami[1], *E. Sakhinia*[2], *B. Baradaran*[3], *M. Sakhinia*[4], *A. Esfahani*[5], *M. Asghari Estiar*[6];
[1]*Department of Biochemistry, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [2]*Department of Medical Genetics, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [3]*Immunology Research Center, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [4]*Faculty of Medicine, University of Liverpool, Liverpool, United Kingdom,* [5]*Hematology and Oncology Research Center, Shahid Ghazi Hospital, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran,* [6]*Department of Medical Genetics, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

The over-expression of the myeloid cell leukemia-1 (Mcl-1) gene and survivin gene are associated with the survival and progression of various malignancies including leukemia. The aim of this study was to explore the effects of Mcl-1 and survivin small interference RNA (siRNA) on the proliferation and apoptosis of HL-60 acute myeloid leukemia (AML) cells. siRNA transfection was performed using a liposome approach. Relative mRNA and protein expressions were quantified by quantitative real-time PCR and Western blotting, respectively. Trypan blue assay was performed to assess tumor cell proliferation after siRNA transfection. The cytotoxic effect of siRNAs on leukemic cells was measured using MTT assay. Apoptosis was also detected by the annexin V/PI double-staining method. siRNAs clearly lowered both Mcl-1 and survivin expression levels in a time-dependent manner, resulting in marked inhibition of cell survival and proliferation. Furthermore, siRNA co-transfection significantly enhanced the extent of HL-60 apoptotic cells relative to single transfection.Our study demonstrated that Mcl-1 and survivin siRNAs could exert antileukemic effects in vitro. It suggested that combinatory gene therapy targeting Mcl-1 and survivin could be used as a new strategy in the gene therapy of AML.

J07.14

Beta-defensin targeting by using anti-cytokine antibodies as a therapeutic approach in psoriasis

M. Ghorbani, *A. Sedighi*;
Islamic azad University of pharmaceutical science, Tehran, Islamic Republic of Iran.

Psoriasis is one of the most prevalent chronic inflammatory disorders which affect patient lifestyle severely. Psoriasis causes are unknown but many studies suggest that a sophisticated interplay between genetic and environmental factors are involved that trigger an excessive inflammatory response in the skin. Dendritic cells and effector T-cells are critical in the development of the psoriastic lesion and production of cytokines by these cells increase keratinocytes proliferation and stimulate the migration of inflammatory cells into the skin, promoting epidermal hyperplasia and inflammation. Previous studies have extensively documented chemotactic activities of beta-

defensin. Human beta-defensin is strongly expressed in lesional psoriatic epidermis. New findings suggest that systemic levels in psoriasis are largely determined by secretion from involved skin and not by genomic copy number. In this review, we showed that inhibition of beta-defensin stimulation by using anti-cytokine antibodies can decrease inflammatory response and plaque formation. Application of new immunologic therapy like anti-cytokines for psoriatic plaque can lead to new therapeutic approaches and introduces novel candidates for immunomodulation.

J07.15
Tenfold expansion of regulatory T cells homozygous for the CCR5 gene variant Δ32 after CD3/CD28 activation in the presence of exogenously added recombinant IL-2 in vitro

K. Pavelcová, *M. Trunda, J. Chalupnikova, J. Jencik, R. Klubal, J. Bodor;*
Czech gene bank, Prague, Czech Republic.

The unprecedented power of the hematopoetic stem cell transplantation of the CCR5Δ32/Δ32 cells resistant to HIV has been proved to cure HIV infection in the case of patients from Berlin, Brigham and Women Hospital in Boston (1,2,3). Viral entry into $CD4^+$ T cells is mediated by the interaction with a cellular chemokine receptor, the most common of which are CCR5 and CXCR4 (1). Cells of persons homozygous for the CCR5 gene variant Δ32 (CCR5Δ32/Δ32) are naturally resistant to infection with CCR5-tropic HIV strains (R5 HIV) because of the lack of functional CCR5 cell-surface expression (2). Our data based on the general population in Czech Republic show a frequency of approximately 20% heterozygous persons. Four homozygous persons bearing Δ32 mutation (CCR5Δ32/Δ32) were identified out of 709 individuals tested. Here we report a more than tenfold increase in the frequency of regulatory T cells (Tregs) following CD3/CD28 co-stimulation within a week of *in vitro* cultivation of human Tregs, irrespective of their genotype. Importantly, similar the treatments, which lead to the activation of Treg function in humans - *e.g.* anti-CD3/CD2/CD28 stimulation (4) simultaneously drove expansion of Tregs *e.g.* using anti-CD3/CD28 and/or IL-2. Our study demonstrates a useful tool for *in vitro* evaluation of Treg function and facilitates further understanding of the mechanisms of immunological self-tolerance, which may also provide insights into how strong immune responses, such as graft rejection, can be restrained and engraftment of HIV resistant cells in HIV patients with AIDS lymphoma or leukemia can be augmented.

Inherited thrombophilia in women with Systemic Lupus Erythematosus (SLE).

S. Andonova[1], *A. Savov*[1], *D. Tanev*[2], *R. Robeva*[3], *T. Malintcheva*[1], *A. Tomova*[3], *P. Kumanov*[3], *R. Rashkov*[2], *Z. Kolarov*[2];
[1]*National Genetic Laboratory, Medical University-Sofia, Sofia, Bulgaria,* [2]*Clinic of Rheumatology, Medical University - Sofia, Sofia, Bulgaria,* [3]*Clinical Center of Endocrinology and Gerontology, Medical University-Sofia, Sofia, Bulgaria.*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by different organ damages and increased mortality. The potential synergic influence of inherited thrombophilias on the SLE clinical manifestation has not been completely clarified. Therefore the present study aimed to investigate the role of several common thrombophilias in SLE patients.
Materials and methods: Factor V Leiden (FVLeiden), prothrombin G20210A mutation (FIIG20210A), MTHFR C677T and ACE 287 I/D mutations were investigated in 112 Caucasian women with lupus by PCR-RFLP analysis. Age of SLE onset, the presence of different ACR criteria, SLICC and SLEDAI indices were registered in all patients.
Results: FVLeiden, FIIG20210A and ACE 287 I/D polymorphisms were not significantly related to the clinical characteristics of the investigated patients (p>0.05 for all). MTHFRC677T TT carriers were more susceptible to photosensitivity than the others (100% vs. 70%, p = 0.034), while the presence of at least one T allele was associated with increased prevalence of anemia (27.6% vs. 8.3%, p=0.026) as well as a tendency for more active disease (SLEDAI [median] 6 vs. 4, p=0.084).
Conclusions: FVLeiden, FIIG20210A and ACE 287 I/D polymorphisms did not aggravate the clinical phenotype of Bulgarian SLE women. The MTHFR C677T polymorphism could modulate the SLE characteristics in affected patients and further studies are needed to establish it precise significance for the disease onset, activity and severity. The present study was financially supported by the Medical University Sofia (Grant 26/2010, Grant 13/2013).

Hereditary thrombophilia and pregnancy. Impact on quality of life of patients and their families

G. Borzak[1], *R. Mihaescu*[2], *L. Hogea*[3], *C. Gug*[4];
[1]*Oncomed, Timisoara, Romania,* [2]*V.Babes" University of Medicine and Pharmacology , "Oncomed" Medical Center, Timisoara, Romania,* [3]*."V.Babes" University of Medicine and Pharmacology- Psychology Department „ Timisoara, Romania,* [4]*."V.Babes" University of Medicine and Pharmacology, Timisoara, Romania.*

Purpose: Hereditary thrombophilia is a disease characterized by a group of various mutations leading to vascular microthrombosis. It is now considered to be one of the multiple causes of pregnancy loss.The purpose of this study is to determine the impact of reproductive failure in the quality of life , both of patients and their families.
Methodology: During 2010-2014 , we evaluated 145 women with reproductive failure , with the ages between 23 and 42 years old.The time of abortion was between 6 and 36 weeks of pregnancy. 86 patients received treatment with Low Molecular Weight Heparin and Folic Acid , since the confirmation of pregnancy until delivery and 6 weeks after giving birth.The rest of the patients are not yet pregnant and they receive only Aspirin and Folic Acid. We used WHOQOL and HADS scales , witch were applied both to patients and their family members.
Results: We have found an increased rate of both depression (85%) and anxiety (80%) , loss of self esteem (65%) , negative feelings (70%) and insomnia (66%).There were significant differences in the quality of life ($p<0.5$) between the lot with multiple pregnancy loss and the lot with only one pregnany loss, but with significant improvement in quality of life for those who delievered healty babies after treatment.
Conclusions : There is need for a multidisciplinary approach (psychologist; gynecologist; haematologist and geneticist) in order to help the patients and their families to better accept the diagnosis and treatment.

Using linkage analysis to determine responsible genes for Glanzmann syndrome: Reporting two large deletions in an Iranian population

F. Zafarghandi Motlagh[1,2], *Z. Salehi*[2], *M. Jamali*[1], *S. Ghasri*[1], *T. Shirzad*[1], *M. Fallah*[1,3], *S. Zeinali*[4,1];
[1]*Kawsar Human Genetics Research Center (KHGRC), Tehran, Islamic Republic of Iran,* [2]*Department of biology, Pardis international, University of Guilan, Rasht, Islamic Republic of Iran,* [3]*Cellular and Molecular Endocrine Research Center, Research Institute For Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [4]*Department of Molecular Medicine, Biotech Research Center, Pasteur Institute of Iran, Tehran, Iran, Tehran, Islamic Republic of Iran.*

Glanzmann thrombasthenia (GT) is a rare abnormality of platelet aggregation with quantitative and/or qualitative abnormality of αIIbβ3 integrin that is encoded by ITGA2B and ITGB3 genes. It is more prevalent in some Middle East population including Iraq, Jordan and Iran. Many different mutations including point mutations, deletions, duplications and in some cases large deletions have been reported in these genes.
In this study we screened the responsible genes (ITGA2B or ITGB3) by linked STRs that were followed by direct sequencing of the entire coding region and exon-intron boundaries of the candidate gene and /or deletion investigation by Long PCR.
From 12 families with an affected child who were referred for mutation detection to our Lab, after initial screening with STRs, 2 cases that were linked to ITGA2B gene showed no point mutation. Investigating the region by Long PCR revealed a homozygous large deletion in exon 2 and 3 of both unrelated affected cases that has not been reported yet. Deletion was present in the affected children parents in heterozygote state.
As GT is a rare disorder and direct sequencing of two genes with 45 exons could increase the test cost, screening with indirect methods like STR can be useful for more rapid and cost-benefit diagnosis.

J07.19
SYBR GreenI RT-PCR for Quantitative Detection of TLR4 Gene Level in Colorectal Cancer Cells

N. Kazemi sefat[1], *M. Mohammadi*[1], *J. Hadjati*[2], *S. Talebi*[3], *G. Kazemi sefat*[4], *M. Ajami*[5,2], *H. Daneshvar*[4];
[1]*Department of Immunology, Kerman university of Medical sciences, Kerman, Islamic Republic of Iran,* [2]*Department of Immunology,Tehran University of Medical sciences, Tehran, Islamic Republic of Iran,* [3]*Department of Genetics, Tehran University of Medical sciences, Tehran, Islamic Republic of Iran,* [4]*Department of Medicine, Iran University of Medical sciences, Tehran, Islamic Republic of Iran,* [5]*Department of Immunology, Shahid Sadoughi University of Medical sciences, Yazd, Islamic Republic of Iran.*

Background: TLR4 is expressed in normal intestinal epithelial cells which has important role in homeostasis, furthermore current studies suggest that TLR4 on immune cells may actually have anticancer properties but aberrant TLR4 expression can promote certain types of cancer. So in order to determine the TLR4 gene expression variations and to facilitate detection

of cut off for pathogenic TLR4 gene level in future research, we developed a quantitative and accurate method by real time (RT PCR).
Method: We used SW480 and HCT116 as the TLR4 gene high and low expressing colorectal cancer cell lines respectively. Designed primers of this gene do not amplify genomic DNA, while recognize functional transcripts specifically. For real time RT PCR, SYBR Green I was the florescent dye and β-actin were used as the house keeping gene for normalization in relative quantitation (RQ) of TLR4 gene.
Result: Designed primers well amplified cDNAs of low and high expression of TLR4 in 2 mentioned cell lines. TLR4 gene expression in SW480 was 28 times more than HCT116 cell line.
Conclusion: These preliminary results indicate that real time PCR may be employed to detect TLR4 level in CRC, successful development of real time quantitative PCR (RQ PCR) by SYBR Green I resulted to an easy method with lower cost in comparison to probe based method.
Key Words: TLR4, RQ PCR, Colorectal Cancer cells.

J07.20
Lymphoid enhancer-binding factor 1 (LEF 1) a possible immunomodulator in triple negative breast cancer

O. Virtic[1], *V. Pileczki*[1], *L. Pop*[1], *I. Berindan Neagoe*[1,2];
[1]*Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania,* [2]*" Ion Chiricuta" Institute of Oncology, Cluj Napoca, Romania.*

Wingless-Int (Wnt) signaling pathway role in embryonic development, proliferation, survival and differentiation of hematopoietic stem cells is already established. There is strong evidence regarding involvement of defects in the Wnt signaling pathway in several solid tumors such as breast, colorectal and prostate cancer. Wnt receptors promote the activation of canonical Wnt /β-catenin and downstream Lymphoid enhancer factor 1/T-cell factor (LEF1/TCF) pathway influencing genes expression of cell proliferation, differentiation and apoptosis. Our proposal was to examine gene expression levels of LEF 1 in peripheral blood of triple negative breast cancer (ER negative, PR negative, Her2 negative) patients by qRT-PCR in association with immunohistochemistry and clinicopathological data in order to establish the modulation effect of LEF 1 in triple negative breast cancer circulating immune cells. Our study included analysis performed on peripheral blood leukocytes collected in EDTA tubes of 16 triple negative breast cancer patients and 7 healthy donors correlated with immunohistochemistry and clinicopathological data. After analysing qRT-PCR data of the expression level of LEF 1 gene, we obtained significant statistical results that revealed LEF 1 downregulation in peripheral blood immune cells of triple negative breast patients compared to control healthy donors peripheral blood. There are evidence-based data that reveals elevated levels of LEF 1 in breast cancer cell lines but considering our analysis describes LEF1 downregulation, a difference of expression signature may arise due to the peripheral blood immune cells different environment implication.

J07.21
Elucidating the microRNA transcriptomic footprint in chronic lymphocytic leukemia

A. J. S. Houben[1], *M. R. Friedländer*[1], *E. Lizano*[1], *M. Gut*[2], *E. Campo*[3], *C. López-Otín*[4], *X. Estivill*[1];
[1]*Centre for Genomic Regulation, Barcelona, Spain,* [2]*Centro Nacional de Análisis Genómico, Barcelona, Spain,* [3]*Department of Anatomic Pathology, Hospital Clínic, University of Barcelona, Institut d'Investigació Biomèdica August Pi i Sunyer (IDIBAPS), Barcelona, Spain,* [4]*Departamento de Bioquímica y Biología Molecular, Instituto Universitario de Oncología (IUOPA), Universidad de Oviedo, Oviedo, Spain.*

Chronic lymphocytic leukemia (CLL) has a heterogeneous clinical evolution. While some patients have an indolent stable disease, others suffer from a rapidly progressing disease. This difference can partly be explained by immunoglobulin gene mutation, cytogenetic abnormalities, and mutations in genes that contribute to the development and course of CLL. Despite progress on the elucidation of driver mutations and genes for CLL malignancy, the precise pathways responsible for the heterogeneous evolution of CLL are currently unknown.
MicroRNAs are small non-coding RNAs that function in regulation of gene expression. Aberrant microRNA expression has been linked to CLL, affecting major oncogenic pathways. We have explored microRNA expression in a well-annotated cohort of 97 CLL patient cases by small RNA sequencing. Data were analyzed using our in-house SMARTAR pipeline. In addition, DNA (whole exome sequencing, WES and whole genome sequencing, WGS) and messenger RNA sequencing (mRNAseq) data was obtained for 88 cases. Integration of mRNA and small RNA sequencing data reveals differential expression of several microRNAs with CLL-related targets. An interesting candidate is miR-150, implicated in hematopoietic differentiation. We found an anti-correlation in expression levels of miR-150 and its targets, suggesting that deregulation of the miR-150 pathway could be implicated in disease evolution of CLL.
Moreover, GES and WES data are used to study the effect of SNVs and CNVs on microRNA expression and processing. Interestingly, expression levels of microRNA pairs within clusters are correlated, suggesting that structural variations in the CLL genome might indeed comprise the loss of microRNAs located in this region.

J07.22
Hemophagocytic lymphohistiocytosis developed in visceral leishmaniasis may have genetic etiology

G. Balta[1], *F. M. Azik*[2], *A. Gurgey*[1];
[1]*Hacettepe University, Faculty of Medicine, Department of Pediatric Hematology, Ankara, Turkey,* [2]*Ankara Diskapi SSK Education and Research Hospital, Department of Pediatrics, Ankara, Turkey.*

Hemophagocytic lymphohistiocytosis (HLH) is a complex immune disregulation disorder developed either by genetic defects in Perforin, UNC13D, Syntaxin 11, STXBP2 genes or secondary to various infections, other disorders, drugs. Distinction is complicated since infections; viral in particular, can trigger genetic HLH. HLH has overlapping clinical symptoms with visceral leishmaniasis (VL) and may remain under-recognized because of difficulties in diagnosis and rapidly fatal outcome. Genetic HLH triggered by VL has not been described. One-year-old girl from a consanguineous family diagnosed as VL by showing Leishmania amastigots in bone marrow aspirates (BMA). Symptoms also fulfilling HLH diagnostic criteria were resolved by therapy for VL initially but reappeared subsequently despite clearance of amastigots in BMA. HLH2004 protocol therapy achieved remission however recurrence observed afterwards. Mutation analysis in HLH genes revealed homozygous 627delT frameshift mutation in exon 8 of UNC13D gene leading to frameshift and premature termination of translation 40 amino acids downstream. Parents were heterozygous for this single nucleotide deletion. Stem cell donor was not available. Until she died at age four, remissions were followed by HLH reactivations and/or five central nervous system relapses under continuous protocol therapy. In conclusion, HLH developed in VL may have genetic etiology and VL may trigger underlying genetic HLH, which may make diagnosis and therapy even more complicated and mortality rate very high. Awareness created among clinicians might thereafter have important public health impact in lifesavings, disease surveillance and eradication especially in endemic tropical and subtropical countries. This study was supported by TUBITAK (Project No: 105S386-SBAG 3193).

Identification of two novel missense mutations on C2 and A3 domain of factor VIII

S. Ghasri[1], *S. Sahebi*[1], *F. Zafarghandi Motlagh*[1], *M. Fallah*[2,1], *S. Zeinali*[3,1];
[1]*Kawsar Human Genetics Research Center (KHGRC), Tehran, Islamic Republic of Iran,* [2]*Cellular and Molecular Endocrine Research Center, Research Institute For Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*Department of Molecular Medicine, Biotech Research Center, Pasteur Institute of Iran, Tehran, Iran, Tehran, Islamic Republic of Iran.*

Hemophilia A, resulting from coagulation factor VIII deficiency is caused by a large variety of disease-causing mutations in FVIII gene and point mutations are the most prevalent and deleterious mutation. Active form of factor VIII includes A1/A2/A3-C1-C2 domains. Each domain plays a critical role in FVIII function and structure. The A3 domain near the phospholipid membrane is in close association with the C1 and C2 domains. Many moderate hemophilia phenotypes are caused by missense mutations that alter the binding of FVIII to VWF. These mutations are clustered within the C1 and C2 domain.
In this study two novel point mutations were investigated form a patient with serum factor VIII level less than 1% and a moderate bleeding phenotype. He has no history of bleeding diathesis and/or coagulation factor transfusion in recent 5 years. Entire coding region and exon-intron boundaries were investigated using direct sequencing method. Two novel point mutations (c.5359G>A and c.6521A>G) were detected which lead to amino acid substitution E1787K and H2174R respectively. These nucleotide variations also present in patient's mother in heterozygote state in Cis. In silico analysis with SIFT, Polyphen 2, PANTER and I-Mutant 2 soft wares showed moderate effect of these mutations on protein structure and function that could explain the moderate phenotype of disease.
According to the finding it seems using bioinformatics in silico analysis of the novel mutation could help to predict functional effect of nucleotide alteration especially in milder clinical presentation.

Homozygosity for a null allele of SMIM1 defines the Vel-negative blood group phenotype

J. Storry, M. Jöud, M. Kronborg Christophersen, B. Thuresson, B. Åkerström, B. Nilsson-Sojka, **B. Nilsson**, *M. Olsson;*
Department of Laboratory Medicine, Lund, Sweden.

This abstract describes the discovery of the gene underlying the Vel blood group system, the last clinically important unresolved human blood group system. The Vel antigen is present on red blood cells (RBCs) from all humans except rare Vel-negative individuals who can form antibodies to Vel in response to transfusion or pregnancy. These antibodies may cause severe hemolytic reactions in blood recipients. We combined SNP profiling and transcriptional network modeling to link the Vel-negative phenotype to SMIM1, located in a 97-kb haplotype block on chromosome 1p36. This gene encodes a previously undiscovered, evolutionarily conserved transmembrane protein expressed on RBCs. Notably, 35 of 35 Vel-negative individuals were homozygous for a frameshift deletion of 17 bp in exon 3. Functional studies using antibodies raised against SMIM1 peptides confirmed a null phenotype in RBC membranes, and SMIM1 overexpression induced Vel expression. Genotype screening estimated that ~1 of 17 Swedish blood donors is a heterozygous deletion carrier and ~1 of 1,200 is a homozygous deletion knockout and enabled identification of Vel-negative donors. Our results establish SMIM1 as a new erythroid gene and Vel as a new blood group system. (Nature Genetics 2013; 45(5):537-541)

De novo homozygous mutation of the C1 inhibitor gene in a patient with Hereditary Angioedema

V. Bafunno[1], *C. Divella*[2], *F. Sessa*[1], *G. Tiscia*[3], *G. Castellano*[4], *L. Gesualdo*[4], *M. Margaglione*[1], *V. Montinaro*[4];
[1]*Medical Genetics, Department of Clinical and Experimental Medicine,University of Foggia, Foggia, Italy,* [2]*Division of Nephrology and Center for the Diagnosis and Treatment of Hereditary Angioedema, Department of Emergency and Organ Transplantation,University "Aldo Moro" Bari, Azienda Ospedaliero-Universitaria "Consorziale Policlinico", Bari, Italy,* [3]*Thrombosis & Haemostasis Unit, IRCCS Casa Sollievo della Sofferenza, S. Giovanni Rotondo, San Giovanni rotondo, Italy,* [4]*Division of Nephrology and Center for the Diagnosis and Treatment of Hereditary Angioedema, Department of Emergency and Organ Transplantation, University "Aldo Moro" Bari, Azienda Ospedaliero-Universitaria "Consorziale Policlinico",, Bari, Italy.*

Background: Hereditary angioedema (HAE; OMIM #106100) is a rare autosomal dominant disease resulting from congenital deficiency of C1 esterase inhibitor protein (C1-INH) that controls complement, contact-kinins, coagulation and fibrinolytic cascades. HAE is due to mutations in the C1 inhibitor gene (*C1NH*) that affect its protein synthesis (HAE type I) or function (HAE type II). **Objective:** We characterized the biochemical profile of a patient with HAE and a homozygous *de novo* null mutation (c.646_647insTCAGTGTCGTGdelA, p.Lys216Serfs*4) in the exon 4 of *C1NH* gene. **Methods:** Biochemical diagnosis of HAE was confirmed by using direct DNA sequencing and western blot analysis on the proband and her family. Furthermore, long range PCR, RFLP, SNP genotyping and real-time PCR were performed to identify the possible mechanisms that could explain the homozygous *de novo* mutation in the patient. **Results:** The patient showed very low antigenic and functional levels of C1-INH and C4, with normal levels of C3 and C1q. Western blot analysis confirmed the absence of native and cleaved forms of the protein. Her parents showed no alterations in complement parameters and did not present the mutation. By using different approaches we could exclude the deletion of exon 4 as the cause for the homozygous *de novo* mutation. **Conclusions:** This is the first report of a patient homozygous for a *de novo* null mutation affecting the *C1NH* gene probably resulting from a small size event of gene conversion. In contrast with the previous homozygous cases, clinical phenotype of the patient resembled typical heterozygous form of HAE.

J08.01

A new case of 2p15p16.1 microdeletion syndrome

M. Yakoreva[1,2], *E. Õiglane-Shlik*[3,4];
[1]*Tartu University Hospital, United Laboratories, Department of Genetics, Tartu, Estonia,* [2]*University of Tartu, Institute of Biomedicine and Translational Medicine, Department of Human Biology and Genetics, Tartu, Estonia,* [3]*Children's Clinic, Tartu University Hospital, Tartu, Estonia,* [4]*Department of Pediatrics, Faculty of Medicine, University of Tartu, Tartu, Estonia.*

2p15p16.1 microdeletion syndrome is a recently identified disorder of which at least 11 cases have been reported so far. Developmental delay, intellectual disability, delayed language skills, microcephaly, structural brain abnormalities, characteristic facial dysmorphism, short stature, feeding and behavioral problems are the major features of this syndrome. Some of the reported patients also displayed craniosynostosis, genitourinary abnormalities, and vision and hearing disturbances. All reported cases have overlapping deletions, varying from 570 kb to 6.9 Mb. Most of them have single 3.6 Mb overlapping region (chr2: 58,747,888-62,363,205 Hg19) that contains 23 genes. Here we describe an Estonian patient carrying a 1.2 Mb deletion inside this critical region, who presented milder phenotype of the syndrome. Detected *deletion* (chr2: 61,178,171-62,376,313 Hg19) contains 14 of 23 genes from the critical region. Unlike previously described cases, our patient is of normal height, and does not have microcephaly, craniosynostosis, structural brain abnormalities and vision or hearing problems. At the age of 4 years, he is slightly dysmorphic without characteristic facial appearance and has moderate delay in intellectual and language development. Also, h*e is slightly spastic and up to age three, he had problems* with chewing solid foods. We thus assume that genes in this deleted region (AHSA2, C2orf74, CCT4, COMMD1, FAM161A, KIAA1841, LOC100130280, LOC339803, LOC647077, PEX13, PUS10, SNORA70B, USP34, XPO1) could not be responsible for growth retardation, microcephaly, skull and brain abnormalities in the patients with 2p15p16.1 microdeletion syndrome and may be candidates for developmental and language delay.

J08.02

Deletion of 3q11.2 region detected by arrayCGH in a girl with an Angelman syndrome-like phenotype

V. Belengeanu[1], *M. Stoian*[2], *S. Farcas*[3], *C. Popescu*[1], *A. Belengeanu*[4], *D. Misceo*[5];
[1]*„Vasile Goldis" Western University of Arad, Discipline of Genetics, Arad, Romania,* [2]*Personal Genetics-Medical Genetics Center, Bucharest, Romania,* [3]*University of Medicine and Pharmacy "Victor Babes" of Timisoara, Department of Morphologic Microscopy, Discipline of Genetics, Timisoara, Romania,* [4]*University of Medicine and Pharmacy "Victor Babes" of Timisoara, Department of Morphologic Microscopy, Discipline of Molecular and Cellular Biology, Timisoara, Romania,* [5]*Olso University Hospital and University of Oslo, Department of Medical Genetics, Oslo, Norway.*

We present a girl with a de novo q11.2 deletion of chromosome 3, with the phenotype reminiscent of Angelman syndrome (AS). At the age of 2 she was evaluated for motor delay, mental retardation and seizures. The girl showed obvious retardation: sitting at 12 months, walking at 22 months with unstable gait and balance problems. During assessment the height was 85 cm, the weight 10.5 kg, and head circumferences 42 cm. She had microcephaly, epicantus, almond shaped eyes, large nasal root, arched upper lip, blond hair and fair skin.
Behavior: she spoke only 3 words and exhibited an excessively happy demeanor; the resemblance to a high functioning AS child was striking. Ophthalmologic examination revealed: optic atrophy, nystagmus convergent strabismus on the left, myopia, astigmatism. MRI of the brain showed: parietal-occipital atrophy and enlargement of lateral ventricles.
Based on the above findings we suspected AS. The routine GTC chromosome and FISH analysis showed no evidence of specific microdeletion.
ArrayCGH was perfomed and a deletion of 292 kb in 3q11.2 region was found. This microdeletion includes 5 known genes: PROS1, ARL13B, STX19, DHFRL1 and NSUN3. The parental arrayCGH analysis were normal.
Interesting is that although haploinsufficiency of two genes in the deleted region (PROS1 and ARL13B) are responsible for specific diseases namely the thrombophilia RA and DA and Joubert syndrome, the clinical features we observed in our case do not meet these conditions.

J08.03

Phenotypic variability in a Hungarian patient with the 4q21 microdeletion syndrome

K. Komlósi[1], *K. Hadzsiev*[1], *M. Czakó*[1], *B. Duga*[1], *A. Fogarasi*[2], *J. Bene*[1], *G. Kosztolányi*[1], *B. Melegh*[1];
[1]*Department of Medical Genetics and Szentagothai Research Center, University of Pécs, Pécs, Hungary,* [2]*Department of Neurology, Bethesda Children's Hospital, Budapest, Hungary.*

Interstitial deletions of 4q21 have been reported in about a dozen patients (Bhoj et al, 2013) with deletions ranging from 2 to 15.1 Mb delineating a common phenotype including marked growth restriction, hypotonia, severe developmental delay with absent or delayed speech and distinctive facial features. A minimal critical region of 1.37 Mb accounting for the common features with 5 known genes (*PRKG2, RASGEF1B, HNRNPD, HNRPDL, ENOPH1*) has been described so far (Bonnet et al, 2010). Here we report on a 5 year-old Hungarian girl presenting with severe psychomotor delay, absent speech, short stature, dystrophy, hypotonia, distinctive facies including broad forehead, frontal bossing, downward slanting palpebral fissures, hypertelorism, hypoplastic ear-lobes, anteverted nostrils, short philtrum, small mouth, high-arched palate, short, small hands and feet, distally narrowing fingers and clinodactily. Cerebral MRI showed ventricular dilation and an increase in periventricular signal intensity. After extensive metabolic tests and exclusion of subtelomeric deletions array CGH analysis was performed using the Agilent Human Genome G3 Sureprint 8x60K Microarray (Agilent Technologies, USA), which detected a 4,8 Mb de novo interstitial de-

letion of 4q21.21-4q21.23. The clinical symptoms only partly overlap with so far reported 4q21 microdeletion cases. Among multiple annotated genes our patient is also haploinsufficient for the genes: *RASGEF1B* being a strong candidate for the neurodevelopmental features and *PRKG2* for severe growth delay. The first Hungarian case of 4q21 deletion adds to the phenotypic spectrum of this novel microdeletion syndrome and underlines the importance of array CGH to uncover the heterogeneous causes of ID.

J08.04
Application of Microarray-based Comparative Genomic Hybridization in pediatric patients with developmental delay and dysmorphic features

G. Cardos[1], *C. Ionescu*[1], *V. Plaiasu*[2], *F. Nedelea*[3], *V. Celmare*[1], *M. Stoian*[1];
[1]*Personal Genetics - Medical Genetics Center, Bucharest, Romania,* [2]*IOMC Prof.dr.Alfred Rusescu - Genetic Department, Bucharest, Romania,* [3]*Filantropia Clinical Hospital, Bucharest, Romania.*

The array Comparative Genomic Hybridization technology (aCGH) is intensively used in research and clinical diagnosis for the detection and identification of genome rearrangements in patients with different physical/intellectual development anomalies.
The aim of our study was to apply the aCGH technology in evaluation with high resolution of the entire genome in pediatric patients with developmental delay (DD), intellectual disabilities (ID) and dysmorphic features (DF) for identifying the genetic causes responsible for the
clinical observation.
Twenty patients with DD, ID and DF from Romania, aged between 4 months and 14 years, were included in high resolution aCGH analysis with NimbleGen ISCA Plus 3x1.4M Platform (Roche). All patients were previously assessed by conventional cytogenetic analysis.
The aCGH analysis detected clinically relevant chromosomal abnormalities in seven of the patients analyzed, as follows:
- micro-deletions ranging between 2.5 Kb-6 Mb, associated with Pitt-Hopkins syndrome (18q21.2), obesity, ID/DF (6q16.1-q16.2-q16.3), DiGeorge syndrome (22q11.2);
- micro-duplications ranging between 12.5 Kb-1.9 Mb, associated with ID (17q23.2), the Potocki-Lupski rare syndrome (17p12-11.2) and autism (Xp22.11);
- a 30 MB duplication (8q13.3-q22.3), leading to the identification and exact characterisation of a marker chromosome indicated by conventional cytogenetic analysis.
Genomic anomalies identified and characterized by aCGH provided accurate diagnosis of unidentified or unexplained diseases suspected to have a genetic cause, contributing to appropriate clinical management of the affected patients.
Our study demonstrated that aCGH technology can play a very important role in identification and characterization of cryptic and/or complex chromosomal rearrangements, being a valuable tool in postnatal diagnosis.

J08.05
Novel alteration in AMPD2 gene segregates with non-syndromic intellectual disability linked to MRT4 locus, conjointly responsible from Pontocerebellar hypoplasia

O. Z. Uyguner[1], *D. Ustek*[1], *G. Toksoy*[1], *Z. Gormez*[2], *O. Hacariz*[2], *M. Sagiroglu*[2], *S. Basaran*[1], *H. Kayserili*[1];
[1]*Istanbul University, Istanbul, Turkey,* [2]*The Scientific and Technological Research Council of Turkey (TUBITAK), Kocaeli, Turkey.*

Non-syndromic autosomal recessive intellectual disability(NS-ARID) with genetic loci are listed with MRT numbering by Mendelian Inheritance of Man (MIM). Since the discovery of the first gene in MRT1, PRSS12, in 2002, to date a total of 34 loci and 17 genes are identified. Only few of these genes are published causative in more than one family, while the rest are identified in a single family that are characterized, disclosing the high heterogeneity of the genetic basis. MRT4 was published in 2007 in an examination of a large consanguineous family with four affected members. The linked region at 1p21.1-1p13.3 was 6.6 megabase commencing 78 genes. Exome sequencing of family members and filtering variations according to the pedigree data revealed a single point mutation c.1526C>T, in AMPD2 gene, located at 1p13.3, altering uncharged polar amino acid threonine, at position 509, to nonpolar methionine (p.T509M), in evolutionally conserved adenosine deaminase domain. This variation was not found in our in house exome sequencing of 150 Turkish individuals or in publically available SNP databases. Furthermore, this variation is assigned to be damaging by diverse prediction software analysis. AMPD2 plays a critical role in energy metabolism, functioning in purine metabolism by converting AMP to IMP via salvage pathways. Recently, deleterious mutations in AMPD2 gene are reported in five families with Pontocerebellar hypoplasia (PCH) with characteristic brain imaging. Affected individuals in our family do not carry progressive context. We conclude that our case will expand the phenotypic spectrum of damaging AMPD2 mutations.

J08.06
Array CGH findings in 280 cases with intellectual and developmental delay, multiple congenital anomalies and autism spectrum disorders in Iran

R. Kariminejad, *K. Najafi, A. Moshtagh, G. Abbassi, N. Sadatian, K. Najafi, A. Kariminejad, M. Kariminejad;*
Kariminejad-Najmabadi Pathology and Genetics Center, 14665/154, Tehran, Islamic Republic of Iran.

Copy number variations have gained increasing recognition in the etiology of disease. Many cohorts have established the significance of genomic imbalances in intellectual/developmental delay, multiple congenital anomalies and autism spectrum disorders. Most of these studies have been conducted in Western populations and have predicted an overall detection of 15-20% when using whole genome arrays.
We have performed 1000 array CGH studies in the past three years. 280 of these cases have been referred for ID/DD, MCA or ASD. We detected a pathogenic CNV in 45 of these cases, with an overall detection rate of 16%. Considering that 13 of the cases with CNVs were referred following aberrations detected in cytogenetic analysis and for confirmation of these abnormalities, the rate of detection among unselected cases is 12% (32/263).
As this is to the best of our knowledge among the first case series of patients from Middle Eastern populations, we would like to postulate the significance of consanguinity in the possible detection rate of genomic imbalances. First, there is an increased possibility of homozygosity for CNVs as a result of consanguinity, as detected in one of our cases with homozygous deletion of *GRID2* gene. Second, the role of consanguinity and consequently increased possibility of autosomal recessive conditions and the way it will decrease the frequency of pathogenic CNVs in the etiology of ID/DD, MCA, ASD in unselected cohorts of patients.

J08.07
9q34.11-q34.12 deletion associated with autism and dysmorphic features: a case report

A. Arghir[1], *M. Budisteanu*[1,2], *S. Papuc*[1], *B. Budisteanu*[2], *I. Borcan*[1], *M. Cristea*[1], *A. Tutulan-Cunita*[1];
[1]*Victor Babes National Institute of Pathology, Bucharest, Romania,* [2]*Alex. Obregia Clinical Hospital of Psychiatry, Bucharest, Romania.*

The use of high resolution array-based comparative genomic hybridization (array-CGH) in whole genome investigation led to an unprecedented rate of discovery of clinically relevant microdeletions/microduplications in neurodevelopmental disorders. We report on a 12-year-old boy with facial dysmorphic features, autism (Asperger syndrome), motor and vocal tics, speech disorder in early childhood presenting a 9q34.11 - q34.12 deletion. Cytogenetic investigations included array-CGH investigation (105K platform, Agilent Technologies) and FISH (BAC probes). Array-CGH revealed a de novo 2.4 Mb deletion spanning cytogenetic bands 9q34.11-q34.12 (genomic coordinates, hg19: 131485878-133931680). Approximately 50 genes are located within the deleted region, some of these being disease-causing OMIM genes: AGM5, CDG1M, TOR1A, ASS1, ABL1. Deletions of genomic region 9q34.11-q34.13, proximal to EHMT1, are rarely described. Few patients with deletions similar to our case have been reported in the literature and centralized in databases (e.g. DECIPHER). Haploinsufficiency of genes located in this region might be responsible for the clinical findings in the reported patients (such as autism, intellectual disability, epilepsy, movement disorders etc). Thus our case adds to the body of knowledge and will help in establishing genotype-phenotype correlations. Acknowledgments: Professor Jean-Michel Dupont from Cochin Hospital, Paris, France for kindly providing the BAC-FISH probe; Project PN 09.33.02.03.

J08.08
A clinical case with autism and 22q13.3 deletion or Phelan McDermid syndrome

B. Radeva[1], *M. Stancheva-Ivanova*[2], *P. Mitev*[3], *R. Staneva*[4];
[1]*Medical Center „Childen's health", Sofia, Bulgaria,* [2]*University Hospital for Active Treatment in Neurology and Psychiatry „St.Naum", Sofia, Bulgaria,* [3]*Medical Center „Children`s Health", Sofia, Bulgaria,* [4]*Chair of Medical genetics, Medical University, Sofia, Bulgaria.*

The 22q13.3 deletion is a contiguous gene deletion syndrome (MIM 606232) with gene locus SHANK3/ProSAP2 on the terminal end of chromosome 22. The syndrome is characterized by neonatal hypotonia, mental retardation, speech delay, autistic behaviour, normal to accelerated growth, minor facial dysmorphism.
The authors present a boy who was successfully treated for VSD at 6 months of age with cardiosurgical operation. After the procedure the child started

losing interest for toys and relatives. At age of 11 years, he was consulted for autistic behaviour. He presented with facial and cranial dysmorphysm (hypertelorism, epicanthic folds, ptosis, dolichocephaly, fleshy hands, severe mental retardation, severe speech delay. The diagnosis of DiGeorge syndrome was suspected at the base of history for VSD, mental retardation and facial dysmorphysm. Heparine blood of the child was investigated with Fluorescent in situ Hybridization (FISH). Test VYSIS - locus specific for 22q11.2 and test ARSA - control of locus 22q13 were applied. In all 30 investigated interphase nucleus and metaphases were found one green signal for ARSA and two red for TUPLE-1. The result showed nuc ish (22)q11.2 (TUPLE-1x2), 22q13 (ARSAx1) which confirmed the diagnosis Phelan McDermid syndrome. The recommended treatment included a free of milk and gluten diet, special education and logopedic therapy. The family attended genetic conseling.

The presented clinical case confirmed the association of 22q13.3 deletion with autism (Itsara et al., 2009. The authors proposed for a first time a new symptom - congenital heart malformation in Phelan McDermid syndrome.

J08.09

Exome sequencing reveals a novel mutation in BBS2 gene in an Iranian family diagnosed with Bardet-Biedl Syndrome

M. Fadaee[1,2], *Z. Fattahi*[1,2], *M. Akbari*[3], *Y. Shafeghati*[4], *H. Najmabadi*[1,2];
[1]*Genetics research center, university of social welfare and rehabilitation sciences, Tehran, Islamic Republic of Iran,* [2]*Kariminejad - Najmabadi pathology & genetics center, Tehran, Islamic Republic of Iran,* [3]*Women's college research institute, University of Toronto, Toronto, ON, Canada,* [4]*Sarem cell research center (SCRC), Sarem Women's Hospital, Tehran, Islamic Republic of Iran.*

Rare autosomal recessive Bardet-Biedl Syndrome (BBS) is a kind of pleiotropic ciliopathies which is more common in developing countries. BBS is characterized by symptoms including obesity, retinitis pigmentosa, polydactyly, learning problems, hypogonadism and kidney abnormalities that vary both within and between families. Nineteen disease-causing genes are involved in 80% of BBS cases and code proteins localized to the cilia which each function affect different parts of a cilium. *BBS2* in contribution with six most conserved BBS genes, form BBSome complex of the cilium.

Here, we report an Iranian family with a ciliopathy disorder ascribing BBS. Whole exome sequencing (WES) was performed for proband which revealed a novel homozygote splice mutation c.535-1 G>C in *BBS2* gene that would probably lead to skipping of exon 5. Using bioinformatics software, Mutation Taster, predicts c.535-1 G>C as a disease causing variant. WES data were confirmed by Sanger sequencing and co-segregation was performed for his family.

Estimating about 8% of BBS reports, *BBS2* is among one of the common genes in BBS (same results in Iranian population-unpublished data). This result was in accordance with our expectations. In conclusion, due to the clinical and genetic heterogeneity observed in Bardet-Biedl syndrome WES could be considered as the method of choice for clinical genetics practice.

J08.10

Further characterization of the 16p11.2 microdeletion phenotypes

A. Beleza-Meireles[1], *P. Louro*[1], *L. Ramos*[1], *M. Campos*[2], *L. M. Pires*[3,4], *S. Ferreira*[3,4], *I. M. Carreira*[3,4], *J. M. Saraiva*[1,5];
[1]*Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal,* [2]*Centro Hospitalar de Leiria, Leiria, Portugal,* [3]*Laboratório de Citogenética e Genómica - Faculdade de Medicina - Universidade de Coimbra, Coimbra, Portugal,* [4]*CIMAGO – Centro de Investigação em Meio-Ambiente, Genética e Oncobiologia - Universidade de Coimbra, Coimbra, Portugal,* [5]*Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal.*

Introduction: Recurrent rearrangements of 16p11.2 are increasingly recognized as one of the most common structural chromosome disorders. Reciprocal 16p13.1 rearrangements predispose to developmental delay. Besides, 16p11.2 rearrangements have been identified in up to 1% of autistic individuals. These deletions have also been associated with obesity. A ~550-kb deletion is commonly reported; and a smaller deletion of an adjacent region on 16p11.2 has also been found in patients with overlapping clinical features. The phenotypic spectrum of rearrangements in this genomic region remains to be fully characterized. **Methods:** We describe two new unrelated cases with 16p11.2 microdeletions diagnosed by whole genome oligonucleotide array-CGH. We also compare the phenotype of our patients with other cases described in the literature. **Results:** One patient, referred to our clinic with moderate developmental delay, significant behavioral problems and unspecific dysmorphisms, has the „typical" ~550-kb deletion. There is a known family history of learning disabilities. However it was not possible to test his relatives because he was placed in institutional care. The second patient presents developmental delay and unspecific dysmorphisms. He has a maternally inherited 187-kb 16p11.2 deletion. His mother has mild cognitive difficulties and obesity. **Conclusions:** Our patients present adjacent, nonoverlapping 16p11.2 microdeletions, and they share some similar clinical features. They also share characteristics with other patients described in the literature. However, it should be underlined that variable expressivity has been described associated with these rearrangements, even between members of the same family and therefore testing of relatives at risk is important for accurate genetic counseling.

Hospital Carlos Haya, Malaga, Spain,* [5]*Universidad de Valladolid- IBGM-CSIC, Valladolid, Spain.*

Introduction and Objectives: Fragile X syndrome (FXS) is a neurodevelopmental disorder affecting intelligence and behaviour. Current treatments are unable to normalize these symptoms. We propose a combination of Ascorbic acid and Alpha-tocopherol to improve learning abilities in young patients.

Material and Methods: 100 FX patients (50 in placebo): A) 3 to 6 years old (N= 19), B) 6 to 17 years old (N= 64), C) older than 18 years old (N= 17).

A clinical questionnaire and neuropsychological tests was performed at the beginning of the trial (T0) and 12 weeks later (T1). Variables: Wechsler intelligence scale for children (WISC-R), manipulative and verbal subscales and Peabody Picture Vocabulary Test (PPVT-R). The percentage of change were tested by U Mann Whitney Test ($p<0.05$)

Results: Significant improvements were detected in group B (6 to 17 years old) with 65% potency. The percentage of change in the Verbal WISC-R scales were: 30.8 in the treated group versus 13.7 in the placebo group ($P< 0.05$). The percentage of change in the manipulative WISC-R scales were: 35.4 in the treated group versus 10.9 in the placebo group, $P= 0.01$. A significant improvement was observed in the percentage of change in the Peabody median scores: 24.4 in the treated group versus 6.8 in the placebo group ($P<0,05$)

Conclusions: Clinical trials for FXS are necessary. Our results demonstrate improvement in learning and receptive language in children after 12 weeks of treatment with a combination of antioxidants: Ascorbic acid and Alpha-tocopherol.

Submicroscopic chromosomal alterations in individuals with idiopathic intellectual disability

L. S. Abreu[1], *M. R. Riegel*[2], *M. J. Campos*[3], *R. S. S. Araújo*[1], *D. R. C. Vidal*[1], *J. M. Pina Neto*[1];
[1]*Department of Genetics of Faculty of Medicine of Ribeirão Preto. University of São Paulo, Ribeirão Preto -SP, Brazil,* [2]*Laboratory of Molecular Cytogenetics. Experimental Research Center. Hospital of Clinical of Porto Alegre, Porto Alegre - RS, Brazil,* [3]*Laboratory of Human Genetics. Oswaldo Cruz Institute. FIOCRUZ., Rio de Janeiro - RJ, Brazil.*

Etiological studies of intellectual disability (ID) show that chromosomal alterations are factors which significantly contribute to this condition. Recently, the techniques of MLPA (Multiplex Ligation-dependent Probe Amplification) and aCGH (Array Comparative Genomic Hybridization) have allowed advances in clinical cytogenetics, enabling the detection of submicroscopic chromosomal abnormalities, ensuring a better knowledge about the causes of ID. We investigated the presence of submicroscopic chromosomal abnormalities by MLPA and aCGH in 50 patients with idiopathic ID that were selected in three institutions of the state of São Paulo - Brazil, after clinical and laboratorial evaluation. All 50 individuals with ID were investigated by MLPA with the kits P036-E1, P070-B1 (subtelomeric rearrangements) and P245-A2 (microdeletion syndromes). The P036-E1 identified one subtelomeric deletion in 4p16.3 (1/50) (2%), confirmed by P070-B1. While the P245-A2 detected two alterations (2/50) (4%), the deletion already identified 4p16.3 and one microduplication in region 22q11.2. The aCGH was performed in only 25 of the 50 subjects with idiopathic ID. Genomic alterations were identified in 14 of them (14/25) (56%), including 07 deletions (04 considered non-pathogenic CNVs) and 09 duplications (two considered non-pathogenic CNVs and two defined as false positive), totaling 08 (08/25) (32%) clinically relevant genomic changes. This research shows the importance of the application of new technologies, especially the aCGH, in the study of individuals with idiopathic ID, moreover should be fundamental part in the investigation of the possible causes of this condition due to the accentuated frequency of submicroscopic chromosomal alterations observed in these cases.

Patients with Prader - Willi and Angelman syndrome in Latvia

Z. Krumina[1,2], *A. Dzalbs*[1,2], *I. Dzivite*[1,2], *I. Grinfelde*[1,2,2,2], *B. Lace*[3], *I. Micule*[1], *D. Locmele*[1], *D. Bauze*[1], *L. Kornejeva*[1,2], *O. Sterna*[1], *N. Pronina*[1], *I. Brivmane*[1];
[1]*Children's University Hospital, Riga, Latvia,* [2]*Riga Stradin's University, Riga, Latvia,* [3]*Latvian Biomedical Research and Study Institute, Riga, Latvia.*

Introduction: Prader - Willi syndrome (PWS) and Angelman syndrome (AS) are imprinting disorders affecting growth, psychomotor development and metabolism. PWS is caused by lack of expression of the paternally contributed 15q11-q13 genes, while lack of expression of maternally contributed 15q11-q13 genes causes Angelman syndrome. **Aim:** To analyze clinical symptoms, age at diagnosis of patients with PWS and AS in Latvia. **Methods:** We analyzed clinical data of 19 patients (12 boys and 7 girls) with PWS and 5 patients (3 boys and 2 girls) with AS who were consulted by clinical geneticists. The diagnosis was confirmed for patients with FISH analysis or DNA methylation analysis or both. **Results:** The age of diagnosis for PWS was in range from 2 weeks till 13 years of age with great difference between girls and boys. The median age of confirmation the diagnosis for boys was 2,4 years, for girls - 8,6 years. All patients had hypotonia and feeding problems during infancy and excessive weight gain later. Patients had characteristic craniofacial features and hypogonadism was early finding in boys. Mental retardation ranged from mild to moderate. The age of diagnosis for AS was in range from 1 year till 7 years of age with median age of 4,4 years. All patients had severe developmental delay: late and jerky gait, 2 patients had absent speech, 4 patients had epilepsy. **Conclusions:** The diagnosis for Prader - Willi syndrome and Angelman syndrome is late and it is necessary to improve knowledge about these disorders among neonatologists, pediatricians, neurologists.

J08.14

Homozygosity mapping of families with intellectual disability and examination of WWOX gene

A. Alkhateeb[1], *S. Aburahma*[2];
[1]*Qatar Biomedical Research Institute, Doha, Qatar,* [2]*Jordan U of Science and Technology, Irbid, Jordan.*

Intellectual disability is a common disorder affecting all populations of the world. A majority of genetically caused intellectual disability phenotype follows an autosomal recessive mode of inheritance. Consanguineous marriage is prevalent in Jordan and other Arab countries. Consanguinity increases the prevalence of rare autosomal diseases. Trying to find out genetic causes for intellectual disability in Jordanian patients we set to collect samples of consanguineous families with the phenotype. We collected samples of 4 families. Extracted DNA of members of those families had undergone genome wide SNP genotyping to identify regions of homozygosity and follow-up with disease causing gene identification. We identified multiple regions of homozygosity and analyzed data for linkage. An area of overlap was identified in two families and the region contained a gene connected to epilepsy and seizures which were found in patients of those families. WWOX gene was sequenced in members of the two families but no pathologic mutations were found. The homozygosity regions identified in all the families provide a narrowed areas in the genome which can be used later to identify disease causing genes, maybe by whole-exome gene sequencing.

Application of array-based comperative genomic hybridization in 251 patients with intellectual disability: Our experience in 2009-2011.

D. Sünnetçi Akkoyunlu[1], *N. Çine*[1], *B. Kara*[2], *H. Savli*[1];
[1]*Medical Genetics Department, University of Kocaeli, Kocaeli, Turkey,* [2]*Department of Child Health and Diseases, University of Kocaeli, Kocaeli, Turkey.*

Intellectual Disability (ID) is one of the most common developmental disorders and its prevalence is considered to be approximately 1-3%. Array-Based Comparative Genomic Hybridization (aCGH), also known as molecular karyotyping, is a high resolution technique developed to scan the segmental genomic copy number variations (CNV) in the genome level. Here, we review our experience with determining CNV's using both oligo- and BAC-based comperative genomic hybridization arrays for patients with ID between 2009 and 2011. In a cohort of 251 patients with ID with or without dysmorphic features, additional neurodevelopmental abnormalities, we found 68 different chromosomal aberrations in 56 patients (22.3%). The most common aberrations were 8p23.1 and 16p11.2 deletions. Our results showed that aCGH is a powerfull tool to detect CNV's causing intellectual disability and is usefull for detection novel candidate genes for neurodevelopmental abnormalities. According to the available literature, this is the first comprehensive aCGH study of a Turkish cohort of patients in this spesific population.

BACKGROUND: Chromosomal microarray (CMA) has become the first-line diagnostic test for individuals with intellectual disability (ID) and autism spectrum disorders ASD), with a 10-20% diagnostic yield. Here, we introduce a cohort of children with ID and ASD in Israel, who have undergone genetic testing by CMA.
METHODS: 203 children with ID and ASD of unknown etiology were prospectively tested between 5/2013 and 2/2014. All children have undergone genetic counseling prior to genetic testing. Oligo's microarray (Bluegnome-Cytochip ISCA 8x60Kv3.3) was used.
RESULTS: Normal array was reported in 132 (65%) cases. 25 cases (12%) were defined as pathogenic. All other probands (23%) were considered as having variants of unknown significance (VOUS) that further subcategorized as likely pathogenic (4), unknown (10), or likely benign (32). Pathogenic alterations included unbalanced sub-telomeic translocations (3), dup19q11-q13.2 mosaic, 12 micro-deletions and 8 micro-duplications. Pathogenic findings included PTEN, deletion syndromes of 5p-, 22q11.2, 16p11.2, Potocki-Lupski, Greigcephalopolysyndactyly and Aarskog; Aarskog syndrome was caused by a 3.5kb intronic deletion, proven as pathogenic by a typical phenotype. Parental origin was evaluated in 11 pathogenic cases; 4 were inherited and 7 were de-novo. Only 3 of the pathogenic cases could be identified by conventional cytogenetic.
CONCLUSIONS: Incidence of pathogenic findings in the Israeli cohort is similar to this reported elsewhere. Accurate clinical report allowed greater diagnostic sensitivity. Our data provides further evidence of the high diagnostic yield of CMA for genetic testing in children with ID and ASD. It confirms its value as first-tier tool regardless of the high prevalence of VOUS.

Identification of a novel variant in TMEM67 gene responsible for JBTS6 by whole exome sequencing

M. Hosseini[1], *L. Musante*[2], *Z. Fattahi*[1], *H. Hu*[2], *T. Wienker*[2], *S. Abedini*[1], *H. Najmabadi*[1], *K. Kahrizi*[1];
[1]*Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran,* [2]*Max Planck Institute for Molecular Genetics, Berlin, Germany.*

Joubert syndrome (JBTS) is a clinically and genetically heterogeneous disorder with autosomal recessive pattern of inheritance. The disorder is characterized by cerebellar hypoplasia, intellectual disability (ID), ataxia and oculomotor apraxia. Other clinical features include retinal degeneration, renal anomalies, hepatic fibrosis, and skeletal involvement. The hallmark of JBTS is a radiological pattern at magnetic imaging resonance (MRI) named "molar tooth sign".
In 2007 Baala et al. identified a new form of Joubert syndrome designated JBTS6 with causative mutation in TMEM67 gene. To now only 5 mutations in this gene has been detected responsible for JBTS6.
Due to high heterogeneity of ID in Iran,ourstudy launched to find more causative genes and their mutations in Iranian families affected with autosomal recessive IDusing whole exome sequencing (WES).One of these families has two affected with profound ID, seizure, strabismus and renal failure in one affected. On WES data a number of variants detected in thisfamily and with respect to the clinical features,a novel variant in TMEM67 gene chose as candidate. Because of suspicion of JS, MRI was performed and molar tooth sign was observed. The variant co-segregated in the family and was absent in normal population.
Underlying causes of ID remain unknown in many cases because of clinical and genetic heterogeneity;therefore, exome sequencing is an effective and helpful technique in detection of de novo mutation in this type of disorders. This approach results in more precise genotype-phenotype correlation and clinical diagnosis.

Novel MECP2 gene mutation (472 T> G) identified in Ukrainian patient with Rett syndrome

S. Chernushyn[1], *N. Zymak-Zakutnya*[2], *L. Livshits*[1];
[1]*Institute of Molecular Biology and Genetics, Kiev, Ukraine,* [2]*Khmelnytsky Regional Medical Genetic Consultation, Khmelnytsky, Ukraine.*

Rett syndrome is a neurodevelopmental disorder that occurs almost exclusively in females with a frequency of 1:10,000. It is characterized by arrested development between 6 and 18 months of age, regression of acquired skills, loss of speech, stereotypical movements (classically of the hands), microcephaly, seizures, and intellectual disability. Most cases of Rett syndrome are sporadic. It was established that the development of Rett syndrome due to the presence of mutations in the MECP2 gene. To date, 315 mutations in MECP2 gene have been identified in patients with Rett syndrome. Because of such a significant number of identified mutations in MECP2 gene and mostly the sporadic origin of the disease, we have developed denaturing gradient gel electrophoresis (DGGE) method for mutant variants screening in exons 2 and 3. Using this method we have analyzed exons 2 and 3 of MECP2 gene in 14 patients with clinical signs of Rett syndrome. In five cases abnormal migration patterns of MECP2 exon 3 PCR products have been shown. The results of Sanger sequencing has revealed 4 known for Rett syndrome mutations R168X (502C> T), A140V (419C> T), T158M (473C> T), R133C (397C> T). In one case (a patient with severe Rett syndrome symptoms) we have identified a novel mutation 472 T> G which led to substitution T158P.

Analysis of chromosomal aberrations in patients with mental retardation using the array-CGH and MLPA technique: a single Czech centre experience

H. Filková[1,2], *D. Blažková*[1], *K. Kašíková*[1,2], *E. Hladílková*[1], *V. Vallová*[1,2], *R. Gaillyová*[1], *R. Beharka*[1], *P. Kuglík*[1,2];
[1]*Faculty Hospital Brno, Brno, Czech Republic,* [2]*Masaryk University, Faculty of Science, Institute of Experimental Biology, Brno, Czech Republic.*

Submicroscopic structural chromosomal aberrations (microduplications and microdeletions) are believed to be common causes of mental retardation. Patients with idiopatic mental retardation in our laboratory are examined according to an algorithm based on experimental and economical efficiency. At first, MLPA technique is applied (P245, P297, P036, P070, P250, MRC Holland) as a screening method of the main microdeletions and microduplications detection. Whole genome screening using array-CGH follows in cases of negative results or as an alteration size specification (4x180K). Afterwards, FISH is usually used for both methods confirmation. Since 2007 to 2013, 1030 patients were examined. Chromosomal aberrations were detected in 124 patients (12%). Using MLPA, 931 patients were examined and alterations were found in 90 cases (9.7%) - 43 subtelomeric changes (P036, P070), 14 DiGeorge syndrome (P250) and 33 another changes including 4 Williams-Beuren syndrome, 3 Slavotinek syndrome, 3 cases of 1q21 microduplication syndrome (P245, P297). There were examined 99 patients by array-CGH and chromosomal aberrations were observed in 32 patients (35.5%). These findings can be devided into pathogenic (11), benign (3) and variation of unknown significance (18). According to the origin, we found 6 de novo cases, 6 cases with familial origin and 20 cases of unknown significance. World databases of patients (e.i. DECIPHER) were used for better case clarification. The suitability of all these methods combination is confirmed by a case report of a girl with unbalanced translocation t(17;22). This aberration simultaneously causes Phelan-McDermid syndrome in this patient. Supported by OP VK CZ.1.07/2.4.00/31.0155 and CZ.1.07/2.3.00/20.0183

Range of mutations of *PAH* gene at patients with a classical form of the phenylketonuria, living in the Novosibirsk region

A. B. Maslennikov[1], **L. F. Mitrohina**[1], *A. R. Shorina*[1,2], *E. V. Maslova*[1], *V. A. Makasheva*[2];
[1]*State Novosibirsk Regional Clinical Diagnostic Center, Novosibirsk, Russian Federation,* [2]*State Novosibirsk Regional Children's Clinical Psychoneurological Dispansery, Novosibirsk, Russian Federation.*

Molecular-genetic inspection of patients PKU carried out throughout 1991-2012, living in the Novosibirsk region, has shown that frequency R408W of PAH gene among all mutations of this gene makes 0,653. These mutation are revealed both in the homozygous form, and in a compound with other rare mutations. For the purpose of identification of a range of mutations of PAH gene with use of a complex of molecular-genetic technologies research of exons 5-12 of PAH gene at 62 patients with PKU, among which 48,38% had easy, 45,17% - the moderate and 6,45% heavy degree of mental retardation was carried out. As a result of the carried-out inspection (besides a major mutation of R408W) in structure investigated exons 5-12 of PAH were identification thirteen more rare mutations and their frequency characteristics - R158Q (0,0323) are established, to E221D222fsdelAG (0,0081), by R243Q (0,0081), R243X (0,0161), R252W (0,0161), R261Q (0,0484), E280K (0,0081), P281L (0,0403), S349P (0,0081), IVS10nt-11g→a (0,0081), A403V (0,0081), Y414C (0,0242), IVS12nt+1g→a (0,0323). The analysis of association of genotypes with features of a clinical picture at the surveyed patients with PKU showed communication existence between moderate and heavy forms of mental retardation and a homozygous genotype of mutations of R408W and IVS12nt+1g→a and their compound homozygous genotype with mutations of R158Q, E221D222fsdelAG, R261Q of PAH. The received results testify to essential clinical and molecular heterogeneity of PKU among inhabitants of the Novosibirsk region and allowed to develop optimum algorithm of molecular and genetic diagnostics of this disease in burdened families.

A rare case of microduplication Xp11.23-11.22

P. Dello Russo, *E. Demori, N. Passon, D. Romagno, G. Damante;*
AZ. OSP.UNIV S. MARIA DELLA MISERICORDIA, Udine, Italy.

Over the last few years, array-comparative genomic hybridization array (CGHa) has considerably improved our ability to detect cryptic unbalanced rearrangements in patients with mental retardation. We report on a young female patient, aged 18, suffering from moderate mental retardation, subjected to CGHa. She was previously studied by conventional cytogenetic techniques, and the karyotype was 46, XX. In addition, Williams syndrome and Fragile X syndrome were excluded. The subject came to our attention had clinical symptoms such as EEG abnormalities (irregular paroxysmal discharges), moviments clumsiness for fine and coarse gesture, flat foot, delayed language development, mild mental retardation, overweight. The array CGHa analysis revealed the presence of a microduplication of the short arm of the X chromosome (Xp11.23-11.22), whose size was 4.6 Mb, and excluded the presence of additional rearrangements along the X chromosome. Only a small number of individuals with duplications within the proximal short arm of the X chromosome have been so far reported, whose clinical findings correspond to that of the subject under consideration. Our findings suggest that overexpression of genes from proximal Xp is likely to have contributed to her clinical phenotype.

An Additional Case of Temple-Baraitser Syndrome: The Sixth Case in the Literature

T. Atik, *S. Akyol, F. Ozkinay, O. Cogulu;*
Ege University Faculty of Medicine, Department of Pediatrics, Izmir, Turkey.

Temple-Baraitser syndrome (TBS) is a very rare disorder characterized by severe mental retardation and anomalies of upper and lower limbs with absence/hypoplasia of the nails. Various dysmorphic facial features may accompany with the syndrome. Only 5 cases have been reported in the literature. Genetic etiology of TBS is still unknown. We report a 13-year-old female who was admitted to the hospital because of severe mental retardation, history of epileptic seizure and facial dysmorphic features. She was born to consanguineous parents at term. On physical examination at admission, her weight was 83 kg (>97p), height: 163 cm (75-90p) and head circumference: 58 cm (>97p). She had broad forehead, myopathic facies, hypertelorism, upslanted palpebral fissures, long and trapezoid philtrum, downturned corners of the mouth, broad thumbs, broad toes, absent nails of upper and lower limbs. X-ray showed central translucency of distal phalanges of thumbs. Cranial MRI was normal. Karyotype and subtelomeric FISH were normal. Temple-Baraitser syndrome should be in the differential diagnosis for cases presenting with mental retardation particularly accompany abnormal thumb with great toes and hypoplastic/absent nails.

J08.23

Recurrent findings of microduplications in the pseudoautosomal region 1 at Xp22.33 - with unknown phenotypical significance

B. S. Kristiansen, *J. Graakjaer, A. Bojesen;*
Dept. of Clinical Genetics, Vejle Hospital, Vejle, Denmark.

Microduplications in the PAR 1 region at Xp22.33 when found by SNP-array analysis, poses a challenge to interpret. As yet no certain clinical significance has been shown.

However, it has been proposed, that the *ASMT* gene, located within this area, can be linked to autism spectrum disorder (ASD) and attention-deficit/hyperactivity disorder (ADHD). *ASMT* encodes the enzyme acetyl serotonin methyl transferase, which catalyzes the last step in converting serotonin to melatonin. Melatonin is synthesized in the pineal gland during the night, and is crucial for sleep induction and circadian rhythm regulation.

In both ASD and ADHD sleep alterations has frequently been reported and it has been shown that there is a decreased level of melatonin in these patients

and that administration of melatonin greatly improves sleep patterns.
Recently we noted frequent findings of microduplications within the area, which gives rise to the question: could there be a link between a dose related activity in the *ASMT* gene (microduplications at Xp22.33) and the phenotypical presentation in our cases.
To investigate this further we wish to present our cases with microduplication at Xp22.33, to show if an association can be established.

J08.24
A novel mutation in the endosomal Na+/H+ exchanger NHE6(*SLC9A6*) causes Christianson syndrome with electrical status epilepticus during slow-wave sleep (ESES).

*G. Zanni[1], **S. Barresi**[1], R. Cohen[2], N. Specchio[3], L. Basel-Vanagaite[4], E. Valente[5], A. Shuper[2], F. Vigevano[6], E. Bertini[1];*
[1]Department of Neurosciences, Unit of Molecular Medicine for Neuromuscular and Neurodegenerative disorders, Bambino Gesù Childrens' IRRCS, ROMA, Italy, [2]Schneider's Children Medical Center of Israel And Sackler School of Medicine, Tel Aviv, Israel, [3]Division of Neurology, Department of Neurosciences, Bambino Gesù Children's Hospital, ROMA, Italy, [4]Schneider's Children Medical Center of Israel And Sackler School of Medicine, Tel Aviv, Tel Aviv, Israel, [5]Unit of Neurogenetics, Mendel Laboratory, IRCCS Casa Sollievo della Sofferenza Institute, San, ROMA, Italy, [6]Division of Neurology, Department of Neurosciences, Bambino Gesù Children's Hospital,, ROMA, Italy.

Mutations in the solute carrier family 9, subfamily A member 6(*SLC9A6*) gene, encoding the endosomal Na+/H+ exchanger 6 (NHE6) are associated with Christianson syndrome, a syndromic form of X-linked intellectual disability characterized by microcephaly, severe global developmental delay, autistic behavior,early onset seizures and ataxia.
In a 7-year-old boy with characteristic clinical and neuroimaging features of Christianson syndrome and epileptic encephalopathy with continuous spikes and waves during sleep, we identified a novel splice site mutation (IVS10-1G>A) in *SLC9A6*. These findings expand the clinical spectrum of the syndrome and indicate NHE6 dysfunction as a new cause of electrical status epilepticus during slow-wave sleep (ESES).

J08.25
Cost-effectiveness of using array CGH for diagnosing learning disability

G. S. Sagoo[1,2], *S. Mohammed[2], G. Norbury[2], J. Ahn[3], C. M. Ogilvie[3], M. Kroese[1];*
[1]PHG Foundation, Cambridge, United Kingdom, [2]Clinical Genetics Department, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [3]Cytogenetics Department, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom.

Whilst chromosomal imbalance has traditionally been diagnosed using karyotype analysis, the advent of array-based comparative genomic hybridisation (array CGH) has provided a more powerful diagnostic tool for clinical genetics services. We present an economic evaluation conducted in a retrospective cohort of patients with undiagnosed learning disability and developmental delay referred consecutively to the regional clinical genetics service at Guy's and St Thomas' NHS Foundation Trust. We compare the use of array CGH as a first-line diagnostic tool versus as a second-line diagnostic tool following karyotype analysis from a clinical genetics service perspective. Data were extracted for 848 patients in the first-line test arm and 742 patients in the second-line test arm. The mean incremental cost of testing patients was -£241.56 which means that using array CGH as a first-line was cost saving. The mean incremental gain in the percentage diagnoses was 0.39% which meant that an additional 0.39 patients would gain a diagnosis for every 100 patients tested. We calculated both the incremental cost-effectiveness ratio and the net monetary benefit and found the first-line testing strategy to dominate the second-line testing strategy. Sensitivity analyses conducted support these conclusions. Based on these findings, we estimate that moving to a first-line testing strategy will have saved in excess of £3 million based on 14,000 patients tested whilst also improving the number of diagnoses identified at Guy's and St Thomas' NHS Foundation Trust.

J09.01
DISC1 polymorphisms are associated with ADHD in Iranian population

M. Kayyal[1], *A. Movafagh[2], H. Darvish[2], M. Akbari[2], S. Kazeminasab[3], B. Emamalizadeh[2];*
[1]Islamic azad university, Tehran medical branch, tehran, Islamic Republic of Iran, [2]shahid beheshti university of medical sciences, tehran, Islamic Republic of Iran, [3]university of social welfare and rehabilitation sciences, tehran, Islamic Republic of Iran.

Attention deficit hyperactivity disorder (ADHD) is a common heritable psychiatric disorder with a worldwide prevalence of 5%. The etiology of ADHD is still incompletely understood, but several studies, consistently indicate the strong role of genetic factors on this disorder. ADHD is known to have polygenetic nature with multiple genes involved in its genetic basis. Disrupted-in-Schizophrenia-1 (DISC1) has been identified as a susceptibility locus for several psychiatric disorders and some of its polymorphisms are studied in many neurological disorders, but are not included in ADHD studies as much. In this study we investigated the association of four SNPs (rs11122330, rs6675281, rs11122319, rs1417584) in the DISC1 gene with ADHD in Iranian population. 600 subjects composed of 300 patients and 300 normal controls were included and tetra-primer ARMS PCR technique was used for genotyping all SNPs. We found differences in genotype distributions of rs11122319 (p = 0.01) and rs6675281 (p = 0.009) variants between patients and controls. Our findings strengthens the role of disc1 gene as a susceptibility locus for ADHD and indicate that rs11122319 and rs6675281 variants are strong risk factors for ADHD in Iranian population.

Genetic analysis of Aicardi-Goutières Syndrome in an Italian cohort

M. Bianchi[1], *I. Olivieri[2], S. Gagliardi[1], G. Ariaudo[2], I. Ricca[1,3], G. Grieco[1], U. Ballottin[2], Y. Crow[4], G. Rice[4], S. Orcesi[2], C. Cereda[1];*
[1]Laboratory of Experimental Neurobiology C. Mondino National Neurological Institute, Pavia, Italy, [2]Child Neurology and Psychiatry Unit, C. Mondino National Neurological Institute, Pavia, Italy, [3]School of Specialization in Neurogy, University of Pavia, Pavia, Italy, [4]Genetic Medicine University of Manchester, Manchester Academic Health Science Centre, Central Manchester Foundation Trust University Hospitals, Manchester, United Kingdom.

Aicardi-Goutières Syndrome (AGS) is a rare genetically determined encephalopathy that may overlap with the phenotype of congenital infection. Mutations in TREX1, RNASEH2A, RNASEH2B, RNASEH2C ,SAMDH1 and ADAR1 genes have been found in the majority of AGS cases .TREX1 gene codes for 3'->5' DNA exonuclease with specificity for ssDNA. AGS2, AGS3, AGS4 patients have mutations in genes coding for the three subunits of the Human Ribonuclease H2 enzyme, complex implicated in ribonucleotides removal from RNA:DNA duplex. The AGS5 gene, SAMHD1, encodes for a triphosphohydrolase that converts deoxynucleoside triphosphates to deoxynucleoside and inorganic triphosphate. AGS6 can be caused by mutations in the ADAR1 gene traslating into an adenosine deaminases acting on RNA which catalyzes the hydrolytic deamination of adenosine to inosine in ds RNA In the last years, IRCCS "C. Mondino" Foundation and International Aicardi-Goutières Syndrome Association (IAGSA) were involved in many projects. An AGS biobank to collect serum, plasma, lymphoblastoid cell lines and PBMCs has been established. .We recruited samples of 23 patients with clinical diagnosis of AGS and their parents.. We collect two AGS1/TREX1 case, 15 AGS2/RNASEH2B cases, one AGS3/RNASEH2B case, one AGS4/RNASEH2C case ,one AGS5/SAMHD1 case and two AGS6/ADAR1 cases. Although one of the screened patients did not show mutations in the mentioned genes above, we may still consider the possibility of the presence of new mutations yet to be identified in other genes. The research leading to these results has received funding from the European Union's Seventh Framework Programme (FP7/2007-2013) under grant agreement number 24177.

Evaluation of PAI-1 gene 844G/A polymorphism in Iranian patients affected by Alzheimer and Normal Individuals

L. Mazhari;
Department of Biology, Pharmaceutical Sciences Branch, Islamic Azad University, Tehran, Islamic Republic of Iran.

It has extensively established that PAI-1 gene is involved in Alzheimer pathogenesis. Numerous genetic risk factors have been related with Alzheimer, but no study has unraveled a possible association between Alzheimer and PAI-1 gene 844G/A polymorphism.There are many common risk factors such as 844G/A polymorphism that play key roles in the development of Alzheimer disease.Polymorphisms in PAI-1 gene have been associated to Alzheimer in some populations. However, other groups failed to replicate this finding in other populations. Evidence suggests that PAI-1 gene 844G/A polymorphism might play a role in Alzheimer, as a result we Studied PAI-1 gene 844G/A polymorphism common polymorphisms in Iranian with Alzheimer.**Materials and methods:**We conducted study including a clinically well-defined group of 52 Alzheimer patients to test the association between 844G/A polymorphism and Alzheimer in Iranian population. In the present case control study, the PAI- gene 844G/A polymorphism has been investigated in 52 patients with Alzheimer and 112 healthy subjects by using ARMS-PCR methods. Then, the data were analyzed by pasw statistics 18 (SPSS) software.**Results:** In patients samples the genotype distribution for PAI-1 844G/A showed 52% , 46%, 2% for AA, AG and GG respectively. In control samples 96% of the cases were AA,4% were AG and 0% were GG.**Conclusion:**The results of this study show significant association between Alzheimer and PAI-1 gene 844G/A polymorphism in Iranian population. ($P < 0.05$)

Apoe Allele frequency in Alzheimer's disease in turkish population

O. Cilingir[1], *D. Ozbabalik Adapinar*[2], *H. Aslan*[1], *M. Ozdemir*[1], *B. Durak Aras*[1], *O. Kutlay*[1], *S. Arslan*[1], *S. Artan*[1];
[1]*Eskisehir Osmangazi University, Faculty of Medicine, Departments of Medical Genetics, Eskisehir, Turkey,* [2]*Eskisehir Osmangazi University, Faculty of Medicine, Departments of Neurology, Eskisehir, Turkey.*

Alzheimer's disease is an irreversible, progressive brain disorder and the most common cause of dementia in older adults. Apolipoprotein E (APOE) is a protein involved in the transport of lipids that is strongly linked to Alzheimer's disease. The APOE gene has three common alleles (epsilon 2, epsilon 3, and epsilon 4) that determine six genotypes in the general population. Especially frequency of the allele for apolipoprotein E type 4 (epsilon 4) is increased in late-onset familial and sporadic Alzheimer's disease (AD). In this study, we have examined APOE4 frequencies in a total of 481 patients and 101 controls for an association with the APOE-epsilon 4 allele. DNA samples of patients were isolated from peripheral blood with standart methods. PCR-Reverse Hybridization (254 patients) and Real-Time PCR (227 patients) was used for APOE genotyping. The allele frequencies obtained in patients and controls, respectively, as follows; e2=55 (5.71%) and 13 (6.43%), e3=750 (77.96%) and 163 (80.69%), e4=157 (16.32%) and 26 (12.87%). E4 allel and E4/E4 genotype is a risk factor for Alzheimer's disease in Turkish population.

J09.05

The association of the rs121918398 with Alzheimer's disease in Iran northern population

F. Mohammadpour Lashkari, *H. Vaziri;*
Guilan University, Rasht, Islamic Republic of Iran.

Introduction and Aim: Alzheimer's disease (AD) is the most common type of dementia characterized by memory impairment and alteration of diverse cognitive abilities. Pathologically, it is the formation of amyloid plaques and neurofibrillary tangles in the brain. The most common form of AD is Late-onset AD (LOAD), and is usually sporadic. Although several susceptibility genes for AD have been reported, by far the strongest genetic risk factor for LOAD is Apolipoprotein E that located on chromosome 19q13.2 and universally recognized as a major disease susceptibility gene for LOAD. APOE has three common alleles, APOE-2, APOE-3, APOE-4. In this study we examined association of the APOE gene polymorphism (rs121918398) with Alzheimer disease in Iran northern population.
Methods: Study included 50 patients with AD and 50 healthy volunteers. An informed consent was obtained from all participants. Genomic DNA was extracted from peripheral blood leukocyte. Genotypes determined by PCR and restriction fragment length polymorphism (RFLP). Statistical analysis was performed using the MedCalc program for windows version 12.
Discussion and Conclusion: The prevalence of genotype frequencies of the APOE A/A, A/G, G/G were 16%, 34% and 50% respectively, in AD subjects, and in healthy volunteers were 10%, 64% and 26% respectively. Statistical analysis has not emerged significant difference from the comparison of either genotype (p>0.05). There was no evidence that APOE variants were associated with AD in this population. However our results may be different by selecting different geographical sites or bigger size population.

Replicative association analysis of Alzheimer's disease in Russian population of Siberian region

A. Bocharova, *A. Marusin, V. Stepanov;*
Research Institute of Medical Genetics of the Tomsk Scientific Center SD RAMS, Tomsk, Russian Federation.

Alzheimer's disease (AD) is a progressive neurodegenerative disorder observed in the elderly. This pathology is the most common cause of dementia and accounts for 50-80% of dementia cases. The World Health Organization estimated that currently about 25 million people worldwide have Alzheimer's disease. It is a complex disorder with genetic, environmental and lifestyle factors. Common neurological disorders including AD are the subject of intensive genetic research based on genome-wide association studies (GWAS). Genetic variants associated with cognitive impairments, which are an important endophenotypes for AD, also have been revealed by GWAS. The aim of this study was to analyze associations of 15 SNPs reported in GWAS with Alzheimer's disease in Russian population of Siberian region. SNPs were genotyped by real-time PCR in 108 AD patients and 285 age-matched controls of Russian origin. The association of rs2616984 located in the region of CUB and Sushi multiple domains 1 (*CSMD1*) gene, previously reported in GWAS by Cirulli et al. (2010), was confirmed in Russians (OR = 1,5, p = 0,01). Genetic markers in loci for *VRK2, SLCO6A1, NOTCH4, TCF4, ZNF804A, AGBL1, TLR4, RELN, ZFP64P1, KCNB2, CPVL, NRGN* and *NRIP1* previously reported in GWAS was not associated with the disease in Russian population. This work is partially supported by RFBR grant #12-04-00595.

Association study of BDNF polymorphism Val66Met in Bulgarian patients with Alzheimer disease

K. Mihova[1], *S. Mehrabian*[2], *R. Pavlova*[2], *A. Jordanova*[1,3], *V. Mitev*[1], *L. Traykov*[2], *R. Kaneva*[1];
[1]*Department of Medical Chemistry and Biochemistry, Molecular Medicine Center, Medical University, Sofia, Sofia, Bulgaria,* [2]*Clinic of Neurology, University Hospital „Alexandrovska", Department of Neurology, Medical University, Sofia, Bulgaria, Sofia, Bulgaria, Sofia, Bulgaria,* [3]*VIB Department of Molecular Genetics, University of Antwerp, Antwerp, Belgium, Antwerp, Belgium.*

Background: Alzheimer disease (AD) is the most common form of dementia characterized by cognitive impairment, memory and personality disorders caused by progressive degeneration of the brain neurons. Brain-derived neurotrophic factor promotes neuronal survival and growth processes during development. The Val66Met (rs6265, G>A) polymorphism in BDNF gene has been extensively studied for association with various neuropsychiatric and neurodegenerative diseases. Several studies show that Val66Met polymorphism is implicated in cognitive impairment, depression, intracellular trafficking, reduced hippocampal volume etc. Materials and methods: In this study 202 patients with AD and 97 healthy controls, matched to the patients by age, gender and ethnicity (NC) were included. Genotypes were determined using TaqMan assay (Applied Biosystems). Statistical analysis was done using Plink toolset and chi square test. Results and discussion: The Val66Met polymorphism showed significant difference in allele frequency distribution between the AD and NC group. The common Val allele was more frequent among AD patients, while the rare Met allele was associated with decreased risk of AD (P=0.01, OR=0.58), When the sample was analysed in sub-groups according to the age of onset, significant association was found in the early onset group (EOAD) (P= 0.01, OR= 0.51), but not in the group with late onset (LOAD) (P= 0.07, OR= 0.62). Conclusions: Our findings show association and increased risk effect of the common Val66 BDNF allele (P= 0.02, OR= 1.732) in Bulgarian patients with early onset AD. Brown-Vialetto-Van Laere syndrome: a case report of a family from Italy

F. L. Conforti[1], *R. Spataro*[2], *R. Mazzei*[1], *A. Magariello*[1], *A. Patitucci*[1], *A. Qualtieri*[1], *M. Muglia*[1], *V. La Bella*[2];
[1]*Institute of Neurological Sciences, Mangone (CS), Italy,* [2]*ALS Clinical Research Center, BioNeC, University of Palermo, Palermo, Italy.*

Background. Brown-Vialetto-Van Laere syndrome (BVVLS) is a rare motor neuron disease (MND) characterized by childhood onset, neurosensory deafness and bulbo-pontine paralysis. Most familial cases are recessive and genetic studies have demonstrated mutations in several riboflavin transporter encoding genes (i.e. SLC52A3 [hRFT2], SLC52A2 [hRFT3] and SLC52A1 [hRFT1]) and the UBQLN1 gene.
Objective.To describe the phenotypic and genotypic characteristics of an Italian family with autosomal dominant BVVLS.
Patients and methods. The proband is a 16-years-old girl affected by BVVLS since she was 3. A second case in the family is the proband's maternal aunt, who was diagnosed with BVVLS at age of 27; however, deafness and bulbar weakness had started during adolescence. No other family members are affected.
DNA was extracted from blood of the proband and several relatives. A screening for patogenic mutations in riboflavin transporter genes and UBQLN1 was performed.
Results. No pathogenic mutations in all three riboflavin transporter genes were detected. We found that the proband was bearing a heterozygous substitution E54D in exon 1 of the UBQLN1 gene, previously suggested to be implicated in the disease. This polymorphism was also present in a healthy adult family member.
Conclusions. We identified a rare BVVLS family with an autosomal dominant pattern of inheritance with incomplete penetrance and variability of age at onset. The UBQLN1 gene might represent a genetic risk factor for this rare motor neuron disease.

Repeat expansion in C9ORF72 is not a common cause of Parkinson's disease among Iranian patients

M. Malakouti Nejad[1], *E. Elahi*[1,2], *A. Alavi*[2], *G. Shahidi*[3];
[1]*Department of Biotechnology, College of Science, University of Tehran, Tehran, Iran, Tehran, Islamic Republic of Iran,* [2]*School of Biology, College of Science, University of*

Tehran, Tehran, Iran, Tehran, Islamic Republic of Iran, [3]Department of Neurology, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran.

Expansion of the hexanucleotide repeat (GGGGCC) in intron 1 of the C9ORF72 gene is the most common cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). C9ORF72 expansions have also been observed in some Parkinson's, Alzheimer and essential tremor patients. The mechanism by which the mutation causes disease is definitively unknown. During a recent screening of only 80 Iranian ALS patients, ALS, FTD, and PD was each observed in three individuals of a single family. The hexanucleotide repeat in C9ORF72 was observed in all three patients. This finding prompted screening of repeat in a cohort of 170 Iranian PD patients by the repeat primed polymerase chain reaction protocol. LRRK2, PRKN, DJ-1, and PINK1 had earlier been screened in many of the patients and those with known mutations in these genes were excluded from the C9ORF72 screening. No pathogenic expansion was found in any of the cases. We conclude that abnormal C9ORF72 repeat expansions are not a common genetic cause of PD in Iranian. The same finding has been reported in C9ORF72 repeat expansion screenings of cohorts from other populations.

Preimplantation diagnosis of CADASIL (cerebral arteriopathy with subcortical infarcts and leukoencephalopathy)

D. Raskova[1], *M. Brandejska[1], R. Jarosova[1], L. Vykysala[1], I. Soldatova[1], J. Mika[1], H. Vlaskova[2], L. Dvorakova[2], M. Hrebicek[2], M. Putzova[1], D. Stejskal[1];*
[1]Centre for Medical Genetics and Reproductive Medicine GENNET, Prague 7, Czech Republic, [2]Institute of Inherited Metabolic Disorders, 1 st Medical Faculty, Charles University, Prague 2, Czech Republic.

Cerebral arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is an autosomal dominant progressive disorder of the small arterial vessels of the brain manifested by migraine, strokes, white matter lesions, diffuse myelin loss, with resultant cognitive impairment in some patients. It is caused by heterozygous mutation in the NOTCH3 gene on chromosome 19p13.The case report presents the preimplantation diagnosis of CADASIL family. The proband had severe transient neurological symptoms (immobility, cognitive impairment) after childbirth. Her sister is clinically healthy, but a MRI scan shows supratentorial white matter changes. Their father has minimal clinical symptoms. All three family members have NOTCH3 gene mutation.

J09.11
Identification of two novel mutations in ERCC6 and ERRCC8 genes in two mildly affected patients with Cockayne syndrome

G. Yesil[1], *U. Cetincelik[2], D. Lessel[3], S. Guler[1], A. Iscan[1], B. Tuysuz[4];*
[1]Bezmialem University, Istanbul, Turkey, [2]Samatya E.A.H, Istanbul, Turkey, [3]Institute of Human Genetics University of Ulm, Ulm, Germany, [4]Cerrahpasa Medical Faculty, Istanbul, Turkey.

Cockayne syndrome is clinically heterogeneous condition in which postnatal growth delay, microcephaly and neurological dysfunction are the cardinal features. Characteristic dysmorphic findings like deep-set eyes, triangular face, aged appearance can be seen in various degrees. Photosensitivity, demyelinating peripheral neuropathy, cataract, cachexia, dental abnormalities and sclerotic epiphyses are also the features of this syndrome. It should be noted that brain calcifications are observed but not a must. ERCC6 and ERCC8 mutations are responsible for the clinical findings of these patients. Here we report three patients with Cockayne Syndrome and two novel mutations in ERCC6 and ERCC8 genes. Two of them had a mild clinical course and very mild dysmorphic findings and the other was severely affected. Insight of these findings we discuss the phenotypic heterogeneity of this condition and aimed to underline the possibility to overlook in the absence of some cardinal criteria and mild facial features.

J09.12
One novel SCN1A mutation in a Bulgarian patient - case report

T. Todorov[1], *I. Yordanova[1], A. Todorova[1,2], P. Dimova[3];*
[1]Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria, [2]Department of Medical Chemistry and Biochemitry, Sofia Medical University, Sofia, Bulgaria, [3]Clinic of Child Neurology, St. Naum University Hospital of Neurology and Psychiatry, Sofia, Bulgaria.

Dravet syndrome (DS) is an early-onset epileptic encephalopathy characterized by polymorphic seizure types. At onset, they are usually induced by fever and often present as tonic-clonic or hemiclonic status epilepticus during the first year of life. Later, patients also manifest other seizure types, including absences, myoclonic, and partial seizures, all being refractory to treatment. The EEG is often normal at onset, but later characteristically shows generalized spike-wave activity. Psychomotor development stagnates around the second year of life, and affected individuals show subsequent mental decline and other neurologic deficits. DS is caused by mutations of the SCN1A gene in more than 80% of patients. Here we report a 1-year old boy with seizure onset at 5 months, presenting by series of febrile or afebrile tonic-clonic or hemiclonic seizures up to status epilepticus, some with postictal hemiparesis. Several interictal EEGs were normal or with background slowing only. Four antiepileptic drugs had no effect and long-lasting seizures occurred every 10-20 days. Based on clinical data, at the age 10 months the diagnosis of DS was proposed. The molecular genetic testing of the SCN1A gene detected a novel de novo mutation - c.3587_3588insCTTC in exon 18 of the gene. The mutation causes frameshift and the shifted mRNA is most probably degraded through nonsense-mediated mRNA decay mechanism.

J09.13
A novel mutation in SLC1A3 gene associated with episodic ataxia

E. Mantuano[1], *L. Veneziano[1], S. Romano[2], M. Spadaro[1], M. Frontali[1];*
[1]Institute of Translational Pharmacology, National Research Council of Italy, Rome, Italy, [2]Neurology and Centre for Experimental Neurological Therapies (CENTERS), S. Andrea Hospital, Rome, Italy.

Episodic ataxia (EA) is an autosomal dominant genetically heterogeneous group of disorders characterized by episodes of incoordination and imbalance. Mutations have been mainly associated to KCNA1 and CACNA1A genes, causing EA1 and EA2. Mutations in other genes, CACNB4 and SLC1A3, have been identified in very few cases, causing EA5 and EA6. Here we describe a patient with episodic ataxia phenotype carrying a novel mutation in SLC1A3 gene, encoding for a glial glutamate transporter (EAAT1). The patient had episodes characterized by vertigo, intentional tremor, gait imbalance, dysarthria lasting from few days to a week, since the age of 30. At examination, when she was 50, she presented with gait ataxia, dysmetria, dysarthria, abnormal eye movements and cerebellar atrophy. DNA mutation screening for all four known EA genes revealed a heterozygous nucleotide substitution (c.227G>A) in SLC1A3 leading to a replacement of a highly conserved arginine to a glutamine (p.R76Q) located between two transmembrane segments. The pathological effect of this missense substitution on EAAT1 structure have been bioinfomatically evaluated. This variant was present in the proband's son showing nistagmus and reporting mild vertigo episodes, at age 40. The proband's daughter, normal at the clinical examination, doesn't carry the nucleotide change.
This variant was not detected in 418 Italian control chromosomes and it is reported in dbSNP with a very low frequency (2/13000 random chromosomes).
This is the third EAAT1 mutation so far reported for SLC1A3 gene associated to EA.

Does the imbalance between agonistic and antagonistic IL-1 play a role in progression of febrile convulsions?

F. Ozen[1], *N. Kocak[2], I. H. Yıldırım[3], G. Hacımuto[4], V. Sen[5];*
[1]Medeniyet University Göztepe Training and Research Hospital, Department of Medical Genetics, Istanbul, Turkey, [2]Selcuk University, Selcuklu Medical Faculty;Department of Medical Genetics, Konya, Turkey, [3]Dicle University,Veterinary Medicine, Department of Medical Genetics, Diyarbakır, Turkey, [4]Medeniyet University Göztepe Training and Research Hospital, Istanbul, Turkey, [5]Dicle University Medical Faculty,Department of Pediatrics, Diyarbakır, Turkey.

Objective: Inflammation may play an important role in the etiopathology of febrile convulsions (FC). IL-1 β is an important mediator of inflammation and fever is also important in formation of FCs. It is suggested that there may be a relationship between polymorphisms of IL-1 β and FC. The aim of the present study is to investigate the polymorphic stituation of promoter region of IL-1 β in two sites (-31 and -511) and assess the IL-1 RA VNTR polymorphisms in FC patients in comparison with healthy control groups.
Materials and Methods: Fifty FC patients and 50 healthy controls (HC) were included in the study. DNA extraction was performed by QIAamp DNA Mini Kit from peripheral blood lymphocytes of all subjects. IL-1β promoter polymorphisms were analyzed by PCR-RFLP, IL-1 RA VNTR polymorphisms were analyzed by PCR-agarose gel electrophoresis.
Results: Genotype distribution of IL-1 β promoter region in position -31 was statisticaly different between FC patients and control groups. Allele I and allele II of IL-1 RA distribution were also statisticaly different in FC patients and healthy controls.
Conclusion: We have found a significant association between IL-1 RA allele distribution and FC and a poor correlation of T/C substitution at the -31 position of IL-1 beta promoter in FC. Further studies are needed to investigate the gene expression levels and polymorphic situation in same samples.

J09.15
The emerging phenotype of FOXP1 haploinsufficiency

J. Pêtre[1], *M. Ravoet[1], F. Christiaens[2], X. Stephenne[3], A. Boschi[4], E. Sokal[3], N. Revencu[1];*
[1]Center for Human Genetics and Medical Genetics Unit, Cliniques Universitaires Saint-

Luc and Université Catholique de Louvain, Brussels, Belgium, [2]Pediatric Neurology Unit, Cliniques Universitaires Saint-Luc and Université Catholique de Louvain, Brussels, Belgium, [3]Pediatric Gastroenterology & Hepatology Unit, Cliniques Universitaires Saint-Luc and Université Catholique de Louvain, Brussels, Belgium, [4]Department of Ophtalmology, Cliniques Universitaires Saint-Luc and Université Catholique de Louvain, Brussels, Belgium.

Background The *FOXP1* gene, located on 3p13, has recently been involved in neurodevelopment. *FOXP1* haploinsufficiency has been reported in about 10 patients with specific facial features, global developmental delay, intellectual disability, and speech impairment, where expressive skills are more severely affected than receptive skills. **Case description** We report on a 2-year-old Caucasian boy, born at term with relative macrocephaly. He developed neonatal cholestasis for which an extensive etiological assessment was performed, including *JAG1* (Alagille syndrome) and *ABCB4* (PFIC3) gene analysis. Ductular paucity was objectified with progressive improvement and genetic work-up was normal. Progressively, global developmental delay was observed. He had axial hypotonia, dyskinetic movements and is still not able to walk. Expressive language has not yet been acquired, though receptive language appears more advanced. Growth is normal. He has frequent respiratory tract infections, bronchial hyperreactivity and gastro-esophageal reflux. Facial features include prominent and broad forehead, bilateral palpebral ptosis, broad nasal tip and arched palate. Hypoplastic nails are also observed. Chromosome molecular analysis using CytoScan HD-array (Affymetrix) revealed a *de novo* ~120kb heterozygous interstitial deletion at 3p13 covering exons 7 to 11 of the *FOXP1* gene. **Conclusion** Global developmental delay, expressive language delay, relative macrocephaly and specific facial features are associated with *FOXP1*. Our patient presents with bilateral ptosis, a sign previously reported in the literature in at least two other patients, and could be a clue for the diagnosis when present. Whether or not the liver involvement is an associated feature remains to be studied in larger series of patients.

J09.16
DXS998-DXS548-FRAXAC1 represents a novel informative haplotype at the FMR1 locus in the Iranian population

M. Shirani, *S. Vallian;*
University of Isfahan, Isfahan, Islamic Republic of Iran.

Fragile X syndrome which is caused by mutation in the FMR1 gene region is one of the most prevalent forms of mental retardation. Direct diagnosis of the disease is based on PCR and southern blot analysis, but because of technical problems, use of polymorphic DNA markers can be helpful for carrier detection and prenatal diagnosis in families with an affected individual. The polymorphic markers usually show a population-based haplotype frequency and heterozygosity. In the present study, genotyping and analysis of haplotype frequency of three microsatellite markers including DXS998, DXS548 and FRAXAC at the FMR1 gene region were carried out in 140 unrelated healthy women and 26 families from the Iranian population. The data indicated the presence of a novel allele for DXS998 in the Iranian population. Estimation of haplotype frequency using Arlequin program showed 50 different DXS998-DXS548- FRAXAC1 haplotypes for the input date of 5, 7 and 4 alleles, respectively. Among these haplotypes four of them showed relatively high frequencies (≥0.05). Analysis of linkage disequilibrium (LD) for the unrelated individuals using the Powermarker computer program, showed that this haplotype combination can be an informative haplotype for linkage analysis in carrier detection and prenatal diagnosis of fragile X in the Iranian population.

J09.17
Effect of GAA repeat on CpG methylation at first intron of frataxin gene in Indian patients of Friedreich's ataxia

S. Agarwal, *S. Muthuswamy, S. Pradhan;*
Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

FRDA is an autosomal recessive neurodegenerative disease characterized by progressive gait and limb ataxia, dysarthria, lower limbs areflexia. The onset of symptoms usually occurs before the age of 25 years, and typically around puberty. The expanded GAA repeat in intron 1 of the frataxin gene is the common cause of FRDA. Unaffected individuals have at least one allele with 8-33 repeats, while most individuals with FRDA have 90 or more repeats in both alleles resulting in deficiency of frataxin, an essential protein of mitochondrial iron metabolism. We studied the epigenetic alterations at first intron in the present study which is one of the mechanisms hypothesized to hinder the frataxin synthesis.
The study was conducted in 10 healthy controls and 15 Friedreich ataxia cases. Two microgram of extracted DNA was bisulfite treated and amplified with nested primers followed by standard Sanger's sequencing procedure and results were evaluated.
Average age of onset of patients was 22±5.5 years. Average size of alleles of patients and controls were 1200±400 and 12±3.5 respectively. No difference in methylation patterns were observed between the cases and the controls of Indian patients. The CpG islands methylated irrespective of GAA repeat number. However this study is limited in sample size which could be one of the factors that may over-represent the methylation phenomenon. We plan to further extend our study on more Friedreich ataxia patients to draw a strong conclusion along with methylation sites at the promoter region as they are more important for gene expression.

J09.18
Atypical parkinsonism and very early-onset dementia in a patient carrying two GBA gene in cis mutations

I. Ricca[1,2], *M. Bianchi*[1], *R. Zangaglia*[3], *N. Pozzi*[3], *M. Picascia*[4], *S. Bernini*[4], *F. Blandini*[5], *E. Sinforiani*[4], *C. Pacchetti*[3], *C. Cereda*[1];
[1]*Laboratory of Experimental Neurobiology- C. Mondino National Neurological Institute, Pavia, Italy,* [2]*School of Specialization in Neurology – University of Pavia, Pavia, Italy,* [3]*Parkinson's Disease and Movement Disorders Unit - C. Mondino National Neurological Institute, Pavia, Italy,* [4]*Alzheimer's Disease Assessment Unit and Laboratory of Neuropsychology - C. Mondino National Neurological Institute, Pavia, Italy,* [5]*Laboratory of Functional Neurochemistry - C. Mondino National Neurological Institute, Pavia, Italy.*

Heterozygous glucocerebrosidase (GBA) gene mutations are a common risk factor for Parkinson Disease (PD). GBA mutation carriers display cognitive and neuropsychiatric disorders more frequently than PD patients without GBA mutations.
We describe a male patient carrying two GBA *in cis* mutations and affected by a severe early-onset parkinsonism associated with behavior disorders and cognitive decline.
The patient had been presenting apathy and memory loss since the age of 33. One year later he developed a bradykinetic parkinsonism partially responsive to levodopa therapy. SPECT study showed mild striatal presynaptic dopaminergic dysfunction. The neuropsychological assessment performed at 34 years of age showed deficits in all tested skills with worse performances in executive function and attention and relative sparing of visuospatial abilities; Mini Mental State Examination (MMSE) score was 26/30. At 37 years of age MMSE score was 22/30.
Brain MRI showed diffuse and symmetric brain atrophy with major involvement of the temporomesial lobes and the cerebellar vermis.
Testing of PARK2, LRRK2, DJ1 and IT15 genes was normal. GBA molecular analysis detected two *in cis* mutations in exon 10 (L444P and A456P) inherited from the father. These mutations are probably due to a recombination event between GBA gene and its pseudogene.
Clinical and neuropsychological examination of the father and family history were unremarkable.
Reports on GBA mutation carriers with parkinsonism may contribute to defining the cognitive phenotype of these patients, the possible genotype-phenotype correlations and the clinical markers that may be useful in identifying candidate subjects for GBA genetic testing.

J09.19
Next Generation Sequencing And Data Interpretation In Recessive Hereditary Spastic Paraplegia Patients From Turkey

B. Ozes[1], *M. Gonzalez*[2], *S. Züchner*[2], *E. Battaloglu*[1];
[1]*Bogazici University, Istanbul, Turkey,* [2]*University of Miami, Miami, FL, United States.*

Hereditary Spastic Paraplegia (HSP) comprises a group of clinically and genetically heterogeneous neurodegenerative disorders. In 'pure' HSP, lower limb spasticity and progressive weakness are observed. 'Complicated' HSP additionally include neurological and non-neurological symptoms. HSP can be inherited in autosomal dominant, autosomal recessive, or X-linked manner. Thirty-two loci and 23 genes are associated with autosomal recessive form of HSP (ARHSP). One patient was selected for whole exome sequencing (WES) from each of six ARHSP families from Turkey. After determining candidate variations, segregation analyses were performed in the families to confirm that the variation can be responsible for the HSP phenotype. In two of the families mutations were identified in known HSP genes. First mutation is the c.4321C>T (p. A1394X) variation in Spastizin gene (SPG15) in family H61. Spastizin is the second most common causative gene for ARHSP with thin carpus callosum that is also observed in our patient. The other mutation is c.325_326insTGTC insertion in ALS2 gene in family H59. ALS2 gene is responsible for juvenile amyotrophic lateral sclerosis (JALS) and infantile onset hereditary spastic paraplegia (IAHSP). Four families were found to be negative for mutations in known HSP genes. In two of the families, novel HSP candidate genes were identified and segregation with the disease was shown in the families. For the remaining two families, WES data is still under analysis. Our WES analysis gives promising preliminary data for identification of novel genes in families from Turkey and it suggests evidence for further genetic heterogeneity in ARHSP.

J09.20

Novel mutation in SPG4 gene in three families with autosomal dominant hereditary spastic paraplegia from Bashkortostan Republic (Russia)

A. Akhmetgaleyeva[1], *I. Khidiyatova*[1], *E. Saifullina*[2], *R. Idrisova*[2], *R. Magzhanov*[2], *E. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation.*

Hereditary spastic paraplegias (HSP) - is a genetically and clinically heterogeneous group of neurodegenerative disorders characterized by progressive spasticity of the lower-limbs. The major pathological feature of HSP is a degeneration of the pyramidal tracts. The HSP frequency in Bashkortostan Republic (BR) is 3,5:100000. Autosomal dominant (AD), recessive (AR), or X-linked inheritance were described. To date, 30 causative genes and 50 loci have been identified. Mutations in the SPG4 gene are responsible for about 45% of the pure AD type of HSP and for 12-18% of the sporadic cases. SPG4 codes for spastin - AAA (ATPase associated with diverse cellular activities) family protein. Disorder onset ranges between 1 and 63 years. Over 300 mutations have now been described, with the majority of them being located in the AAA domain.
We examined HSP patients from BR and detected one rearrangement of DNA sequence in 12-th exon in patients from three unrelated families. This previously not described mutation is inversion translocation, starts at c.1469. Twelve exon codes the region that corresponds to a highly conserved ATPase domain, which is also called AAA cassette. This region is responsible for ATPase activity of the spastin protein. New polymorphism in 11-th intron (c.1413+43_46dup (TATA)) and polymorphisms (c.1098+118 A>G (rs 12617289) and c.1098+127 A>G (rs 12617290)) in 7-th intron were revealed in the same patients.
Large chromosomal rearrangements are frequent cause of SPG4 HSP. The mutation we found is among them. We supposed that this mutation was spread in BR by the founder effect.

J09.21

Two novel compound heterozygous mutations in ROBO3 gene in a sporadic case of Horizontal Gaze Palsy with Progressive Scoliosis

R. Mazzei[1], *S. Valentini*[2], *F. L. Conforti*[1], *A. Magariello*[1], *O. Gallo*[1], *A. Cerasa*[3], *M. Muglia*[1], *P. Perrotta*[3], *A. Patitucci*[1], *P. L. Lanza*[1];
[1]*Institute of Neurological Sciences-National Research Council, Mangone (CS), Italy,* [2]*Department of Neuroradiology, Cosenza Hospital, Cosenza, Italy,* [3]*Institute of Bioimaging and Molecular Physiology-National Research Council, Catanzaro, Italy.*

The syndrome of horizontal gaze palsy with progressive scoliosis (HGPPS) is characterized by absence of conjugate horizontal eye movement and scoliosis. HGPPS is an autosomal recessive neurologic disorder caused by homozygous or compound heterozygous mutations in the ROBO3 gene on chromosome 11. Here we report a case of a 34-year young woman from non consanguineous parents. No history of scoliosis or gaze palsy in the other family members. At six months was noticed a fixation in her eyes. At the age of 9 years a dorsal-lumbar scoliosis was diagnosed and a physical examination showed absence of the horizontal eye movements and absence of nystagmus. The morphologic MR examination, the colour map DTI and the f-MRI showed typical signs of HGPPS. Similar results have been confirmed by neurophysiological tests (PESS, PEM). So we perform a molecular screening of the ROBO3 gene. Sequencing of the all 28 coding exons and relative intron/exon boundaries revealed two novel mutations: a heterozygous missense mutation and a splice-site mutation. The information provided by a multimodal approach (conventional RM, DTI, fMRI, neurophysiology, and molecular genetics) are crucial in confirming the clinical diagnosis, and when integrated with each other allow to clarify the possible different expressions of the lack of decussation of the cortical spinal tracts in the brainstem.

J09.22

Holoprosencephaly complicated by neurogenic hypernatremia

T. Bizerea[1,2], *M. Puiu*[1,2], *O. Marginean*[1,2], *R. Stroescu*[1,2];
[1]*University of Medicine and Pharmacy, Timisoara, Romania,* [2]*Clinical Emergency Hospital for Children „Louis Turcanu", Timisoara, Romania.*

Holoprosencephaly is defined as a structural anomaly of the brain in which there is failed or incomplete separation of the forebrain early in gestation. It occurs in 5-12/10,000 live births. Classic holoprosencephaly is classified as alobar, semilobar, lobar and middle interhemispheric variant typeș. It can result from environmental causes, an inherited or de novo chromosome abnormality, an inherited monogenic syndromic disorder, an inherited or de novo mutation for a gene associated with nonsyndromic autosomal dominant holoprosencephaly, copy number variations or unknown causes. We report the case of a 3 month old infant admitted for to oure clinic for sepsis, with characteristic clinical features of HPE. Lab tests revealed severe incoercible hypernatremia alternating with three episodes of severe hyponatremia. During admission,under the established treatment, the sepsis was remitted; nevertheless high natrium levels were maintained. In this case HPE was complicated by neurogenic hypernatremia. Genetic testing revealed a normal cariotype and the uncharacteristic phenotype of the mother ruled out autosomal dominant transmission. In the presented case, neurogenic hypernatremia was the consequence of impaired osmoregulation of ADH release due to malformations involving midline structures of the brain.

J09.23

Homozygosity in Huntington's disease

N. Erginel-Unaltuna[1], *E. Lohman*[2], *M. Poda*[1];
[1]*Istanbul University, DETAE, Genetics Dept., Istanbul, Turkey,* [2]*Istanbul University, Istanbul Faculty of Medicine, Neurology Dept., Istanbul, Turkey.*

Huntington disease is caused by a dominantly transmitted CAG repeat expansion mutation that is believed to confer a toxic gain of function on the mutant protein. Huntington disease patients with two mutant alleles are very rare. In other poly(CAG) diseases such as the dominant ataxias, inheritance of two mutant alleles causes a phenotype more severe than in heterozygotes. We identified a homozygous female patient, 89 years old and compared clinical features with those of a group of heterozygotes. The age of onset was within the range expected for heterozygotes with same CAG repeat lengths. However, she showed a rather different clinical course with emotional instability and behavioral disorders. Cerebral magnetic resonance imaging showed no evident atrophy, notably not in the cerebral cortex or the striatum. Clinical examination revealed she had chorea predominating on the upper limbs and the trunk. She was partially unable to control the speed and the force of her movements and mild dysarthria was noted. Severe memory deficits associated with a severe frontal deficit were found, all symptoms suggesting Huntington disease. Mutation analysis revealed two HTT alleles with CAG repeats of 43 and 45. This suggests that although homozygosity for the Huntington disease mutation does not lower the age at onset of symptoms, it affects the disease phenotype and progression. These data, once confirmed in a larger series of patients, will point to the possibility that the mechanisms underlying age at onset and disease progression in Huntington disease may differ.

J09.24

Gene expression profile in fibroblasts of Huntington's disease patients and controls

E. Marchina, *S. Misasi, A. Bozzato, S. Ferraboli, C. Agosti, L. Rozzini, G. Borsani, S. Barlati, A. Padovani;*
University of Brescia, Brescia, Italy.

Huntington's disease is an inherited disorder caused by expanded stretch of consecutive trinucleotides (CAG) within the first exon of the huntingtin gene (HTT) on 4p16.3. The mutated huntingtin (mHTT) gains toxic function, probably through mechanisms that involve aberrant interactions in several pathways, causing cytotoxicity. Pathophysiology of disease involves several tissues; indeed it has been shown that there is a broad toxic effect of mHTT in the peripheral tissue of patients with HD. In this study we compared gene expression profiles of HD fibroblasts and matched controls using microarray technology. We used RT-PCR to test the consistency of the microarray data and we found four genes up-regulated in HD patients with respect to control individuals. The genes appear to be involved in different pathways that have been shown to be perturbed even in HD models and patients. Our study shows that gene expression profiles seem to be altered in the fibroblasts of HD patients. Validation of the differential expressions at the protein level is required to ascertain if this cell type can be considered a suitable model for the identification of HD biomarkers.

Identifying the genomic imbalance of individuals with mental retardation in Taiwan with G-banding, MLPA, and aCGH

Y. Li[1,2], *I. Chou*[3], *F. Tsai*[3,2], *C. Lin*[2];
[1]*Department of Biomedical Sciences,Chung-Shan Medical University, Taichung, Taiwan,* [2]*Department of Medical Research, China Medical University Hospital, Taichung, Taiwan,* [3]*Department of Pediatrics, China Medical University Hospital, Taichung, Taiwan.*

Mental retardation (MR) occurs in 1-3% of the general population and about one-half of the cases their etiology is still elusive, thus appropriate treatment and genetic counseling remains as great challenges. About 50% of idiopathic MR with IQ less than 50 is likely to have genetic defects. Some of them are involving genomic disorders. However, submicroscopic genomic disorders can not be detected by conventional cytogenetic analysis. With the recent advances in molecular cytogenetics analysis and genome-wide array-based comparative genome hybridization (aCGH) technology, submicroscopic genomic disorder bases of MR can be identified and characterized.
The array CGH profiles of 204 idiopathic MR patients in Taiwan have been

obtained. 28 MR patients were found to have genomic imbalance (microdeletion/microduplication) with a detection rate of 13.86%. Our finding is within or in agreement with the most recent multiple centers studies on chromosomal microarray study of MR. The identification of genomic imbalances in our study could lead to the identification of some pathogenic CNVs for MR. This could lead to the discovery of a network of neuro-developmentally associated genes. The informed network of neurodevelopmentally-associated genes will help us understand the etiology of MR disorders and will assist in diagnosing, managing and treatment of the disorders.

J09.26

Deletion in exon 15 of KCNQ2 gene responsible of Benign Familial Neonatal Seizures in a large Spanish family.

J. Juan[1], *I. Aleixandre*[2], *M. Ortiz*[3], *A. Zúñiga*[2];
[1]*Servicio de pediatría. Hospital Univ. De la Ribera, Alzira/Valencia, Spain,* [2]*Servicio de genética. Hospital Univ. De la Ribera, Alzira/Valencia, Spain,* [3]*Servicio de genética. Hospital univ. De la ribera, Alzira/Valencia, Spain.*

Benign familial neonatal convulsion disease (BFNC, OMIM #121200) is a rare autosomal dominant inherited epilepsy characterized by unprovoked generalized or multifocal tonic-clonic convulsions. The convulsions typically start around the third day of life and resolve spontaneously after several weeks or months. In the majority of BFNC families the disease is linked to chromosome 20q13.3, and mutations of the voltage-gated potassium channel gene KCNQ2 have been identified as the underlying defect.
The proband is the first daughter of healthy non consanguineous parents. She was born by normal vertex delivery at full term after an uneventful pregnancy. Her birth weight, head circumference, and length were in a standard range. Her Apgar scores were 8 and 10 at 1 and 10 minutes, respectively. On the fourth day she manifested convulsions with apnea and clonic movements. The attacks were of short duration and ceased spontaneously. Clinically, the patient demonstrated no abnormal facial features, with normal skin, power, tone, and reflexes. Basic laboratory investigations produced normal results. Cranial ultrasound and magnetic resonance imaging also produced normal results. After interrogation, there were members of the family with a history of repeated seizures in their childhood,
Direct DNA sequencing of the KCNQ2 gene exons and their flanking intronic sequences, of the proband and members of her family, revealed a deletion in exon 15 of a cytosine nucleotide; c.1960 in the amino acid 595 (NM_172107), that is predicted to cause a frameshift in the protein. This mutation has not been previously described in literature.

J09.27

Mutational analysis of cathepsin F and CLN6 genes in a Japanese patient with Kufs disease, an adult onset neuronal ceroid lipofuscinosis

T. Inazu[1,2], *S. Tsujimoto*[1], *K. Sawada*[1], *T. Makifuchi*[2];
[1]*Department of Pharmacy, College of Pharmaceutical Sciences, Ritsumeikan university, Kusatsu, Japan,* [2]*Department of Clinical Research, Saigata National Hospital, Joetsu, Japan.*

Kufs disease is an adult onset neuronal ceroid lipofuscinosis, which is autosomal recessive progressive lysosomal disorders. Kufs disease are clinically divided into two types; Type A and B. Type A presents with progressive myoclonus epilepsy, whereas type B presents with dementia and motor abnormalities. Recently, the genes responsible for Kufs disease are discovered. Mutations in CLN6 are the major cause of recessive type A, whereas mutations in cathepsin F is the cause of type B.
In the past, we have reported a type B Kufs patient, whose parents were consanguineous marriage (Sakajiri K et al. Intern Med, 1995;34:1158-63). Here we present the first mutational report from Japan. In this study, we performed mutational analysis of responsible genes for this Kufs patient. We found several SNPs in cathepsin F gene, and a known but homozygous mutation (c231C>G, pN77K in exon 3) in CLN6 gene. PCR-RFLP analysis revealed that the mutation was not a SNP. The amino acid is perfectly conserved between human, mouse and rat. Furthermore in silico analysis using PolyPhen2, the mutation is predicted to be probably damaging. These data suggest that the mutation must be pathogenic one. Since we found a known but homozygous mutation in CLN6 gene in a type B patient, genotype-phenotype correlation seems to be complex than we expected.

The Association of Migraine and Endothelial Nitric Oxide Synthase Haplotypes

H. Zolghadr[1], *M. Ansari*[2], *M. Moghaddasi*[2], *S. Ghasemi*[3], *P. Ghazizadeh Tehrani*[4], *A. Ebrahimi*[5];
[1]*Department of Cellular and Molecular Biology, Islamic Azad University Medical Branch of Tehran, Tehran, Islamic Republic of Iran,* [2]*Department of Biochemistry, Tehran university of medical science, Tehran, Islamic Republic of Iran,* [3]*Parseh genetic counseling center, Rouyan Alley, Keshavarz Blv, Tehran, Islamic Republic of Iran,* [4]*Department of Genetic, Islamic Azad University Science and Research Zanjan Branch, Tehran, Islamic Republic of Iran,* [5]*Cellular and Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Migraine is a complex and debilitating neurovascular disorder predominantly affecting women. It recurs as attacks of severe headache associated with nausea, vomiting, phonophobia, and photophobia. Despite its high prevalence, migraine is a disease involving complex pathogenetic mechanisms that remain to be clarified. As other multifactorial diseases migraine also has a genetic basic combined with triggering environmental factors. There is strong evidence implicating nitric oxide (NO) in the pathophysiology of migraine. Therefore, genetic polymorphisms in the endothelial NO synthase (eNOS) gene have been studied as candidate markers for migraine susceptibility. NO plays an essential role in the control of cerebral blood flow and may be involved in the activation of nociceptors in the trigeminovascular system and release of vasoactive neuropeptides during neurogenic inflammatory response. There are several studies on the association of eNOS gene variations and the risk of migraine in different populations. In the present study, we focused on one of the most common single nucleotide polymorphisms (SNP) of the eNOS gene. The prevalence of the rs1799983 in Iranian population has been evaluated by ARMS-PCR method. We have not found interaction between the selected SNP and the risk of the migraine in 90 patient samples compared to 113 normal individuals.

J09.29

Plasminogen Activator Inhibitor Haplotypes Associated with Migraine

P. Ghazizadeh Tehrani[1], *M. Ansari*[2], *M. Moghaddasi*[2], *S. Ghasemi*[3], *H. Zolghadr*[4], *A. Ebrahimi*[5];
[1]*Department of Genetic, Islamic Azad University Science and Research Zanjan Branch, Tehran, Islamic Republic of Iran,* [2]*Department of Biochemistry, Tehran university of medical science, Tehran, Islamic Republic of Iran,* [3]*Parseh genetic counseling center, Rouyan Alley, Keshavarz Blv, Tehran, Islamic Republic of Iran,* [4]*Department of Cellular and Molecular Biology, Islamic Azad University, Tehran Medical branch, Tehran, Islamic Republic of Iran,* [5]*Cellular and Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Migraine is a common disorder affecting approximately 16-10% of the world population, almost three times more women than men. It is characterized by recurrent moderate to severe headaches often in association with a number of autonomic nervous system symptoms. Studies of twins indicate a 34 to 51% genetic influence of likelihood to develop migraine headaches and a number of specific variants of genes have been established to increase the risk by a small to moderate amount. Like other multifactorial diseases genetic basics of migraine are combined with triggering environmental factors.
There are some data supporting the involvement of endothelial, haemostatic and haemorheological functions in the pathogenesis of migraine. Plasminogen Activator Inhibitor subtype 1 (PAI-1) gene encodes a member of the serine proteinase inhibitor (serpin) superfamily, concentrations of the gene product are associated with thrombophilia. Inasmuch as it's plasma level decreases in migraine, PAI-1 seems to play a determinant role in vascular diseases related to migraine.
In the present study, we focused on one of the most common single nucleotide polymorphisms (SNP) of the PAI-1 gene. The prevalence of the rs2227631 in Iranian population has been evaluated by ARMS-PCR method. We have not found a significant association ($P<0.05$) between the selected SNP and the risk of the migraine in 98 patient samples compared to109 normal individuals.

J09.30

Identified a neonatal Spanish patient with Miller-Dieker Lissencephaly Syndrome by MLPA

G. Pi[1], *I. Aleixandre*[2], *M. Ortiz*[1], *A. Zuniga*[1];
[1]*Servicio de Pediatria. Hospital Univ. de la Ribera, Alzira (Valencia), Spain,* [2]*Servicio de Pediatria. Hospital Univ. de la Ribera, Alzira /Valencia, Spain.*

Miller-Dieker syndrome (OMIM #247200); 17p 13.3 deletion with haploinsufficiency of PAFAH1B1) is a contiguous gene deletion syndrome that is characterized by lissencephaly, facial dimorphisms, growth restriction and seizures. PAFAH1B1 encodes LIS1, a protein essential for neuronal migration, proliferation and survival. It participates in a complex to regulated spindle orientation during neuronal progenitor divisions.
The patient is the first child of healthy non consanguineous parents. He was born at full term after an uneventful pregnancy. His birth weight, head circumference, and length were in a standard range with Apgar index of 8/10. Clinical examination at birth only showed undescended testicles as remarkable aspect. At 4 months old male referred for evaluation because of hypotonia, microcephaly and developmental delay. Cranial sonography sho-

wed agyria-pachygyria with thick cortex, a less severe form of lissencephaly. Electroencephalographic monitoring showed a diffuse dysfunction for the age of the patient.
DNA was isolated from EDTA-blood collection by standard protocol and the diagnosis of deletion of exon 3 and exon 5 of the PAFAH1B1 gen was established by MLPA. The array-CGH cytochip focus constitutional array (Cambridge Bluegnome) showed no evidence of a clinically significant deletion or duplication (result: ISCN: arr (1-22)x2, (XY)x1) with a medium resolution of 1Mb in the whole genome (backbone) and 100Kb in 97 regions associated with birth defects OMIM of 143 genes. In our case phenotype was mild than in a classical Miller-Dieker syndrome probably due to a small deletions in PAFAH1B1 that are not detected by array analysis.

J09.31
Association of HLA-DRB1 alleles with Multiple Sclerosis in patients from Bogotá, Colombia

D. M. Narváez[1], *H. Groot de Restrepo*[1], *S. Reyes*[1], *C. Díaz*[1], *J. Toro Gómez*[2,1];
[1]*Universidad de los Andes, Bogota, Colombia,* [2]*Hospital Universitario. Fundación Santa Fe de Bogota, Bogota, Colombia.*

Multiple Sclerosis (MS) is a chronic autoinmune inflammatory disease that attacks the central nervous system. Multiple factors are associated with the development of this disease, many of them related to the environmental and to the personal genetics. It has been shown a closed relationship between the HLA-DRB1 variant, HLA-DRB1*1501, and the pathology. In fact, the presence of HLA-DRB1*1501 increases the risk to present it. The aim of this study is to find the association of HLA-DRB1 alleles with MS in patients from an heterogeneous population as the one we have in Bogotá, Colombia. The study population is composed of 99 patients diagnosed with MS and 198 healthy controls. Every participant signed an informed consent and the inclusion and exclusion criteria were confirmed by a professional. Peripheral blood lymphocytes were used to obtained DNA, and the variant determination was done using a PCR-SSP. We found that the HLA-DRB1*1501 allele confers a significant higher risk of suffering MS (OR= 2,89; 95% CI= 1,60 - 5,19); in contrast, HLA-DRB1*1401 allele exhibit a protector effect (OR=0,29 ; 95% CI= 0,11 - 0,76) in our population. The association of HLA-DRB1 alleles with MS will enrich our knowledge of the disease and will focus new approximation to a better diagnosis and treatment.

J09.32
Genetic characterization of narcolepsy patients from Estonia

M. Teder-Laving[1], *M. Pindmaa*[2], *H. Rein*[1];
[1]*Estonian Genome Center, University of Tartu, Tartu, Estonia,* [2]*Mae Pindmaa Sleep Clinic, Tartu, Estonia.*

Human narcolepsy is a complex genetic disorder, characterized by excessive daytime sleepiness, cataplexy, hypnagonic hallucinations, sleep paralysis, and disturbed nocturnal sleep. Most cases are sporadic and approximately 0.02% of the population is affected worldwide. An autoimmune mechanism for the disease has been suspected based on its strong association with the genetic marker - HLA DQB1∗06:02. Recent studies support this hypothesis. To date thousands of patients and matched controls have been genotyped from different populations and genome-wide association studies (GWAS) carried out. Significant associations with narcolepsy include polymorphisms in the *TCR* alpha, *CTSH*, *TNFSF4*, 3´untranslated region of *P2RY11*. Nevertheless, the overwhelming portion of risk and protection is still found within HLA region. Other common variants found through GWASs have little contribution.
Narcolepsy in Estonia is presumably underdiagnosed disorder. Patients are diagnosed by standard protocols, including assessment of excessive daytime sleepiness, polysomnography and test for Multiple Sleep Latency Time. Hypocretin levels in CSF were not measured.
Estonian Genome Center has an is ongoing project to gather narcolepsy patients all over Estonia. To date we have 17 patients, sent by sleep doctors: age 19-66, 10 men and 7 women. In these patients *DQA1*01:02-DQB1*06:02* variants were tested and 50% of patients with cataplexy were *DQB1*06:02* carriers.
Simultaneously, we are using control individuals from our database, who were genotyped by either Illumina ImmunoChip (1000 individuals) or Illumina HumanExome Beadchip (4400 individuals), to identify the DQB1variants and assess the frequency of *DQB1*0602* in general population. Distribution of other significantly associated SNP alleles will also be presented.

J09.33
Two novel mutations in NF1 identified in Mexican patients with neurofibromatosis type 1

J. Villa Morales*[1], *E. López Muñoz*[1], *D. Juaréz Melchor*[1], *F. Minauro Sanmiguel*[1], *D. Arenas Aranda*[1], *J. Aguirre Hernández*[2];
[1]*IMSS, Mexico,D.F., Mexico,* [2]*HIMFG, Mexico,D.F., Mexico.*

Neurofibromatosis type 1 (NF1) is an autosomal dominant genetic disorder with worldwide incidence of 1 in 2500 to 1 in 3000 individuals. It is caused by mutations in neurofibromin 1 (*NF1*), located on chromosome 17q11.2. The main signs and symptoms are café-au-lait spots, Lisch nodules in the eye, and fibromatous tumors of the skin. Other clinical manifestations that have been reported include bone dysplasia and an increased risk of malignant tumours.
The aims of this study were to describe the clinical manifestations of the disease in 22 patients with neurofibromatosis type 1, and to identify the underlying *NF1* mutations, by sequencing all 60 exons of this gene. Five different mutations were identified in 7 patients. Two of these mutations have not been previously described (Table 1).
Given the clinical variability of this disorder, and the small sample size, no statistical genotype-phenotype correlations were preformed. However, the prevalence of clinical manifestations and the type of mutations seen are in agreement to what has been reported in other populations.

Sample	Exon	Mutation	Mutation Type
25	28	c.3810_3820delCATGCAGACTC	Deletion (new)
29	30	c.4077_4078insG	Insertion (new)
39	24	c.3194_3195insA	Insertion
38	37	c.5257_5258delG	Insertion

J09.34
Mutational spectrum of the NF1 gene in Greek patients with Neurofibromatosis Type 1

M. Tsipi[1,2], *M. Tzetis*[1,2], *K. Kosma*[1,2], *S. T. Kitsiou*[1,2], *E. Frysira*[1,2], *E. Kanavakis*[1,2];
[1]*University of Athens, Athens, Greece,* [2]*Department of Medical Genetics, Athens, Greece.*

Neurofibromatosis Type I is one of the most common autosomal dominant disorders with a birth incidence of one in 3,500 individuals worldwide. It is caused by mutations of the NF1 tumor suppressor gene, located at 17q11.2. Neurofibromin, the NF1 gene product, is an important negative regulator of cellular Ras signaling pathway. The main clinical features of the disease include café-au-lait spots, skinfold freckling, benign cutaneous neurofibromas, plexiform neurofibromas, optic gliomas and Lisch nodules of the iris. Disease penentrance is about 100%, while expressivity is extremely variable.
In our study we focused on the elucidation of the genetic causes underlying the disease. A multi step protocol based on genomic DNA has been established for molecular diagnosis in Greek patients fulfilling the NHI diagnostic criteria. This protocol includes multi-step PCR, sequencing of all NF1 gene exons and multiplex ligation-dependent probe amplification for deletions/ duplications. The protocol was validated in a cohort of 34 NF1 patients and 20 relatives, identifying the germline mutations in most cases.
Our results include 13 genetic variants, in coding and non-coding regions of NF1, most of them already reported in Human Gene Mutation Database. Among the novel variants the majority were stop codon mutations or variants which may affect the splicing process. Some novel mutations were found in patients with unusual phenotypes. All novel variants were analyzed with the use of bioinformatic tools. In an attempt of possible phenotype/ genotype correlations, we detected different mutations in patients within the same family, indicating the genetic complexity of the disease.

J09.35
Missense mutation (Met1035Arg) of the NF1 gene revealed through NGS

M. Hejtmankova[1], *L. Cerna*[1], *B. Honysova*[1], *B. Petrak*[2], *M. Putzova*[1], *D. Stejskal*[1];
[1]*GENNET, Praha 7, Czech Republic,* [2]*Motol Hospital, Praha 5, Czech Republic.*

Neurofibromatosis type 1 (NF1) is an autosomal dominant condition, with a high allelic heterogeneity of the *NF1* mutations and variable expressivity. We present a case of a male, with a diagnosis of the NF1, first made on clinical grounds by observation of his phenotype at age of 3, although the causal mutation was identified much later. Family history was negative. The patient has had hypotonia since neonatal period. By the time the boy was one year old first café-au-lait spots were developed and more than 11 spots came into being till adolescence. Freckles, neurofibromas, glioma, Lisch nodules were not present. He was shorter than average. Later he has had learning difficulties (ADHD) and sporadic migraine. He was referred to a geneticist to specify the diagnosis at the age of 14. The young patient has been tested through Next-Generation-Sequencing (NGS), which allows detection of a much higher level of detail of the NF1 gene. NF1 diagnosis was confirmed by using the MiSeq system and the TruSight Cancer sequencing panel (Illumina). Sequencing of exon 23 revealed the missense mutation c. 3104T›G (p.M1035R). The mutation was absent in the parents. Although missense mutation can be associated with a mild progress of NF1 condition the effect

of apparent *de novo* mutation is difficult to predict. Confirmation of NF1 diagnosis may provide a possibility of more specific health supervision for the patient's condition and monitoring of potential long-term complications.

J09.36

Influenza A virus infection changes the expression of NMDA receptor subunits in mice

M. Yegorova, *M. Plotnikova, S. Klotchenko, A. Garshinina, V. Zarubaev, A. Vasin; Research Institute of Influenza, St-Petersburg, Russian Federation.*

N-methyl-D-aspartate receptors (NMDARs) play an essential role in the process of synapses formation, neuronal differentiation, brain plasticity as well as participate in the molecular response to the neurotoxic substances action. The NMDAR dysfunction is associated with schizophrenia, Alzheimer's disease, and Huntington's disease. The influenza virus infection is also one of the potential negative factors influencing NMDAR function, but the molecular mechanisms of neurological complications of influenza are not well understood. The aim of our research was to study the influence of influenza A virus infection on the expression of NMDAR subunits (NR1, NR2(A-D), NR3(A-B)) in mice. We analyzed the expression of seven genes, coding NMDAR subunits, in brains and lungs on the 1, 3, 5 and 10 days post infection using real-time PCR. Two groups of mice were infected with H1N1 and H3N2 strains at 0,2 LD50 respectively. The expression of all seven NMDAR transcripts was detected only in brains of non-infected animals. The infection with influenza A virus strain led to the changes in expression levels of NR2A, NR2B, NR2D and NR3B mRNAs in brains. In lungs NMDAR mRNAs were not detected. Further we are going to make the more detailed analysis not only of NMDARs expression but also of other genes involved in the regulation of the central nervous system during influenza A virus infection in mice.

New insights in non-syndromic intellectual disability: a case report

A. C. Tutulan-Cunita[1], *A. Arghir*[1], *S. M. Papuc*[1], *M. Cristea*[1], *I. Borcan*[1], *M. Budisteanu*[1,2]; [1]*Victor Babes National Institute of Pathology, Bucharest, Romania,* [2]*Prof. dr. Alex. Obregia Clinical Hospital of Psychiatry, Bucharest, Romania.*

A 15 years old girl with obesity, dysmorphic features (down-slanting palpebral fissures, short nasal bridge; short philtrum; micrognathia), moderate mental retardation, psychosis, dyslalia, hyperkinesis, aggressivity, bilateral hypoacusis was referred for genetic investigations. aCGH on an 105K Agilent platform revealed arr 5p13.2(37,479,936-38,118,402) x3,11q13.5q14.1(76,158,015-83,043,032)x1, 17q25.3(79,829,409-79-,910,442)x1. Interestingly, the ~6.88 Mb deletion on 11q includes 21 OMIM genes, among which two disease-causing entities: *MYO7A*, and *ALG8.* The first one encodes for an unconventional myosine, a motor molecule with structurally conserved heads moving along associated actin filaments and highly divergent tails suggested to act as carriers of various macromolecular cargo molecules; *MYO7A* is known to carry heterozygous mutations in nonsyndromic neurosensorial deafness and homozygous mutations in most cases of Usher syndrome. The second gene encodes for alpha-3-glucosyltransferase which, when mutated to compounded heterozygosity, produces the congenital disorder of glycosylation, a severe phenotype resulting in multiple dysmorphisms and defects leading to early infant death. The 0.63 Mb duplication on 5p harbors only one OMIM gene, *GDNF*, encoding for a specific dopaminergic protein associated with motor neuron function and Hirschsprung disease. Finally, the 0.08 Mb deleted fragment on 17q contains 8 OMIM genes, among which pyrroline-5-carboxylate reductase 1 that causes cutis laxa disease when it losses functions. The correlations of the identified genetic defects with the observed phenotype will be discussed, as well as their impact upon patient management.

Introduction. The disease of Niemann Pick type "C", is an alteration in storage lisosomal, characterized for decline neurological progressive and death premature. He has un pattern of recessive autosomal inheritance, caused by mutations in the NPC1 and NPC2 genes. Clinical manifestations include, mental decline, ataxia, cataplexy, dystonia, vertical supranuclear gaze palsy(VSGP) and clumsiness. Case report. Female patient of 29 years old, daughter of the fifth pregnancy of non-consanguineous healthy parents. Family history: One sister died at age of 25-years-old with the same disease. The patient initiate at 17-years-old with, loss progressive of memory, cognity disorders, disartria, and dysphagia . At the 22-years-old, she presented coreics and dystonics movements of upper and lower extremities and gait problems. Phisical exploration: she had ataxia and dystonics and coreoatetosics movements and VSGP. The score performed for NPC was 201 points. The abdominal ultrasound showed splenomegaly and the magnetic resonance cortical atrophy. Methods. It was performed PCR and sequencing of 25 exons of the NPC1 gene and the five exons of the NPC2 gene. This study was carried out in parents and health sister of the patient. Results: We detected two different pathogenic mutations: [c.2604+1G>A] + [c.3630T>G], compatible with compound heterozygous genotype. The NPC2 gene sequencing was normal. Conclusion: This is the first case informed in Mexican population of Niemann-Pick type C. Miglustat is the important therapy in NPC disease.

Identification of The Human Natural Resistance-Associated Macrophage Protein 2 (NRAMP2) Gene Polymorphism in Schizophrenia Patients

H. Kurt[1], *Z. Ozdemir*[1], *C. Yenilmez*[2], *I. Degirmenci*[1], *M. Baltacioglu*[2], *F. Mutlu*[3], *H. Gunes*[1];
[1]*Eskisehir Osmangazi University, Faculty of Medicine, Department of Medical Biology, Eskisehir, Turkey,* [2]*Eskisehir Osmangazi University, Faculty of Medicine, Department of Psychiatry, Eskisehir, Turkey,* [3]*Eskisehir Osmangazi University, Faculty of Medicine, Department of Biostatistics, Eskisehir, Turkey.*

Natural resistance associated macrophage protein 2 (NRAMP2), also known as divalent metal transporter 1 (DMT1) is responsible for the uptake of iron and iron translocation from the endosome. The regulation of metal ion transport within neurons is critical for normal brain function. Iron defciency is in charge of long-term results of behavioral abnormalities especially in fetal hippocampus and striatum. Five single nucleotide polymorphisms are identified within the NRAMP2 gene. One of them 1303C/A occurs in the coding region of NRAMP2 and results in an amino acid change from leucine to isolecine. Mutations or polymorphisms of NRAMP2 gene may affect the iron metabolism and have an impact on human health. So, we were investigated of one-single-nucleotide mutation (1303C/A) polymorphism in schizophrenia firstly by us.

The NRAMP2 1303C/A polymorphism was analyzed by PCR restriction fragment length polymorphism analysis (PCR-RFLP) in 100 subjects (scizophrenia patients: n=50; healthy controls: n = 50) of Turkish origin. PCR products were digested with SfaNI restriction enzyme. The 362 bp PCR product is digested to a 197 and 165 bp fragment when the normal 1303C is present. Comparisons of the data were performed by chi-square test. We were found that no significant differences in allele (for C allele χ^2=1.01, P=0.315; for A allele χ^2=1.77, P=0.018) and genotype (χ^2=3.95, P=0.138) frequencies. The study was supported by ESOGU (Grant no:201211007)

PAC1 gene associated with PTSD: preliminary data

A. Di giacinto[1], *C. Lai*[2], *F. Cieri*[1,3], *T. Ialacci*[1], *E. Cinosi*[1], *A. Pasquini*[1], *S. Sperduti*[1], *G. Massaro*[2], *V. Gatta*[4], *L. Stuppia*[5,6], *M. di Giannantonio*[1];
[1]*Department of Neuroscience and Imaging, University d'Annunzio, chieti, Italy,* [2]*Department of Dynamic and Clinical Psychology, Sapienza University, Rome, Italy,* [3]*Department of Psychological Sciences, G. d'Annunzio University, Chieti, Italy,* [4]*Functional Genetics Unit, Center of Excellence on Aging (CeSI), chieti, Italy,* [5]*Department of Psychological Sciences, G. d'Annunzio University, chieti, Italy,* [6]*Functional Genetics Unit, Center of Excellence on Aging (CeSI),, Chieti, Italy.*

The study tested the association between the development of PTSD and genetic variants of ADYAP1R1 (PAC1): C/C vs C/G vs G/G in survivors to 6 April 2009 L'Aquila earthquake. The sample examined so far consists of 103 subjects. Cells of the buccal mucous were collected to obtain DNA and Clinician-Administered PTSD Scale (CAPS) test is administered.

It has been conducted an analysis of variance (ANOVA) with LSD Post Hoc test to assess differences between groups in terms of CAPS scores compared to the three polymorphic variants. In line with the literature, the results suggest a strong role of SNP rs2267735 of PAC1 C/C genotype in the regulation of physiological response to stress, showing as a risk factor for the development of post-traumatic symptoms after a natural disaster. Further genetic investigations are still ongoing concerning: Val66Met BDNF allele and the S allele of 5HTTLPR , in addition to evaluation of various psychometric scales : the Hamilton Depression Scale (HAM-D), Hamilton Rating Scale for Anxiety (HAM-A), Mini-International Neuropsychiatric Interview (MINI), Temperament and Character Inventory (TCI-R), Toronto Alexithymia Scale (TAS -20) and Childhood Trauma Questionnaire (CTQ). These data will be subsequently analyzed in order to verify other possible associations in the development of PTSD. These data to shed light on the role of genetic factors in the formation or modulation of the stress response.

The role of Vitamin D and FokI Variant in the Vitamin D receptor Gene among Iranian Parkinson's Disease Patients

R. Meamar[1], *M. Ostadsharif*[2], *The first and the second authors are in equal position and corresponding authors;*
[1]*Department of Medical Sciences, Islamic Azad University, Najaf Abad Branch, Isfahan, Islamic Republic of Iran,* [2]*Medical Basic Sciences Department, Esfahan (Khorasgan) Branch, Islamic Azad University, Isfahan, Islamic Republic of Iran.*

Introduction: Today, A role for vitamin D and it's receptor (VDR) in Parkinson's disease (PD) has been proposed. Several studies concerning the association between the VDR gene polymorphism and PD have been published. In this study, firstly we determined the correlation between 25 hydroxy vitamin D (25 OHD) and severity of PD then accessed frequency of FokI polymorphism in PD patients and healthy Iranian population.
Methods: The severity of PD was evaluated by using Hoehn & Yahr (HR) stages and Unified Parkinson's Disease Rating Stage (UPDRS) Part III. After amplification of DNA samples from 62 unrelated normal individuals and 60 PD patients by PCR, polymorphism was genotyped by RFLP according to FokI site.
Results: Our study revealed that 25OHD level in patients with PD was not associated with HR stage and UPDRS scores . The most frequency of genotype in PD group and normal individuals was FF (51.7%) and Ff (51.6%), respectively. Protection against the development of PD was applied when F allele be present, but it was not significant (OR= 0.7, 95%CI: 0.44-1.28, p=0.29). In contrast, insignificant susceptibility to PD (OR= 1.3, 95%CI: 0.437-1.283, p=0.29) was associated to f allele.
Conclusion: Our finding does not show correlation between vitamin D and HR stage and UPDRS scores during the early disease stages of PD in Iranian patients. Furthermore, after genotypes analysis, no significant association was seen for FokI polymorphism with Parkinson . Further studies are needed to reveal the main role of vitamin D and VDR gene in PD progression.

Alpha-synuclein 3´UTR polymorphism is a risk factor for Parkinson's disease in Iranian population

M. Akbari[1], *A. Movafagh*[1], *H. Darvish*[1], *S. Kazeminasab*[2], *B. Emamalizadeh*[1];
[1]*shahid beheshti university of medical sciences, tehran, Islamic Republic of Iran,*
[2]*university of social welfare and rehabilitation sciences, tehran, Islamic Republic of Iran.*

Parkinson's disease (PD) is one of the most common neurodegenerative disorders and both genetic and environmental factors are involved in its etiology. The incidence of PD differs by race and ethnicity, is greater in men than women, and increases markedly with age. One of the well-known genes involved in PD development, is alpha-synuclein (SNCA) gene and several polymorphisms in this gene have been identified to be associated with PD susceptibility. In this study, we investigated the association of four SNPs (rs2301134, rs2301135, rs356221, rs11931074) in the promoter region and 3´UTR of the SNCA gene, with Parkinson's disease in Iranian population. A total of 960 subjects (480 PD patients and 480 normal healthy controls) were included and genotyped for all four polymorphism. The method used for genotyping was tetra-primer ARMS PCR. We found significant differences in genotype distributions of rs11931074 variant in patients compared to controls (odds ratio = 7.6970, 95% CI = 5.7514-10.3006, p = <0.0000001). Our findings indicate a significant association of rs11931074 SNP with PD in Iranian population.

J09.43

Association analysis of Parkinson's disease with polymorphic variants in SNCA, LRRK2 genes and MAPT-region (17q21.31) in three ethnic groups from Bashkortostan Republic of Russia (GWAS replication results)

I. M. Khidiyatova[1], *G. N. Akhmadeeva*[1], *I. R. Gilyzova*[1], *A. R. Baytimerov*[2], *R. V. Magjzanov*[2], *E. K. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Bashkir State Medical University, Ufa, Russian Federation.*

We performed replication of genome-wide association analysis (GWAs) with Parkinson's disease (PD) in three ethnic groups from Bashkortostan Republic (BR) on 550 PD patients (Russians - 215, Tatars - 243, Bashkirs - 90) and 622 controls (Russians - 190, Tatars - 338, Bashkirs - 94). The study included analysis of 5 polymorphic loci: rs653219 in SNCA gene, rs1491942, rs1907632 in LRRK2 gene, rs1981997 and rs12373139 in chromosomal region of MAPT gene (17q21.31).
The results of GWAs received on the indicated polymorphic loci of SNCA gene and MAPT-region were confirmed only for Tatar ethnic group. We found that genetic markers for PD development were genotype C/T (p = 0,002; OR = 1,73; CI = 1,21 - 2,46) and allele T (p = 0,04; OR =1,4; CI=1,01 - 1,8) of SNCA gene (rs653219); genotype G/G (p=0,001; OR=1,84; CI=1,16 - 2,92) and allele G (p = 0,01 ; OR=1,72; CI =1,11 - 2,65) of MAPT gene (rs1981997); genotype G/G (p=0,02; OR=1,7; CI=1,09 - 2,64) and allele G (p=0,04; OR=1,53; CI=1,02-2,3) of SPPL2C gene (rs12373139, MAPT-region). There was no association of PD with rs1491942 and rs1907632 in LRRK2 gene in the investigated ethnic groups.
The possible reasons for the discordance between results in different ethnic groups and previous GWAs may include effects of population structure and population-specific environmental interactions. Our findings suggest that additional studies are necessary to establish the role of these loci in modifying risk for Parkinson's disease in different populations.

Molecular basis of mechanism of gene expression modulation induced by hypericin in genes involved in the pathogenesis of Parkinson's disease

J. Feruszova[1], *A. Soltysova*[1,2], *L. Kadasi*[1,2];
[1]*Institute of Molecular Physiology and Genetics, Slovak Academy of Sciences, Bratislava, Slovakia,* [2]*Faculty of Natural Sciences Comenius University, Dpt. of molecular biology, Bratislava, Slovakia.*

Parkinson's disease is a multifactorial heterogeneous neurodegenerative disorder manifested particularly in the elderly people. Although originally thought not to be hereditary, recent studies have identified several genes that are responsible for the manifestation of the disease. Clarification of the molecular basis of disease would allow more accurate diagnosis of the disease and would also help in treatment and prevention. The aim of our work was to study the effect of hypericin, a substance isolated from the plant Hypericum perforatum L., on expression modulation in genes involved in the pathogenesis of Parkinson's disease. Experiments were carried out on the A549 (alveolar adenocarcinoma), 42-MG-BA (glioma) and MSC (mesenchymal stem) cell lines using microarray and qPCR. Our results show that hypericin can modulate expression of more with Parkinson's disease associated genes. We focused on 8 genes, which play main roles in Parkinson's disease pathway. We detected prolonged changes in expression of DDC, LRRK2, CYCS and short term changes of other genes during 96 hours of monitoring. Our results may help in understanding the molecular mechanism of hypericin action in various neurodegenerative diseases as Parkinson's and Alzheimer's disease. Our results may help to indicate a potential of hypericin to be implemented as a medicine or prevention of major neurodegenerative diseases.

J09.45

RIT2, a susceptibility gene for Parkinson's disease in Iranian population

B. Emamalizadeh[1], *A. Movafagh*[1], *R. Mirfakhraie*[1], *M. Akbari*[1], *S. Kazeminasab*[2], *H. Darvish*[1];
[1]*shahid beheshti university of medical sciences, tehran, Islamic Republic of Iran,*
[2]*university of social welfare and rehabilitation sciences, tehran, Islamic Republic of Iran.*

Parkinson's disease (PD) is the second most common and a complex neurodegenerative disorder arising from a complex interaction between genetic and environmental factors. Determining the pathogenic gene contributed to Parkinson's disease have always been controversial. In a large meta-analysis study on Caucasian populations another novel PD susceptibility locus, RIT2, on chromosome 18, was identified. A genetic variant in RIT2, rs12456492, was found to be associated with risk of sporadic PD. In the present study, we investigated the association of the rs12456492 variant with Parkinson's disease in Iranian population. A total of 960 subjects (480 PD patients and 480 normal healthy controls) were included and genotyped for rs12456492 polymorphism (A/G) of RIT2 gene. Genotyping was done by tetra-primer ARMS PCR technique. We found significant differences in distributions of GG genotype in patients compared to controls (odds ratio = 1.60, 95% CI = 1.14-2.23, p = 0.005). Our findings increase the likelihood of association between PD and RIT2 variant in Asian populations.

J09.46

Partial duplication Xq27.1 in a dysmorphic and mentally retarded girl

N. Andreescu[1], *S. Dumitriu*[1], *V. Plaiasu*[2], *M. Puiu*[1];
[1]*Victor Babes University of Medicine and Pharmacy, Timisoara, Romania,* [2]*IOMC Hospital, Bucuresti, Romania.*

Background. Duplications of the long arm of chromosomes X have been related to mental retardation, different dysmorphic features, hypopituitarism and short stature.
Aim. We aim to examine the relation between the partial duplication of the Xq27 region and the presence of clinical manifestation in in a dysmorphic and mentally retarded girl.
Methods. We report on a 3 year old girl associating facial dysmorphism, hypotonia, delayed milestones, mental retardation. Proposita is the first child of a young couple, born at 39 weeks of gestation by caesarean section due

to pelvic presentation. Birth parameters were: weight 2850 g, length 52 cm, cranial circumference 31 cm.
Results. A good evolution was recorded after birth, with no sucking or swallowing difficulties. Craniofacial dysmorphisms includes: microcephalia, hypertelorism, astigmatism, wide nasal base, low set ears, carp shaped mouth. At age of 3 she cannot walk without support, respond to simple commands, says only 2-3 words. The girl is sociable and presents a happy attitude. EEG, EMG and MRI were normal. Conventional cytogenetic investigation showed a normal female karyotype. Revealed a 408 kb duplication on chromosome Xq27.1. The duplication encompasses SOX3 and CDR1 genes.
Conclusion. Further studies including the analysis to prove the X inactivation pattern will be done, knowing that a preferential inactivation of the aberrant chromosomes X in female preventing genetic imbalance is often reported. Array CGH was an essential tool for molecular characterization of this case and for establishing the recurrence risk for a future pregnancy.

J09.47
A 9 year-old boy diagnosed with Pantothenate Kinase-Associated Neurodegeneration after a 6 year history of psychiatric disturbances

T. Diemer[1], *G. Andersen*[2], *H. C. Laugaard-Jacobsen*[3], *M. B. Petersen*[1,4];
[1]*Dept. Clinical Genetics, Aalborg University Hospital, Aalborg, Denmark,* [2]*Dept. Radiology, Aalborg University Hospital, Aalborg, Denmark,* [3]*Dept. Pediatrics, Aalborg University Hospital, Aalborg, Denmark,* [4]*Dept. Clinical Medicine, Aalborg University, Aalborg, Denmark.*

Pantothenate Kinase-Associated Neurodegeneration (PKAN) is a form of neurodegeneration with brain iron accumulation (NBIA) formerly called Hallerworden-Spatz disease. PKAN is an autosomal recessive condition characterized by iron deposition in the basal ganglia leading to progressive extrapyramidal dysfunction as dystonia, rigidity and/or choreoathetosis, pigmentary retinopathy, psychiatric disturbances and speech defects. PANK2 is the only known gene related to PKAN. MRI shows the highly specific "eye of the tiger" sign in almost all affected individuals with at least one PANK2 mutation. We report a Danish family in which a 9 year-old boy, of a sibship of 4 children, has been diagnosed with PKAN after a 6 year history of psychiatric disturbances. At the age of 2-3 years the patient developed behavioral problems, and was diagnosed with Attention Deficit/Hyperactivity Disorder (ADHD), and the first MRI was performed. At the age of 3-4 years the psychomotoric development slowed combined with some speech problems, and the patient was diagnosed with mild mental retardation. At the age of 7 he is diagnosed with infantile autism and the second MRI was performed, where the "eye of the tiger" sign was reported. At the age of 9 the patient developed choreoatic dystonia in the right arm and the right side of the neck, and the third MRI was performed confirming the "eye of the tiger" sign. Genetic analysis was performed and revealed compound heterozygotic for a pathogenic mutation in exon 5 and a deletion of exon 2 of the PANK2 gene, confirming the diagnosis of PKAN.

J09.48
Whole exome sequencing analysis in a large Primary Angle Closure Glaucoma (PACG) pedigree

F. Suri[1], *E. Elahi*[1], *I. Safari*[1], *S. Yazdani*[2];
[1]*School of Biology, University College of Science, University of Tehran, Tehran, Islamic Republic of Iran,* [2]*Ophthalmic Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Glaucoma is a heterogeneous group of optic neuropathies characterized by progressive degeneration of the optic nerve head and visual field loss. It is sub-grouped according to the anatomy of the anterior chamber angle into two main forms: Primary Open Angle Glaucoma (POAG) and Primary Angle Closure Glaucoma (PACG). POAG is the more predominant form of glaucoma in Europeans, Africans, and possibly most populations. PACG is most prevalent in countries of the far East; 80% of PACG affected individuals live in Asia. PACG is characterized by a narrow iridocorneal angle which obstructs normal aqueous humor outflow and causes increased Intraocular Pressure (IOP). Although epidemiological studies have suggested a genetic basis for PACG, a causative gene for the disease has not been identified.
A relatively large pedigree with at least nine members diagnosed with PACG or PACG suspect all of whom presented with a closed iridocorneal angle, was introduced to us. Manifestation of PACG in multiple family members suggested a strong genetic contribution for the disease in the family. With the objective of identifying a causative gene, whole exome sequencing was performed on three affected members of the family. Output data were analyzed with appropriate softwares. After filtering against existing SNP databases, 72 novel, non-synonymous variants common among the three patients were identified. The variations were distributed in 68 genes. Some of these genes have defined functions related to eye and glaucoma pathology. Screening of the variations in control individuals and segregation analysis in the pedigree are in process.

J09.49
Sequence variants of PRNP gene in probable prion disease patiens

H. Aslan[1], *D. Ozbabalik Adapinar*[2], *O. Cilingir*[1], *B. Durak Aras*[1], *M. Ozdemir*[1], *O. Kutlay*[1], *K. Koken*[1], *S. Artan*[1];
[1]*Eskisehir Osmangazi University, Faculty of Medicine, Departments of Medical Genetics, Eskisehir, Turkey,* [2]*Eskisehir Osmangazi University, Faculty of Medicine, Departments of Neurology, Eskisehir, Turkey.*

Prion diseases are a family of rare progressive neurodegenerative disorders, caused by abnormally conformed infectious proteins, called prions. The functions of these normal prion proteins are still not completely understood. The abnormal folding of the prion proteins leads to brain damage and the characteristic signs and symptoms of the disease. There are 4 types of this disease: the sporadic (Jakob-Creutzfeldt disease, 85-90%), familial/genetic (10-15%), iatrogenic (1%), and variant types. Genetic form of prion diseases are caused by mutations in the prion-related protein gene (PRNP), and classified based on the phenotype, mutation and neuropathological findings. In this study, we analyzed PRNP gene to evaluate the frequency of PRNP sequence variants and their genetype-phenotype correlation in 60 probable Prion disease patients. Genetic analysis of the PRNP gene was performed on peripheral blood samples using polymerase chain reaction and direct-sequencing. We found four different PRNP sequence variants in thirty-six patients (G54S, M129V, D178N, octapeptide repeat deletion: c.247_270del). The rate of PRNP sequence variant was 60% in our samples. PRNP screening may be useful for genotype-phenotype correlation in Prion disease.

Eight new cases of PEHO or PEHO-like syndrome?

R. Posmyk[1], *R. Leśniewicz*[1], *I. Leśniewicz*[1], *D. Sielicka*[2], *M. Chorąży*[3];
[1]*Department of Clinical Genetics, Podlaskie Center of Clinical Genetics, Bialystok, Poland,* [2]*Ophthalmology Clinic, Children's University Hospital, Białystok, Poland, Bialystok, Poland,* [3]*Neurology Clinic, University Hospital, Białystok, Poland. inical Genetics, Bialystok, Poland.*

PEHO syndrome (**P**rogressive **E**ncephalopathy with oedema, **H**ypsarrhythmia and **O**ptic atrophy) (OMIM#260565) belongs to a rare neurodegenerative disorders of unknown etiology and probable autosomal recessive inheritance. Only 50 patients have been described worldwide so far, with the vast majority in Finland. We present eight new patients who fulfill diagnostic criteria of PEHO or PEHO-like syndrome. Patients were selected from a group of patients with a diagnosis of "Progressive encephalopathy of unknown etiology" or "Cerebral palsy". In all of them onset occurred during the first few weeks or months of life. The leading symptoms were hypotonia, poor feeding, drowsiness, infantile spasms, seizures with hypsarrhythmia in EEG, absent eye contact, optic atrophy, no any progress in psychomotor developmental. Dysmorphic features were peculiar and consisted of: microcephaly, "pear-shaped" face, narrow forehead with prominent metopic ridge, full cheeks, receding chin, epicanthic folds, an open mouth with a curved upper lip, hypertrophic gums, protruding ear lobes, a short nose with anteverted nares, edema of upper and lower extremities and tapering fingers.
In six patients cerebral, cerebellar and/or brainstem atrophy were found by MRI. This group was named as PEHO syndrome and rest two child's without any abnormalities in MRI as PEHO-like.

J09.51
Association of GRM3 gene polymorphic loci with schizophrenia

K. O. Kinyasheva, *A. Gareeva, E. Khusnutdinova;*
Institute of Biochemistry and Genetics Ufa Scientific Center of RAS, Ufa, Russian Federation.

Schizophrenia is a devastating psychiatric disorder with a morbid risk of 7.2 per 1,000 which is affected by genetic and environmental factors. The disruption of the glutamatergic system is becoming recognized as an essential component of the pathogenesis of schizophrenia .The type-three metabotropic glutamate receptor gene (GRM3) which codes for the mGluR3 protein localized to the periphery of pre- and post-synaptic neurons is essential for optimal signaling of glutamate in the brain.
The subject of the present study was the research of the association of two polymorphic loci rs274622 and rs187993 of GRM3 gene with the development of schizophrenia in a sample of 338 cases (50% Russians and 50% Tatars) and 350 controls (50% Russians and 50% Tatars) from Volga-Ural region of Russia. The genotyping of these polymorphic loci was carried out by PCR-RFLP. All observed genotype frequencies were consistent with Hardy-Weinberg equilibrium. It was found by analysis of variance that genotype GRM3*G/*G of polymorphic locus rs187993 was a statistically significant risk marker of schizophrenia development in Russian ethnic group (OR=2,16; P=0,043). However polymorphic locus rs274622 of GRM3 gene was not shown statistically significant differences between case-control groups of Russians and Tatars.

In addition this study can be useful for understanding of the pathogenesis of schizophrenia and is required to continue.

J09.52
Effect of PAI-1 gene on predisposition of schizophrenia in Turkish population

Z. Ozdemir[1], *H. Kurt*[1], *C. Yenilmez*[2], *M. Gundogan*[2], *E. Colak*[3], *H. Gunes*[1], *I. Degirmenci*[1];
[1]Eskisehir Osmangazi University, Faculty of Medicine, Department of Medical Biology, Eskisehir, Turkey, [2]Eskisehir Osmangazi University, Faculty of Medicine, Department of Psychiatry, Eskisehir, Turkey, [3]Eskisehir Osmangazi University, Faculty of Medicine, Department of Biostatistics, Eskisehir, Turkey.

PAI-1 is a protease belonging to the family of serine proteases. It regulates proteolysis and fibrinolysis via inhibition of tissue type plasminogen activator (tPA) and urokinase (uPA). It has a important potency in cerebrospinal fluid homeostasis. Fibrinolytic system in responsible in CNS affects long-term synaptic plasticity and remodelling. Activity of tPA is neurite outgrowth, neuronal migration and learning. Polymorphisms in this gene may influence disease development. Therefore, we aimed to investigate the effect of the 4G/5G insertion / deletion polymorphism localized in -675 upstream promoter region of PAI-1 gene and can modify the expression of protein levels, on predisposition of disease.
The presence of the 4G/5G polymorphism in the PAI-I gene was determined using the polymerase chain reaction (PCR) method. Samples identified according to whether they have 139 bp band or not. Samples produced 139 bp band with 4G primer were identified as homozygous 4G genotype, samples produced 139 bp band with 5G primer were identified as homozygous 5G genotype, samples produced 139 bp band with both 4G and 5G primer were identified as heterozygous 4G/5G genotype.
In our study, we invastigate the frequency of genotype and allele of PAI-1 gene 4G/5G polymorphism among schizophrenic patienst and healty controls. Significant correlation was found between genotypes ($p<0,05$), but no statistically significant differences were found in allele frequencies ($p>0,05$). Studying of more larger population may help to explain the effect of disease-related gene.The study was supported by ESOGU (Grant no:201211007)

A new mutation at the SLC20A2 gene in an italian family with idiopathic basal ganglia calcification

M. Gagliardi[1,2], *P. Tarantino*[1], *E. Saracchi*[3], *F. Ferri*[4], *S. Morzenti*[5], *M. Musarra*[5], *M. Patassini*[6], *G. Annesi*[1], *L. Brighina*[3];
[1]Institute of Molecular Bioimaging and Physiology, Section of Neuroimaging, National Research Council, Germaneto(CZ), Italy, [2]University of Magna Graecia, Catanzaro, Italy, [3]Dept. Of Neurology, San Gerardo Hospital, Monza, Italy, [4]Neuropsychology Section, S. Gerardo Hospital, University of Milan Bicocca, Monza, Italy, [5]Nuclear Medicine, San Gerardo Hospital, Monza, Italy, [6]Neuroradiology Service, San Gerardo Hospital, Monza, Italy.

Idiopathic basal ganglia calcification (IBGC), also known as "Fahr disease (FD)", is a rare neurological disease characterized by symmetric and bilateral calcifications mostly located in the basal ganglia, but often involving also the thalami, the cerebellar hemispheres and subcortical white matter. Familial IBCG (fIBGC) is genetically heterogenous and typically transmitted in an autosomal dominant fashion, sometimes displaying anticipation. In a recent study SLC20A2 gene mutations were found to be responsible for 40% of the IBGC families studied. We describe a novel SLC20A2 variant in exon 9 (G1618A), consisting in a gly-to-arg substitution at position 540 of the protein highly conserved consensus region, in two family members clinically diagnosed with IBGC. This variant was not found in 200 unrelated Italian controls. The index case was a 67-year-old male patient who presented with a mild parkinsonism and a more relevant reduction in spontaneous speech, which evolved steadily over a few years to an almost complete inability to communicate. The proband's daughter developed symptomatic epilepsy at 19 years of age as the only clinical manifestation of IBCG, suggesting an anticipation of the disease over generations and striking intrafamilial phenotypic heterogeneity, as previously observed. This is the first SLC20A2 mutation associated to fIBGC reported in the Italian population. This mutation is damaging according to all prediction programs and it suggest a lost of function of the protein. In conclusion, the discovery of deleterious mutations in SLC20A2 as a cause of fIBGC greatly advances our understanding of this complex disease.

Somnambulism in a Colombian family with dominant inheritance

M. C. Lattig, *L. C. Hernández;*
Universidad de los Andes, Bogota, Colombia.

Sleepwalking and night terrors are sleep disorders classified into the group of excitement Parasomnias. These disorders generate a considerable decree in the individual's quality of life. However the inheritance patterns for these disorders are poorly known and there is a lack of knowledge of the responsible genes for these disorders. We report a three-generation Colombian family with 18 affected individuals, showing a dominant inheritance pattern with reduced penetrance. There is only one study that previously reported the same inheritance pattern in an American family demonstrating linkage with a region between the SNP type markers rs728331 and rs286819 (Licis, et al. 2011). However, there are some mayor differences between the reported family and ours. Onset prevalence and sex-affected ratio are the mayor phenotypic distinctions. We propose that we may have a new condition that is caused by different genes.

J09.55
The clinical phenotype of Polish patients with SPG11 gene mutations - preliminary description

I. Stepniak, *A. Sulek, E. Elert-Dobkowska, W. Krysa, M. Rajkiewicz, M. Rakowicz, W. Lojkowska, J. Zaremba;*
Institute of Psychiatry and Neurology, Warsaw, Poland.

Hereditary spastic paraplegias (HSP) are a group of clinically and genetically heterogeneous, neurodegenerative disorders characterized by progressive spasticity of the lower limbs. The most common causes of autosomal recessive HSP with thin corpus callosum (TCC), associated with complicated form of HSP, are mutations in the SPG11 gene.
In a group of 159 index patients clinically diagnosed as HSP (criteria according to Fink), in whom SPAST and ATL1 mutations were previously excluded, MLPA analysis revealed homozygous mutation and compound heterozygous mutation in the SPG11 gene, confirming definitive diagnosis in two probands. Moreover, in three patients (from other families) the only one mutation was found. Direct sequencing analysis will be necessary to confirm diagnosis. Individuals were assessed by Spastic Paraplegia Rating Scale and classification used by Dürr.
In a 4 patients from two families with definitive diagnosis, age at onset ranged 10-16 years (mean 13±3), disease duration 9-23 years (15±6), SPRS scores 42-49 (mean 45±3). All patients had fast progression of symptoms and severe phenotype. One of them could not move without walking aids, three were wheelchair-bound. Brain MRI showed TCC (100%), cortical (100%) and cerebellar (75%) atrophy. Nerve conduction study revealed sensorimotor neuropathy axonal type in three individuals. All patients presented mild to moderate cognitive impairment.
The present study confirmed early onset, remarkable progression and severe clinical phenotype of all 4 individuals with mutations in SPG11 gene. The clinical picture in our patients was consistent with typical manifestation of HSP-TCC. Among five index patients only one had family history of AR-HSP.

Setting up a registry and database for the purpose of genetic studies of stroke in the northeast of Iran

A. Sadr-Nabavi[1,2,3], *A. Pasdar*[1,4,5], *P. Sasan nezhad*[6], *M. Farzadfard*[6], *M. Azarpazhooh*[6];
[1]Department of Medical Genetics, School of Medicine, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran, [2]Molecular medicine research department, ACECR- Mashhad Branch, Mashhad, Islamic Republic of Iran, [3] Medical Genetic Research Centre (MGRC), School of Medicine, Mashhad University of Medical Sciences, Mashad, Islamic Republic of Iran, [4]Department of Modern Sciences and Technologies, Faculty of Medicine, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran, [5]Division of Applied Medicine, Medical School, University of Aberdeen, Foresterhill, Aberdeen, United Kingdom, [6]Department of Neurology, School of Medicine, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran.

Background: Based on the first population-based study of stroke during a 12-month period (2006-2007) in a north east region of Iran (Mashhad), the incidence of stroke was reported considerably greater than it was in neighboring countries where it could affect people at least one decade earlier. In line with the International Stroke Genetic Consortium, we aimed to build up a local database (ISD) to register all new cases of stroke for further research on dissecting genetic basis of stroke. **Methods**: Consecutive patients presenting to the Hospital in Mashhad with first ever stroke were recruited. Diagnosis of stroke was made based on clinical presentation and confirmed by imaging including CT and MRI. Control subjects without any stroke background, age and sex matched with patients, were also recruited. This will remain an ongoing project to allow researcher carry out further clinical and genetic studies. **Results:** The age of patient was ranged 18 to 85 years (both sexes). So far, data on 2000 patients with acute stroke has been collected. 99% of patients have complete follow-up. Association studies of 20 different genes involved in pathogenesis of stroke has already been done and the results are due for publication. **Conclusions:** The ISD dataset provides a source of primary data which could be used for planning further trials, genetic and clinical investigations.

Metal levels in blood as biomarkers for ataxias.

S. Squadrone[1], *C. Mancini*[2], *E. Giorgio*[2], *E. Pozzi*[2], *S. Cavalieri*[3], *E. Di Gregorio*[3], *M. C. Abete*[1], *A. Brusco*[2,3];

[1]*Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e valle d'Aosta, Chemical Dept., Torino, Italy,* [2]*Department of Medical Sciences, University of Torino, Italy, Torino, Italy,* [3]*A.O. Città della Salute e della Scienza, S.C.D.U. Medical Genetics, Torino, Italy.*

Metals are crucial for synaptic transmission, enzyme activity, proteins folding/conformation. Copper, zinc, iron and manganese are all localized to various subcellular compartments and their regulation is controlled by a diverse range of co-factors and chaperones. Loss of homeostasis of some of these elements is present in neurological disorders including Alzheimer, Parkinson and Huntington diseases, amyotrophic lateral sclerosis and Friedreich Ataxia. Metals are also key factors for ATP generation and to control oxidative damage in mitochondria.

We selected a cohort of spinocerebellar ataxia (SCA, n=20) and Ataxia-Telangectasia (A-T, n=20) patients, and we measured copper, zinc, iron, manganese and selenium levels in their blood samples, using atomic absorption spectrometry.

We found a significantly reduced manganese levels in SCA patients and increased copper levels in A-T patients compared to controls ($p<0.01$). Cu and Mn have essential roles in mitochondria: the former is a component of complex IV; manganese has a central role in maintaining antioxidant enzyme function and it is the superoxide dismutase co-factor (MnSOD; SOD2).

We evaluated in patients vs. controls LCLs mRNA levels of catalase-CAT, glutathione peroxidase-GPX1 and SOD2, enzymes involved in antioxidative response. We found SOD2 and CAT up-regulation in A-T patients and a SOD2 down-regulation in SCA patients.

We considered SOD enzymes activity and showed a reduction of MnSOD-activity in SCA LCLs, whereas Cu/ZnSOD-activity was halved in A-T LCLs.

These data, although preliminaries and restricted to a small number of samples, suggest a role for metals in ataxias and may represent biomarkers of pathology.

J09.58

Screening of TARDBP in Iranian amyotrophic lateral sclerosis (ALS) patients

M. Khani[1], *E. Elahi*[1], *A. Alavi*[1], *S. Nafissi*[2], *M. Malakooti Nejad*[3];

[1]*School of Biology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran,* [2]*Department of Neurology, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*Department of Biotechnology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran.*

Amyotrophic lateral sclerosis (ALS) is a fatal motor neuron disorder characterized by dysfunction and degeneration of both upper motor neurons in the cortex and lower motor neurons in the brainstem and spinal cord. Genetic analysis of familial ALS (FALS) pedigrees has led to the identification of at least 21 loci and 18 ALS-causing genes. After C9ORF72 and SOD1, mutations TARDBP gene are the most frequent cause of disease in FALS families. TARDBP encodes transactive response DNA-binding protein-43 (TDP-43). In addition to its prominent role in ALS, TDP-43 is important because of its potential involvement in the etiology of various neurodegenerative diseases. TDP-43 is a major component of aggregates of misfolded proteins in neurons of ALS, frontotemporal dementia, Alzheimer's and Parkinson's disease patients. As C9ORF72 and SOD1 have already been screened in cohorts of Iranian ALS patients, we here screened TARDBP in 90 unrelated patients. Fifteen were FALS and 75 were sporadic ALS (SALS) cases. The coding exons of the gene were sequenced by the Sanger protocol. A single missense mutation was observed in exon 6 in one FALS patient; no putative disease causing variation was found among the SALS patients. Although the sample size was relatively small, it appears that the frequency of Iranian ALS patients and specifically FALS patients (6.7%) who harbor mutations in TARDBP is similar to frequencies reported for other populations.

Autism spectrum disorder (ASD) is an early childhood neurodevelopmental disorder characterized by a significant genetic aetiology and prevalence currently estimated at 1/100. Several biological pathways have been highlighted, particularly the excitatory synapse, affected by copy number variations (CNV) and enrichment in mutations in genes belonging to the NMDA receptor complex (NRC). We performed a global genetic study of 100 French families including at least 1 individual with autism, who were included in the research project (ClinicalTrials.gov NCT01770548).

Our project aimed to evaluate both the contribution of CNV in ASD, and secondly the presence of mutations in the NRC complex. For each family, we firstly performed a high-resolution pangenomic comparative genomic hybridization (CGH) analysis with 1M CGH Agilent Array format to identify rare or de novo CNVs. In parallel, a high-throughput targeted sequencing of 216 genes mostly belonging to the NRC complex (179) was carried out with the SureSelect Agilent strategy in order to assess the contribution of gene mutations in our cohort.

The first results of our study allowed us to characterize candidates and likely pathogens genetic alterations in at least 10% of patient. We have found mutations or CNV in genes encoding receptors (*NLGN4X, GRM5*), and in cytosolic (*UPF3B*), nuclear (*MACROD2*), and synaptic (*NXPH3*) proteins. They also emphasized that the NRC is targeted both by mutations and CNV, inherited or *de novo*.

These results underscore the fundamental role of this multiprotein network in the process of neuronal communication and learning and its pathophysiological impact in autism.

J09.60

The study on the effect of fibrillation inhibitory compounds on the depolymerization of amyloid fibrils of alpha-synuclein using fluorescent-labeled protein.

A. Tayaranian[1,2], *D. Morshedi*[2], *F. Aliakbari*[2];

[1]*University of Tehran, Tehran, Islamic Republic of Iran,* [2]*National Institute of Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran.*

Parkinson's disease (PD) is the most prevalent movement disorder in the world which is caused by dopaminergic cell degeneration in substantia nigra pars compacta of midbrain. One of the major explanations for occurrence of this cell death is the aggregation of a protein called alpha-synuclein which produces cytotoxic aggregates and amyloid fibrils in brain. Many studies have done to find fibrillation inhibitory compounds for preventing and treating PD patients. But studying on concealed dimensions and side effects of these compounds is a great concern. In this research we studied on the depolymerization of alpha-synuclein firbils under induction of fibrillation inhibitory compounds include Curcumin, Cuminaldehyde and Baicalein by using fluorescent labeled alpha-synuclein protein. Our result shows that these compounds induce depolimerization of alpha-synuclein fibrils that is highly related to their cytotoxicity. Some studies on alpha-synuclein fibrillation revealed that intermediate aggregates include oligomeric species may play a greater role than amyloid fibrils in dopaminergic cell death. This depolimerization phenomenon can produce some intermediate aggregates with cytotoxic properties that can worst the patient's condition. Among these compound Cuminaldehyde shows lower depolimerization induction that define this natural organic compound as a valuable candidate for PD therapy.

5-HT2A and Body Dissatisfaction involved in the development of Eating Disorders

T. Ialacci[1], *G. Castellini*[2], *F. Cieri*[1,3], *A. Di giacinto*[1], *M. Franzago*[1], *R. Ferrante*[3], *I. Antonucci*[3], *G. Stanghellini*[4], *V. Ricca*[2], *L. Stuppia*[3,5];

[1]*Department of Neuroscience and Imaging, Chieti, Italy,* [2]*Psychiatric Unit, Department of Neuropsychiatric Science, Florence University School of Medicine, Florence, Italy,* [3]*Department of Psychological Sciences, G. d'Annunzio University, Chieti, Italy,* [4]*Department of Biomedical Sciences, University G. d'Annunzio, Chieti, Italy,* [5]*Functional Genetics Unit, Center of Excellence on Aging (CeSI), Chieti, Italy.*

Despite numerous studies about Eating Disorders (EDs) their etiopathogenesis is currently debated and poorly understood. Studies carried out on families and twins have highlighted genetic factors' role; molecular genetic studies have identified the candidates genes potentially involved in ED's etiology. To date research has not produced conclusive results, nevertheless genes of serotonergic and dopaminergic neurotransmitters systems seem to be promising candidates. Among these important candidate genes in the EDs susceptibility, various studies have evaluated the possible role of the −1438 G/A polymorphism within the 5-HT2A. In this study 202 Eating Disorder patients (EDp) and 150 control subjects were analyzed for distribution of the 5-HT2A receptor promoter polymorphism and we shown that the AA genotype is more frequent in patients ($\chi2=6.69$; $p=0.01$) than in control suggesting an association of 1438 G/A polymorphism within the 5-HT2A with EDs, in agreement with the past literature. Moreover within our healthy sample subjects with a AA genotype reported higher Body Dis-

satisfaction subdimension of Eating Disorder Inventory - 2 (EDI-2; Garner et al., 2009), as compared with other subjects (F=3.73; p=0.02), demonstrating the important role of endophenotype concept. Both results show the involvement of a genetic component in the development of EDs.

J09.62

Red blood cells hemolysis influences the level of total but not oligomeric plasma alpha-synuclein in Parkinson's disease patients and controls

P. A. Andoskin[1,2], *A. K. Emelyanov*[1,2], *A. F. Yakimovsky*[2], *A. A. Timofeeva*[2], *S. N. Pchelina*[1,2];
[1]*St. Petersburg Nuclear Physics Institute, St.-Petersburg, Russian Federation,* [2]*First Pavlov's State Medical University of Saint-Petersburg, St.-Petersburg, Russian Federation.*

Parkinson's disease (PD) is the second of most common neurodegenerative disorders. Oligomeric alpha-synuclein is the principal neurotoxic agent of PD pathogenesis. Plasma alpha-synuclein has been suggested as biomarker for PD with inconsistent results. As red blood cell (RBC) are the main source of plasma alpha-synuclein the level of total plasma protein are influenced by the degree of RBC contamination and hemolysis in plasma. The correlation between plasma hemoglobin and oligomeric alpha-synuclein levels remains unknown.

The aim of our investigation was to establish if RBC contamination and hemolysis in plasma influences the level of total and oligomeric plasma alpha-synuclein in PD patients and controls. The dataset was composed of 18 drug-naïve PD patients (the mean age 67±8.7 years) and 23 control individuals (mean age 65,67±11,27). All subjects were residents of the North-Western region of Russia. The total, oligomeric forms of alpha-synuclein as well as hemoglobin levels were estimated by means of ELISA (Human alpha-synuclein ELISA kit (Invitrogen, USA) and Hemoglobin (Human) ELISA kit (Abnova, USA), correspondingly).

Measured levels of blood plasma hemoglobin vary from 12614 ng/ml to 591041 ng/ml. The correlation between the total alpha-synuclein and hemoglobin level has been shown (N=39, r2=0.426, p=0.0001). However, there were no significant differences in the levels of the total and oligomeric plasma alpha-synuclein between groups.

Therefore our data suggest that hemolisys has effect on a total but not oligomeric alpha-synuclein levels in peripheral blood plasma. At the same time both total and oligomeric alpha-synuclein could not be used as a suitable marker of PD.

J09.63

A key element of Endocannabinoid System PPARγ2 and leptin are associated in turkish schizophrenia patients

S. Acar[1], *G. Akan*[2], *O. Ozge*[3], *F. Oncu*[4], *H. Yanbay*[4], *D. Yesilbursa*[4], *S. Turkcan*[4], *F. Atalar*[5];
[1]*Department of Bioengineering, Yıldız Technical University, Istanbul, Turkey,* [2]*Department of Medical Biology and Genetics, Istanbul Bilim University, Istanbul, Turkey,* [3]*Department of Molecular Medicine, Institute of Health Sciences, Istanbul University, Istanbul, Turkey,* [4]*Psychiatry Clinics, Turkish Ministry of Health Bakirkoy Research and Training Hospital for Psychiatry, Neurology and Neurosurgery, Istanbul, Turkey,* [5]*Endocrinology Laboratory, Department of Nutrition, Metabolism and Endocrinology, Child Health Institute, Istanbul University, Istanbul, Turkey.*

Background: Because the endocannabinoid system(eCB)is deeply involved in body weight regulation,other than the obesity genes,endocannabinoid genes may also have a role in the antipsychotic-induced weight gain in schizophrenia(SCH) patients.**Aim**:To further investigate this hypothesis,we performed an association study with PPARγ2 gene codifying for a key element of the eCB system and obesity related genes, leptin, leptin receptor and MC4R,in a sample of 320 SCH patients and 237 controls.**Methods:** Biochemical analyses, the effects of LEP c.-2548G>A, LEPR c.668A>G, PPARγ2 c.-2-28078C>G, MC4R c.307G>A polymorphisms and the impact of those genes mRNA and serum levels on metabolic adversities in SCH patients and control groups were studied.**Results:**Significantly higher BMI and fasting blood sugar and significantly lower HDL levels were present in SCH patients compared to controls(p<0.001).PPARγ2 and LEP polymorphisms were significantly different between SCH and control groups, while a significant difference was present in PPARγ2 polymorphism between male SCH patients and male controls(p<0.005)and LEP polymorphism between male and female SCH patients(p<0.005).Interestingly,MC4R c.307G>A(G/A+G/G)carriers showed significant differences in BMI and LEP mRNA levels compared to wild type SCH patients(A/A).LEP, LEPR, PPARγ2 mRNA levels and leptin serum levels were also significantly higher in SCH patients compared to controls(p<0.001, respectively).Leptin serum and mRNA levels were positively correlated in PPARγ2 c.-2-28078C>G carriers(p<0.001)and LEP c.-2548G>A carriers have significantly higher PPARγ2 mRNA levels(p<0.001).**Conclusion:** Our findings suggest a strong association between PPARγ2 and leptin genes in Turkish SCH patients which might indicate their potential role in the antipsychotic-induced weight gain,but further studies are needed in order to elucidate their involvement in the pathophysiology of SCH.

J09.64

Linkage of a locus for autosomal recessive familial spastic paraplegia to chromosome 8q24

E. Jaberi[1], *F. Sina*[2], *G. Shahidi*[2], *E. Elahi*[1,3,4];
[1]*School of Biology, University College of Science, University of Tehran, Tehran, Islamic Republic of Iran,* [2]*Department of Neurology, Tehran University of Medical Sciences, Tehran, Iran., Tehran, Islamic Republic of Iran,* [3]*National Institute of Genetic Engineering and Biotechnology, Tehran, Islamic Republic of Iran,* [4]*Center of Excellence in Phylogeny of Living Organisms in Iran, School of Biology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran.*

Hereditary spastic paraplegia (HSP) is characterized by insidiously progressive lower-extremity weakness and spasticity. HSP being a group of genetic disorders, they follow general inheritance rules and can be inherited in an autosomal dominant, autosomal recessive or x-linked recessive manner. The mode of inheritance involved has a direct impact on the chances of inheriting the disorder. This neuronal degeneration is thought to be caused by mutations at specific genes. Genetic mapping has identified at least 52 different HSP loci, designated SPG (Spastic Paraplegia) 1 through 52. We studied An Iranian family with autosomal recessive HSP with three affected and four unaffected siblings of two consangeous parents. Clinical, neurophysiologic, and neuroradiologic studies were undertaken. Genetic linkage analyses were carried out with polymorphic DNA markers. The candidate gene within the linked region was sequenced in order to verify the observation. Homozygousity mapping showed linkage to 8q24. As a result the first candidate gene for screening was SPG8 also known as KIAA0196 because this gene is located in the linked region and is one of HSP related genes. The KIAA019 contains 29 exons. Precise screenings of all 29 exons of the gene with their boundaries were carried out using sequencing but all patients were negative for *SPG8* mutations. In conclusion, these data confirm the presence of another SPG gene on chromosome 8q24 related to autosomal recessive HSP.

J09.65

The role of estrogen receptor alpha (ESR1) and oxytocin receptor (OXTR) genes in personality traits variation

Y. Y. Kutlumbetova[1], *A. V. Kazantseva*[2], *R. F. Kanzafarova*[1], *S. B. Malykh*[3], *E. K. Khusnutdinova*[1,2];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics, Ufa Scientific Centre, Russian Academy of Sciences, Ufa, Russian Federation,* [3]*Psychological Institute, Russian Academy of Education, Moscow, Russian Federation.*

Estrogen and oxytocin integrate many processes including social behaviors, cognitive function and activity in the autonomic nervous system. We aimed to assess the main, haplotypic and GxE effect of ESR1 (rs9340799, rs2077647) and OXTR genes (rs4686302) on personality traits variation. We recruited 1018 healthy individuals (68% women) of Caucasian origin (Russians-409, Tatars-290, Bashkir-130, Udmurts-189) from Russia (mean age: 19.81±2.65 years) without any history of psychopathologies subjected to personality assessment (TCI-125). Genotyping of SNPs was performed using PCR-RFLP. Statistical analysis was conducted with PLINK v.1.07, Haploview 4.1 followed by correction for multiple testing under FDR-procedure. Subsequent haplotype analysis revealed an association of ESR1 A*C-haplotype (rs9340799, rs2077647, D'=0.76) and A*T-haplotype (PFDR=0.008) with high and low self-transcendence (ST) (PFDR=0.042), respectively, in Bashkir group. GxE analysis revealed the model ESR1*ethnicity explained variations in ST (PFDR=0.036) and self-directedness (SD) (PFDR=0.036). Accordingly, Udmurts carrying rs9340799 G-allele demonstrated decreased SD and Bashkirs with rs2077647 C-allele reported increased ST. Moreover, association of OXTR rs4686302 A-allele and lower Persistence (PFDR=0.031) was observed only in non-smoking group. Additionally, OXTR rs4686302* ethnicity model determined variations in SD (PFDR=0.021): Russian individuals with rs4686302 A-allele scored higher on this trait. Reported findings suggest that ethnicity and "smoking status" modulate the association between ESR1 and OXTR gene polymorphisms and personality traits. Thus, ESR1 and OXTR genes might be responsible for mental health and neuroprotection, since character traits (ST and SD) are predictive for personality disorders development. Study was supported by Russian foundation for humanities grant (№ 13-06-00583a).

Exome sequencing reveals two compound heterozygous DDHD2 mutations in a non consanguineous Italian family with ARHSP-TCC

A. Magariello[1], *L. Citrigno*[1], *V. Sofia*[2], *A. Patitucci*[1], *F. L. Conforti*[1], *R. Mazzei*[1], *C. Ungaro*[1], *I. Pappalardo*[2], *M. Zappia*[2], *M. Gonzalez*[3], *S. Zuchner*[3], *M. Muglia*[1];
[1]*Institute of Neurological Sciences -CNR-, Piano Lago di Mangone (CS), Italy,* [2]*Dipartimento "G.F. Ingrassia" Sezione di Neuroscienze, Università di Catania,, Catania, Italy,* [3]*Department of Human Genetics and Hussman Institute for Human Genomics, Miller School of Medicine, University of Miami, Miami, FL, United States.*

Autosomal recessive spastic paraplegia with thin corpus callosum (ARHSP-

TCC) is a common form of complex HSP, representing about one third of the autosomal recessive forms. Eight genetic loci for ARHSP-TCC have been identified: SPG11, SPG15, SPG21, SPG32, SPG35, SPG46, SPG47 and most recently SPG54. DDHD2 gene, encoding one of the three intracellular phospholipases A1, has been recently identified as cause of the SPG54 form, characterized by intellectual disability, developmental delay and onset in childhood.
We identified two compound heterozygous mutations in the DDHD2 gene by using whole exome sequencing in a non consanguineous family with ARHSP-TCC. The family includes two affected sibling and unaffected parents. The coding region of one patient was enriched and captured by SureSelect Human All Exon V4, and exome sequencing was performed using the Hiseq2000 instrument. BWA and GATK software packages were used to align sequence reads to the reference. The data were then imported into Gem.app, a web-based database and analysis tool for next generation sequencing data. Exome sequencing data revealed two compound heterozygous point mutations in the index case in the DDHD2 gene: the novel c.307T>C and the already described c.1978G>C. Both mutations were validated by Sanger sequencing and they were confirmed in the second affected brothers.
In conclusion, we report the first Italian patients with two compound heterozygous point mutations in the DDHD2 gene. This finding enlarges the clinical spectrum related to DDHD*2* mutations, providing to determine the worldwide distribution and the diverse clinical features of SPG54 form.

J09.67
Mutational screening of GJB1, MPZ and PMP22 genes in a cohort of CMT patients from Southern Italy

A. Patitucci[1], *A. Magariello*[1], *F. L. Conforti*[1], *R. Mazzei*[1], *A. Mazzeo*[2], *I. L. Simone*[3], *M. Muglia*[1];
[1]*ISN-CNR, Mangone (CS), Italy,* [2]*Department of Neurosciences, University of Messina, Messina, Italy,* [3]*Department of Basic Medical Sciences, Neurosciences and Sense Organs, University of Bari, Bari, Italy.*

Charcot-Marie-Tooth (CMT) is the most common inherited neuromuscular disorder. To date, mutations in more than 40 genes are responsible for CMT disease. We have analyzed 500 patients coming from Southern Italy, referred to our centre with a suspected diagnosis of CMT. Firstly, all patients have been screened for the 17p.11.2 duplication. The non duplicated cases were further investigated for point mutations in the GJB1, MPZ and PMP22 genes. Among the 500 unrelated CMT patients, 209 of them (41.8%) harbored the CMT1 duplication. A subsequent mutation analysis of GJB1, MPZ, and PMP22 genes in 291 CMT patients, revealed 26 different mutations in 48 cases: 14 in GJB1, 7 in MPZ, 5 in PMP22. Out of 14 GJB1 missense mutations identified in 16 patients, seven are novel (Ser49Phe, Ala88Val, Ser128Leu, Leu131-Arg, Val148Phe, Phe153Leu and Arg164Leu). Out of 7 mutations in the MPZ gene identified in 27 patients, two are novel (Trp57X and Gly93Arg). Noteworthy, in 14 patients from Apulia the known Val102fs mutation has been detected, whereas seven patients from Sicily carried the known Ser78Leu mutation, confirming our previous results of a founder effect for the Ser78-Leu. Finally, in the PMP22 gene we detected two novel variants (Ala35Tyr and Pro122Leu). In conclusion, our data confirm that the duplication is the most common genetic cause of the CMT, followed by mutations in GJB1 and MPZ. Furthermore, this study recommends that for the patients from Apulia and Sicily the diagnostic test, after the exclusion of the duplication, might be start from MPZ gene.

J09.68
Variation in the miRNA-433 binding site of *FGF20* is a risk factor for Parkinson's disease in Iranian population

L. Haghnejad[1], *F. Shafeishiraz*[2], *A. Soltanzadeh*[2], *A. Fazeli*[3], *M. Motalebi*[4], *M. Kayyal*[5], *B. Emamalizadeh*[1], *G. Shahidi*[6], *A. Movafagh*[1], *H. Darvish*[1];
[1]*Department of Medical Genetics, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Department of Neurology, Shariati University Hospital, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*Islamic Azad University, Damghan, Islamic Republic of Iran,* [4]*Islamic Azad University , Damghan, Damghan, Islamic Republic of Iran,* [5]*Tehran Medical Branch, Islamic Azad University, Tehran, Islamic Republic of Iran,* [6]*Movement Disorders Clinc, Hazrat Rassol Hospital, Iran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

DNA variation at the *FGF20* gene has been associated with Parkinson's disease (PD). Specially, single nucleotide polymorphism (SNP) rs12720208 in the 3' untranslated region (3' UTR) was linked to PD-risk through a mechanism that would implicate a differential binding to microRNA-433 (miR-433). In this study, we genotyped the rs2720208 SNP in a total of 480 PD patients and 480 healthy controls from Iran. We found significant differences in allele and genotype frequencies between patients and controls (Fisher exact $p<1\times10^{-7}$). The results obtained in this study revealed that the rs12720208 (C/T) polymorphism is a strong risk factor for late-onset PD in Iranian population.

J09.69
Evidence of Dysbindin gene promoter hypermethylation in peripheral blood lymphocytes as a potential biomarker in major psychosis

M. Bahar[1], *M. Noruzinia*[2], *N. Beyraghi*[3], *Z. Rezaei*[4];
[1]*Tarbiat Modares University, Bahar Medical Laboratory, Tehran, Islamic Republic of Iran,* [2]*Tarbiat Modares University, Tehran, Islamic Republic of Iran,* [3]*Shahid Beheshti University of Medical Sciences. Taleghani General Hospital, Psychiatric Department, Tehran, Islamic Republic of Iran,* [4]*Behavioral Sciences Research Center of Psychiatry Department of Shahid Beheshty Medical University, Tehran, Islamic Republic of Iran.*

DTNBP1 is the gene encoding Dysbindin or Dystrobrevin binding protein. DTNBP1 is established as a genes associated with certain psychotic disorders. Genetic variations of DTNBP1 have been found in association of Schizophrenia, Major Depressive Disorder, Bipolar Disorder, Substance induced Psychosis and certain cognitive properties. Functional studies have concluded that reduction of expression is the likely mechanism of effect of DTN-BP-1 in pathophysiology of mental conditions. Moreover, due to dysbindin protein functions in neurotransmission, dysfunction mechanisms have been postulated in cognitive and psychotic conditions.
In an EWAS on methylome of post-mortem brain of major psychoses patients, hypermethylation of an intron, promoter and an upstream region of DTNBP1 gene was found to be FDR-significant in association with bipolar disorder. Furthermore, variation of DTNBP1 mRNA levels in post-mortem cerebellum has been shown to be concordant with it in peripheral blood lymphocytes (PBL) of the individual in expression profiling studies. In addition, the expression reduction of DTNBP1 has been demonstrated in PBL of psychotic patients.
Here, we investigated DTNBP1 promoter methylation variation in psychotic bipolar disorder patients. Preliminarily, methylation level of a promoter CGI of DTNBP1 gene in 46 cases against 85 age and sex-matched controls was measured with Quantitative Methylation-Specific High-Resolution Melting(MS-HRM). We observed a statistically significant hypermethylation in psychotic bipolar cases against normal samples. Provided the results be replicated in broader investigation, PBL DTNBP1 promoter hypermethylation could be considered a potential biomarker of psychotic bipolar disorder.

Clinical, Neuroimaging, and Genetic Characteristics of Megalencephalic Leukoencephalopathy With Subcortical Cysts in Egyptian Patients

A. Abdel Aleem, *Alice Abdel Aleem' group, Iman Mahmoud, Marian Girgis , Nevin Waked, AmeeraEl Badawy, Laila Selim, Sawsan Hassan;
Weill Cornell Medical College Qatar, Doha, Qatar.*

Megalencephalic leukoencephalopathy with subcortical cysts (MLC) is a rare cerebral white matter disease. Clinically, it is characterized by macrocephaly, developmental delay, and seizures. We explore the clinical spectrum, neuroimaging, and gene involvement in the first MLC patients described from Egypt. Patients: Six patients were enrolled from three unrelated families. Patient inclusion criteria were macrocephaly, developmental delay, normal urinary organic acids, and brain imaging of diffuse cerebral white matter involvement. Direct sequencing of the MLC1 gene in patients' families and GliaCAM in one questionable case was performed. Results: Clinical heterogeneity, both intra- and interfamilial, was clearly evident. Developmental delays ranged from globally severe or moderate to mild delay in achieving walking or speech. Head circumference above the ninety-seventh percentile was a constant feature. Neuroimaging featured variability in white matter involvement and subcortical cysts. However, findings of posterior fossa changes and brain stem atrophy were frequently (66.6%) identified in these Egyptian patients. Discrepancy between severe brain involvement and normal mental functions was evident, particularly in patients from the third family. MLC1 mutations were confirmed in all patients. Deletion/insertion mutation in exon 11 (c.908-918delinsGCA, p.Val303 Gly fsX96) was recurrent in two families, whereas a missense mutation in exon 10 (c.880 C > T, p.Pro294Ser) was identified in the third family. CONCLUSIONS: This report extends our knowledge of the clinical and neuroimaging features of MLC. It confirms the apparent lack of selective disadvantage of MLC1 mutations on gamete conception and transmission as supported by the presence of multiple affected siblings in Egyptian families.

J09.71
Association and Gene-Gene Interactions of the HPA Axis Genes with Suicidal Behaviour

Z. Khalilova[1], *A. Zainullina*[2], *E. Khusnutdinova*[2,3];
[1]*Bashkir State Agrarian University, Ufa, Russian Federation,* [2]*Institute of Biochemistry and Genetics, Ufa Scientific Center of Russian Academy of Sciences, Ufa, Russian Federation,* [3]*Department of Genetics and Fundamental Medicine ofBashkir State University, Ufa, Russian Federation.*

The hypothalamic-pituitary-adrenal (HPA) axis is activated in different ways

during chronic stress and involved in the neurobiology of different mood disorders including suicide behavior. The CRHR1 gene controle the activation of HPA axis via expression and functionality. Immunophillin FKBP51 is expressed in cortical neurons and regulate the function of the glucocorticoid receptor which regulates HPA axis. Genetic variants in the FKBP5 gene encoding FKBP51 are linked to suicide.

The aim of our study was to examine association of rs878886 polymorphism of CRHR1 gene, polymorphisms rs4713902 and rs7757037 in FKBP5 gene with suicidal behavior in Russian and Tatar patients from Bashkortostan. We genotyped DNA samples of 312 cases (101 - Male, 152 - Female, 150 - Russian, 120 - Tatar) who had suicide attempts and 346 control subjects (194 - Male, 152 - Female, 263 - Russian, 248- Tatar) from Russia using PCR-RFLP and PCR with fluorescent detection (FLASH/RTAS) techniques.

We observed a strong association between CRHR1 rs878886 and suicide: allele C was significantly overrepresented both in Russian (P=0,013, OR=1,79, 95%CI 1,13-2,86) and Tatar ethnicity groups (P=0,00001, OR=3,06, 95%CI 1,99-4,71).

No significant differences in either allele, genotype or haplotype frequencies of FKBP5 gene SNPs were found between suicidal and control groups. However, gene-gene interactions showed strong association in Tatar patients between investigated genes: rs7757037*A/G - rs878886*C/G (P=0,0012, OR=4,03, CI95% 1,75-9,35) and rs4713902*C/T - rs878886*C/G (P=0,0009, OR=4,84, CI95% 1,92-12,41).

Our results show contribution of investigated genes in predisposition to suicidal behavior, and confirms ethnic specifity of this association.

J10.01

Phenotype-genotype correlation in patients with dysferlinopathy in families from Daghestan

V. P. Fedotov[1], *Z. Umahanova*[2], *O. Ryzkova*[3], *G. Dalgatov*[4], *A. Polyakov*[3], *A. Isaev*[4], *R. Deev*[4];
[1]1 Regional Clinical Hospital Genetic counseling, Voronezh, Russian Federation, [2]Dagestan State Medical Academy, Makhachkala, Russian Federation, [3]Research Center for Medical Genetics, Moscow, Russian Federation, [4]Human Stem Cell Institute, Moscow, Russian Federation.

Dysferlinopathies are autosomal recessive muscular dystrophies caused by mutations in dysferlin gene (*DYSF*, MIM# 603009). Dysferlin deficiency leads to two main phenotypes: limb girdle muscular dystrophy (LGMD) 2B and Miyoshi myopathy (MM). Dysferlin is located on the plasma membrane of skeletal muscle and is deficient in patients with MM and LGMD2B.

We've retrospectively reassessed the disease history (onset and progression). Earlier the phenotype genotype correlation was established in patients with dysferlinopathy variants in Daghestan families. Illarioshkin et al. in 1996 examined a large 6-generation family, which include 12 patients whom 9 were manifestations LGMD 2B and 3 were MM.

Clinical assessment was performed with a standardized protocol, including the Medical Research Council scale, a serum creatine kinase level, electromyography, and a muscle computed tomographic scan, sequencing DNA.

11 patients from 7 families, originally from a mountain village (9 males and 2 women), were examined. All of them had severe symptoms of progressive muscular dystrophy and the same mutation in exon 3 of the *DYSF* (c.573-574 TG>AT transition, in the homozygous state with replacement p.Val67Asp).

During the period 2013 we have been re-examining 5 patients and detailing disease history (onset and progression). Five elderly patients of 11 were clinically and molecular examined. Two of 5 patients over the age of 40 years had proximal pattern of muscle involvement (the hip and shoulder belts), 2 others had distal variant Miyoshi myopathy.

J10.02

Homozygosity mapping in an Iranian pedigree affected with muscular dystrophy limb girdle (LGMD) reveals linkage to chromosome 2p12-14 and a mutation in Dysferlin gene

A. Alavi[1,2], *E. Elahi*[1,2], *M. Khani*[1,2], *M. Malakooti Nejad*[1,3];
[1]University of Tehran, Tehran, Islamic Republic of Iran, [2]School of Biology, College of Science, University of Tehran, Tehran, Islamic Republic of Iran, [3]Department of Biotechnology, College of Science, Tehran, Islamic Republic of Iran.

Homozygosity mapping is a powerful gene mapping method applicable to rare recessive disorders in inbred populations. Limb-girdle-muscular-dystrophy (LGMD) is heterogeneous group of disorders affecting the voluntary muscles, mainly around the pelvic and shoulder. Mutations in different genes can cause different types of LGMD. To date, at least 15 different genes have been identified as LGMD causative genes. Because, there are many genes for this group of disorders, mutation screening of all these genes is cumbersome and costly. Linkage analysis can be used for selection of the appropriate candidate gene. An Iranian family with four sibling affected with LGMD was identified. Genome-wide SNP genotyping was carried out on DNAs of three affected and one unaffected individuals using HumanCNV370-Quadv3_C BeadChips. Subsequently, homozygous regions common to affected individuals and absent in the unaffected sibling were sought. Disease status in the family linked to a homozygous region on chromosomes 2. The DYSF gene that associates with LGMD type 2B was positioned within the linked region. DYSF encodes dysferlin, a protein believed to be involved in the maturation of new muscle fibers and in repairing damage to muscle cells. Sequencing of DYSF exons in the proband of the Iranian revealed a novel insertion-deletion that is the likely cause of LGMD in the family. The phenotypic features of the patients harboring the mutation are uncommon because of prominent proximal presentations. To date, over 400 mutations disease in DYSF have been reported. The novel mutation reported here represents only the second mutation observed among Iranian LGMD patients.

J10.03

A multi-exonic *RYR1* deletion identified in individual with confirmed malignant hyperthermia

I. Valaskova[1,2], *S. Dudova*[1,2], *Z. Svestkova*[1], *R. Gaillyova*[1,2];
[1]University Hospital Brno, Medical Genetics Dpt., Brno, Czech Republic, [2]Masaryk University, Faculty of Medicine, Brno, Czech Republic.

Malignant hyperthermia susceptibility (MHS) is an autosomal dominant pharmacogenetics disorder of skeletal muscle calcium regulation associated with uncontrolled skeletal muscle hypermetabolism. The MH crisis is induced by exposure of the predisposed patients to halogenated volatile anaesthetics. Molecular genetic testing indicates that mutations in *RYR1* are identified in up to 80% cases of MHS. More than 400 mutations in *RYR1* have been associated with MHS. Most of the *RYR1* mutations are private. Almost all MHS-causative mutations are missense; however, an in-frame deletion of a single amino acid in the central region of *RYR1* and a single-nucleotide deletion at the extreme C-terminal end of the protein have also been reported. Large-sized genomic deletion of 6 520 bp was identified as the first genomic rearrangement in the *RYR1* gene.

Here we report the detection of large-sized deletion in the C-terminal end of the RYR1 in the MHS confirmed individual. At first, the deletion of exons 90 and 94 was identified using MLPA. In the second step, the deletion from exon 90 to 98 was determined using quantitative fluorescent PCR (QF PCR). We described novel multi-exonic deletion of 2 kb that belongs to new class of mutation of the *RYR1* gene. This is the second published multi-exonic deletion identified in the *RYR1* gene to our knowledge. This will clearly have consequences for the molecular investigation of RYR1-related diseases.

J10.04

Detection of deletions and duplications in the Duchenne muscular dystrophy in Russian patients

A. N. Loginova;
Medical Genetics Research Center, Moscow, Russian Federation.

DMD gene duplications detection and analysis of deletions at female relatives of the patient has not yet been carried out in Russian patients. Thus, the aim of this work is the development of methods of quantitative analysis of DMD gene duplications and deletions and determining the frequency of duplications in the selection of patients with DMD/BMD from Russia. To perform this task, we have developed a quantitative method based on specific ligation reaction (MLPA). Using this method, we analyzed 237 patients with Duchenne/Becker muscular dystrophy, which didn't reveal deletions of „hot exons". Duplications have been detected among 37 patients. Deletions not in „hot exons" have been found among 9 patients. Thus duplications are found in 6% of cases, which is supported by the literature data. In addition, this method allows detecting deletions / duplications in female genome, which allows to determining mutations in DMD gene in carrier.

A Novel POMT2 mutation defined in a girl with Walker Warburg syndrome.

E. Yilmaz Gulec[1], *E. Karaca*[2], *G. Yesil*[3], *D. Pehlivan*[2], *T. Gambin*[2], *S. Jhangiani*[4], *D. Muzny*[4], *R. Gibbs*[2,4], *J. Lupski*[2,4,5];
[1]Medical Genetics Section, Kanuni Sulltan Suleyman Research and Training Hospital, Kucukcekmece, Istanbul, Turkey, [2]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, United States, [3]Department of Medical Genetics, Bezmialem University Medical School, Fatih, Istanbul, Turkey, [4]Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, United States, [5]Department of Pediatrics, Baylor College of Medicine, Houston, TX, United States.

Disorders disrupting normal brain development represent a clinically and genetically heterogeneous group. Genomic technologies are being used widely, especially in recent years, and enabling the discovery of many novel genes that are involved in brain development. However, many more are likely waiting to be brought to light. Here we present a girl with hydrocephaly which was diagnosed during antenatal period. She had hypotonia, occipital encephalocele, dandy walker malformation of the brain, pachygyria, agenesis of corpus callosum, microophtalmia and corneal opacity on the right

eye, retinal and choroid coloboma on the left eye, slight desquamation of the skin. Her creatinine kinase and lactate dehydrogenase levels were high. Whole exome sequencing revealed a homozygous novel mutaion (c.T431G:p.M144R) on Protein O-Mannosyltransferase 2 (POMT2) gene. Walker-Warburg Syndrome (WWS) is a rare form of autosomal recessive congenital muscular dystrophy associated with brain and eye abnormalities. Until now several mutations were found in the POMT1 and POMT2 genes. Increasing use of genomic sequencing approaches, along with other genome-wide interrogation technologies are helping to identify causative rare variants not only in disorders of brain development but also in other disorders showing Mendelian inheritance.

Clinical characteristics and genotype-phenotype correlation of Korean patients with spinal and bulbar muscular atrophy

J. Song[1], *K. Kim*[2], *C. Ki*[1], *J. Kim*[1], *D. Sung*[3], *J. Min*[4], *B. Kim*[4];
[1]*Departments of Laboratory Medicine and Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,* [2]*Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,* [3]*Departments of Physical and Rehabilitation Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,* [4]*Departments of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of.*

Introduction Spinal and bulbar muscular atrophy (SBMA) is slowly progressive and adult-onset motor neuron disease caused by a CAG repeat expansion in the AR gene. Few data are available for clinical characteristics and genotype-phenotype correlation in Korean SBMA patients. **Methods** Forty consecutive patients diagnosed by genetic testing were included in this study. The age of onset was defined as the time of the patient's initial recognition of symptoms and disease duration was represented by the time taken from onset of symptoms to genetic diagnosis. The severity of symptoms was assessed by nine ADL milestones. Rate of disease progression was expressed as a number, differences of ADL scores between at onset and diagnosis/disease duration. **Results** The median age at onset and diagnosis was 44.5 and 52.5 years, respectively. The median disease duration was 5.00 years, median rate of disease progression was 0.2 score/year and median number of CAG repeats in the AR gene was 44. The number of CAG repeats showed significant inverse correlations with the age of onset of muscle weakness and the age of onset of any symptoms. Interestingly, a statistically significant correlation between rate of disease progression and age at onset was observed while an inverse correlation between rate of disease progression and disease duration was noticed. **Discussion** This study reaffirms the inverse correlation between the age at disease onset and the number of CAG repeats. It is of note that the rate of disease progression is influenced by age at disease onset in Korean SBMA patients.

J10.07

Molecular analysis of mutations smn1, smn2 and naip genes by multiplex ligation-dependent probe amplification (mlpa)

B. Kamaliyeva, *A. Borovikova, A. Nagimtaeva, A. Satieva, G. Abildinova;*
National Research Center Maternal and Child Health, Astana, Kazakhstan.

Spinal muscular atrophy (SMA) is autosomal recessive neurodegeneration disease. The cause of the disease is mutations in the SMN gene. SMN1 gene has high homologue copy - SMN2 gene, the number of copies depends on the type of severity of the current disease and the patient's quality of life.

To identify mutations in the SMN1, SMN2 and NAIP genes, MLPA analysis was performed by using 3730xl DNA Analyzer. Molecular study of 43 patients was conducted in unrelated families with suspicion of spinal atrophy. The diagnosis was confirmed in 21 cases.

In three patients with SMA type I identified deletion of exons 7 and 8 of SMN1 and not marked increase in the number of copies of SMN2, two patients identified deletions of exons 7 and 8 and a deletion of the SMN1 gene and NAIP gene. In patients with SMA type II in 3 cases met deletion of exons 7 and 8 of SMN1 gene and increases the number of copies of the SMN2 gene and only in one case the deletion of exons 7 and 8 of the SMN1 gene. At the same time, in nine patients SMA type III - 8 cases of predominate deletions 7 and 8 exons SMN1 gene and increase the number of copies of the SMN2 gene, in one case revealed a deletion of 7 and 8 SMN1 gene.

Thus, these studies show that the number of copies SMN2 gene is not always associated with the severity of clinical manifestations in patients with SMA.

J10.08

Definition breakpoints in the dystrophin gene for heterozygous carrier revealing

Z. Abdrakhmanova[1], *K. Mahambetov*[2], *B. Kamaliyeva*[3], *A. Borovikova*[3], *G. Abildinova*[3];
[1]*National Research Center of Mother and Childhood, Astana Medical University, Astana, Kazakhstan,* [2]*Astana Medical University, Astana, Kazakhstan,* [3]*National Research Center of Mother and Childhood, Astana, Kazakhstan.*

Duchenne muscular dystrophy - a disease caused by the presence of deletions, duplications and point mutations in the dystrophin gene (DMD), destroying one to several exons. An important aspect in the diagnosis of the disease is to determine the break points for the diagnosis of carriers of the abnormal gene. Objective: to develop a method of determining breakpoints of deletions of the intron of DMD gene to identify heterozygous carrier. Material research was genomic DNA of two patients suffering from Duchenne muscular dystrophy and their parents. DNA was extracted from whole blood using a kit Wizard ® Genomic DNA Purification Kit (Promega). Diagnosis of Duchenne muscular dystrophy was carried out using the MLPA, followed by capillary electrophoresis. Design of primers was performed using the program Primer 3 (http://primer3.ut.ee/). Determination of break points in the region of exons 45-50 was performed using PCR RT, the 7300 „Applied Biosystems" (USA). MLPA- analysis revealed a deletion of a segment encompassing exons 45-50 of the gene. The first break point occurred between exons 44-45, the second - between exons 50-51. Using genomic databases (http://www.genome.ucsc.edu) defined size between exons: 44-45 includes ~ 250,000 nucleotides 50-51 includes ~ 45 500 nucleotides. Using several sets of primers, these areas have been divided into several parts, followed by PCR RT, to identify the region deletions. At the last stage of the experiment break point was determined by sequencing. As a result, this study developed a method to identify heterozygous carrier in preclinical diagnosis of Duchenne muscular dystrophy.

Novel pathogenic mechanism of a mid-intronic mutation in DMD gene

M. Trabelsi[1], *C. Beugnet*[2], *N. Deburgrave*[2], *v. Commere*[2], *L. Orhant*[2], *F. Leturcq*[2], *J. Chelly*[2];
[1]*Service des maladies congenitales et hereditaires, EPS Charles Nicolle, tunis, Tunisia,* [2]*Laboratoire de biochimie et génétique moléculaire, Hôpital Cochin, Paris, France.*

Duchenne and Becker muscular dystrophy are X-linked allelic disorders caused by mutations in the *DMD* gene. The majority (65%) of these mutations are intragenic deletions/duplications that often lead to frameshift errors. Among the remaining ones, we find the mid-intronic mutations that usually create cryptic exons by activating potential splice sites. In this report, we identified, in a Becker Muscular Dystrophy patient, a mid-intronic mutation that created two ESE sites in intron 26 of DMD gene resulting in the insertion of a new cryptic exon in mRNA.

To our knowledge, this is the first case report describing this novel pathogen mechanism of mid-intronic mutations of *DMD* gene.

J10.10

Analysis of subtle mutations in SMN1 gene in non-deleted SMN1 gene Russian SMA patients

V. V. Zabnenkova[1], *S. B. Artemieva*[2], *G. E. Rudenskaya*[1], *E. L. Dadali*[1], *A. V. Polyakov*[1];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2]*Moscow Research Institute of Pediatrics and Children Surgery, Moscow, Russian Federation.*

SUMMARY: The proximal spinal muscular atrophy (SMA) is a severe autosomal recessive neuromuscular disease characterized by degeneration of alpha motor neurons in the spinal cord, resulting in progressive proximal muscle weakness and paralysis. 95% SMA patients have homozygous deletion of *SMN1* gene. The remaining 5% cases are caused by compound heterozygous mutation: a *SMN1* deletion on the one allele and a subtle mutation on the other allele.

OBJECTIVE: To identify the intragenic mutations in *SMN1* gene in the 11 unrelated SMA patients with the one copy of *SMN1* gene.

METHODS: MLPA was carried out to measure the copy number of *SMN1* and *SMN2* genes. The subtle mutation analysis of *SMN1* gene was performed by direct sequencing.

RESULTS: We have identified seven mutations in eight patients with proximal SMA.(Tab.1) Mutation c.824G> C (p.Gly275Ala) has been met twice.

In six of eight cases mutations are inherited from the father.

Mutations are well correlated with the type of disease.

It has been found no mutations in three patients. Possibly, in these cases, mutations are located outside the investigated sequences, f.e. at promoter region. Or these patients are carriers having another SMA-like disorder.

CONCLUSION: Analysis of subtle mutations in *SMN1* gene is essential to genetic counseling in non-deleted *SMN1* gene SMA families.

Phenocopies as a possible cause of molecularly unconfirmed cases of Emery-Dreifuss muscular dystrophy

T. Adyan[1], *G. Rudenskaya*[1], *E. Dadali*[1], *O. Ryzkova*[1], *O. Groznova*[2], *D. Vlodavets*[2], *V. Fedotov*[3], *A. Polyakov*[1];
[1]*Research Center for Medical Genetics, Moscow, Russian Federation,* [2]*Moscow Scientific Research Institute of Pediatrics and Child Surgery, Moscow, Russian Federation,* [3]*Regional Clinical Hospital, Genetic Counseling Department, Voronezh, Russian Federation.*

Emery-Dreifuss muscular dystrophy (EDMD) is genetically heterogeneous muscular disease; 6 genes have been identified by now: EMD, LMNA, FHL1 causing major forms and very rare SYNE-1, SYNE-2, TMEM43. However, in >60% patients with EDMD phenotype no mutations are found. Common opinion about this issue is existence of other causative genes not recognized yet. In our sample of 102 unrelated patients (74 men, 28 women) with EDMD phenotype tested for mutations in LMNA (all patients), EMD and FHL1 (men only) EDMD was confirmed in 38 (37.2%); 22 patients (21,6%) were heterozygous for LMNA mutations, 15 (14.7%) hemizygous for EMD mutations and one (0.9%) hemizygous for FHL1 mutation. Patients with no mutations and pedigrees compatible with autosomal recessive inheritance were additionally tested for common mutations in CAPN3, FKRP, SGCA, ANO5, DYSF genes responsible for limb-girdle muscular dystrophies 2A, 2I, 2D, 2L, 2B respectively. Four patients were found homozygous or compound heterozygous for CAPN3 mutations and one - heterozygous for ANO5 mutation (allelic mutation is in search); the five patients had typical EDMD features including primary contractures and cardiomyopathy with arrhythmia. Thus, part of molecularly verified diagnoses in the initial sample made up 42.1%. Our findings show that EDMD can be clinically mimicked by mutations in genes responsible for other muscular dystrophies. It explains, to some extent, high percentage of cases with EDMD phenotype but no mutations in EDMD genes. EDMD phenocopies (as well as rare clinically atypical EDMD cases) should be taken into account in practical diagnostics and genetic counseling in families.

J11.01
17q22 microdeletion syndrome; a case report

T. Kalayci, *N. B. Satkın, U. Altunoğlu, B. Karaman, H. Kayserili;*
Istanbul University, Istanbul Medical Faculty, Medical Genetics Department, Istanbul, Turkey.

The recognition of microdeletion/duplication syndromes have been facilitated by the development of array comparative genomic hybridization techniques. One of the microdeletion/duplication syndromes recently identified is '17q22 microdeletion syndrome' which has been defined in 2013. This syndrome presents with intellectual disability, conductive hearing loss, facial dysmorphism and skeletal anomalies. Only nine patients have been reported previously. The common deleted region includes NOG gene which is essential for joint formation and the phenotype assosiated with 'NOG-related symphalangism spectrum disorder' is characterized by symphalangism, joint contractures and conductive hearing loss.
Here, we present a new case with 17q22 microdeletion syndrome. She was refered to genetics department due to facial dysmorphism, long and tapering fingers and preauricular skin tags. On physical examination at the age of seven, she showed narrow forehead, midfacial hypoplasia, hemicylindrical nose, short and flat philtrum, thin border of upper lip, joint contractures and proximal symphalangism. She had severe intellectual deficit. Since she displayed symphalangism, NOG gene was sequanced and no mutation was revealed. Further testing by array-CGH showed a de novo 3,1 MB deletion on 17q22. The deleted region contains 36 genes, including NOG gene. The case will be discussed in view of the literature.

TripleX Syndrome with short stature: a case report

G. Cerbone, *C. Rosania, I. De Maggio, C. Piscopo, A. Pedicini, A. Colucci;*
aosgmoscati, avellino, Italy.

Triple X syndrome (47,XXX) is a sex chromosomal aneuploidy characterized by tall stature, microcephaly, hypertelorism, epichantal folds, congenital abnormalities and motor and language delays. We present a rare phenothype of the syndrome: a 10 years-old girl admitted to our hospital for short stature. She was born from non consanguineous parents at term of uneventful pregnancy weighting 2500 gr and measuring 47 cm. The girl was 117.7 cm (height SD score -2.87)< to the parental target eight of 154.5 cm, with a weight of 19Kg (SD score -2.13) and head circumference of 45.5 cm (below the 3rd percentile). The girl's growth rate was of 4-5 cm annually. The genitalia were of normal female phenotype with Tanner 1 stage of breasts. In addiction she presented clinodactyly, ogive palate and mild cognitive and speech delays. Karyotype was 47,XXX; FISH (probe CEP-X) on 200 interphase nuclei confirmed cytogenetic data. There was no evidence of growth hormone deficiency. Laboratory tests showed low insulin-like growth factor-1 (IGF-I). Bone radiographic imaging of the left carpal demonstrated a difference between bone age and chronological age of 2 years. Blood routine test, liver and kidney function, blood glucose and insulin, thyroid function were normal. The ultrasound examination of heart, uterus, ovary and urinary system, as well as cranial magnetic resonance imaging (MRI) were normal. A possible explanation might be the aploinsufficiency of the short stature-homeobox-containing gene (SHOX gene) that is present in the pseudoautosomal region of sex chromosomes. This study performed in our patient is yet ongoing.

De Novo 4p deletion and 4q duplication in a female dysmorphic child

M. Ozdemir[1], *H. Onur Kucuk*[1], *E. Simsek*[2], *N. Düzkale*[1], *B. Durak Aras*[1], *H. Aslan*[1], *O. Cilingir*[1], *S. Artan*[1];
[1]*Eskisehir Osmangazi University, Faculty of Medicine, Department of Medical Genetics, Eskisehir, Turkey,* [2]*Eskisehir Osmangazi University, Faculty of Medicine, Department of Pediatric Endocrinology, Eskisehir, Turkey.*

Wolf-Hirschorn Syndrome (WHS) is a well recognized chromosome 4p16.3 microdeletion syndrome with characteristic craniofacial features, pre and postnatal growth retardation, hypotonia, intellectual disability, EEG abnormalities, congenital heart defects and corpus callosum agenesia. Direct duplications on the chromosome 4q represent an infrequent chromosomal finding. Here, we report the cytogenetic and molecular cytogenetic findings and clinical manifestations observed in a 19 months old female infant with terminal del4p and dup4q. The infant was delivered by Cesarean section at the 36th week of the mother's twin pregnancy. Her twin was normal. The birth weight of the case was 1750 gr (<-1 sd) and heigth was 42 cm (<-2 sd). She had significant features specific to WHS. Additionally she had bitemporal narrowing, square forehead, mild brachycephaly, large antihelix, bilaterally hand and foot fifth finger clinodactyly. Our patient has increased renal parenchyma echogenity, large antihelix and umblical hernia which are similar to chromosome 4qdup anomalies. Conventional cytogenetic analysis revealed 46,XX,dup(4)(4qter-4p16?::4q31-4qter) and molecular cytogenetic analysis was 46,XX,ishder(4)dup(4)(q31qter)(wcp4+)del(4)(p16.3pter). The karyotypes of the healthy, non-consanguineous parents were normal.
The de novo abnormal karyotype seen in the case have not been described previously. Although phenotypic features of the case are similar to WHS, the patient also has features, including ear and renal anomalies, which may be attributed to the 4q duplication. The patient's phenotype may represent the combined effect of both chromosome aberrations. In order to identify regions of the relevant genes, further advanced molecular analyses are planned.

J11.04
Deletion of 4q28.3-31.23 in the background of multiple malformations

B. Duga[1,2], *M. Czako*[1,2], *K. Komlosi*[1,2], *K. Hadzsiev*[1,2], *K. Torok*[3], *K. Sumegi*[1,2], *P. Kisfali*[1,2], *G. Kosztolanyi*[1,2], *B. Melegh*[1,2];
[1]*Department of Medical Genetics, Pecs, Hungary,* [2]*Szentágothai Research Centre, Pecs, Hungary,* [3]*Department of Pediatrics, Pecs, Hungary.*

We would like to address a case regarding a patient who suffered from multiple malformations. The symptoms include small kidneys, epilepsy, dystrophy, hyponatraemia, immunodeficiency with decreased lymphocyte number, most of which are well known in medical literature, however some of them are unique like hypocalcaemia and pulmonary hypertension. Despite preliminary tests, which include GIEMSA banding and FISH, we were not able to detect the genetic alterations behind these symptoms, which is why we expanded the routine method to array CGH. We used Agilent Human Genome G3 Sureprint 8x60K Microarray to detect the cytogenetic deletions in

the patient. We found 14.56MB interstitial deletion on the long arm of chromosome 4, more specifically in the region of 4q28.3-31.23, where a total of 47 genes were affected. Eight out of these genes affected could play and important role in the manifestation of these symptoms. These genes include NR3C2, IL15, PCDH18, SETD7, ELMOD2, GAB1, HHIP, and SMAD1. We also examined the patient's parents with the same type of microarray. As no deletions were detected in either parent we concluded that the deletion found in the patient was a de novo alteration, which leads us to believe that the loss of these genes could give us a possible explanation for the clinical features.
This research was supported by TÁMOP-4.2.3-12/1/KONV-2012-0028.

Troina - Genetica Medica, Università degli Studi, Catania, Italy.*

We report ok a 5 years old boy with a prenatal ultrasound diagnosis of biventricular hydrocephalus. He was born with a birth weight of 2580 g, a length of 46 cm and a head circumference of 33 cm. He did not show muscular hypotonia but his psychomotor development was delayed: he sat at the age of 11 months and he walked independently at the age of 17 months. He spoke single words at the age of 12 months but he could not make complete sentences until 3 years of age. Brain MRI showed colpocephaly, thinned corpus callosum and pons, hypertrophy of massa intermedia. His EEG was normal. Neurological evaluation showed muscular atrophy and hypotonia, joint laxity and mild intellectual disability. On the clinical examination at 5 years of age, the patient had a weight of 15 kg (3th centile), a height of 105 cm (10th centile) and a OFC of 47 cm (<<3th centile). The examination showed failure to thrive, microcephaly, triangular face, downslanting palpebral fissures, sparse eyebrows, large and posteriorly rotated ears, muscular atrophy and hypotonia, ligamentous laxity, scapular winging and bilateral flat foot . Array-CGH showed a 2.5 Mb microduplication of 2q37 and a 5.3 Mb microdeletion of 6q27 generating a de novo derivative 6 chromosome: this rearrangement is likely to be the result of a translocation involving the distal region of long arm of chromosome 2 and the distal region of long arm of chromosome 6. Array-CGH showed also a maternal 714 Kb microduplication of Xq26.2.

J11.06
A case report with de novo interstitial deletion in 7q21

A. H. Cebi[1], *A. Okten*[2], *S. Seyhan*[1], *R. Polat*[2], *M. İkbal*[1];
[1]*Karadeniz Technical University Faculty of Medicine Department of Medical Genetics, Trabzon, Turkey,* [2]*Karadeniz Technical University Faculty of Medicine Department of Pediatrics Division of Endocrinology, Trabzon, Turkey.*

In this case we report a male patient with a de novo interstitial deletion in 7q21 which is determined by G-banding. Patient was referred our clinic for undescended testes and mild intellectual disability. He was five years old and one of the triplet pregnancies. Two other siblings were girls. The pregnancy resulted from in vitro fertilization. The siblings and parents karyotype analyzes were normal. The clinical features of the patient were cerebral cerebellar hypoplasia, partial androgen resistance, undescended testis and mild intellectual disability. We are now planning to make further molecular investigations to find a relationship between the candidate genes of these features.

J11.07
New case of 7q11.23 duplication syndrome in a polymalformed Saudi child

H. Elghezal, *A. Alhashem, I. Ben Abdallah, K. Al Fayez, A. Alabdulaaly;
Riyadh Military Hospital, Riyadh, Saudi Arabia.*

7q11.23 duplication syndrome referred to as "duplication of the Williams syndrome region;" is a recently-documented genetic disorder caused by a heterozygous duplication of contiguous genes at 7q11.23 mediated by nonallelic homologous recombination (NAHR) between large flanking Low Copy Repeats, leading to duplication or to deletion like observed in williams beuren syndrome.
Less than 100 cases have been described and the phenotype is not yet well defined. Most prominent phenotypic characteristics, mentioned in literature review are severe speech delay, language delay, a characteristic facies, hypotonia, developmental delay, and social anxiety. Congenital anomalies as heart defects, diaphragmatic hernia, cryptorchidism and non-specific brain abnormalities are sporadically reported.
We report here an 1 year-old male with 7q11.23 microduplication detected by array-CGH analysis performed because of speech delay, growth retardation, hypotonia and polymalformative syndrome associating congenital heart diseases, hydronephrosis, cleft lip, macrocephaly and polydactyly. Fluorescence in situ hybridization, using ELN gene probe, confirmed the diagnosis, revealing a tandem duplication of the Williams-Beuren critical region detectable only on interphase nuclei and karyotype study was normal.
This case is one of the most severe reported in the literature and it allows us to expand the phenotypic spectrum of this syndrome.

J11.08
A new familial case with 8q24.11-q24.3 complementary rearrangements: phenotypes associated with pure deletion and mosaic duplication

F. Malvestiti[1], *C. Izzi*[2], *B. Grimi*[1], *B. Malvestiti*[1], *L. Martinoni*[1], *S. Paganini*[1], *L. Marcato*[1], *E. Baldi*[1], *N. Palai*[2], *F. Maggi*[1], *G. Simoni*[1], *F. R. Grati*[1];
[1]*Research and Development, Cytogenetics and Molecular Biology, TOMA Advanced Biomedical Assays, Busto Arsizio, Italy,* [2]*Prenatal Diagnosis Unit, Department of Obstetrics and Gynaecology, University of Brescia, Brescia, Italy.*

Genomic rearrangements of 8q distal bands have been associated with several clinical entities, such as Langer-Giedion Syndrome. We report a unique familial case with complementary chromosomal aberrations involving the same distal 8q region, detected on fetus (deletion) and mother (mosaic duplication). Chromosome analysis on chorionic villi at 13 weeks of gestation for increased Down Syndrome risk after maternal serum screening revealed 46,XX,del(8)(q?23q?24.2) karyotype. The 8q deletion was defined as interstitial by subtelomeric and painting specific FISH probes. The deletion size was investigated by microarray and parental karyotype was performed. Microarray result was arr[hg19] 8q24.11q24.3(119,142,459-144,825,972) x1 with a 25 Mb deletion. The involved region included 74 OMIM genes and no recurrent microdeletion syndromes. Maternal karyotype was mos 46,XX,dup(8)(q?24.1q?24.3)[22]/46,XX[28]; the mosaic interstitial duplication was confirmed also by FISH and microarray, which disclosed the same fetal breakpoints. Only two cases have been described with pure 8q24 duplication characterized by microarray (Concolino et al., 2012;Wheeler, 2010) and none in mosaic condition. Mother had hydrocephalus at birth, short stature, facial dismorphisms, psychomotor and mild cognitive delay. Fetal ultrasound investigation was normal. Similar deletions have never been reported. We speculated about possible clinical consequences evaluating the role of genes mapped in the deleted/duplicated region, such as KCNK9, associated with Birk-Barel mental retardation dysmorphism sindrome (#612292); in brain tissues, it is expressed only from maternal allele and this might have a possible role in maternal and newborn phenotype. We have also suggested a possible mechanism of formation of this unique familial case

Application of array CGH technique for postnatal identification of constitutional abnormalities

H. Pikó[1], *I. Halltrich*[2], *G. Fekete*[2], *V. Karcagi*[1];
[1]*National Institute of Enviromental Health, Budapest, Hungary,* [2]*2nd Department of Paediatrics of Semmelweis University, Budapest, Hungary.*

The identification of cytogenetic imbalance is an important component of clinical genetics. Genetic abnormalities have been associated with 6-13 % of stillbirth, but the true prevalence may be higher. Chromosomal abnormalities often cause specific and complex phenotypes resulting from an imbalance in the normal dosage of genes located in a particular chromosomal segment. Furthermore, many multiple malformation syndromes are caused by deletion or duplication of genomic region. In the interest of diagnosis, conventional cytogenetic analysis such as chromosomal banding technique is applied as the first choice, which allows for the unambiguous identification of each human chromosome with the detection of aneuploidy and many large structural rearrangements, including translocations, large deletions and duplications. The molecular cytogenetic platform on which our study is based on is array comparative genomic hybridization (aCGH), which is a useful diagnostic method to detect a complex cytogenetic syndromes and diseases. The aim of our study is to extensively apply, further applied and validate sensitive high throughput array CGH to efficiently investigate the cytogenetic abnormalities in all regions of Hungary. We introduced the NimbleGene array platform and we started the molecular cytogenetics analyses in 7 cases. Out of the 7 samples, in which the causative chromosomal effect was confirmed, a gain was identified at four patients (range of the gain was from 39 Mb to 1.3 Mb) and in three cases loss of different regions was detected (from 67.4 Mb to 0.17 Mb). The underlying genes were selected and the results are currently discussed with the clinicians.

Chromosomal imbalances are the major cause of developmental delay combined with dysmorphic facial features. Many of these imbalances are caused by submicroscopic deletions or duplications that are undetectable at the level of traditional cytogenetic analysis. Array-based comparative genomic hybridization (array CGH) is a powerful and high-resolution approach for detection of DNA copy number variants (CNVs).
We report a 7 month old boy with mild dysmorphic features, developmental delay, excessive skin grooves of limbs and hypoplasia of the corpus callosum. We have used genomic array CytoChip Oligo (BlueGnome, Cambridge, UK), format 2x105K, version 1.1. and BlueFuse Multi software, version 2.2. The 2x105K array detects 100 Kb imbalances on the backbone and has tiling of 20 probes over 137 OMIM disease loci. Array CGH- analysis revealed cryptic deletion of 15q11.2 region spanning 4,68 Mb and an amplification spanning 19,31 Mb of 13q12.11-13q13.3. The CytoChip results were confirmed with MLPA. The influence of the known genes in the imbalanced regions and their correlation to the phenotype will be discussed.

J11.11

The BBS12 gene mutation is cause of Bardet Biedl syndrome in two individuals from south west Iran

H. Galehdari[1], *G. Shariati*[2,3], *A. Saberi*[3], *M. Hamid*[4];
[1]*Department of Genetics, Shahid Chamran University, Ahvaz, Islamic Republic of Iran,* [2]*Narges Genetic & PND lab, Ahvaz, Islamic Republic of Iran,* [3]*Department of Genetics, Medical School of Ahvaz Jundishapur University, Ahvaz, Islamic Republic of Iran,* [4]*Department of Biotechnology, Pasteur Institue, Tehran, Islamic Republic of Iran.*

Bardet Biedl Syndrome (BBS) is a muli-organic disorder with variation in symptoms in affected individuals. Nevertheless, the main signs of the BBS disease are: vision less, Obesity, Polydactyly in hand and foot, intellectual disability, and abnormalities in the genitalia. To date, 14 genes are identified involving in the pathogenesis of the BBS. Mutations in these genes cause difficulties in the cell movement and other chemical signaling pathways.The BBS1, BBS2 and BBS10 count for more than 50% of all detected mutations in BBS affected individuals, worldwide. In contrast, the BBS12 gene mutation is causative for less than 1%. However, two BBS patients with above mentioned clinical symptoms referred to us for genetic counseling and molecular genetic testing. We screened firstly the BBS1, BBS2, and BBS10 genes for both individuals with negative results. But to our surprising, we found a novel nonsense mutation in the one and a novel missense mutation in the other affected individual within the BBS12 gene. In both cases, parents were heterozygous for detected changes. To validate the pathogenic consequence of the missense mutation, 65 healthy individuals were checked. Recently, a BBS patient has been reported from north Iran with a disease causing mutation in the BBS12 gene. We also suggest the BBS12 gene as a strong candidate for mutation hunting in the BBS affected individuals in the Middle East, at least in Iran.

Case report of patient with Charlie M syndrome - cytogenetic and molecular analysis

B. Dobric[1], *D. Radivojevic*[1], *T. Lalic*[1], *M. Miskovic*[1], *S. Cirkovic*[1], *S. Ostojic*[1], *M. Guc-Scekic*[1,2];
[1]*Mother and Child Health Care Institute of Serbia, Belgrade, Serbia,* [2]*Faculty of Biology, Belgrade, Serbia.*

Charlie M syndrome, oromandibular-limb hypogenesis syndrome, is a rare facio-neuro-skeletal disorder characterized by limb defects amputation-like, cleft palate, hypoplastic incisors, midfacehypoplasia, dysmorphic face and facial nerve paralysis. Authors in this paper present a case of a boy, age 6, who was referred for genetic consultation because of clinical appearance suggestive of Charlie M syndrome.
Cytogenetic analysis of the proband's peripheral blood using GTG banding showed unbalanced karyotype with derivate chromosome 4: 46,XY,add(4)(p15?). Molecular analysis using multiplex ligation-dependent probe amplification (MLPA) (commercial kit for microdeletion syndrome detection P096, MRC Holland) detected LOH for WHSC1 critical region in 4p16.3. Further karyotype analysis of both parents revealed that mother was a carrier of reciprocal translocation 46,XX,t(1;4)(q42;p15). Final conclusion was that patient had unbalanced rearrangement, 46,XY,der(4)t(1;4)(q42;p15) mat including derivative chromosome 4 with partial deletion of 4p15-4pter and partial trisomy of 1q42-1qter, which has resulted in fusion of genes on two different chromosomes.
In this work authors will discuss details of genetic analysis and possible combined effect of identified unbalanced chromosomal alterations on phenotype of the proband.

J11.13

A rare chromosomal rearrangement of 46,XX, der (7) in dysmorphic female with mental retardation

S. Seyedhassani[1], *H. Khodaee*[1,2], *M. Saffar*[3], *F. Saeb*[1];
[1]*Dr. Seyedhassani Genetic Center, Yazd, Islamic Republic of Iran,* [2]*National institute for genetic engineering and biotechnology, Tehran, Islamic Republic of Iran,* [3]*Shahid Sadughi university of medical science, Yazd, Islamic Republic of Iran.*

Chromosomal rearrangements are rare structural rearrangements with three or more breakpoints and exchange of genetic material between two or more chromosomes. The rearrangements may be balanced or unbalanced, and are classified into type I with three to four breaks and familial origin; and type II with five or more breaks, which generally arise de novo. Unbalanced chromosomal rearrangements may lead to significant clinical consequences such as multiple congenital anomalies, dysmorphic features, and mental subnormality in the progeny. Balanced chromosomal rearrangements are often not associated with any phenotypic abnormalities and may remain undetected in family members through multiple generations. Case presentation: The patient was a 5.5 years old girl referred to genetic center with delayed development. She was born from second cousin familial marriage by normal vaginal delivery, walked and spoken from 2 years old. Congenital right knee dislocation was treated. Delayed speech was limited in about 3 words and was suffering from speech apraxia. The signs were hypertelorism, strabismus, epicanthal fold, narrow palpebral fissure, sparse eyebrows, strabismus, decayed teeth, clinodactyly of fifth fingers, increased distance between toes 2 and 3, semisyndactyly of the toes 2 and 3, and shortened fourth and fifth metatarses. There were two mental retardation girls in common cousins of parents. Also, parents had three other pregnancy resulting two spontaneous abortions and one male neonatal death due to multiple congenital heart disease. Chromosomal study of proband on the basis of GTG-banding was revealed 46,XX, der(7), t(7;10)(p22; q24).

J11.14

Focus on chromosome 22 - Rare Chromosome Disorders

V. Plaiasu[1], *D. Ochiana*[1], *G. Motei*[1], *F. Brezan*[1], *I. Olteanu*[2], *I. Anca*[1];
[1]*IOMC Prof.dr.Alfred Rusescu, Bucharest, Romania,* [2]*Pediatric Emergency Hospital "Grigore Alexandrescu", Bucharest, Romania.*

Many genetic conditions are related to changes in particular genes on chromosome 22. We present three unrelated cases diagnosed in our Genetics Department with rare chromosomal abnormalities involving the structure of this chromosome.
Cat-eye syndrome is characterized by a recognizable clinical picture, although the variability of the physical features is enormous. A female infant, one month old, was referred with following major malformations: hypertelorism, narrow palpebral fissures, cleft palate, bilateral preauricular pits, bilateral coloboma of the iris, anal atresia with a fistula from the rectum to the vagina, complex heart malformation. Cytogenetic evaluation identified an additional marker and by FISH examination has been confirmed the involvement of chromosome 22.
Phelan-McDermid syndrome/22q13 Deletion Syndrome is a genetic syndrome caused by disruption of the SHANK3/ProSAP2 gene on the terminal end of chromosome 22. A newborn male with neonatal hypotonia, mild dysmorphic features and large, fleshy hands was suspected with chromosomal abnormality. G-banded chromosome analysis identified terminal deletion involving 22q13.3. Parental karyotypes were normal. FISH analysis confirmed deletion of SHANK3 gene.
Microdeletion 22q11.2 syndrome associated with XXY karyotype (Klinefelter syndrome). This double chromosomal abnormality is a rare finding in clinical practice. A case with DiGeorge phenotype was confirmed by conventional cytogenetic testing and FISH analysis, but the results revealed also XXY karyotype.
There is a great variability of clinical phenotypes in chromosomal disorders: some of clinical findings are distinct and others are very common. Clinical skills combined with standard and molecular technologies could offer a definite diagnosis and proper genetic counseling.

J11.15
Microstructural genomic imbalances in patients with congenital malformations

S. P. Hadjidekova[1], *D. Avdjieva-Tzavella*[2], *B. Rukova*[1], *D. Nesheva*[1], *R. Staneva*[1], *R. Tincheva*[1], *R. Tincheva*[2], *D. Toncheva*[1];
[1]*Department of Medical Genetics, Medical University-Sofia, Sofia, Bulgaria,* [2]*State University Pediatrics Hospital "Queen Evdokia", Section of Clinical Genetics, Medical Faculty, Medical University, Sofia, Bulgaria, Sofia, Bulgaria.*

In the current study 52 patients were selected for array CGH analysis after implementing stringent criteria (a combination of congenital malformations, dysmorphic features and behavioral disorders, and patients with multiple abnormalities and the presence of at least one major anomaly). A combination of methods was applied - cytogenetic analysis, FISH method, oligo DNA microarrays.
The results of analysis of microarrays revealed definite etiology in 9 out of 52 patients tested. Fifteen pathological aberrations were found in them. All pathological findings were validated by FISH analysis. Genotype/phenotypic correlations between different patients were confirmed. In addition, the majority of the patients tested (41 patients) showed 124 normal variations in the number of copies and 108 variations of unknown clinical significance (34 patients). Analyses of the type and distribution of the different variations was performed and the clinical significance of variants of unknown nature was discussed.
Our results show the advantages of high resolution microarrays for clinical diagnosis of patients with congenital malformations associated intellectual disability. The results also highlight the need for extensive population studies revealing the molecular nature and clinical significance of different CNVs and the creation of detailed maps of variations in the Bulgarian population. This would facilitate greatly the precise interpretation of specific genomic imbalances in clinical aspect and would ease the widespread introduction of microarrays in diagnostic practice not only for postnatal diagnosis of individuals with developmental delay and dysmorphism, but also for prenatal genetic diagnosis.

J11.16
Duplication on chromosome 17 and deletion on chromosome 20 in a patient with craniosynostosis

R. Pogue[1], *F. A. Marques*[1], *R. S. Heredia*[2], *J. F. Mazzeu*[3], *M. O. Cardoso*[1];
[1]*Universidade Católica de Brasília, Brasília, Brazil,* [2]*Secretaria de Saúde do Distrito Federal, Brasília, Brazil,* [3]*Universidade de Brasília, Brasília, Brazil.*

We present molecular cytogenetic analysis of a boy with syndromic craniosynostosis. He was born to healthy parents after an uncomplicated pregnancy. At birth he presented with saggital craniosynostosis and seizures. Further examination revealed complications including a cardiac malformation. At eight years and two months the patient showed neuropsychomotor and behavioral anomalies. G-banding showed an apparently normal male karyotype. A DNA sample was taken for chromosome microarray analysis (CMA) using the Affymetrix 750k CytoScan array. The results showed terminal alterations of chromosomes 17 and 20. Specifically, there was a duplication on the long arm of chromosome 17 (chr17:78,952,204-81-,060,886), together with a deletion of 1.4 Mb of long arm of chromosome 20 (chr20:61,643,144-63,003,805). The deletion on chromosome 17 includes more than 80 genes and miRNAs, while the deletion on chromosome 20 includes more than 50 genes and miRNAs. The data are indicative of an unbalanced translocation of part of chromosome 17 to chromosome 20. Partial trisomy of chromosome 17q has been previously reported in the literature, and the patient reported here shows phenotypic overlap with the previously reported spectrum, including psychomotor delay, craniofacial assymetry and other dysmorphisms. Previous reports also suggest that severity of the phenotype associated with 17q partial trisomy may be associated with partial monosomies of other chromosomes, and this also appears to be the case with the current patient.

J11.17
Atypical presentation of 17q21.31 microdeletion syndrome

H. M. Kathom;
Department of Clinical Genetics, University Pediatrics Hospital, Medical University Sofia, Sofia, Bulgaria.

The combination of developmental delay and dysmorphic features is frequently caused by different chromosomal imbalances. Many of these imbalances are result of submicroscopic deletions or duplications that are impossible to detect by conventional karyotyping. One of the best analysis which can be used in such cases is the array-based comparative genomic hybridization (array CGH) as it is a high-resolution approach for detection of DNA copy number variants (CNVs).
We report a 15-month-old boy with dysmorphic features, mild developmental delay, congenital glaucoma and partial coronal craniostenosis. We have used genomic array CytoChip Oligo (BlueGnome, Cambridge, UK), format 2x105K, version 1.1. and BlueFuse Multi software, version 2.2. The 2x105K array detects a loss of 231 Kb that overlaps 3 HGNC and 1 OMIM gene. OMIM disease: Chromosome 17q21.31 deletion syndrome (610443). The maximum overlap between an ISCA pathogenic region of type loss and this region is 30%. 56% of the region is covered by significant polymorphisms of type loss (DGV: 56%, ISCA: 0%). The CytoChip results were confirmed with MLPA. The influence of the known genes in the imbalanced regions and their correlation to the phenotype will be discussed. The above mentioned features do not correlate with the typical presentation of Koolen-De Vries syndrome as aspected from the aCGH results.

J11.18
5p13.3p13.2 duplication associated with severe intellectual disability, congenital malformations and chromosome instability manifested as aneuploidy

I. A. Demidova[1,2,3], *S. G. Vorsanova*[1,2,3], *Y. B. Yurov*[1,2,3], *I. Y. Iourov*[1,2,4];
[1]*National Research Center of Mental Health, RAMS, Moscow, Russian Federation,* [2]*Institute of Paediatrics and Paediatric Surgery, Ministry of Health, Moscow, Russian Federation,* [3]*Moscow City University of Psychology and Education, Moscow, Russian Federation,* [4]*Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation.*

Chromosome 5p13 duplication syndrome is usually attributed to increased copy number of NIPBL and FLJ13231 genes. Here, we report on a duplication producing phenotypic outcome similar to chromosome 5p13 duplication syndrome, spanning 5p13.3p13.2. Using SNP/oligonucleotide CGH, a duplication within 5p13.3p13.2 affecting a genomic locus of 994 kb spanning TARS, ADAMTS12, RXFP3, SLC45A2, AMACR and C1QTNF3 in a one-year-old boy presented with severe intellectual disability, developmental delay, corpus callosum hypoplasia, microcephaly, congenital cataract, congenital optic atrophy and large ears. It is noteworthy that the present case exhibits more severe phenotype than previously described in chromosome 5p13 duplication syndrome. Therefore, duplication of these disease-associated genes causes a more severe subtype of this duplication syndrome. Additionally, chromosome instability manifesting as aneuploidy has been observed in the index case. Bioinformatic pathway analysis has shown that chromosome insatiability is likely to result from alteration of aneuploidization and cell cycle regulation pathways through interaction of RXFP3 product with APP and PSEN1/2, alteration to which disrupts the mitotic spindle and directly inhibits mitotic microtubule motors. Furthermore, the duplication has the potential to cause chromosome instability through altered interactions between AMACR product and ubiquitins. Thus, high-resolution analysis of copy number variations in this case provided for efficient correlation between genotype and phenotype data, which can be used to elucidate pathogenic processes in a given patient. In addition, this case representing a severer variant of chromosome 5p13 duplication syndrome has also allowed defining previously unknown pathway to chromosome instability. Supported by the Russian Federation President Grant (MD-4401.2013.7).

A patient with partial 12q dublication and 10q deletion

H. Çoban[1], *Y. Soysal*[2,3], *K. Hekimler Öztürk*[3], *S. Kurtgöz*[3], *M. A. Ergün*[1];
[1]*Gazi University Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey,* [2]*Dokuz Eylül University, Department of Molecular Medicine, İzmir, Turkey,* [3]*Afyon Kocatepe University Faculty of Medicine, Department of Medical Genetics, Afyonkarahisar, Turkey.*

We report a female patient with facial dysmorphic features, prenatal and postnatal growth retardation and diarrhea. This patient was 18 months old and referred from pediatric service. She was born at 8 months, weighing 2000 g (<3 centile). Her mother and father were healty. On physical examination, her weight was 4500 g (<3 centile) her height was 64 cm (<3 centile) and her head circumference was 39 cm (<3centile). The dysmorphic features were frontal bossing, arched eyebrows, hyperrtelorism, and wide nose bridge. Secundum ASD and PDA were also detected with echocardiography. After cytogenetics analyses, partial 12q duplication (q24.11-q24.33) and partial 10q deletion (q26.3) were detected with array CGH. We observed that the patient features and array CGH results were compatible. As a result, array CGH can be used to define a better karyotype phenotype correlation in patients with unbalanced chromosome abnormalities.

J11.20
Identification of microdeletion 8q23.3q24.11 by MLPA in patient with multiple hereditary exostoses

L. Morozin Pohovski, *I. Barisic;*
Children's Hospital Zagreb, University of Zagreb Medical School, Zagreb, Croatia.

Multiple hereditary exostoses (EXT) is an autosomal dominant disorder characterized by multiple projections of bone capped by cartilage, most numerous in the metaphses of long bones, but also occuring on the diaphyses of long bones. EXT type I is caused by mutation in the gene encoding exostosin-1 (EXT1) which maps to chromosome 8q24. Here, we report on the second case microdeletion of 8q23.3q24.11. The patient is a 15-year and 6 month-old boy with dysmorphic features, dyslaly, multiple exostoses, delayed bone maturation and short stature. Dysmorphic features included expressed thick eyebrows, sinofris, large and prominent ears, protruding philtrum, microcephaly. Initial conventional karyotyping was normal. The MLPA (multiplex ligation-dependent probe amplification) screening with SALSA P245 kit showed deletion of EXT1 gene. The deletion was than confirmed by SALSA MLPA P228 indicating 1.46 Mb distal deletion in 8q23.3q24.11 region including EIF3H gene (exon 8) and EXT1 gene (exon 2-11). Because the parents were not available for study, we were not able to determine if this deletion was de novo or inhereted. There is only one case which included 1.46 Mb 8q23.3q24.11 deletion reported so far. This case highlights the importance of using MLPA technique for accurate characterization of rare chromosomal rearrangements in order to make possible genotype-phenotype correlations and to understand the genetic mechanisms involved. Finally, we recommend to perform MLPA in a patients with multiple hereditary exostoses phenotype in whom no mutation is identified in the EXT1 gene.

The clinical phenotype in a familial deletion 18p syndrome

G. M. Cozaru, *M. Aschie, A. F. Mitroi, I. Poinareanu;*
Constanța County Emergency Hospital, CONSTANTA, Romania.

Deletion 18p syndrome is characterized by dysmorphic features, growth deficiencies, and mental retardation with a poorer verbal performance. About 1 in 50,000 babies is born with a deletion of 18p. Most reports suggest that 18p deletions affect girls more often than boys. Until now, few families have been described with limited clinical description. Women with del(18p) are fertile and seem to have a normal miscarriage rate. We report transmission of deletion 18p from a mother to his son. The proband is 8 years old and has short stature, dysmorphic features, polymorphous dyslalia and moderate mental retardation. The mother also presents dysmorphic features, mild mental retardation and has better verbal abilities than his son. Our report presents a mother with del(18p) syndrome having two miscarriage and no analysis was performed on the fetus. Chromosome analysis from the proband and their mother revealed the same chromosomal deletion: 46, XX, del(18)(p11.2).
This report sheds new lights on the familial del(18p) syndrome. Cognitive performance may be more variable than previously suggested within the same family. Management needs to be handled by a multidisciplinary team and includes speech therapy, hormonal (if necessary) and psychological care. Patients have an essentially normal life expectancy but will need to attend regular medical visits. Genetic counselling for these patients should take into account these new data, especially in regard of a wider variability of intellectual outcomes and better verbal performance.

Tetrasomy 18p is a very rare chromosomal disorder which affects males and females equally. The small extra metacentric marker chromosome results from a spontaneous mutation early in embryonic development in most of the cases. Here we report a de novo supernumerary i(18p) in a 8 months old female dysmorphic child. The case was delivered by Cesarean section at the 38th weeks of gestation with anthropometric parameters <-2 sd. Other significant features of the case were growth retardation, neonatal feeding problems, microcephaly, seizures, hearing loss, strabismus, refractive errors, high arched palate, and constipation. An additional metacentric marker chromosome was revealed by conventional cytogenetic analysis. The chromosome constitutions of the parents were normal. Based on physical features of the case, FISH analysis specific to chromosome 18 were performed and tetrasomy 18p was diagnosed. The clinics of the patient was compared with the previously published cases.

J11.23
Clinical and genetic examination of syndromic limb defects

D. Căpățînă, *G. C. Cozaru, A. F. Mitroi, M. Aşchie;*
Constanța County Emergency Hospital, CONSTANTA, Romania.

Limb developmental defects are known to be rare conditions that occur in about 10 / 10 000 live births, but their significance cannot be negligible. Our aim was to work out a genetic examination protocol that can help to find the most effective way to reveal the background of limb developmental defects. Following detailed clinical inspection, genetic examinations were performed in selected cases. Firstly, we usually indicated chromosomal analysis that was followed by FISH in negative cases and in the other cases specific we performed molecular diagnosis. In this paper we would like to feature some of our cases - with compound syndrome including limb developmental defects - where genetic examinations were available: 4q deletion syndrome, Holt-Oram syndrome, CHARGE syndrome, Down syndrome.
Dysmorphic features, connected symptoms may help to find exact diagnosis in compound syndromes and give chance for genetic examinations in chromosomal or monogenic syndromes. Interdisciplinary collaboration is recommended for proper diagnosis, genetic counseling and understanding of the pathogenesis. Despite the latest techniques, genetic background of limb development and its defects still belongs to an unrevealed part of science.

J11.24
A de novo marker chromosome derived from 15q in a patient with growth retardation: genotype-phenotype correlation

S. Kurtgöz[1], *K. Hekimler Öztürk*[1], *Y. Soysal*[2,1], *K. Yararbaş*[3];
[1]*Afyon Kocatepe University, Faculty of Medicine, Department of Medical Genetics, Afyon, Turkey,* [2]*Dokuz Eylül University, Department of Molecular Medicine, İzmir, Turkey,* [3]*Duzen Laboratories Group, İstanbul, Turkey.*

We report a female patient with growth retardation who was referred to our clinic from pediatric service. She was the first child of 41 year old mother and was born at 31 weeks with 1640 gr birth weight. Her mother and father was healthy and have normal karyotypes. On physical examination, shorth neck, shorth philtrum, high arched palate, hypertelorism, simple ear, sacral diple, macrocephaly and hypothenia were detected. Cardiological evaluation was normal. In the cytogenetic analysis 47,XX,+mar was detected. We performed chromosomal microarray using an Affymetrix 750K SNP array platform. The application of array offered a precise characterization of the marker chromosome plus additional findings. The most significant finding confirming the conventional analysis was a 10,145 kbp duplication on chromosomal location15q11.2-13.3. Additional unconfirmed findings above the cut off values involvingthe sites containing OMIM genes were: A 837 kbp gain within 4p15.32, and a 1066 kbp loss on the X chromosome's short arm, p22.33. We observed that the patient features and array CGH results were compatible. As a result, array CGH can be used to define a better karyotype phenotype correlation in patients with dysmorphic featues which can not be expained by known syndromes.

J11.25
Recurrent pregnancy loss and familial marker chromosome: case report

K. Hekimler Öztürk[1], *Y. Soysal*[2,1], *S. Kurtgöz*[1], *K. Avcı*[1];
[1]*Afyon Kocatepe University, Faculty of Medicine, Department of Medical Genetics, Afyon, Turkey,* [2]*Dokuz Eylül University, Department of Molecular Medicine, İzmir, Turkey.*

19-year-old female patient with recurrent pregnancy loss referred to Department of Medical Genetics from Department Obstetric and Gynecology of Afyon Kocatepe University. Her physical evaluation was normal. Biochemical and hormon test results were normal. They had second cousin marriage. There was an ectopic pregnancy and a 10 week intrauterine dead history in their 6 years marriage. The karyotype of the abort fetus was 46,XY. The family history was not specific, but postnatal exitus was reported in two of her sisters. The karyotype of the propand was detected as 47,XX+mar[108]. The marker chromosome was regular and had same structure in every metaphase plate. Centromere was not detected by C-banding. Physical examination of the Proband's husband was normal and his karyotype was 46,XY. The mother of the proband had 46,XX[71]/47,XX,+mar[29] karyotype and father had 46,XY karyotype. The proband has 7 sisters and two of them had regularly the same marker chromosome in their karyotype, the rest had normal karyotype. Sisters who had marker chromosome have postnatal exitus history in their pregnancies. Fluorescence in situ hybridization-FISH report is expected in order to detect the origin of extra chromosomal structure. In our case report, we aimed to evaluate the effect of marker chromosome in recurrent pregnancy loss ethiology.

In this study we present data on the temporal bone computed tomography of rare case of inner ear malformation - Michel aplasia in patient with congenital bilateral sensorineural deafness from Russia (Sakha Republic, Yakutia, Eastern Siberia). The CT-images (1 mm) of temporal bone has been performed. This case of Michel aplasia was characterized by symmetrical agenesia of the cochlea and semicircular canals, bilateral abnormality of the facial nerve canal, and abnormality of the internal auditory canal on both sides. Results of this study confirm high diagnostic importance of the temporal bone computed tomography for detailed characterization of developmental abnormalities of inner ear.

Study was supported by RFBR (#12-04-00342_a, #12-04-98520_r_vostok_a, #12-04-97004_r_povolzhye_a, #14-04-01741_A), SB RAS Integration project #92 «Ethnogeny of indigenous peoples in Siberia and North Asia: comparative, historical, ethno-social and genomic analysis», the Sakha Republic President grant for Young Researchers for 2014 (RP#80), RAS Program «Fundamental Sciences for Medicine» (#30 for 2013-2015), and «Scientific and Educational Foundation for Young Scientists of Republic of Sakha».

Interstitial del(3)(p26.3p26.1) in a patient with deletion 3p syndrome

M. Martins, *M. Souto, P. Botelho, O. Moutinho, R. Pinto Leite;*
Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal.

Partial deletion of chromosome 3p is a rare disorder with variable chromosomal breakpoints and consequently phenotypes. Although most of these deletions involve the 3p terminus, interstitial deletions may also give rise to features of the syndrome.

We report the case of male patient with mental retardation and minor dysmorphic features and a 7.4 Mb deletion of 3p26.3p26.1 [arr 3p26.3p26.1 (61,891 7,527,372) ×1], encompassing the genes CHL1, CNTN6, CNTN4, CNTN4-AS2; IL5RA, TRNT1, CRBN, LRRN1, SETMAR, SUMF1, ITPR1, EGOT, LOC100507582, BHLHE40, ARL8B, EDEM1, MIR4790 AND GRM7. We compare the clinical phenotype of this patient to previously reported cases of 3p syndrome.

Microarray technologies are increasingly becoming the tool of choice to accurately determine the underlying genetic cause and resulting phenotype in patients with mental retardation and multiple anomalies. aCGH allows to precisely determine the length and breakpoints in order to better understand a child's future development and needs.

In the present case molecular karyotyping has characterized a 3p deleted region with haploinsufficiency of neurodevelopmental genes associated with cognitive deficit and mental retardation, which may help to identify genes important to growth and development that contribute to the deletion 3p syndrome phenotype and aid in better understanding the molecular basis of the 3q syndrome.

J11.28
16p13.11 microduplication: a case report

B. Marques[1], *C. Ferreira[1], C. Ventura[1], S. Pedro[1], D. Antunes[2], L. Nunes[2], H. Correia[1];*
[1]Unidade de Citogenética, Departamento de Genética Humana, Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisboa, Portugal, [2]Serviço de Genética Médica, Hospital D. Estefânia, Centro Hospitalar de Lisboa Central, EPE, Lisboa, Portugal.

The short arm of chromosome 16 is very rich in segmental duplications, predisposing this region of the genome to a number of recurrent rearrangements, namely deletions and duplications. Although it is already known that there is a strong association between 16p13.11 deletion and neuropsychiatric disorders, the clinical significance of its reciprocal duplication is not clearly defined yet. 16p13.11 microduplication that results of non-allelic homologous recombination is a very rare genetic alteration which can be associated with variable clinical features including behavioural abnormalities, developmental delay, congenital heart defects and skeletal anomalies. We report a 7-years-old boy with global developmental delay, speech absence, microcephaly, dysmorphic facial features and inexpressive *facies*. Microarray analysis revealed a 3.3Mb duplication comprising the 16p13.11-p12.3 region, which was confirmed by fluorescence *in situ* hybridization with a BAC clone for 16p13.11. Eight annotated genes are present in this region including *NDE1*, the candidate gene for neurological and behavioural phenotype. Although this microduplication has been found in the normal population, is significantly enriched in patients with autism, schizophrenia and cognitive impairment. Several case reports until now suggest that this genomic abnormality has incomplete penetrance and variable expressivity and can constitute a new syndrome. With this case we intend to contribute to expand the spectrum of clinical findings associated to this genomic abnormality and provide further knowledge of the pathogenic involvement of this duplication.

J11.29
Immun deficiency in monosomy 18p

M. Alikaşifoğlu, *P. Zengin Akkuş, A. Çetinkaya, D. Çağdaş Ayvaz, G. E. Utine, K. Boduroğlu;*
Hacettepe University Faculty of Medicine, Ankara, Turkey.

Immune deficiency may be a rare feature in chromosomal disorders. A 31-year-old man with immunodeficiency, intellectual disability and facial anomalies was admitted to the genetics department. The patient was born to nonconsanguineous parents. He had congenital hypothyroidism and intellectual disability. During childhood, he had recurrent oral aphthous lesions, ear infections and pneumonia. Investigations revealed IgA, IgG and IgM deficiencies with a normal lymphocyte count. Magnetic resonance imaging of brain showed hyperintense lesions in peripheral white matter. On physical examination, he had short stature, and dysmorphic facial characteristics including flat nasal bridge, low-set ears, epicanthic folds, and short philtrum. Facial dysmorphic features, intellectual disability and immunodeficiency may suggest some dysmorphic syndromes including 22q11.2 deletion, ICF and others. Karyotype analysis revealed a partial chromosome 18p deletion: 46,XY,del(18)(p11.1).

Chromosome 18p partial deletion is one of the most common deletion syndromes. The estimated frequency is 1 in 50,000 live-born infants. The cause of this disorder is deletion of short arm of chromosome 18 or sometimes deficiency in a ring 18 chromosome. IgA deficiency, central nervous system abnormalities such as holoprosencephaly, and mild to severe intellectual disability usually accompany.

J11.30
A report of partial monosomy of distal 5p and partial trisomy of distal 19q in a family with Charcot-Marie-Tooth disease

O. Liaugaudiene, *A. Utkus, Z. Ciuladaite, E. Preiksaitiene;*
Vilnius University Santariskiu Klinikos, Centre for Medical Genetics, Vilnius, Lithuania.

We present two sisters with mild developmental delay/ intellectual disability and additional clinical features. The younger girl, 21 months of age, had hypotonia, short stature, microcephaly, hip dysplasia, delayed teeth eruption, bilateral epicanthus, wide nasal bridge, short philtrum, short neck, clinodactyly of fifth finger, low serum calcium and parathormone. Clinical features in her sister, 11 years of age, were similar, but in contrast, she had macrocephaly, and additional skeletal anomalies: kyphosis, pectus carinatum, contractures of elbows and knees, right clubfoot. Positive family history of Charcot-Marie-Tooth disease was revealed (patient`s mother had duplication of CMT1A region, patient`s grandfather had clinical symptoms of CMT). Testing for PMP22 duplication was performed, and it was positive for the older sister. Karyotype of both sibs established by GTG banding was 46,XX, der(5)t(5;19)(p15.3;q13.2). Subsequent chromosome analysis in parents revealed maternal balanced translocation t(5;19)(p15.3;q13.2), which was later confirmed by FISH. The same translocation was detected in grandmother.

Both del5p and dup19q are described in literature as pathogenic imbalances. 5p terminal deletion causes cri-du-chat syndrome (mewing cry, microcephaly, epicanthus, depressed nasal bridge, fifth finger clinodactyly, hypotonia). 19q13.2àqter duplication is associated with wide range of congenital anomalies and dysmorphic facial features, including growth retardation, microcephaly, heart defects, hypoplasia of the gallbladder, renal anomalies, hypertelorism/flat nasal bridge, dysplastic ears, downturned mouth corners, clinodactyly. Synthesis of del5p15.3 and dup19q13.2 symptoms determines the clinical phenotype of our patients. Additional skeletal malformations in older sister are caused by CMT. This report provides clinical characterization of previously unreported chromosomal rearrangement.

J11.31

Clinical characterization of a patient with mosaic microdeletion 7q36.1-qter

N. Kapitanova[1], *Ž. Čiuladaitė*[1,2], *B. Burnyte*[1,2], *A. Utkus*[1,2];
[1]*Vilnius University Hospital Santariskiu Klinikos, Centre for Medical Genetics, Vilnius, Lithuania,* [2]*Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.*

Individuals with 7q36.1-qter microdeletion may have a wide range of clinical manifestations including developmental delay, craniofacial abnormalities (agenesis/hypoplasia of corpus callosum, microphthalmia, choanal atresia/stenosis), skeletal anomalies (absent sacrum), heart defects (atrial septum defect, patent ductus arteriosus, pulmonary segmentation defects), obesity, urogenital system anomalies (ectopic/supernumerary kidneys, hydronephrosis, micropenis), seizures and behavioral changes. We present the clinical features of a 3-year-old boy with mosaic7q36.1-qter microdeletion. Our patient presented with unspecified developmental delay and cognitive impairment with speech delay. Mild facial dysmorphism was noticed, such as upslanted palpebral fissures, prominent nasal bridge and narrow palate. Another phenotypic finding was tapered fingers. Additional features included unilateral cryptorchidism, low testicular volume and childhood obesity. He had numerous motor mannerisms including body rocking, facial posturing, self-touching. Cytogenetic and molecular cytogenetic FISH analysis revealed a mosaic male karyotype with a terminal deletion of the long arm of chromosome 7 in 90% analyzed blood cells. The karyotype is described as 46,XY,del(7)(q36.1q36.3)/46,XY. Both parents have normal karyotypes. No family history of congenital anomalies or mental retardation was referred. Our findings, therefore, suggest that the phenotypic consequences are very variable. We came to a conclusion, that a post zygotic terminal deletion occurred in this boy, after performing FISH analysis, which is a powerful tool in low quantity mosaic cell line detection. Further investigation by array-CGH is needed to identify chromosomal breakpoints and the exact deleted region.

J11.32

Mowat-Wilson phenotype in two patients with normal ZEB2 gene study: an example of somatic mosaicism?

M. Mariani, *C. Fossati, L. R. Bettini, S. Maitz, A. Selicorni;*
UOS Genetica Clinica Pediatrica Clinica Pediatrica, Fondazione MBBM, A.O. S.Gerardo, Monza, Italy.

Mowat-Wilson syndrome (MWS) is a multiple congenital anomaly syndrome characterized by typical facial dysmorphism, moderate to severe intellectual disabilities, epilepsy and variable congenital malformations. MWS is caused by eterozygous mutations or deletions in the Zinc finger E-box-binding 2 gene, ZEB2: sequence analysis detects mutations in approximately 81% of individuals; FISH detects large deletions encompassing all or part of ZEB2 in approximately 15% of persons; chromosomal rearrangements that disrupt ZEB2 cause MWS in approximately 2% of individuals; an additional 2% have intermediate-sized deletions that can be detected by techniques such as quantitative PCR, MLPA, or gene-specific array-CGH. We describe two patients with a clinical diagnosis of MWS not confirmed by genetic tests. The first patient is a 5 years old female with typical facial dysmorphisms, aganglionic megacolon, hypoplasia of the corpus callosum, growth retardation with microcephaly, psychomotor retardation with speech delay and epilepsy. Sequence analysis and FISH study of ZEB2 gene detected no alterations; arrayCGH was normal too. The second patient is a 4 years old female with typical facial features, pulmonary stenosis and bicuspid aortic valve, partial agenesia of the corpus callosum, ambiguous genitalia with scrotal labia, growth retardation with microcephaly, psychomotor retardation with speech delay, epilepsy, chronic constipation, RGE and dyschromic cutaneous areas. Sequence analysis of ZEB2 gene and arrayCGH did not find any alteration.
The two patients could be a first example of somatic mosaicism for ZEB2 gene anomaly. Study are in progress in order to demonstrate this hypothesis.

J11.33

Multiple pterygium syndrome: a case report

G. Erkoca Goktolga, *H. Kucuk Kurtulgan, M. E. Yildirim, N. Akkus;*
Cumhuriyet University Medical Genetics, Sivas, Turkey.

Multiple pterygium syndromes include a group of multiple congenital anomaly disorders characterized by webbing (pterygia) of the neck, elbows or knees and joint contractures . Males had small penis and scrotum or cryptorchidism; females had aplasia of the labia majora and small clitoris. This syndrome included fusion of cervical vertebrae, scoliosis, flexion contraction of fingers, and rocker-bottom feet with vertical talus and facial dysmorphism with long face, high-arched palate, small mouth, and retrognathism. The multiple pterygium syndrome is phenotypically and genetically heterogeneous. It is also called as Pterygium Colli syndrome, Escobar syndrome or Pterygium syndrome. Multiple pterygium syndrome is a rare syndrome. This condition may behave sometimes as a dominant, but there clearly appears to be a recessive pterygium syndrome. İn this case, described a 9 year old female patient with pterygia of the neck, axilla and popliteal, flexion contraction of fingers, camptodactyly and rocker-bottom feet, short neck, kyphoscoliosis, downslanting palpepral fissüres, low-set ears, high-arched palate, low-set hairline, aplasia of the labia majora. To provide molecular verification of Multiple pterygium syndrome, direct sequencing of CHRNG gene is planned.

J11.34

Novel mutation in exon 13 of the TCOF1 gene in the patient with Treacher-Collins syndrome

B. A. Marszalek-Kruk[1], *R. Smigiel*[2], *M. M. Sasiadek*[3];
[1]*Department of Genetics, Wroclaw University of Environmental and Life Sciences, Wroclaw, Poland,* [2]*Department of Pediatrics and Rare Disorders, Wroclaw Medical University, Wroclaw, Poland,* [3]*Department of Genetics, Wroclaw Medical University, Wroclaw, Poland.*

Treacher-Collins Syndrome (TCS) is a rare craniofacial disorder, associated with an abnormal differentiation of the first and the second pharyngeal arches during fetal development. The major features of the disease include: midface hypoplasia, micrognathia, microtia, conductive hearing loss and cleft palate. The estimated incidence is 1/50000 live births, with 60% of the cases resulting from *de novo* mutations. The syndrome is mostly caused by mutations in the *TCOF1* gene, which encodes the serine/alanine-rich protein named Treacle. TCS can be also caused by mutations in the *POLR1C* and *POLR1D* genes. Over a hundred mutations of the *TCOF1* gene in TCS patients have been described. About 70% of recognized mutations are deletions, which lead to a frame shift, formation of a termination codon and shortening of the protein.
We report a novel mutation of *TCOF1* gene in male patient with typical facial symptoms of TCS. Patient presented: prominent forehead, absent of auricular canals, third degree microtia, conductive deafness, sparse eyebrows, cleft of right eyelid, palpebral fissures slant down, broad base to nose, underdevelopment of zygomatic region, malar flattening, micro- and retrognathia. No internal defects were diagnosed.
A multitemperature single-stranded conformation polymorphism (MSSCP) analysis and direct sequencing were performed. A novel, heterozygous deletion c.1978delC was detected. Patient's parents were tested and no mutation was observed. The c.1978delC deletion causes a reading-frame shift and premature termination of translation at 677aa. We believe, that these findings will facilitate a precise diagnosis of the patient and extend our knowledge on the pathogenesis of TCS.

J11.35

Novel PTPN11 gene mutation in Iranian patient with Noonan syndrome

A. Tafazoli[1,2], *P. Eshraghi*[3], *R. Vakili*[3], *M. Nasiri Aghdam*[1,2], *M. R. Abbaszadegan*[2,1];
[1]*Medical Genetics Research Center, Department of Medical Genetics, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran,* [2]*Division of Human Genetics, Immunology Research Center, Avicenna Research Institute, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran,* [3]*Department of Pediatrics, Imam Reza Hospital, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran.*

Introduction Noonan Syndrome (NS) is an autosomal dominant, variably expressed, multisystem disorder with an estimated prevalence of 1 in 1000-2500. After trisomy 21, NS is the second most common syndromic cause of congenital heart disease. In recent years study on the molecular mechanisms of this disorder have been improved and expressed some pathophysiological mechanisms that cause the complications up to this abnormality such as the great range of medical and developmental features. **Methods** Genomic DNA samples were extracted from peripheral whole blood of 25 NS patients using the standard procedure. For each patient, exons 1-15 of the PTPN11 gene individually amplify by polymerase chain reaction (PCR) using 15 sets of designed primers. The amplified fragments of PTPN11 gene were purified and directly sequenced. **Result** Three known PTPN11 mutation hotspots (exons 3, 8, 13) were checked first, and a previously identified mutation (Asn308Asp) was found in only two patients. We also found a novel non-synonymous substitution (Asp155Asn) in exon 4 of an eight years old patient. **Conclusion** This study is the first report of PTPN11 mutations in Iranian patients with NS. A non-synonymous mutation was found in exon 4 that is novel in NS but has registered before as somatic mutation in cancer patients with large intestine tumor. The affected probands who are negative for PTPN11 mutations will be screened for other 10 genes mutations involved in NS using next-generation sequencing.

Oromandibular-limb Hypogenesis Syndrome Type IIIC? A case in Russia

S. A. Kurbatov, *N. A. Gretsova, F. A. Filiptsov;*
Medical Centre „Diagnostika-plus", Voronezh, Russian Federation.

Oromandibular limb hypogenesis sindromes (OLHS, OMIM %103300) are extremely rare hereditary syndromes with overlap of phenotypes, most of them occur sporadically. OLHS constitutes combinations of congenital malformations of mandible, tongue, upper and lower limbs and normal mental development. The pathogenesis of OLHS is still unknown, however, it is considered to have several possible causes: heat-induced vascular disruption; teratogenic etiology and genetic origin of these syndromes. According to Hall's classification OLHS is divided into five categories; with the only necessary criteria for inclusion - hypoglossia. However, in some cases, there is a considerable overlap of symptoms, making it difficult to define the phenotypic boundaries between OLHS. We report the case of a 3-year-old girl. She is the second child of healthy, nonconsanguineous parents, born after an uneventful pregnancy, by normal delivery. She was born in 39gw with low birth weight(1700g) and length(46cm). She has a sister, who is normal. There is no family history of congenital abnormalities. Currently she has low weight(9kg), height(80cm) and microcephaly(44cm). She has a mental retardation and absence of speech. Her face has signs of hypoglossia, ankyloglossia, cleft palate, malocclusion with normal teeth, epicanthal folds, low-set and rotated ears. She also has oligodactyly hands and feet. Chromosomal study of peripheral blood lymphocytes confirmed the 46,XX karyotype. By Hall's classification our case conforms to OLHS type IIIC: Glossopalatine ankylosis with hypoglossia - hypodactilia. However, as we know, combination OLHS type IIIC with mental retardation, microcephaly, low weight and height has not been described before.

J11.37

A case with frontonasal dysplasia and 2q36.1q31.2 deletion

K. Najafi[1,2], *G. Abbassi*[1], *N. Sadatian*[1], *A. Moshtagh*[1], *K. Najafi*[1], *A. Kariminejad*[1], *R. Kariminejad*[1];
[1]*Kariminejad Najmabadi Pathology and Genetics Center, Shahrak Gharb, Tehran, Islamic Republic of Iran,* [2]*Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.*

A 7 years old girl was referred to our genetics lab. The first and only child of non- consanguinuous parents, she was delivered at 9 months by C-section. Her birth weight was 2690 grams. She was diagnosed with renal stones at 6 months. She had bilateral deafness and underwent surgery. At examination she had normal intelligence and development. Her facial features include epicanthal folds, hypertelorism, blue eyes, arched eyebrows, high nasal bridge and short philtrum. She had bilateral simian crease, camptodactyly of fourth finger of right hand and syndactyly of second and third toes.
Her karyotype was normal. Whole genome Oligo Array Comparative Genomic Hybridization was performed using CYTOCHIP ISCA 4X44K whole genome oligo array version 1.1 and was analysed using BlueFuse Multi software. A 3.09 Mb deletion of 2q36.1q36.2 was detected.
The deletion spans nucleotides 222 Mb to 225.1 Mb covering 10 OMIM genes and 13 refseq genes. We compare phenotypic and genotypic findings of other overlapping cases. The deleted region in our patient includes the EPHA4 and PAX3 genes that have been formerly implicated in frontonasal dysplasia.

J11.38

Six patients from four unrelated Tunisian families with Peters plus syndrome harboring the same splice site mutation in the B3GALTL gene

N. Belguith[1,2], *O. Siala*[2], *A. Ben Mahmoud*[2], *N. Gharbi*[1], *I. Chabchoub*[3], *N. Hmida*[4], *F. Fakhfakh*[2], *H. Kamoun*[1,2];
[1]*Service de génétique CHU Hedi chaker, Sfax, Tunisia,* [2]*Laboratoire de Génétique Moléculaire Humaine Faculté de Médecine, Sfax, Tunisia,* [3]*Service de pediatrie CHU Hedi chaker, Sfax, Tunisia,* [4]*Service de néonatologie CHU Hedi chaker, Sfax, Tunisia.*

Peters plus syndrome is an autosomal recessive rare disorder Peters' plus syndrome is an infrequently described entity that combines anomalies in the anterior chamber of the eye with short stature, distinctive facial features often associated with other major/minor additional defects and a developmental delay. Peters plus syndrome is related to mutations in the B3GALTL gene, localized on chromosome 13 (q12.3q13.1), leading to the inactivation of the B1-3glucosyltransferase.
In this study, we screened the B3GALTL gene in six patients, from four unrelated families, with typical Peters plus syndrome. We reveled inter and intra familial phenotype variation. However the novel homozygous c.597-2-A>G mutation was identified in all patients suggesting an effect founder of this mutation. Functional study using an ex-vivo approach showed that this mutation causes complete skipping of exon 8 in the B3GALTL cDNA, which altered the open reading frame of the mutant transcript and generated a PTC within exon 9. This finding potentially elicits the nonsense mRNA to degradation by NMD.
All these data confirm an important role of the B3GALTL gene test that provides diagnosis confirmation and improves genetic counseling for the families.

J11.39

PITT-HOPKINS Syndrome: A new case of intragenic deletion detected by array-CGH

B. Buldrini, S. Bigoni, E. Italyankina, R. Gruppioni, A. Bonfatti, V. Aiello, **S. Fini***, A. Ferlini; U.O. Medical Genetics, University Hospital „Sant'Anna", Ferrara, Italy.*

Pitt-Hopkins syndrome is a rare syndromic mental disorder, mainly characterized by severe intellectual disability with stereotypic movements, typical facial gestalt (deep-set eyes, broad beaked nose, wide mouth with bow-shaped upper lip and widely spaced teeth), childhood-onset hyperventilation and seizures.While PTHS appears to be a recognizable clinical entity,it seems to remain underdiagnosed principally when characteristic dysmorphic features are less typical due to similarities with other known genetic syndromes (Rett, Angelman).PTHS is an autosomal dominant condition caused by haploinsufficiency of the TCF4 gene on 18q21.2. The molecular abnormalities identified in more than 100 patients include 40% of point mutations, 30% small deletion or insertion and 30% of partial or total gene deletions. We report on a 25-year old boy with severe intellectual disability,absent language, ataxic gait, anxiety and agitation, dysmorphic features and smiling appearance.Due to the lack of the hyperventilation and the presence of atypical dysmorphisms, we decided to start genetic investigations by array-CGH (Bluegnome LTD, 44K-feature whole genome). The result was a loss of 103Kb on 18q21.2 spanning from 53,045,402 bp to 53,149,037 bp (hg19) within the TCF4 gene. This gene has 20 exons (the first and the last non coding), with several isoforms reported. Our deletion includes exons 4-6(NM_001083962) and is predicted to result in a frameshift. At our knowledge, this is the second one described in literature involving these 3 exons. Reporting our case we want to contribute to the phenotype-genotype correlation in Pitt-Hopkins syndrome, mainly in those cases with a small intragenic deletion and a less typical phenotype.

J11.40

Genotype-phenotype correlation with ring chromosome 11

L. Martelli[1], *A. G. Gomes*[1], *C. H. P. Grangeiro*[1], *C. S. Pereira*[1], *L. R. Silva*[2], *R. M. Scarparo*[1], *J. A. Squire*[1];
[1]*University of Sao Paulo, Ribeirao Preto, Brazil,* [2]*Uberlandia Federal University, Uberlândia, Brazil.*

Ring chromosomes usually result from distal breakage of both chromosomal arms and carriers often exhibit a general overlap in phenotype. Jacobsen syndrome (JBS) is a rare contiguous gene disorder caused by terminal 11q deletion, characterized by intellectual disability, various physical anomalies and a distinctive facies. In this study we report a 12 yo boy with a ring chromosome presenting with global developmental delay, characterized by hyperactivity and repetitive behavior, hypertension, obesity, dyslipidemia and food compulsion. Clinical findings include short stature, microcephaly, bitemporal narrowing and occipital flattening, short nose with long filter, small carp mouth, low-set ears, short neck and systolic murmur. Cytogenetic analysis by GTG banding revealed karyotype 45,XY,-11[18]/46,XY,dicr(11;11)[4]/46,XY,r(11)[78]. Array-CGH using 2X400kb platform (Agilent) showed a large 8.6Mb terminal deletion: 11q24.2q25(126,368,150-135,006,516)x1, which includes 40 genes. There was no deletion in the 11p region suggesting that the ring was formed by fusion at 11q24.2 with 11ptel region. This interpretation was validated by FISH using 11q25, 11ptel and 11qtel probes. Our genotypic results could explain the short stature, compulsive behavior and ADHD, as well the early-onset hypertension (associated with KCNJ5 gene) compatible with JBS. However, his phenotype does not include thrombocytopenia (related to FLI-1, ETS-1 and NFRK3 genes) or kidney abnormalities (KCNJ1 and ADAMTS15 genes). We suggest that some characteristics described in JBS cannot be explained by monosomy of single genes, but rather the combination of contiguous genes, or gene-gene interactions.

J11.41

Partial SHOX duplication in a daughter and her father associated with short stature.

V. Curtisova[1], *M. Trková*[2], *P. Čapková*[1];
[1]*Department of Human Genetics and Fetal Medicine, Fakultní nemocnice Olomouc, Olomouc, Czech Republic,* [2]*Gennet, Praha, Czech Republic.*

We report a case of a familial partial duplication of the SHOX gen detected in a 14 year old girl and her father. The girl was referred to us for short stature and development delay. She has a Dandy Walker abnormality of the brain and

no other congenital malformations. She was born at term, her developmental milestones were delayed, she has borderline mental retardation and attends special school. Her height is 152.5 cm (3rd percentile), weight 70.3 kg (97th percentile) and head circumference 51.5 cm (3rd percentile). She has mild dysmorphic features. Karyotype is 46,XX. SNP a CGH (HumanCytoSNP-12-v2.1 Illumina) detected 190,9 kb duplication of Xp22.33 (422.642-613.567) encompassing most of the SHOX gene. The finding was confirmed by MLPA (MRC, Holland, Human Telomere -5, kits P036 - E1; P070 - B2; P245-B1; P106-B1 MRX), which detected a duplication in the SHOX gene region. The same duplication was revealed by MLPA in her father, who measures 170 cm (10th centile) and has no congenital malformations. Isolated duplications of SHOX gene are rare and their effect on height is not clear. Seventeen patients with full and sixteen with partial duplication of the SHOX gene were reported in the literature. Some were ascertained through studies of particular conditions associated with short stature (idiopatic short stature, Léri-Weill dyschondrosteosis), in those who were not, the stature varied from normal to tall. The effect of SHOX gene duplication on stature is still not clear.

J11.42
Somatic mosaicism in patients with r(18) and congenital heart disorder

N. Yani, *T. Nikulina, A. Zlotina, E. Grekhov, M. Gordeev, A. Kostareva;*
Federal Almazov Medical Research Centre, St. Petersburg, Russian Federation.

Syndrome r(18) - ring 18 chromosome cytogenetically is characterized by a complete or mosaic forms a ring chromosome 18 with the absence of the distal portions of the long and short arm of the chromosome. The clinical picture includes multiple dysmorphia, combined with varying degrees of mental retardation. Committal involvement of cardiovascular system and congenital heart defects typically are not described in cases of r(18).
We observed 18-year-old patient with mental retardation, multiple facial dysmorphia, and subaortic stenosis. During standard karyotyping by PHA-stimulated lymphocytes patient revealed 46, XY, r(18) karyotype. Since congenital heart defects are not common feature of r(18) we hypothesized mosaic chromosomal aberrations and performed additional FISH analysis on blood smears using Aneu Vision (CEP 18) and To Tell Mix 11, Mix 12 probes.
The study revealed three signals of chromosome 18 centromere and subtelomeric deletion of chromosome 18 in 15% of the cells, contained two signals from the centromere of chromosome 18 with subtelomeric deletion to form a ring in 80% of cells, 5% of the uncultured cells in blood smear contained two signals from the centromere of chromosome 18 without subtelomeric deletion.
In conclusion we describe clinical case of somatic mosaicism in patients with r(18) in combination with 18 trisomy in 15% of blood cells, leading to combined phenotype of mental retardation and congenital heart defect.

J11.43
Molecular study of the gene TCOF1 in the syndrome of Treacher Collins : about 7 cases

H. Safraou[1], *i. ouertani*[1], *A. Tajouri*[2], *M. Kharrat*[2], *F. Maazoul*[1], *R. Mrad*[1], *H. Chaabouni*[1,3];
[1]*department of congenital and hereditary disorders, tunis, Tunisia,* [2]*Laboratory of human genetics, faculty of medecine of Tunis, tunis, Tunisia,* [3]*Laboratory of human genetics, faculty of medecine of Tunis, Tunis, Tunisia.*

Treacher Collins Syndrome (TCS) is a rare clinical entity which associates essentially craniofacial dysmorphism and deafness. Symptoms can sometimes be severe being life-threatening when choanal atresia exists. Our objective is to look for the TCOF1 (5q32-q33.1) mutations most frequently reported in the literature in Tunisian patients affected by TCS. We were interested in the study of the mutations in 11 of the 24 exons of the gene TCOF1 by the method of direct sequencing in 7 patients among whom 4 family cases. These exons are reported as hotspots of mutations. The confirmation of TCS diagnosis by molecular biology was possible for 3 of our 7 patients. The sequencing allowed to identify a new mutation not reported in the literature which was found in 2 cases from the same family (a father and his daughter). An already described mutation was found in 1 sporadic case. Eight polymorphisms were found, among which five are known. The mutations found in our patients occur in repetitive sequences which support the hypothesis of polymerase errors. No mutations were detected in exon 24 which account for 20 % of already reported cases. The molecular study of the TCS allows the confirmation of the diagnosis, the orientation of the clinical follow up and the prenatal diagnosis in the severe forms.

J11.44
Co- occurence of tetrasomy 12p and trisomy 12q

K. Boduroğlu, *M. Demirel, E. Kılıç, G. E. Utine;*
Hacettepe University Faculty of Medicine, Ankara, Turkey.

A female neonate was born at a gestational age of 38 weeks by spontaneous vaginal delivery, with a birth weight of 3600 gr (50th-75th centiles). Antenatal ultrasound had shown minimal pelvicalyceal dilatation of left kidney, and no other abnormalities were detected on abdominal ultrasound scan. Postnatally, she was noted to have hypertelorism, prominent and wide forehead, upslanting palpebral fissures, long philtrum, pigmentary mosaicism in both feet, hyperplasia of the gingiva and hypotonia. Cranial magnetic resonance imaging showed an asymmetrical dilatation of right pontocerebellar cistern, with a suspicion of an arachnoid cyst. On follow-up, she had progressive hyperpigmentation over both lower extremities and a skin biopsy was performed with a clinical diagnosis of Pallister-Killian syndrome. Karyotype analysis from peripheral blood lymphocytes revealed 46,XX and karyotype analysis of skin fibroblast sample revealed 47,XX,+i(12)(p10). This finding was confirmed by fluorescence in situ hybridization by whole chromosome paint 12, that revealed 47,XX,i(12)(p10).ish (wcp12+). Further FISH analysis for 12p and 12q terminals with Vysis ToTelVysion 12 probe (12p – 8M16, 12q – VIJRM2002) revealed 47,XX,+i(12)(p10).ish +i(12p)(8M16x4, VIJRM2002x3). Combination of tetrasomy 12p and trisomy 12q is a previously unreported condition.

J11.45
Tetrasomy 18p in a patient with happy demeanor

G. E. Utine, *Ö. Akgün Doğan, A. Çetinkaya, K. Boduroğlu;*
Hacettepe University Faculty of Medicine, Ankara, Turkey.

An 8 years old female patient was referred to clinical genetics department because of facial dysmorphic features, speech and motor delay. She was the second child of nonconsanguineous parents. Maternal age at delivery was 31 years, and the baby was born by spontaneous vaginal delivery at 39th gestational weeks, with a birth weight of 1200 gr (below 3rd centile). Psychomotor development was delayed; she sat independently at 2 years of age, walked at 6 years of age, and spoke a few words at 6 years of age. On physical examination at the age of 8 her anthropometric measures were as follows: height 119.5 cm (3rd-10th centiles), weight 22 kg (3rd-10th centiles), head circumference 49 cm (below 3rd centile). She presented with microcephaly, prominent nasal bridge, prognathism, malformed ears and long fingers. Her behaviour was characterised by inappropriate and frequent laughter. In echocardiographic evaluation patent foramen ovale and atrial septal defect were detected. Cranial magnetic resonance evaluation was normal. Peripheral blood specimens were collected for chromosomal analysis and 47,XX,+i(18)(p11. 2) was detected. This finding was confirmed by whole chromosome paint fluorescence in situ hybridisation that revealed 47,XX,+i(18)(p11. 2). ish i(p18)(p11.2) (WCP 18++). Tetrasomy of 18p is found one in every 140,000 live births, affecting males and females equally. The syndrome expresses itself with developmental delay, cognitive impairment, happy demeanor, growth retardation, muscle tone abnormalities, microcephaly, malformed ears, prognathism and congenital heart diseases. This condition must be considered in differential diagnosis of syndromes with microcephaly, happy demeanor and intellectual disability.

The weight of a translocation

C. Barone[1], *A. Cataliotti Del Grano*[2], *L. Bernardini*[2], *L. Indaco*[2], *C. Ettore*[2], *M. Giuffrida*[3], *A. Capalbo*[3], *A. Novelli*[3], **S. Bianca**[2];
[1]*Genetica Medica Dipartimento Materno Infantile, ARNAS Garibaldi Nesima, Catania, Scuola di Specializzazione in Genetica Medica Università degli Studi Messina - Catania, Catania, Italy,* [2]*Genetica Medica-ARNAS Garibaldi Nesima, Catania, Italy,* [3]*Istituto Mendel, Roma e Ospedale Casa Sollievo della Sofferenza, IRCCS, San Giovanni Rotondo, Roma, Italy.*

We report on a 29 years old woman with secondary amenorrhea and short stature. Pelvic ultrasound revealed a normal uterus and little ovaries. There was no intellectual disability. She has two healthy sisters and her mother had a first trimester spontaneous miscarriage. Chromosome analysis revealed 46,X,der(X)t(X;15)(p14;q22.3) of maternal origin. Array-CGH showed a 39.6 Mb Xp22.33→Xp11.4 deletion and a 33 Mb 15q23→15q26.3 duplication. It was also observed a 92 Kb 5q22.2 microdeletion which involves MCC gene. Any genomic imbalances, deletions or duplications of an X chro¬mosome have a much more severe impact on males than fe¬males. In males, most cytogenetically visible de¬letions of the X chromosome involve the terminal portion of Xp (Xp22.2→Xpter), which leads to nullisomy of the deleted region, has been recognized as a cause of variable contiguous gene syn¬dromes. The phenotypes depend on the extent and posi¬tion of the deletion and are limited by the presence of male lethal genes in Xp22.2 at about 10-11 Mb from the telomere so larger Xp deletions extend¬ing beyond the KAL1 locus are very rare. Females with similar Xp22 deletions are often phenotypically normal except for short stature, because of skewed X-chromosome inactivation. Xp deletion women show primary amenorrhea or sometimes secondary amenorrhea. This is a pregnancy planning's dilemma: if our couple

will decide to undergo medically assisted procreation programs transmission of derivative X chromosome to sons would be letal instead transmission to daughters would determine a unpredictable variable phenotype in order to skewed X-chromosome inactivation.

J11.47
Trichorhinophalangeal syndrome type II due to a novel 8q23.3-q24.12 microdeletion detected by oligo-SNP array associated with novel genital findings.

L. Plaza-Benhumea[1], *J. Valdes-Miranda*[1], *J. Toral-Lopez*[2], *A. Perez-Cabrera*[1], *L. Gonzalez-Huerta*[1], *S. Cuevas-Covarrubias*[1];
[1]*Genetica, Facultad de Medicina, Hospital General de Mexico, Universidad Nacional Autonoma de Mexico, Mexico D.F., Mexico,* [2]*Genetica, Department of Medical Genetics. Ecatepec Medical Center, ISSEMYM, EdoMex, Mexico D.F., Mexico.*

Trichorhinophalangeal syndrome type II (TRPS2; OMIM 150230, Langer-Giedion syndrome, LGS) is a contiguous gene deletion syndrome located on 8q23.1-q24.1. Depending on the size and position of the heterozygous deleted region, the genetic defect principally involves TRPS1, RAD21 and EXT1 genes. TRPS2 presents characteristic clinical findings with multiple cartilaginous exostoses and frequently, intellectual disability. In the present study we analyzed a female with TRPS2 by Oligo-SNP array and detected a de novo 8q23.3-q24.12 microdeletion of 5.464 Mb on 8q23.3- q24.12 involving seven OMIM genes (CSMD3, TRPS1, EIF3H, RAD21, SLC30A8, MED30 and EXT1). In addition, UTP23, MIR3610 and exon eight of SAMD12 were deleted. The final cytogenetic result was 46,XX, arr [hg19] 8q23.3-q24.12 (113,858,753-119,323,017) x1 dn. Parental testing of all procedures showed normal results. Our patient had genital anomalies with normal intelligence not previously reported. The analysis at molecular level of delete region in TRSP2 is imperative to understand the pathogenesis of the disease

Congenital absence of the portal vein in a child with Turner Syndrome

Ö. N. Şahin[1], *S. Şal*[2], *S. Yalti*[1], *P. Bayındır*[3];
[1]*Acıbadem Bodrum Hospital, Muğla, Turkey,* [2]*Acıbadem Bodrum Hospital, Mugla, Turkey,* [3]*Ege university pediatric radiology department, İzmir, Turkey.*

Congenital absence of the portal vein in a child with Turner Syndrome Introduction: Turner Syndrome is a disease caused by a total or partial loss of an X chromosome in women, showing a frequency of 1 per 2500-4000 live-born females. (1,2) Characteristic features of the disease are short stature, gonadal dysgenesis, webbed neck,cubitus valgus and congental cardiovascular anomalies. Congenital absence of portal vein, however, is rare, and there are no systemic reviews detailing the prevalance of the absence of the portal vein in patients with Turner Syndrome. 13 year old girl was admitted to emergency service for high fever. At the physical examination her respiratory rate was 60/min, she had toxic appearence. She had webbed neck and short stature.She had a shilded chest with no breast tissue and prepubertal nipples. She had splenomegaly. Laboratory tets revealed high transaminases. Chromosomal studies showed monosomy pattern compatible with Turner Syndrome (45XO). Echocardiography was consistent with aortic coarctation and bicuspid aortic valve. Patient underwent dynamic biphasic computerized tomography(CT) imaging to investigate the causes of liver disease. CT revealed the absence of portal vein. She had grade II esophageal varices in the upper gastrointestinal endoscopy. The final diagnosis was a case of Turner's Syndrome with absent portal vein, portal hypertension and hypersplenism.

J11.49
An ~1,6 Mb interstitial deletion on Xp22.31 in a patient with psychomotor developmental delay, microcephaly, epilepsy, ichthyosis, and spastic tetraplegia.

N. Bezniakow, *A. Kutkowska-Kaźmierczak, M. Bartnik, B. Wiśniowiecka-Kowalnik, B. Nowakowska, E. Bocian, E. Obersztyn;*
1. Department of Medical Genetics, Institute of Mother and Child, Warsaw, Poland.

We present a 6-year-old boy, born at 41 weeks of gestation to non-consanguineous, healthy parents. The pregnancy was complicated by respiratory infection in the first trimester of gestation. At birth, body weight and length were normal, and head circumference was 33 cm (3 centile). The boy was evaluated at genetic counselling unit at the age of 3 years because of severe psychomotor retardation, absent speech, epilepsy, spastic tetraplegia and severe microcephaly (- 4,04SD). Generalized ichthyosis was observed. There were no dysmorphic features or structural malformations. Brain MRI showed thin corpus callosum without other abnormalities. Results of oligonucleotide arrayCGH (180 K V8.1) showed an ~1,6 Mb interstitial deletion on chromosome Xp22.31 encompassing a few genes, including VCX (candidate gene for intellectual disability), PNPLA4 , and STS associated with X-linked ichthyosis (XLI). Further analysis of the family revealed that the deletion is maternal in origin. The same Xp22.31 deletion was also found in her two healthy sisters; her grandfather presented only with ichthyosis. Some authors have reported single cases of the Xp22.31 deletion, involving the VCX gene in patients with ichthyosis and normal intelligence. Therefore, it is not clear whether the deletion is the only cause of patient's pathology, especially intellectual disability, epilepsy, and spastic paresis. Incomplete penetration or another gene within Xp22.31 deletion (e.g. PNPLA4) or unknown mechanisms might be responsible for these symptoms in our patient. Comparison with the similar cases from the literature and genotype - phenotype correlation will be discussed.

J11.50
Partial deletion of 9p: familial case of Alfi syndrome

N. Timofeeva, *A. Kazakova, Y. Olshanskaya, E. Matveeva, A. Polivichenko, D. Kachanov, S. Varfolomeeva;*
Federal Scientific and Clinical Center of Pediatric Hematology, Oncology and Immunology named after, Moscow, Russian Federation.

Monosomy 9p syndrome also known as Alfi syndrome is a rare genetic disease characterized by mental retardation, developmental delay, facial dysmorphism and various type of feminization in male.
We report two cases of Alfi syndrome in siblings.
One patient (9 year old girl) was initially diagnosed with dysgerminoma of the right gonad and gonadoblastoma of the left gonad. Following symptoms were identified: severe mental retardation, general development delay, generalized hypotonia, contractures of all joints including talocrural, knees, and phalanges as well as complete gonadal dysgenesis. Floating movements of eyeballs and epilepsy were also observed. The external female genitalia were normal. Histological analysis of gonads revealed sclerosis and no follicles as well as absence of cilia on the surface of salpinx.
Cytogenetic analysis of peripheral blood cells identified male karyotype with unbalanced translocation 45,XY, der(9)t(9;21)(p22;q11),-21. Deletion of fragment 9p22-pter was confirmed by serial FISH analysis.
Patient's sister (5 year old girl) had identical symptoms except for sex reversal and karyotype 45,XX,der(9)t(9;21)(p22;q11),-21.
Family history was remarkable for unidentified genetic disorder with mental retardation and some chromosome 21 abnormality in mother and severe genetic disease in maternal brother. Most probably abnormal karyotype in this family was inherited through female line.

Aspects Of The Early Neurogenetic Diagnostics Of Klinefelter Syndrome

M. Sprincean[1,2], *E. Halabudenco*[1], *T. Samoilenco*[1], *A. Misina*[1];
[1]*Institute of Mother and Child, Chisinau, Moldova, Republic of,* [2]*State University of Medicine and Pharmacy "N. Testemitanu", Chisinau, Moldova, Republic of.*

Background: In the study are analyzed peculiarities of clinical manifestations and cytogenetic features in Klinefelter syndrome, which is a sex chromosome abnormality. The aim of research is to help achieve an early neurological diagnosis and initiation of measures to improve the development of children.
Material and methods: A group of 84 boys with Klinefelter syndrome was investigated during medical genetic counseling in the Center for Reproductive Health and Medical Genetics, presenting phenotype selection criteria such as: developmental anomalies of the external genitalia - peno-scrotal hypospadias, micropenis, small testes, cryptorchidism, cranio-facial dysmorphism, waist high and disproportionate, hypogonadism, gynecomastia, mental retardation, psychosocial problems.
Results: Homogeneous form or trisomy 47, XXY (27 cases - 84.5%) was the most common chromosomal abnormality diagnosed in the 32 patients with Klinefelter syndrome, followed by mosaic form (47 XXY/46, XY: 1 case - 3.1%), polysomy X-Y (48, XXYY: 1 case - 3.1% and pentasomia - 49, XXXXY: 1 case - 3, 1%) and variants of structural abnormalities of autosomal chromosomes (47, XXY, inv (5): 1 case - 3.1%), associated with robertsonian translocation (47, XXXY, Rob (13:14): 1 case - 3.1%). Most patients with KS had been diagnosed in puberty (23 cases - 71.9%), 6 patients (18.7%) were diagnosed at prepubertal, and only 3 patients (9.4%) were diagnosed during early childhood.
Conclusion: Neurogenetic diagnosis during early ontogenetic development and cytogenetic analysis (karyotyping, Barr test) is necessary for better investigation of children with suspection on SK to confirm the clinical diagnosis and timely provide genetic counseling.

Prophylaxis of Congenital Malformations in Pregnant Women of a Risk Group

E. Halabudenco[1], *M. Sprincean*[1,2], *R. Stratila*[1];
[1]*Institute of Mother and Child, Chisinau, Moldova, Republic of,* [2]*State University of Medicine and Pharmacy "N. Testemitanu", Chisinau, Moldova, Republic of.*

Background: Efficient stabilization of genetic diseases spreading in population of Moldova means, first of all, to improve prophylaxis of congenital malformations in pregnant women. The role of genetic counseling in the prevention system of genetic diseases is analyzed in the study. The main prophylaxis measures and prenatal diagnosis methods applied to pregnant women of risk group are identified by authors.
Materials and methods: Retro-prospective study of investigation included 8937 pregnant women who have asked for medico-genetic counseling in CRHMG, in 2008-2012. Group I: 4473 pregnant women from medium and high risk group. Group II: 4464 pregnant women from low risk group.
Results: Two researched groups were comparable in age, gestation period, degree of genetic risk. The age of women in genetic risk group was from 17 years to 44 years (average age 26,1 ± 5,3 years). Prenatal diagnosis contributed to the identification of severe fetal pathologies to 478 pregnant women, which constituted 5,4% of total number of investigated cases. Amniocentesis with study of the fetal karyotype has allowed the identification of numerical and structural chromosomal abnormalities to 67 patients (3,0%). Abnormalities of the central nervous system are the most common in the structure of the serious fetal pathologies (1,4%), followed by abnormalities of the cardio-vascular system (0,87%), osteomuscular system anomalies (0,51%), abnormalities of renal system (0,64%) and digestive system (0,6%).
Conclusion: Genetic counseling and prenatal diagnosis methods (fetal ultrasound, biochemical screening, karyotyping) helps to reduce up to 50% of the frequency of chromosomal abnormalities and congenital malformations to newborns.

The results of clinical and molecular analysis of data of patients with branchio-oculo-facial syndrome

T. Meshcheryakova[1], *R. Zinchenko*[2], *S. Zhilina*[1], *T. Vasileva*[2], *N. Petrova*[2], *A. Petrin*[1], *G. Mutovin*[1], *T. Kozhanova*[1];
[1]*Scientific and Practical Center of medical care for children, Moscow, Russian Federation,* [2]*Research Centre of Medical Genetics of the Russian Academy of Medical Sciences, Moscow, Russian Federation.*

Branchio-oculo-facial syndrome (BOFS, OMIM #113620) is a rare autosomal dominant disorder, characterized by branchial cleft sinus defects, ocular anomalies, a dysmorphic facial appearance including lip/palate cleft or pseudocleft and associated with mutations in TAFAP2A gene. Clinical features analysis and DNA-testing are performed in 7 BOFS patients. 3 patients present three main clinical BOFS features: cervical cutaneous aplasia linear loci, ocular anomalies, orofacial cleft, 4 patients are symptomatic with ocular anomalies, orofacial cleft and accessory BOFS signs. 5 patients have lacrimal duct stenosis, one has distopy of lacrimal point in upper lip area. Orofacial clefts are observed in all 7 patients (2 - upper lip pseudocleft, 2 - upper lip cleft, 3 - upper lip/palate cleft). 2 patients have developmental abnormalities of auditory ossicles, 1 - atresia of external acoustic meatus, 4 - anatomically narrow acoustical ducts. Conductive hearing loss is diagnosed in 5 BOFS patients. Sequensing of TFAP2A gene coding region revealed missense- mutations in 4 BOFS patients. One patient has p.Arg251Gly mutation previously described, 3 patients from 2 families have novel mutations: p. Arg213Ser and p.Val280Asp. Novel mutations are not detected in healthy members of the families.

Establishment of national birth defect surveillance in Lebanon: preliminary data

C. Farra[1], **R. El Rafei**[1], *R. Bejjany*[1], *L. Charafeddine*[1], *G. Mumtaz*[1], *F. El-Kak*[2], *P. Nakad*[1], *M. Badran*[1], *G. Abdallah*[1], *K. Yunis*[1];
[1]*Department of Pediatrics & Adolescent Medicine, American University of Beirut Medical Center, Beirut, Lebanon,* [2]*Department of Health Promotion and Community Health, American University of Beirut, Beirut, Lebanon.*

Background: Following the WHO recommendations in 2012, the National Collaborative Perinatal Neonatal Network (NCPNN) in collaboration with the Centers for Disease Control and Prevention and the Ministry of Public Health (MOPH) inaugurated the establishment of a national Birth Defect (BD) surveillance program. A previous study conducted on 19 Lebanese hospitals, members of the NCPNN, between 2003 and 2007 had shown an incidence of 3.25% of BDs in neonates with a significantly higher occurrence in consanguineous mating. This is our preliminary data on BDs in Lebanon, from May 1st to November 30, 2012. **Methods: I**nfants born with major BDs from hospitals across Lebanon were reported. Incidence of BDs was calculated using data provided from the MOPH. **Results:** 464 infants born with a major BD were reported. The overall rate was 18.2/1000 live births. The most common were musculoskeletal defects (4.2%), mainly clubfoot (24.3%), central nervous system defects (4.01%), mainly spina bifida (40.2%) and cardiovascular defects (3.29%), with septal defect accounting for 29.7%. Facial/neck defects represented only 0.63%. Among infants with spina bifida, 8.3% of the mothers were on folic acid before pregnancy while 36.1% started it after conception. Among infants with clefts, 64.1% of the mothers reported smoking exposure during pregnancy. 30.8% of all mothers were overweight/obese before pregnancy. Parental consanguinity was reported in 33.4% of the cases; among those, 53.2% were first cousins. **Conclusion:** Ascertaining the prevalence and determinants of BDs through proper surveillance would lead to preventive measures contributing to a measurable reduction of BDs in our country.

Arthrogryposis and perisylvian polymicrogyria: report of an emerging phenotype

A. Peron[1], *E. Baldwin*[2], *J. C. Carey*[1];
[1]*Division of medical genetics, Department of pediatrics, University of Utah School of Medicine, Salt Lake City, UT, United States,* [2]*ARUP Laboratories, Salt Lake City, UT, United States.*

In recent years a few patients with perisylvian polymicrogyria associated with arthrogryposis have been reported. The underlying genetic cause of this condition is not yet known.
We report on a newborn male whose pregnancy was characterized by the detection of arthrogryposis, bilateral club feet, micrognathia, and a small VSD on prenatal sonogram. The patient was born full term: BW 2673 g (5th centile), BL 46 cm (5th centile), OFC 34 cm (20th centile). Physical examination at birth showed minor facial anomalies, proximal and distal contractures of the upper and lower limbs consistent with arthrogryposis multiplex congenita, lack of palmar and plantar creases, and bilateral talipes equinovarus. A brain MRI evidenced bilateral perisylvian polymicrogyria. Family history was not contributory.
The SNP array [Affymetrix Cytoscan HD microarray (average resolution of 50 Kb for deletions and 400 Kb for duplications)] showed a microduplication of 825 Kb in chromosome 14q12 (29.372.798-30.197.863, hg 19) and a microdeletion of 420 Kb in chromosome 7p22.1 (4.743.281-5.163.491, hg19). The duplication contains a control region for the *FOXG1* gene. The deletion contains several genes associated with muscular function, including *FOXK1*. The interpretation of this result is still unclear, and analysis of the parents is pending. We will proceed with exome sequencing if neither of the chromosomal imbalances are considered to be causative.
In conclusion, we propose that the association between perisylvian polymicrogyria and arthrogryposis is a novel discrete phenotype. The results of the genetic analysis will allow better insight into the molecular etiology of this recently described entity.

J11.56

Prader Willi syndrome clinical signs and phenotypic features at Lithuanian health science university hospital

E. Savickaite[1], *D. Serapinas*[1,2];
[1]*Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania,* [2]*Mykolas Romeris university, Vilnius, Lithuania.*

Backround: Prader Willi syndrome (PWS) - a rare genetic disease that manifestates in 1:10000 or 1:25000 births. The aim of the study was to evaluate when first starting to emerge Prader Willi syndrome symptoms and how they are distributed according to sex.
Methods: In this retrospective analysis data were collected from 29 outpatients, who had clinical symptoms of PWS. The patients weight and height were evaluated at birth and the first visit to the doctor at the time (weight and height procentile evaluated), as well as the face, extremities, breast development and other changes.
Results: All patients were applied for the obesity to the doctor, when average age was 3.23 years. Comparison of average age between boys and girls showed no statistically significant difference .The almond -shaped eyes were 33.3% of girls and 47.4% boys. Thin upper lips 33.3% of girls and 36.6% boys. Short limbs were 50.0% of girls and 57.9% boys. Tapering fingers 22.2% of girls and 26.3% boys. Sandal gap 11.1% of girls and 15.8% boys.
A comparison of the other symptoms (sucking reflex absence, epilepsy, stigma) dependence on sex, a statistically significant relation has not been established. These symptoms occurred in 66.7% girls and 47.4% boys.
Conclusions:
Average ages of patients was 3.23 years, when they first applied for the obesity to the doctor. Weight on first visit to the doctor does not depend on birth

weight.Statistically significant association between all clinical symptoms and sex has not been established

J11.57
First case report of Seckel in Ecuador

A. J. Toapanta Ortiz[1], M. Cartelle Gestal[1], M. D. Sanchez[2], F. A. Tama[3];

[1]Faculty of Public Health. ESPOCH, Riobamba, Ecuador, [2]Health Centre "Francisco de Orellana" MSPE, Guayaquil, Ecuador, [3]Faculty of Health Sciences, Guayaquil, Ecuador.

Introduction: Seckel syndrome was described in 1960 and it is also known as bird-headed dwarfism. This syndrome is a rare autosomal recessive disorder. It is characterized by severe intrauterine and postnatal growth retardation, low birth weight, severe microcephaly, craniofacial dysmorphism with characteristic bird headed appearance, prominent beaked triangular nose, micrognathia and variable mental retardation. Other multiple anomalies associated are cleft lip and palate, club foot, scoliosis, gastrointestinal malformations, multiple skeletal malformations, cardiovascular, endocrine, hematopoietic and central nervous systems abnormalities. At the moment 100 cases has been reported and this is the first case reported in Ecuador and the second in Latin America

Case report: Woman of 15 years old. The mother did not have bad habits during the pregnancy. The father is a first cousin of the mother. The patient is 91 cm in length and weights 9.2 Kg., exhibits severe signs of malnutrition. The patient is bird-headed, presents microcephaly, multiple skeletal malformations, ears are deformed and positioned very low, scoliosis, multiple anomalies associated are cleft lip, deformed teeth, clinodactyly, asymmetric pelvis, as well as other characteristics signs. She is aggressive and presents severe mental disability and she suffered convulsions for the first years of her life. Gonadotropin hormones are at a low level. FSH: 1,07mUI/ml, LH: <0,10mUI/L, these suggest a structural problem in the hypothalamus. Karyotype is normal 46,XX. But the patient has no uterus, ovaries or secondary sexual characteristics, but she is not diagnosed as a case of turner syndrome.

Polymorphism of P53 gene - exone 4 codon 72 in endometrial carcinoma: Correlation with tumor type

T. Kafshdouze Pourpolsangy[1], *A. Dastranj Tabrizi*[2], *S. Mohaddes Ardabili*[3], *L. Kafshdooz*[1], *M. Gojazadeh*[1];

[1]Medical Faculty, Tabriz, Islamic Republic of Iran, [2]Women Reproductive Health Research Center, Tabriz, Islamic Republic of Iran, [3]Medical fFculty, Tabriz, Islamic Republic of Iran.

Endometrial carcinoma is the fourth most common cancer among women in developed countries. Endometrial cancer patients may benefit from systemic chemotherapy, alone or in combination with targeted therapies if the disease is clinically diagnosed prior to expansion and metastasis to other organs. The aim of this study was to evaluate the prognostic role of p53 polymorphism and comparison with tumor type and grade in human uterine endometrial carcinoma. Seventy five patients with endometrial carcinoma and seventy five patients with o malignancy were studied for possible mutations in exon 4 p53 gene using polymerase chain reaction and restriction fragment length polymorphism techniques and sequencing. P53 polymorphism in exon *4* showed no significant difference in the genotype or allele prevalence between case and control groups. We found the Pro allele and genotype frequency to be insignificantly higher in cases than controls (Pro allele 6 and 8/3% respectively; genotypes: Arg/Pro 61 and 84/7%, Pro/Pro 5 and 6/9%, respectively). there was no significant difference in the allele distribution between tumor type and grade because it was need many number of cases.

J12.002
Association between polymorphisms rs1801270(Ser31Arg) ,rs762624,rs3176336 of CDKN1A gene in sporadic colorectal cancer

N. M. M. Zali;

Azad University Islamic Tehran Medical Branch, Tehran, Islamic Republic of Iran.

Background: Colorectal cancer is the third most commonly diagnosed cancer in both men and women. Progressive loss of cell cycle control is an important feature on the colorectal cancer. p21 (CDKN1A/CIP1/WAF1), one of the cyclin-dependent kinase inhibitors, plays a key role in regulating the cell cycle. The aim of this study was to investigate associations of the CDKN1A gene polymorphisms (rs3176336,rs1801270,rs762624) with risk of colorectal cancer (CRC) in an Iranian population.

Methods: The study subjects were 150 cases of colorectal cancer and 150 controls for any polymorphisms. Genomic DNA was extracted using standard salting out method. Genotypes were determined using the polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP) method.

Results: A significant relation was found between rs1801270 in the CDKN1A gene and colorectal cancer. The distribution of AC genotypes among sporadic CRC patients was more frequent than that in the control group (P value = 0.003).We found no significant difference between studied polymorphismS and colorectal cancer .

Conclusion: to our knowledge this is the first study on association of CDKN1A \polymorphisms with CRC risk in Iranian population. Our findings indicated that there is association between rs 1801270 and risk of colorectal cancer

J12.003
The 1303CA mutation of solute carrier family member 2 gene in lung cancer

C. Ozbayer[1], *I. Degirmenci*[1], *D. Ustuner*[2], *G. Ak*[3], *F. Saydam*[1], *M. C. Ustuner*[1], *H. V. Gunes*[1], *M. Metintas*[3];

[1]Eskisehir Osmangazi University, Medical Faculty, Department of Medical Biology, Eskisehir, Turkey, [2]Eskisehir Osmangazi University, Vocational School of Health Services, Eskisehir, Turkey, [3]Eskisehir Osmangazi University, Medical Faculty, Department of Pulmonary Diseases, Eskisehir, Turkey.

As an essential element for human life, iron is widely involved in many important metabolic processes, such as DNA synthesis, electron transport, and oxygen delivery. Numerous studies have found a positive correlation between iron storage and risk of cancers such as hepatic cancer, renal cancer and lung cancer(LC). Solute carrier family-member-2(SLC11A2) is the only transmembrane iron transporter known to be involved in cellular iron uptake. Mutations in SLC11A2 gene are associated with hypochromic microcytic anemia with iron overload. One of SLC11A2 gene variants, 1303C/A, occurs in the coding region of SLC11A2 and results in an amino acid change from leucine to isolecine. Due to the role of SLC11A2 in iron regulation, 1303C/A mutation in SLC11A2 gene (rs144863268) was investigated in 100 subjects (LC patients: n=50; healthy-controls: n=50) by method of PCR-RFLP. The resulting 362-bp amplification products were digested by SfaNI and were analyzed by electrophoresis in a 2% agarose gel. The 1303C/A mutation destroys a SfaNI site. Accordingly mutant alleles showed only the undigested, 362-bp band, whereas wild-type alleles were identified on the basis of a digestion pattern showing a 197- and a 165-bp band. No significant differences in allele (A allele χ^2=0.91, p=0.338; C allele χ^2=1.01, p=0.315) and genotype (χ^2=2.70; p=0.259) frequencies of the gene polymorphism were found between the healthy controls and lung cancer patients. According to our preliminary data SLC11A2 1303C/A mutation is not linked with lung carcinogenesis. We would expect significance with the increasing number of patients. The project was supported by ESOGU (Grant no:201241020)

J12.004
Variant type PML-RARA fusion transcript in AML: Detection and interpretation of results by RT-PCR

J. Vukajlovic[1], *N. Ilic*[1], *M. Djurisic*[1], *M. Guc-Scekic*[1,2];

[1]Mother and Child Health Care Institute of Serbia, Belgrade, Serbia, [2]Faculty of Biology, Belgrade, Serbia.

Acute myeloid leukemia (AML) is characterized by a number of features that requires accurate diagnostic and specific treatment approach. The t(15;17)(q24;q21) which generates the PML-RARA fusion transcript presents the diagnostic hallmark of AML. PML-RARA positive patients express one of three hybrid transcripts within PML gene and are denoted bcr1 (long), bcr2 (variant), and bcr3 (short) forms. The importance of specific breakpoint region is its utility as prognostic factor for individual's likelihood of relapse and possibly their response to therapy treatment.

In this study we present detection of the most uncommon breakpoint region, bcr2, by RT-PCR technique. We analyzed 95 pediatric AML patients and examined the incidence of three most frequent fusion transcripts obtained by standardized RT-PCR protocol (European BIOMED-1 Concerted action). In 28 cases, positive for one of the AML rearrangement, 9 patients (32%) had AML1-ETO rearrangement, 3 (11%) had CBFB-MYH11, and 16 (57%) had PML-RARA. Among 16 PML-RARA patients, five (42%) were presented as bcr1 positive (multiplied with PMLA1-RARAB primers) and showed nonspecific extra band multiplied with bcr3 primers (PMLA2-RARAB). These results are interpreted as bcr2 positive, but to ultimately determine whether it is bcr1 or bcr2 transcript, we are now investigating length of these products by sequencing. After these analyses we will determine the rate of bcr2 products among our patients.

Cytogenetic analysis from bone marrow samples showed normal karyotype. Establishment of bcr2 rearrangement is important because of its decreased response to treatment with all-trans retinoic acid (ATRA) depending on where the break occurs within PML exon 6.

J12.005

Novel Additional Chromosomal Abnormalities in patient with Acute Promyelocytic Leukaemia and ATRA resistance

D. Morotti[1], *G. Reda*[2], *S. Guerneri*[1], *R. Silipigni*[1], *V. Giannone*[1], *S. Motta*[1], *M. Baccarin*[1], *M. Pomati*[2], *M. Zappa*[2], *M. Sciumè*[2], *R. Cassin*[2], *A. Neri*[3], *A. Cortelezzi*[2];
[1]*Lab.of Medical Genetics, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy,* [2]*Hematology and Transplantation Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, Milano, Italy,* [3]*University of Milan, Milano, Italy.*

Additional chromosome aberrations (ACA) have been observed in 23-43% of Acute Promyelocytic Leukaemia (APL) cases, with trisomy 8 being the most frequent (31-46%). Here we describe one case of APL with ACA at presentation occurred in our hematology department in April 2013 and never been reported in literature. A 22 years old male patient who was referred to our institution for mucosal and cutaneous bleeding. Laboratory exams showed anemia, leucopenia and thrombocytopenia, with increasing prothrombin time, activated partial thromboplastin time and fibrin degradation products. A blood smear evidenced atypical agranulate promyelocites with Auer Rods in faggots. Bone marrow aspirate for morphological, immunophenotyping , cytogenetic and biomolecular analyses was performed. The patient showed a 46,XY,t(5;21)(q31;q22)[17]/46,XY,t(5;21)(q31q22),t(15;17)(q24;q21)[3].ish t(15;17)(PML+;RARA+,PMLdim)[8] karyotype. The aquired , non constitutional nature of the translocation t(5;21) has been confirmed by a cytogenetically normal result of phytohemagglutinin-stimulated blood analysis. Molecular analysis performed by RT-PCR disclosed the presence of bcr-1 PML-RARα gene fusion transcript. Follow up laboratory exams showed persistence of a normal karyotype and molecular remission, but in January 2014 bone marrow cytogenetic analysis revealed a complex karyotype:49,XY,t(5;21)(q31;q22),t(15;17)(q24;q21),+mar1,+mar2,+mar3[2]/
46,XY[18].ish t(15;17)(PML+;RARA+,PMLdim)[7/100] with presence of bcr-1 isoform in RT-PCR, normal CBC count and MRI imaging showing initial NCS envolvment. The incidence and prognostic significance of ACA in APL is still a controversial matter and when such abnormalities are found there is no evidence to support the use of alternative therapeutic strategies to ATRA(all-trans retinoic acid) and chemotherapy. Now patient is under treatment with arsenic-trioxide.

J12.006

Increased frequence of the rs2066853 variant of aryl hydrocarbon receptor gene in patients with acromegaly

P. Romeo[1], *M. Ragonese*[1], *F. Ferraù*[1], *M. Torre*[1], *S. Puglisi*[1], *M. Amorini*[2], *S. Barati*[2], *C. Liuzzo*[2], *L. Rigoli*[2], *F. Trimarchi*[1], *S. Cannavò*[1];
[1]*Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy,* [2]*Department of Pediatric, Gynecological, Microbiological and Biomedical Sciences – Genetics and Immunology Pediatrics, University of Messina, Messina, Italy.*

Introduction Aryl Hydrocarbon Receptor (AHR) regulates Cytochrome P4501A1 (CYP1A1) expression and other xenobiotic target genes to antagonize environmental contaminants effects. It controls also cellular proliferation, senescence and apoptosis. AHR gene polymorphisms were associated with several tumours' occurrence and deregulation of AHR expression was demonstrated in somatotropinomas. In this study, we analyse the sequence of the AHR gene in patients with sporadic acromegaly. Patients and methods We evaluated 70 patients (M = 27, age 57.5 ± 12.8 aa ± SD) and 157 controls. Exons 1, 2, 3 5 and 10 of AHR was screened by direct sequencing in patients and controls. **Results** Polymorphism rs2066853 (c.1661 G>A) was identified in 18/70 acromegalic patients and in 9/157 healthy subjects (25.7 vs 5.7%, $\chi 2$ 18.98 p <0.0001, OR 5.7, 95% CI: 2.4081 - 13.4558). Moreover, rs4986826 (c.1708 G>A) variant was identified in two patients but not in controls ($\chi 2$ 4.62 p <0.05). Mean IGF-1 ULN (2.93 ± 1.07 vs 2.29 ± 0.86, p <0.05) and the prevalence of cavernous sinus invasion (χ^2 6.08, p <0.05) were higher in patients with rs2066853 polymorphism than in the other ones. Moreover, an increased prevalence of differentiated thyroid cancer (χ^2 7.53, p 0.02), bladder tumour (χ^2 34.66, p 0.0001) and lymphohematopoietic neoplasm (χ^2 6.41, p <0.05) was found in the former group than in the latter. Further studies are needed to better elucidate the functional consequence of this AHR polymorphism, whether it could impact on xenobiotic sensitivity or affect other AHR-mediated cell-cycle deregulation mechanisms.

J12.007

Cytogenetic pattern profilling in Acute Lymphoblastic Leukemia of childhood in North Indian population

D. Kumar;
Maulana Azad Medical College, New Delhi, India.

Acute lymphoblastic leukemia(ALL) comprises of 70 - 80 % of childhood leukemias. Its diagnosis is based on hematological parameters like blast population, blast morphology, flow cytometry. ALL arises as a result of genetic damage to the lymphohematopoetic progenitor cell leading to malignant transformation. This study was a cross-sectional study done on paediatric age group patient of North Indian population on confirmed cases of ALL on bone marrow examination. The bone marrowsamples were subjected to cytogenetic study using immediate, 24hr and 48hr protocols. FINDINGS: 1.Hypodiploidy was the commonest finding in our study with an incidence of 78.57% which is similar to that found in studies from East India where it is reported to be 63.6% and in West India it is 38.4%. In World Literature, this is similar to Africa population studies where hypodiploidy showed an incidence of 37.5%.Hyperdiploidy was commonest in North India (27%) in another study and South India(14.8%) and Asia(69.5%) and Europe(63%). Pseudodiploidy was commonest in America(41%). 2.B Cell ALL(95%) and T Cell ALL(5%) in our study is dissimilar from other studies, B Cell (70%-76%) and T Cell(24%-30%) 3. Structural abnormalities seen :43,X,del(4),dic(5)-(6)-(2)-(20)+(14) in 1(7.14%) and 42Y6p del dic 13-(7),-(9),-(16),-(X) in 1(7.14%). RECOMMENDATIONS Cytogenetics should play a key role in risk stratification and treatment protocols considering the heterogeneity of the pediatric ALL

J12.008

New, prognostically relevant chromosomal lesions in AML assessed by array CGH - a preliminary study

S. Zmorzyński[1], *D. Koczkodaj*[1], *E. Wąsik-Szczepanek*[2], *A. A. Filip*[1];
[1]*Medical University of Lublin, Department of Cancer Genetics, Lublin, Poland,* [2]*Medical University of Lublin, Department of Hematooncology and Bone Marrow Transplantation, Lublin, Poland.*

Acute myeloid leukemia (AML) is a biologically heterogeneous disease. Identification of chromosomal aberrations, as well as cryptic genome lesions is important for precise diagnosis and risk assessment. The aim of our study was to determine the most frequent clonal chromosomal aberrations, to assess their prognostic value and to compare the results obtained by classical cytogenetics and by array CGH. Bone marrow aspirates were collected from 21 patients diagnosed with AML and from 8 healthy blood donors. The material was divided into two parts. One part was used for classical cytogenetic analysis (GTG-banding and RHG-banding) and FISH. The second part was used for DNA isolation and array CGH analysis. Chromosomal abnormalities detected by classical cytogenetic techniques most often relate to chromosomes: 5, 17 (24%), 8, 15, 16, 18, 21 (19%), 3, 7, 11, 14, 20 (14%), 4, 12, 13 and 22 (9,5%). The array CGH study indicated regions: 16p13.3, 16p22.3q24.2, 5q14.1q35.2, 8p23.1p11.21, 8q12.1q24.3, 15q11.2, 15q15.1q15.3, 15q22.1q24.1, 15q25.2q25.3, 18p11.32q23, 3p26.3, 3p14.1p12.2, 3q11.2q21.1, 3q27.2q29, 7p12.3q36.3, 17p13.3p13.1 and 17q12. The above aberrations were confirmed by FISH. Array CGH method enabled to determine the regions of the feasible prognostic value during 36 months follow up. Aberrations in regions 5q14.1q35.2, 16p13.3 and 18p11.32q23 had a negative impact on the prognosis. AML patients with these lesions had shorter overall survival. The changes in the region 15q22.2q25.3 were associated with longer survival and favorable prognosis. Larger group of AML patients included in the study will enable the verification of prognostic significance of reported chromosomal changes.

J12.009

Complex translocation t(8;21;17)(q22;q22;p11.2): a masked variant of t(8;21) in a patient with AML-M2

A. Valenti[1], *M. Tonelli*[1], *B. Giannini*[1], *L. Bagli*[1], *G. Poletti*[2], *M. Rondoni*[2], *M. Rosetti*[2], *F. Monti*[2], *A. Clementoni*[2], *L. Baldrati*[2], *R. Dorizzi*[3], *A. Lucchesi*[4], *P. Fattori*[4], *E. Zuffa*[5], *A. Zaccaria*[6], **A. Sensi**[1];
[1]*Laboratorio Unico di Area Vasta Romagna- U.O. Genetica Medica, Pievesestina di Cesena (FC), Italy,* [2]*Laboratorio Unico di Area Vasta Romagna- U.O. Corelab sez. Ematologia, Pievesestina di Cesena (FC), Italy,* [3]*Laboratorio Unico di Area Vasta Romagna- U.O. Corelab, Pievesestina di Cesena (FC), Italy,* [4]*Istituto Tumori della Romagna-IRST, Meldola (FC), Italy,* [5]*U. O. C. Ematologia, Ravenna, Italy,* [6]*U.O.C. Ematologia, Ravenna, Italy.*

The t(8;21) translocation occurs in 5-12% of acute myeloid leukemia (AML) cases, and in 40% of AML FAB M2 type, with well defined and specific morphological features. Over 70% of patients show additional chromosome abnormalities: loss of Y or X chromosome in half cases. Variant translocations involving a variable third chromosome account for approximately 3-4% of all AML-M2 with fusion transcripts. Although the t(8;21) is easy to recognize cytogenetically, rearrangements between 8q22 and 21q22 may be masked with complex or cryptic translocations. This translocation leads to the fusion of the AML1 (RUNX1) gene on chromosome 21 and the ETO gene on chromosome 8, and results in a transcriptionally active chimeric gene, AML1-ETO on the derivative 8 [der(8)]. Here, we present a case of a patient, 41 years old male, with AML-M2 with a three-way translocation, involving the chromosomes 8, 21, and 17. The diagnosis, evaluated by morphology and immunophenotype in bone marrow, was indicative of AML M2 without specific features suggesting the presence of t(8;21). Cytogenetic study of

bone marrow cells revealed the karyotype as 45,X,-Y,t(8;17)(q22;p11.2) in 20 metaphases. FISH analysis using a 17p13 probe (Cytocell p53 Deletion) on previously G-banded metaphases showed that one of the LSI p53 signals was on chromosome 21. This led to the discovery of the cryptic translocation t(8;21;17); the presence of rearrangement AML1-ETO was confermed by RT-PCR (using BIOMED-I protocol). Variant t(8;21) translocations should be suspected in AML M2 and specifically looked for whenever 8q22 and 21q22 rearrangements are found.

Molecular-genetic investigation of aFAP/MAP syndromes among Russian patients

A. S. Tsukanov, *N. I. Pospekhova, V. P. Shubin, I. Y. Sachkov, A. M. Kuzminov, V. N. Kashnikov, Y. A. Shelygin;*
State Scientific Center of Coloproctology, Moscow, Russian Federation.

Attenuated Familial Adenomatous Polyposis (aFAP) and *MYH*-associated Polyposis (MAP) are the important inherited colorectal cancer syndromes. Germline mutations in *APC* gene provide aFAP, biallelic (or heterozygous in some populations) mutations in *MYH* gene cause MAP. We investigate *APC* and *MYH* genes among 25 patients with adenomatous polyps (4-95). Heterozygous missense mutations in *MYH* gene were analyzed in control group including 106 healthy probands. As a result 2 mutations p.I1307K in *APC* and 4 missense variants in *MYH* (2 p.G169D, p.G382D and p.D382D) genes were found. All 6 patients with mutations had more than 20 polyps (p=0,0026). Only 1 missense variant (p.G169D) in *MYH* gene was found among 106 healthy probands (p=0,016). Frequency of germline mutations in *APC* is 8% (2/25) and 16% (4/25) in *MYH*. The value of the heterozygous mutations for *MYH*-associated Polyposis was demonstrated for the first time among Russian patients.

Expression of genes for drug resistance and metabolism in muscle-invasive bladder tumors

O. S. Antonova[1], *R. G. Staneva*[1], *Z. A. Hammoudeh*[1], *S. Karachanak-Yankova*[1], *V. Sabriev*[2], *E. Popov*[2], *R. Cherneva*[3], *C. Slavov*[2], *D. Toncheva*[1];
[1]*Department of Medical Genetics, Medical University- Sofia, Sofia, Bulgaria,* [2]*Department of Urology, University Hospital Aleksandrovska, Sofia, Bulgaria,* [3]*Department of internal Medicine, University Hospital Aleksandrovska, Sofia, Bulgaria.*

Background:
The primary endpoint of this study was evaluation of the expression of genes related to the resistance to the most common anticancer drugs in muscle invasive bladder carcinomas.
Materials & Methods:
Gene expression analysis of the 168 genes from two panels for Cancer drug resistance and metabolism (PAHS004) and Cancer Drug Targets (PAHS507z) was performed. A total of 47 transitorial cell bladder cancer samples of stage pTa, pT1, pT2, pT2b and lymphoepithelioma-like pT2a were investigated. Gene expression analyses of the individual samples as well as the pool samples (pTa, pT1 and pT2) in comparison to negative and positive (non-malignant lesions) controls were carried out.
Results:
The pool analysis revealed statistically significant difference (p<0,0001) in the expression level between muscle invasive and non-invasive bladder tumors. More than 10 times higher expression is observed for AKT1, AURKA, CSTB, EGFR, ERBB2, ERBB4, HDAC and MDM2 genes which are targets for current and trial anticancer drugs. More than 5 times up-regulation was established for ABCC1, ABCC3, ARNT, CYP1A5, CYP3A5, EPHX1, MVP, PPARG and TXN genes. These are involved in the multi-drug resistance and metabolism of cyclosporine, steroid hormones, PAHs as well as anticancer drugs Vincristine, Thiopurine and Taxol.
In the fourteen tested individual samples we found an up-regulation for AHR, AR, CCNE1, CLPTM1L, CYP1A1, CYP3A5, MVP and TOP2B genes. In the 78,5% from them the expression of the PPARG gene, which activity is influenced by retinoid, was elevated.

The aim was to investigate MMP1 (rs494379, -519 A>G), MMP9 (rs3918242, -1562C>T; rs17576, 2660A>G), MMP12 (rs2276109, -82 A>G), MMP2 (rs2285053, -735C>T), TIMP3 (rs 9619311, -1296T>C) polymorphisms and bladder cancer susceptibility in population of The Republic Bashkortostan (Russian Federation). A total of 307 bladder cancer patients and 271 controls were genotyped by PCR- RFLP. It was found 2660A> G MMP9 association with bladder cancer development in the dominant model (p=0.044, OR=1.45, 95 % CI (1.01-2.07)) and MMP9 2660G/-1562C haplotype significantly more common in patients (34.52 % vs. 21.17%, OR=1.90, 95 % CI (1.22-2.97)) compared with control. It was defined MMP2 -735C>T significant association with bladder cancer development in the overdominant model (p=0.0009, OR=2.21, 95 % CI(1.38-3.53)). -1296T>C TIMP3 associated with disease in additive model (p=0.016, OR=1.44, 95 % CI(1.07-1.95)). No association with bladder cancer was observed for -519 A>G MMP1 and -82 A>G MMP12. It was found -735C> T MMP2 was significantly associated with the development of bladder cancer as an invasive (OR=1.93) and non-invasive forms (OR = 2.17). Analysis of gene - environment interactions showed a statistically significant interaction between MMP2 and MMP9 polymorphisms with the status and smoking index (p=0.014 and p=0.017, respectively) in dominant model. Thus we can assume MMP9, MMP2, TIMP3 polymorphisms under investigation make a definite contribution to the bladder cancer development.
The investigation was partially supported by RFBR 14-04-97006 r_povolzye_a, 14-06-97003 r_povolzye_a, 13-04-00287 A; RFH 13-06-00101.

Bladder cancer risk associated with XPD polymorphism in the Belarusian population

V. Ramaniuk, *N. Nikitchanka, N. Savina, T. Kuzhir;*
Institute of Genetics and Cytology of National Academy of Sciences of Belarus, Minsk, Belarus.

Bladder cancer (BC) is the fourth most common cancer among men in Europe, and the annual incidence rate is 1000 in Belarus. Among risk factors, cigarette smoking and occupational chemical exposure lead to accumulation of DNA damage contributing to carcinogenesis. In this context, polymorphism of error-free excision repair genes seems to affect the cancer risk. Polymorphism of XPD Asp312Asn, XRCC1 Arg399Gln, OGG1 Ser326Cys, ERCC6 Met1097Val was studied in the group of BC patients (336 individuals) as compared to the control group (370 volunteers). The allelic variants were determined in DNA samples using the PCR-RFLP method. Minor allele frequencies in Belarus were close to those in Caucasians and significantly differed from their frequencies in Asians. Analysis of polymorphisms in a single gene revealed increased BC risk in carriers of heterozygous genotype Asp/Asn of XPD gene that was pronounced in the elderly (OR95%CI=3.34 [1.35-8.28] p=0.009). The combination of this genotype with homozygous genotypes Ser/Ser of OGG1 or Met/Met of ERCC6 also increased cancer risk. Analysis of interaction between four genes showed that carriers of combinations Asp/Asn, Arg/Arg, Ser/Ser, Met/Val and Asn/Asn, Arg/Arg, Cys/Cys, Met/Val possessed more predisposition to cancer (OR95%CI=3.20 [1.47-6.95] p=0.003 and OR95%CI=9.97; p=0.1 respectively). Thus, XPD312 polymorphism was predominantly associated with BC risk in Belarus.

Aim of the study Cell free DNA (cfDNA) represents one of the new bladder cancer markers. Comparision of total urine cfDNA values of the control group and of the patient one was the aim of our study. Patients and methods Naturally voided second morning urine samples were collected from 99 individuals and 3 different groups of individuals were compared: (16 healthy volunteers (HV), 20 control patients with urological diagnoses different from bladder cancer (CP) and 63 patients with bladder cancer (BCP) (pT0 in 5 cases, pTa in 21, pT1 in 17, pT2 in 8, pT3 in 6, pT4 in 6 cases, both LG and HG in each stage group). Results: The comparison showed statistically significant difference between HV and BCP (p value = 0,000049). There were no statistical differences between the CP and BCP (p value = 0,372059) or between CP and HV groups, as well (p value = 0,046749). Patients were then divided into two groups according to their cancer stage. The group 1 (pTa patients, patients with another urological diagnoses and healthy volunteers) and the group 2 (patients with stages pT1 and more). Comparing these two groups by Mann-Whitney test we have shown significant difference with p value < 0.001. Conclusion: pTa patients significantly differ from pT1

ones and more regardless to the cancer grade. Patients with stages pT1 and more have significantly higher ucfDNA levels than other individuals. Acknowledgements: Supported by the Internal Grant Agency of the Ministry of Health of the Czech Republic no. NT12417.

BRCA1 Gene Polymorphisms and chromosomal aberrations as a risk of borderline ovarian cancer patients in Tamil Nadu population, South India

S. Arun, *K. Sasikala;*
Human Molecular Genetics laboratry, Department of Zoology, School of Lifescience, Bharathiar University, Coimbatore, India.

Ovarian cancer is the leading cause of death due to gynaecological malignancies among women. The aim of the study was to analyse the BRCA1 gene polymorphisms and major chromosomal aberration in the borderline ovarian cancer (BOC) patients. A population-based, case control study of ovarian cancer was performed in Tamil Nadu. Inferred consent forms were obtained from 34 BOC patients individually (Case & Control). We have examined for BRCA1 Q356R amino acid changing polymorphisms. Cytogenetic analyses were carried out using 3 mL of blood (100 metaphase). The major chromosomal aberrations were gains from chromosome arms and deletions of 1p, 12q, 14q, 15q, 16p, 17p, 17q, 19p and 19q sites in BOC patients. The correlation between family history, age, infertility, and diet - body weight were selectively evaluated and analysed. The most significant chromosomal abnormalities like deletions were recorded in BOC patients compared to the control subjects. Findings reveal that the patients above 60 years of age were at high risk. Thus the study concludes that the BRCA1 gene polymorphisms and chromosomal aberrations play a key genetic role along with the risk factors for BOC patients.

The role of BRAF V600E mutation as a potential marker for prognostic stratification of papillary thyroid carcinoma: A long-term follow-up study

a. Aarabi[1], *M. R. Abbaszadegan*[1], *m. Daliri*[2], *N. Taghehchian*[1], *R. Zakavi*[3];
[1]Avicenna research institute, immunology research center,Mashhad university of medical sciences, mashhad, Islamic Republic of Iran, [2]Surgical Oncology Research Center, Imam Reza Hospital, Faculty of Medicine, Mashhad University of Medical Sciences, mashhad, Islamic Republic of Iran, [3], Nuclear Medicine Research Center Mashhad University of Medical Sciences, mashhad, Islamic Republic of Iran.

Papillary carcinoma is the most prevalent malignancy of thyroid gland, and its incidence has been recently increased. The BRAFV600E mutation is the most frequent genetic alteration in papillary thyroid carcinoma (PTC). The role of BRAFV600E mutation as a potential prognostic factor has been controversially reported in different studies, with short-term follow-up. In this study we evaluated the role of BRAFV600E mutation as a potential marker for prognostic stratification of patients with papillary thyroid carcinoma in long-term follow-up. We studied 69 PTC patients with a mean follow-up period of 63.9 months (median: 60 m). The BRAFV600E mutation was analyzed by PCR-single-strand conformational polymorphism and sequencing. The correlation between the presence/absence of the BRAFV600E mutation, clinicopathological features and prognosis of PTC patients were studied. The BRAFV600E mutation was found in 28 of 69 (40.6%) PTC patients, and it was significantly more frequent in older patients (P<0.001), in advanced tumor stages (P=0.006), and in patients with history of radiation exposure (P=0.037). Incomplete response to treatment in PTC patients was significantly correlated with certain clinicopathological characteristics (follow up time, distant metastases, advanced stage, first thyroglobulin (fTg), history of reoperation and external radiotherapy, and delay in iodine therapy) but it wasn't related to the presence of BRAFV600E mutation. Prevalence of BRAFV600E mutation was 40.6% in patients with papillary thyroid cancer in northeast of Iran. The BRAFV600E mutation was associated with older age and advanced tumor stage but was not correlated with incomplete response during follow up.

Study of genes BRCA1 and 2 in clinical cases of breast and/or ovarian cancer in the Molecular Genetics Unit of Ferrara

M. Neri[1], *R. Selvatici*[2], *A. Balboni*[1], *A. Venturoli*[1], *C. Trabanelli*[1], *B. Dolcini*[1], *A. Spinelli*[1], *A. Ravani*[1], *A. Ferlini*[2];
[1]Dip. Riproduzione e Accrescimento, Ferrara, Italy, [2]Dip. Scienze Mediche e Dip. Riproduzione e Accrescimento, Ferrara, Italy.

Germinal mutations in two high susceptibility genes BRCA1 and BRCA2 explain around 25 % of familial breast cancers. Patients with a probability value above 10% in the risk assessment calculated by different prediction tools (CaGene, BOADICEA and Cuzick-Tyrer)) or belonging to the profile 3 of Modena's criteria were selected for the molecular analysis of BRCA 1 and 2 genes by direct sequencing and MLPA. Molecular analysis was completed on 80 patients and for both genes we identified 8 pathogenic mutations (frameshift, missense, nonsense) recurrent in unrelated patients or private. According to the literature, in about 10% of the identified variations the pathogenic significance was not known. The mutations were distributed along the entire gene sequence, therefore the search for specific mutations hotspot it is not adoptable as a procedure for the implementation of genetic testing. To date, the Breast Cancer Information Core Database (BIC) contains more than 3000 different sequence variations in BRCA1 and BRCA2 genes. We have found the same mutation in different patients associated to the occurrence of different cancer at a different age, therefore to date it is not possible a specific genotype-phenotype correlation. The data obtained in our laboratory so far suggest that the genetic risk of breast cancer could be caused by rare variants and being able to distinguish as deleterious or neutral the large number of new variations with unknown pathogenic significance is a difficult task. Early identification of individuals at risk allow to implement protocols and periodic clinical surveillance for certain risk profiles.

J12.018

Analysis of a novel BRCA1 splicing mutation in hereditary breast and ovarian cancer woman

V. D'Argenio[1,2], *M. Esposito*[1,2], *M. D'Aiuto*[3], *A. Calabrese*[3], *G. D'Aiuto*[3], *F. Salvatore*[1,2,4];
[1]CEINGE Biotecnologie Avanzate, Naples, Italy, [2]Department of Molecular Medicine and Medical Biotechnologies, University of Naples Federico II, Naples, Italy, [3]Department of Senology, Istituto Nazionale Tumori – IRCCS Fondazione Pascale, Naples, Italy, [4]IRCCS-Fondazione SDN, Naples, Italy.

Hereditary breast and ovarian cancer (HBOC) is the commonest malignancy in women. HBOC is a familial disease accounting for about 10% of all breast cancers, BRCA1 and BRCA2 being the most prevalent genes involved in this pathology (1). They play a role in the maintenance of genome stability, particularly in the homologous recombination (HR) pathway for double-strand DNA repair (2). BRCA1/BRCA2 germline mutations are related to an increased risk of developing HBOCs, therefore the carrier identification is crucial especially before the onset of the disease. Furthermore, testing for BRCA gene mutations allow to improve the clinical management of high-risk patients and of their mutation carriers family members. However, the correct interpretation of variants with uncertain significance or of novel variants still remains a problem for genetic counseling.
Here we describe a novel intronic variant identified in a HBOC patient and involved in the BRCA1 gene splicing regulation. This variant is predicted to be deleterious according to Human Splice Finder and NetGene2, causing the loss of a canonic donor splice site at position +2 in the intron 21 of BRCA1 gene. Variant effects were experimentally verified on patient cDNA by PCR amplifications using different primers pairs *ad hoc* designed. Our results indicate that intron 21 is completely retained in the transcript RNA. Despite other studies are needed to confirm the role of this splice variant, our preliminary results strongly support the pathogenicity of the novel found mutation.

Polymorphisms in the FGFR2 and miR146 genes are associated to increased risk in familial breast cancer in young women.

A. Pascual Rodríguez[1,2], *D. Fernández García*[1], *J. Fernández Mateos*[2], *E. M. Sánchez Tapia*[1,2], *T. Martín Gómez*[3], *J. J. Cruz Hernández*[3], *R. González Sarmiento*[1,2];
[1]Center of Cancer Research IBMCC (USAL/CSIC), Salamanca, Spain, [2]Institute of Biomedicine Research (IBSAL), Salamanca, Spain, [3]Oncology Service Universitary Hospital, Salamanca, Spain.

Breast cancer is the most common cancer diagnosed in women worldwide and 7% of all breast cancer cases occur in women under 40. Only 5-10% of all breast cancer have genetic predisposition and the number of women in the general population with breast cancer attributable to mutations in highly penetrance genes BRCA1 And BRCA2 is very low. These observations have led to the proposal that breast cancer susceptibility is largely polygenic and recent GWAS studies have identified some regions in the genome which contains SNP that can involved risk of developing breast cancer including FGFR2 (rs2981852) and miR146 (rs2910164). Moreover, several SNPs at the BRCA1 gene such as c.2731C>T (rs7999917), c.3232A>G (rs16941), c.3667A>G (rs16942), could modify the risk. We studied 124 women under 40 with breast cancer divided in two main groups: patients who carried pathogenic mutation in BRCA1/2 genes (BRCA+ n=22) and noncarriers (BRCA- n=102). DNA was extracted from peripheral blood and allelic discrimination was performed using TaqMan SNPGenotyping Assay. We found a significant association between genotype TT in the FGFR2 polymorphism and BRCA+ group (OR=0,133 CI95%=0,026-0,687p=0,024). Furthermore, we found that the G allele in the miR146 polymorphism is related with

BRCA- group (CG OR=6,792 CI95%=1,489-30,978 p=0,013 ; CG+GG OR=4,16 CI95%=1,316-13,152p=0,015) Thus we can conclude that genotype TT of FGFR2 polymorphism might be associated to increased the risk of breast cancer in presence of BRCA1/2 mutation while allele G of mir146 polymorphism could be related to an increase of breast cancer in patient noncarriers of BRCA1/2 mutation.

Cytogenetic heterogeneity in breast cancer and its relationship with the morphological types of infiltrating component

N. A. Skryabin[1], *E. V. Denisov*[2], *V. M. Perelmuter*[2], *S. A. Vasilyev*[1], *I. N. Lebedev*[1];
[1]*Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Tomsk Cancer Research Institute, Tomsk, Russian Federation.*

Solid tumors are characterized by considerable interindividual and intratumoral genetic heterogeneity. High genetic variability of breast cancer (BC) probably manifested in the presence of various types of structures of infiltrative component (morphological structures): tubular, trabecular, solid, alveolar and discrete groups of tumor cells. It may be assumed that different types of morphological structures are manifestations of phenotypic diversity, which is based on a set of specific cytogenetic differences. The aim of this study was to investigate intratumoral cytogenetic variation in BC and its relationship with the morphological subtypes of breast cancer. Material for analysis was taken from single patient with breast cancer. We isolated five morphological structures from two regions of breast cancer with laser microdissection (PALM, Carl Zeiss, Germany). Analysis of chromosomal aberrations was performed using Agilent microarrays (SurePrint G3 Cancer CGH + SNP Microarray Kit, 4x180K). The number of identified unbalanced chromosomal aberrations in the various structures ranged from 24 to 270. While the least amount of rearrangements found in tubular structures and the largest - in solid. The cluster analysis results indicate that the samples from different types of histological structures obtained from the same region of tumor clustered together rather than between similar cellular phenotype across the tumor. Furthermore, number of common chromosome aberrations between different tumor regions was not higher in samples with similar morphology than in samples with different morphology. It is suggested that similar histological structures may originate from cell clones with different karyotype.

J12.021

Analysis of BRCA1 and BRCA2 mutations in breast cancer patients from Uzbekistan

A. N. Abdikhakimov[1], *M. T. Tukhtaboeva*[1], *B. S. Adilov*[2], *A. R. Chernova*[2], *S. U. Turdikulova*[2];
[1]*Tashkent Institute of Postgraduate Medical Education, Tashkent Regional Oncological Dispenser, Tashkent, Uzbekistan,* [2]*Institute of Bioorganic Chemistry, Academy of Sciences Republic of Uzbekistan, Tashkent, Uzbekistan.*

Breast cancer is the most common malignancy in women and affects approximately 1 out of 10 females. Risk of developing breast cancer is strongly influenced by genetic factors. Germ-line mutations in BRCA1 and BRCA2 genes are the primary cause of up to 5-10% of breast cancer incidence. To reduce increased risk of developing cancer or to increase the likelihood of early detection, carries of BRCA1 or BRCA2 mutations are offered surveillance programs and effective preventive medical interventions. This study aimed to investigate the contribution of BRCA mutations to breast cancer cases in Uzbekistan. 67 patients with breast cancer as well as the sex and age matched control group of healthy individuals (n=103) were included in this study. By means of real-time allele-specific PCR we analyzed DNA samples of these groups for the presence of BRCA1 5382insC, BRCA1 4153delA, BRCA1 185delAG, BRCA1 300T>G and BRCA2 6174delT mutations. 3 unrelated samples (4.5%) were found to be positive for the heterozygous 5382insC mutation representing a possible founder mutation in the Uzbek population. In the investigated group of patients we didn't find BRCA1 4153delA, BRCA1 185delAG, BRCA1 300T>G and BRCA2 6174delT mutations. All investigated mutations were not found in any DNA sample of control group. The presented data confirm contribution of BRCA1 5382insC mutation to breast cancer development in Uzbek people and taking into account a high disease penetrance in carriers of BRCA1 mutation, it seems reasonable to suggest inclusion of 5382insC mutation test in screening programs for breast cancer prevention in Uzbekistan.

J12.022

Preliminary study of BRCA1/BRCA2 mutations in Bulgarian women with breast cancer

Z. Kamburova[1], *K. Kovacheva*[1], *S. Popovska*[2], *I. Ivanov*[2], *M. Simeonova*[1], *R. Dodova*[3], *D. Dacheva*[3], *P. Angelova*[1], *V. Mitev*[3], *A. Mitkova*[3], *R. Kaneva*[3];
[1]*Section of Medical Genetics, Medical University, Pleven, Bulgaria,* [2]*Department of Pathology, Medical University, Pleven, Bulgaria,* [3]*Molecular Medicine Center, Medical University, Sofia, Bulgaria.*

The mutations in BRCA1 and BRCA2 genes are the most significant genetic determinants of predisposition to develop breast cancer (BC). There is still insufficient data about BRCA1/2 mutations in Bulgarian BC population. It was a preliminary study aiming to investigate the frequency of five common deleterious point mutations (reported before in Bulgarian patients) and large genomic rearrangements (LGR) in BRCA1/2 genes in a target group (defined by preliminary prepared selective criteria) of Bulgarian women with BC.

The list of patients diagnosed with BC was taken from the Cancer Registry (2009-2013) of University Hospital, Pleven. One hundred and seventy five women with BC were interviewed and pedigree was constructed for each of them. The patients were classified into ten categories, according to personal, disease and family history. Based on the selective criteria we defined a target group of 79 Bulgarian women with BC. They were screened for five deleterious point mutations (5382insC; C61G, in BRCA1 6174delT, 9326insA; 9908delA in BRCA2) by DNA sequencing and for LGR by Multiplex Ligation Probe Amplification. Among the screened women we found: one deleterious mutation (5382insC in BRCA1) with frequency 1.2%; two polymorphic variants in BRCA2 gene - rs4987117 in exon11N and rs9534262 in exon17 with frequency 2.7% and 36% of the patients, respectively. None LGR was detected.

In conclusion, the insufficient results of our study suggest that the strategy for genetic screening in Bulgarian patients requires complete analysis of the BRCA1/2 genes and stringent compliance to the internationally accepted BCLC/NCCN criteria.

Mutation Analysis of ESM-1 Gene in Breast Cancer Patient Tissues

S. Dede[1], *M. Acar*[1], **M. Oznur**[1], *G. Nas*[1], *O. Hatipoglu*[1], *M. Gunduz*[1,2], *E. Gunduz*[1];
[1]*Turgut Ozal University, Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey,* [2]*Turgut Ozal University, Faculty of Medicine, Department of otolaryngology head and neck surgery, Ankara, Turkey.*

Breast cancer is the second common type of cancer in the world. In developed countries, breast cancer is one of the leading causes of women deaths. In recent years, many genes have been identified related to breast cancer. But underlying molecular mechanisms have not been clarified yet. Endocan, (ESM-1: endothelial cell-specific molecule-1) soluble proteoglycans, is secreted by endothelial cells. Expression of ESM-1 gene is regulated by the cytokines. The expression increases with the stimuli of VEGF, TGNF-α, LPS and IL-1β in endothelial and epithelial cells. The ESM-1 gene function has an important role in tumor angiogenesis and growth. It has been shown to involved in pathogenesis of lung, liver, gastric and breast cancer. ESM-1 gene is reported to have an effective role in cell proliferation, cell migration, invasion, and metastatic spread of cancer cells in recent studies.

In this study, we analyzed ESM-1 gene mutation in breast cancer from paraffin-embeded tissue samples of breast cancer patients. All three exons for ESM-1 gene mutation were sequenced by Sanger Sequencing.

Our results showed a homozygous silent mutation (CAG>CAA) in the second exon at codon 118. Another case displayed the same mutation heterozygously. In nine cases, the polymorphism TTG>CTG was evaluated as being remarkable in the third exon of poly-A region which maybe the miRNAs binding site.

J12.024

Association of estrogen receptor-α A908G (K303R) mutation with breast cancer risk

S. Abbasi[1], *M. Rasouli*[2], *S. Kalbasi*[3];
[1]*Dept. Medical Biotechnology,Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Laboratory of Vaccines and Immunotherapeutics , Institute of Bioscience, University Putra Malaysia, UPM, Serdang, Malaysia,* [3]*Faculty of Veterinary, University of Tehran, Tehran, Islamic Republic of Iran.*

Genetic mutations in premalignant breast lesions may have a role in malignancy progression or influence the behavior of subsequent disease. A point mutation in estrogen receptor-α (ER-α) as A908G (Lys303→Arg) was originally involved to hypersensitive to estrogen breast hyperplasia. We detected this mutation among Iranian women with invasive breast cancer. A population-based case-control study was conducted in 150 newly diagnosed invasive breast cancer and 147 healthy control individuals controls to screen for presence of the ER-α A908G mutation by using single-strand conformation polymorphism (SSCP) analysis and 33Pcycle DNA sequencing. We detected the 10.7% ER-α A908G mutation in the form of heterozygote genotype only among cancer patients ($\chi 2=22.752$, $P=0.00$). The allelic frequency of mutant allele AGG in codon 303 was significantly ($\chi 2=29.709$, $P=0.001$) higher in patients with the family history of breast cancer (28.9%) than those without the family history of breast cancer (1.9%). Our data suggest that ER-α

codon 303 mutation is correlated with various aspects of breast cancer in Iran. ER-α genotype might represent a surrogate marker for predicting breast cancer developing later in life.

The association between G-2548A polymorphism of leptin gene and breast cancer risk

S. Rostami, *I. kohan;*
Arsanjan Branch, Islamic Azad University, Department of Biology, Arsanjan, Islamic Republic of Iran.

Introduction: The Breast cancer is the most common cancer in woman and the second cause of death in women between 35 to 55 years. Risk creation the breast cancer is in time life woman 12/5% (one of the eight cases) and risk of death from breast cancer 3/6% (one case of twenty eight case). Leptin hormone is secreted from adipocytes which is involved in the regulation of body weight and serum levels are correlated with breast cancer risk. Genetic polymorphisms G-2548A promoter region of leptin gene expression and hormone secretion rates of faty tissue will be affected. The purpose of this study is to investigate the relationship between G-2548A polymorphism in the leptin gene and breast cancer risk.
Material and methods: We here carried out a case-control study that included 50 patients and 50 healthy subjects. We examined the genotype distribution of Leptin promoter G-2548A polymorphism, using the polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) approach,to investigate the possible role of this SNP as a risk factor in breast cancer.
Results: Statistical analysis showed is that the AG genotype frequencies in the patient group 26% and in the control group 48%.AG genotype the region -2548 leptin gene has a protective effect on breast cancer risk and this genotype than other genotypes reduces the breast cancer risk (OR:0.4, 95%CI: 0.16-0.97, P: 0.04). There is a significant association between G-2548A polymorphism of leptin gene and breast cancer risk. This polymorphism can be used as a diagnosis marker for breast cancer.

Evaluation of immunostaining by hormone receptors and the receptor HER2 in breast cancer

H. Bensaber[1], *D. Bicot*[2], *M. Benjamaia*[3], *H. Bouakline*[3], *A. Bensnouci*[3], *Y. Cheblounе*[4], *F. El Kebir*[1];
[1]*Université d'Oan laboratoire de recherche en cancérologie ,Biologie de Développement et de la différenciation LBDD,Faculté des sciences ,Département de Biologie, Oran, Algeria,* [2]*Laboratoire TIMC – UMR 5525 Faculté de Médecine, Domaine de la Merci .Grenoble, France, .Grenoble, France,* [3]*Laboratoire d'anatomopathologie de l'hôpital Militaire Universitaire et Régional d'Oran (HMURO)., Oran, Algeria,* [4]*Laboratoire Adaptation et Pathogénèse des Micro-organismes, LAPMO, UMR 5163 CNRS –Université Joseph Fourier, Institut Jean Roget, Grenoble, France.*

Breast cancer is the most common cancer in women worldwide. The evaluation of the expression of estrogen receptors and progesterone and HER- 2 has become essential for the treatment of patients bearing breast cancer since it provides information of prognostic and therapeutic order. The purpose of this study was to evaluate the expression of hormone receptors and Her-2 protein in breast cancer , study the correlations between them and with other prognostic factors, compare our results with those in the literature and evaluate our immunohistochemical technique . This is a prospective study of 130 cases of breast cancer diagnosed at the Laboratory of Pathology of the University Military Hospital and Regional Oran (HMURO) since the year 2006 until 2009. The evaluation of the expression of hormone receptors and HER2 by immunohistochemistry was performed . ERs are expressed in 64% of cases, PR in 71% of cases and HER2 in 31 % of cases. The correlation between the percentage and intensity of marking the RE and RA was statistically significant . On PR , they were correlated with age but not with tumor size or lymph node status with . HER2 was associated with histological type . Our results are generally consistent with those in the literature and our immunohistochemical technique has proved its reliability. The development of molecular study and collaboration with the various departments of our University and Regional Military Hospital of Oran (HMURO) means help understanding some of our patients .

Analysis of microRNA expression in breast cancer tumor: identification of cluster co-expressed miRs.

T. Muzaffarova[1], *N. Pospekhova*[1], *S. Poyarkov*[1], *E. Zenit-Zhuravleva*[1], *V. Shubin*[1], *F. Kipkeeva*[1], *V. Khaylenko*[2], *A. Karpukhin*[1];
[1]*1) Research Centre for Medical Genetics 115478, Moscow, Russian Federation,* [2]*Blokhin Cancer Centre, 115478 Moscow, Kashirskoe sh., 24., Moscow, Russian Federation.*

The investigation of 14 microRNA (miR-10b, miR-21, miR-31, miR-155, miR-29a, miR-195, miR-192, miR-182, miR-125b, miR-145, miR-221, miR-222, miR-34a, miR-335) expression levels in a sample of breast cancer tumors in relation to the normal breast tissue was performed. All patients of the sample were not subject to radiation, neither to chemotherapy. The expression level of miR-182 most often was increased - in 81% of cases. In 59% of cases there was over expression of miR-182 - more than 10 times. The expression of miR-31, potential metastasis suppressor, was decreased in 54% of cases. There was identified cluster co-expression 5 microRNA: with increased expression miR-10b, miR-21, miR-155, miR-34a and miR-335. The cluster includes 33% of studied tumors. Frequency over expression of these miRs among tumors in the cluster was 4 times higher compared to other tumors ($p < 0.00001$). The transcriptional regulation analysis shows that 4 microRNAs of cluster are transcriptional targets of p53 and RelA-NF-kB. All the tumors in the cluster were characterized by infiltrating lobular and mixed variants (infiltrating lobular combined with infiltrating ductal) breast cancer and were positive in the expression of estrogen and progesterone receptors. The cluster includes 60% of all tumors with local metastases in lymph nodes (i.e., metastases occur approximately 3 times more often than in the other tumors of the sample). It allows assuming existence of the association co-expressed in this cluster microRNA with pathomorphological features of the tumors, in particular, with a predominant presence of metastases.

Breast carcinomas with negative estrogen and progesterone receptor status and the expression of various potential useful biomarkers

M. Frangou, **E. Plemenos**, *D. Karandrea, E. Boutou, D. Vlachodimitropoulos;*
Athens University, Athens, Greece.

In primary breast cancer, hormonal receptor status is very useful in predicting response to endocrine therapy and prognosis. Negative ER, PR cases have limited therapeuting options, so it is very helpful to identify biomarkers that can be used as targets for the new targeting therapies, or can be used for prognostic value. We studied 623 tissue samples from operable primary breast adenocarcinomas and 101 of them had negative receptor status. From these 101 cases 52.3% was c-erbB2 positive vs 27.3% of the total amount, and the HER-2 gene was amplified in 36.6% vs 16.8% of the total cases. p53 was expressed in the 59.5% of the negative ER cases vs 26.6% of the total amount. The expression of the stem cell markers was almost identical in positive and negative ER cases, except of cd24 which was expressed in 25%vs80% respectively (p0.02) of the cancer cells of this group. According to our results the positivity of c-erbB2 is higher in negative cases and many of the negative c-erbB2 immunohistochemically cases show amplification of the gene, proposing that herceptin may be a benefit in these cases. The high percentages of the p53 and cd24 expression shows that this group of cases tends to have poorer prognosis, as cd24 is expressed in the more primitive mammary stem cells. A CISH or FISH test is recommended for this group, whatever the c-erbB2 result of the protein is, in order to give the oncologist more detailed information about the biological behaviour of these cancer cells.

Study of Her-2/neu and TOP2A Expression in Familial Versus Sporadic Breast Carcinoma

S. A. Hammad[1], *A. M. S. El-Gerzawy*[1], *M. M. S. Al Ansary*[2], *I. L. Hussein*[3], *A. M. Mohamed*[1], *F. M. El-Kasem*[4], *S. G. Abd-Allaha*[1];
[1]*National Research centre, Cairo, Egypt,* [2]*Department of Clinical and Chemical Pathology, Faculty of Medicine,, Cairo, Egypt,* [3]*Departments of Pathology and dMedical Oncology, National Cancer Institute, Cairo University, Cairo, Egypt,* [4]*Pathology and dMedical Oncology, National Cancer Institute, Cairo University, Cairo, Egypt.*

Genetic predisposition is one of the risk factors that increase the incidence of breast cancer. Her-2/neu gene is considered the most frequently amplified oncogenes and is accompanied with amplification or deletion of TOP2A gene. Our study aims to compare familial breast cancer (FBC) patients with sporadic breast cancer (SBC) and to evaluate the hormonal status, immunostaining for Her-2/neu, and Her-2/neu and TOP2A copy number alterations by fluorescence in-situ hybridization (FISH). Twenty two patients with invasive breast cancer were involved: 12 positive for the criteria of FBC. Sections of formalin-fixed paraffin embedded blocks were subjected to immunostaining for Her-2/neu (Hercep test), estrogen receptors, progesterone receptors and FISH for Her-2/neu and TOP2A genes copy number alterations. Pathological parameters and immunohistochemical markers proved that FBCs were more aggressive than SBC. TOP2A gene amplification was observed in 25% of FBCs compared with 20% of SBC patients. Co amplification of both Her-2/neu and TOP2A genes were observed in 8.3% of FBC patients and in 20%SBCs. In contrast, Her-2/neu amplification was observed in 25% of FBCs compared with 10% of SBCs. Importantly, TOP2A amplification without Her-2/neu gene amplification was observed in 16.7% of FBCs but was

not observed among SBC patients.
In conclusion TOP2A gene amplification occurs both in FBCs and SBCs but more frequently among FBCs independent of Her-2/neu amplification. This study highlights the importance of TOP2A gene amplification in diagnosis of FBC. In addition, a combined approach using immunohistochemical analysis and FISH can optimize Her-2/neu testing for breast cancer patients.

Recently, Hematology has been witness to great strides in genetic advancement. Lymphoma is now regarded as heterogeneous genetic disease. The genetic aberrations not only aid diagnosis, but also dictate choice of therapy, therapeutic response and portend prognosis. This is such a case exampling application of cytogenetics. A 4 year frail child presented with abdominal pain and distension of 15 days duration. Ultrasonography and Magnetic Resonance Imaging revealed bilateral renal mass. Provisional clinical diagnosis of Bilateral Nephromatosis / Neuroblastoma was offered. Preliminary guided Fine Needle Aspiration showed monomorphous population of vacuolated lymphoid cells suggestive of malignant lymphoma - Burkitt type. Peripheral smear and bone marrow study on aspirate material revealed 46,XY,t(2;8), add(11)(q24) confirming cytological diagnosis. The patient succumbed to organ failure with short hospital stay of 20 days. We present our case of Burkitt lymphoma with unusual presentation, variant translocation and poor performance. Documentation of such cases can direct compile new prognostic factors, advent of new therapeutic regimens in the future.

Expression analysis of four cancer-testis antigens in breast cancer tissues and cell lines

G. Kazemi oula[1], *A. Bushehri*[1], *S. Ghafouri-fard*[2], *M. B. Mobasheri*[1], *L. Geranpayeh*[1,3], *M. H. Modarressi*[1];
[1]*Tehran University of Medical Sciences (TUMS), Tehran, Islamic Republic of Iran,* [2]*Shahid Behehshti University of Medical Sciences (SBUM), Tehran, Islamic Republic of Iran,* [3]*Sina Hospital, Department of Surgery, Tehran, Islamic Republic of Iran.*

Introduction: Testis-specific genes which has normal expression in restricted tissues, contains a subgroup demonstrating expression in various malignancies known as Cancer-Testis Antigen (CTAs). Considering testis as an immune privileged organ, aberrant expression in cancers could cause spontaneous humoral and cell-mediated immune responses. Breast cancer is a promising target for vaccination and immunotherapy using CTAs. **Methods and material:** We analyzed the expression of 4 CTAs, PEPP-2, ODF4, ACRBP and SPATA19 in 40 samples of invasive ductal carcinoma (IDC), adjacent normal tissue and 10 fibroadenomas, as well as MCF-7 and MDA-MB-231 cell lines using RT & Real Time RT-PCR. **Results:** ACRBP was expressed in normal tissue. SPATA19 expression was not significantly different in normal and cancer tissues. ODF4 and PEPP-2 were expressed in 62.5% and 22.5% of IDC samples respectively. Real Time results showed increased expression of ODF4 and PEPP-2, 2.96 ($p<0.001$) and 3.31 ($p<0.01$) times in IDCs samples, respectively in comparison with testis tissue. Both genes were up-regulated in MCF-7 and MDA-MB-231 cell lines compared with normal testis sample. Comparing the expression of ODF4 & PEPP-2 in MDA-231 with MCF showed 1.758 & 1.77 ($p<0.001$) times up regulation in MDA-MB-231, respectively. **Conclusion:** ODF4 and PEPP-2 could be potential cancer biomarkers. Therefore, they can be used for active immunotherapeutic interventions. Expression of ODF4 and PEPP-2 in malignant tissues and their absence in benign and normal tissues make them putative cancer biomarkers. We showed ACRBP expression in normal breast tissue, so its application as cancer biomarker or in immunotherapeutic approaches is under question.

CAT C262T, GSTM1, GSTT1 and CML risk

V. G. Moldovan, *C. Duicu, A. Crauciuc, F. Tripon, E. Moldovan, C. Banescu;*
University of Medicine and Pharmacy, Tîrgu Mureş, Romania.

Background: Polymorphisms of oxidative stress related genes enzymes are known to influence the metabolism of different carcinogens and have been associated with incidence of various types of cancer. **Matherial and method:** The aim of this study is to evaluate the influence of catalase (CAT) and glutathione S-transferase (GSTM1/GSTT1) as risk factors for Chronic Myelogenous Leukemia (CML) development. We performed a case-control study which included 75 CML patients and 150 healthy volunteers, with no history of malignancy. The genetic polymorphism of CAT C262T was assessed by RFLP-PCR while for GSTM1 and GSTT1 Multiplex PCR assay was used, both followed by gel electrophoresis. **Results:** For CAT gene polymorphism the molecular analysis identified homozygous mutant allele TT in 13.33% of CML patients and 5.34% in the control group (p=0.3072), while heterozygous CT was found in 21.33% of study population and in 46.66% control cases (p=0.0008). The prevalence of GSTM1 null genotype in the patients group was 60% and in the control group 53.33% (p=0.3939). GSTT1 null genotype frequency in CML patients was 17.33% while in the control population it was 16% (p= 0.8494). We found no correlation between GSTM1 and GSTT1 null genotypes in CML development. Our results show that CAT C262T variant genotype is significantly associated with CML risk (p=0.016, OR=2.042 CI95% 1.151-3.623) **Conclusion:** These preliminary results show that CAT C262T genetic polymorphism might be related with CML development. Expression analysis of CD44 isoforms in Esophageal Squamous Cell Carcinoma patients

M. Gholamin[1], *A. Mansouri*[1], *M. R. Abbaszadegan*[1], *B. Memar*[2];
[1]*Division of Human Genetics, Immunology Research Center, Avicenna Research Institute, Mashhad University of Medical Sciences, Mashhad, Iran,, Mashhad, Islamic Republic of Iran,* [2]*Department of Pathology- Omid hospital, Mashhad, Islamic Republic of Iran.*

Background: CD44 is a member of the cell adhesion molecules family. In normal cells, CD44S, along with CD44V3 and CD44V6 play roles in cell motility, migration, and adhesion, while in tumor cells they are involved in tumor invasion, progression, and metastasis. The aim of this study was to evaluate the expression of CD44S, V3 and V6 in esophageal squamous cell carcinoma (ESCC) and their correlations with clinicopathological features of the patients.
Methods: The expression of CD44S, V3 and V6 was compared in tumoral and distant tumor-free tissues of the esophagus in fifty ESCC patients using comparative real-time PCR.
Results: A significant overexpression of CD44S, V3 and V6 mRNA was observed in 13, 11 and 9 tumor specimens, respectively. The co-expression of the genes (S&V3) were significantly associated with grade of tumor differentiation, stage of tumor progression, and depth of tumor invasion and (S&V6) with grade of tumor differentiation and (V3&V6) with grade of tumor differentiation, stage of tumor progression and depth of tumor invasion.
Conclusion: Our finding suggested that the reduced expression of CD44 v6 is associated with invasion and stage of tumor and the level of CD44V3 mRNA expression was associated with tumor invasion. In addition, Simultaneous expression of these genes has an important role in tumor prognosis. Investigating the potential role of alternative splicing in cancer progression may therefore lead to the development of novel therapeutic interventions.

J12.034
Is the chromosome Y loss in oncohematological male patients a disease-related marker or an age-associated phenomenon?

S. Ransdorfova[1], *L. Lizcova*[2], *J. Brezinova*[1], *Z. Zemanova*[2], *I. Sarova*[1], *L. Pavlistova*[2], *A. Berkova*[2], *K. Svobodova*[2], *S. Izakova*[2], *E. Malinova*[2], *K. Michalova*[1,2];
[1]*Institute of Hematology and Blood Transfusion, Prague 2, Czech Republic,* [2]*Center of Oncocytogenetics, General University Hospital and 1st Faculty of Medicine, Charles University, Prague 2, Czech Republic.*

Loss of the Y-chromosome (-Y) is observed in peripheral blood of healthy elderly men, however it may be found also in bone marrow cells of males with different subtypes of hematological malignancies. Therefore it is unclear whether -Y occurs as normal age-related event or it is a marker of neoplastic clone. The aim of our study was to review molecular cytogenetic findings in bone marrow cells of patients with oncohematological diseases and to assess the role of the Y-loss during malignant process.
We found loss of the Y-chromosome in bone marrow samples of 142 males (median age 72 years, range 21-89 years) with myeloid or lymphoid disorders. The most frequent diagnosis was myelodysplastic syndromes and acute myeloid leukemia (54 patients). All samples were analyzed by conventional G-banding and by interphase FISH. Cut-off level for FISH was established at 10% and the extent of cell clones with Y-loss varied from 12 to 98%. Most of the patients (131) showed a clone with -Y at the time of diagnosis. In 114 cases Y-loss was the sole abnormality and in 17 patients it was associated with autosomal structural and/or numerical aberrations. In 11 patients -Y clone was detected during the progression of the disease.
As quoted in the literature (Van Dyk, 2001) the presence of >75% cells with -Y is associated with the malignant disease. In our cohort, this was found in 25 patients (18%) and therefore such findings may be considered as related to malignity.
Supported by MHCR 00023736, RVO-VFN64165, GACR P302/12/G157/1.

Polymorphism of *XRCC1*, *XRCC3* and *XPD* genes and risk of chronic myeloid leukemia in a Romanian population

M. Dobreanu[1], *A. Trifa*[2], *C. Duicu*[1], *V. Moldovan*[1], *D. Dima*[3], *S. Demian*[1], *C. Banescu*[1];
[1]University of Medicine and Pharmacy, Tîrgu Mureş, Romania, [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania, [3]Department of Hematology, "Ion Chiricuta" Cancer Institute, Cluj-Napoca, Romania.

The genetic polymorphisms of X-ray repair cross-complementing group 1 (*XRCC1*), X-ray repair cross-complementing group 3 (*XRCC3*) and xeroderma pigmentosum complementation group D (*XPD*) repair genes may lead to genetic instability and leukemogenesis. The purpose of the study was to evaluate the association between *XRCC1* gene Arg399Gln, Arg280His and Arg194Trp, *XRCC3* Thr241Met and *XPD* Lys751Gln repair gene polymorphisms and the risk of development of CML in Romanian patients. A total of 156 patients aged 20 to 78 years diagnosed with CML (mean age 51.5 ± 1.1 years) and 180 control individuals (mean age 49.8 ± 2.1 years) were incuded in this study. The *XRCC1, XRCC3* and *XPD* genotypes were determined by the polymerase chain reaction-restriction fragment length polymorphism assay. We found no association between chronic myeloid leukemia and *XRCC1* and *XRCC3* variant in any of investigated cases. A significant differences were observed in the variant genotype frequencies of the *XPD* Lys751Gln polymorphism between the the patients with CML and control group (for variant homozygous genotypes, OR = 2.37; 95% CI = 1.20-4.67; p-value = 0.016 and for combined heterozygous and variant homozygous genotypes, OR = 1.72; 95% CI = 1.10-2.69; p-value = 0.019). This was also observed when analyzing the variant 751Gln allele (OR = 1.54; 95% CI = 1.13-2.11; p-value = 0.008). Our results suggest that the *XPD* Lys751Gln variant genotype increases the risk of chronic myeloid leukemia.

Investigation of the role of VHL and SETD2 gene mutations in human clear cell renal cell carcinoma development in patients from Russia

E. Klimentova[1], *I. Gilyazova*[2], *L. Kutlyeva*[2], *A. Zagidullin*[3], *G. Kunsbaeva*[1], *A. Khaliullin*[3], *A. Nazarov*[3], *A. Itkulov*[3], *R. Ishemgulov*[3], *V. Pavlov*[3], *E. Khusnutdinova*[1,2];
[1]Bashkir State University, Ufa, Russian Federation, [2]Establishment of the Russian Academy of Sciences Institute of Biochemistry and Genetics, Ufa, Russian Federation, [3]Bashkir Medical State University, Ufa, Russian Federation.

Renal cell carcinoma is the most common neoplasm affecting the adult kidney. One of the most frequent events in clear cell renal cell carcinoma (ccRCC) is inactivation of Von Hippel-Lindau gene (VHL). A series of studies recently demonstrated that a number histone modifying and chromatin remodeling genes, including SETD2, have mutation in ccRCC. Furthermore, SETD2 gene is within a 50-Mb region on chromosome 3p that encompasses VHL and is deleted in ~90% of ccRCC.

The goal of the study was to investigate inactivation of VHL and SETD2 genes by mutations. We studied 105 DNA samples of tumor tissues and normal renal parenchyma in ccRCC patients from Bashkortostan Republic of Russia, using PCR, SSCP and direct sequencing. Mutations in VHL gene were found in tumor tissues with the frequency of 21,9% (23/105). We detected 22 mutations in 23 ccRCC patients, including 8 point mutations (35%), 13 deletions (60%) and 1 insertion (5%). Ten somatic mutations hadn't been described in literature previously. VHL inactivation through sequence alterations in tumor DNA didn't differ by histopathologic characteristics or occupational exposure. Analysis of SETD2 gene was performed in 50 ccRCCs DNA samples and matched normal tissues. According to literature, mutations in SETD2 gene are detected in 4-15% cases of ccRCC. In our research SETD2 gene mutations were not found. This may be due to an insufficient number of samples in the investigated cohort. Further studies of chromosome 3 tumor suppressor genes in ccRCC tumorigenesis and validating the clinical impact of these novel mutations are required.

Familial inversion accompanying unbalanced karyotype in a case with CML

A. Acar, *M. Balasar, E. Tuncez, P. Tasdemir, N. Somuncu;*
Necmettin Erbakan University, Meram Medical Faculty, Department of Medical Genetics, Konya, Turkey.

%90-95 of patients with CML have t(9;22)(q34;q11) Philadelphia chromosome. Other abnormalities besides the Ph chromosome are observed as %7 in chronic phase and %40-70 in blast crisis. Generally additional abnormalities are translocations and deletions, the inversion rate is just %2. Inversions constitute %10 of all structural chromosome aberrations and generally had no phenotypic effects. In inversion carriers, depending on which chromosome or segment are involved, the risk of reproductive wastage increase.

Here we reported a 43 years old female patient with Ph chromosome and additive chromosomal abnormalities which has been diagnosed in CML. In the analyses performed using BCR-ABL1 FISH probe into the bone marrow interphase cells, %12 of the cells were normal, %20 had classical fusion, in %68 of the cells increased ABL signals were present giving rise to complex rearrangements. In the molecular genetic analysis the BCR-ABL1 was positive (IS:0.75924).

The karyotype of bone marrow cells was 46,XX,?add(16)(q24),inv(18), add(21)(q22),Ph(+).C and G-banded metaphases of peripheral blood had 16qh+ and inv18, however add21(q22) and Ph chromosome which are observed in the bone marrow cultures were not encountered. The patient had 7 pregnancies but she had only 2 healthy children. Her father and 1 child also had 16qh+ and inv18. It was concluded that only Ph+ and add 21(q22) was present in the leukemic clones of the patient and that 16qh+ and inv18 was inherited.

As a result, it was concluded that evaluation of the contribution of inversions identified in haematologic malignancies to unbalanced karyotypes and carcinogenesis should be made wisely.

The comparison of cytogenetic & fluorescence in situ hybridization study on bone marrow & peripheral blood cells in 30 chronic myelogenous leukemia patients

S. Manaflouyan Khajehmarjany[1,2], *S. Rahmani*[1,2], *S. Chavoshi*[3,4], *A. Esfahani*[3,4], *A. Movassaghpour*[3];
[1]Department of Cellular & Molecular Biology, Islamic Azad University, Ahar, Islamic Republic of Iran, [2]Medical Genetic Lab, Tabriz, Islamic Republic of Iran, [3]Department of Hematology & Oncology Research Center -Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran, [4]Emam Reza Hospital, Tabriz, Islamic republic of Iran, Tabriz, Islamic Republic of Iran.

BACKGROUND: Chronic myeloid leukemia (CML) is a myeloproliferative disease. The cytogenetic hallmark of CML is philadelphia chromosome (Ph). The aim of this study was to diagnose assumed CML patients, to monitor CML patients under Imatinib therapy on the bone marrow and peripheral blood samples by cytogenetic and fluorescence in situ hybridization (FISH), and also to compare the results on both specimens. **MATERIALS & METHODS:** Chromosome banding and FISH analysis was performed on 30 suspected CML patients on the bone marrow (BM) and peripheral blood (PB) specimens. **RESULTS:** The comparison of FISH and karyotyping in 30 patients on BM and PB specimens, respectively showed that 9 (30%) and 8 (26.66%) of them were Ph+, and only (18.18%) of Ph positive patients showed atypical patterns. In comparison between BM-cytogenetic and PB I-FISH, BM-cytogenetic was more reliable than PB I-FISH to detect Ph. **CONCLUSION:** Our data demonstrate FISH analysis is a rapid, reliable and sensitive technique. Our study in comparison between BM and PB, showed BM can't replace by PB, even in detecting by FISH.

J12.039

Translocatioon t(7;11)(p15;p15) in a patient with chronic myelogeneous leukemia (CML) Ph-positive

L. Militti[1], *R. Di Gianfilippo*[1], *A. Soranno*[1], *D. Fantasia*[2], *A. Di Nardo*[1], *A. Simone*[2], *R. Spadano*[3], *P. Guanciali Franchi*[2], *G. Calabrese*[2,1];
[1]Medical Genetics, Pescara Hospital, Pescara, Italy, [2]Medical Genetics, University of Chieti, Chieti, Italy, [3]Hematology Unit, Pescara Hospital, Pescara, Italy.

Translocation t(7;11)(p15;p15) is observed in 2% de novo AML and, much rarely, in Ph-positive CML in blastic phase (BP). The translocation results in a fusion between NUP98 and HOXA9 with a pathogenetic role in leukemogenesis. A 40-yr old caucasian male was diagnosed with CML-BP. He came to our attention for a marked leukocytosis (190 x 10^3/ml) and anemia (Hb 7.6 g/dl), with a normal platelet count and mild splenomegaly. Conventional cytogenetic and fluorescent in situ hybridization (FISH) analyses detected a t(9;22)(q34;q11) combined with a translocation t(7;11)(p15;p15), and BCR-ABL together with NUP98-HOXA9 rearrangements, respectively. The patient was at first treated with hydroxyurea briefly followed by high dose imatinib (400-600 mg daily). Then, based on the absence of complete response (CR), sequential therapy with dasatinib (140mg daily) was administered which resulted in primary resistance. Sequencing analysis of ABL-KD domains revealed mutation E255K, within the P-loop site. Two months later a new induction protocol (AML1310) was administered without response. The patient is alive in relapse six months from diagnosis. To date, only seven CML-BP Ph positive cases have been reported associated with translocation t(7;11). In the present case, TKIs resistance was likely subsequent both to mutation E255K, which shows a moderate resistance to dasatinib, combined with the presence of t(7;11) as an additional chromosomal abnormality. Furthermore, unsuccessful chemotherapy still represent a possible effect of t(7;11)/ NUP98-HOXA9 fusion gene which is known to be associated with

severe prognosis in AML cases inhibiting hematopoietic precursor differentiation and increasing self-renewal of hematopoietic stem or progenitor cells.

Study of *C-MYC* amplification and expression in gastric cancer samples using CISH and IHC methods

M. Khaleghian, *C. Azimi, I. Jahanzad, A. Shakoori Garakani;*
Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Cancer is a leading cause of death worldwide and accounted for 7.6 million deaths (around 13% of all deaths). Gastric cancer is the fourth and fifth most common cancer in men and women, respectively. The northern and northwestern regions of Iran are high risk areas for gastric cancer.
Gastric cancer carcinogenesis refers to accumulation of genetic alteration of multiple genes such as oncogenes, tumor suppressor and mismatch repair genes. *C-MYC* proto-oncogene is one of the most frequently activated oncogenes, and is estimated to be involved in 20% of all human cancers.
To evaluate *MYC* copy number and its protein expression, CISH and IHC analyses were performed in 50 gastric adenocarcinomas among Iranian individuals. 29 samples showed low amplification, 9 and 12 samples showed moderately and high amplification, respectively. MYC immunoreactivity was observed in 27 samples. In 31 samples either *MYC* amplification or MYC immunoreactivity were observed. 19 samples showed low amplification and were negative IHC. Among 31 samples, 9 samples showed low amplification, 8 and 14 samples were moderately and high amplification, respectively. Among 31 samples, 9 samples had strong signal, 16 samples moderately signal, 2 samples poor signal and 4 samples negative signal for IHC. The majority of patients with IHC negative had low amplification. Therefore, *C-MYC* amplification was correlated with the C-MYC protein overexpression.
This study showed that there was amplification in early gastric cancer and could be used as a therapeutic target. Therefore, this will contribute to early diagnosis, therapeutic and prognosis of gastric adenocarcinoma.

Extended genetic analysis of Swedish patients with suspected hereditary colorectal cancer (The SWEN study)

I. Holm[1], *T. Zagoras*[2], *C. Aravidis*[3], *M. Stenmark-Askmalm*[4], *E. Björck*[5], *K. Lagerstedt-Robinson*[5], *M. Nordling*[2], *Å. Borg*[6], *S. Gebre-Medhin*[1];
[1]*Department of Clinical Genetics, Lund, Sweden,* [2]*Department of Clinical Genetics, Sahlgrenska University Hospital, Gothenburg University, Gothenburg, Sweden,* [3]*Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden,* [4]*Division of Clinical Genetics, Department of Clinical and Experimental Medicine, Faculty of Health Sciences, Linköping University, County Council of Östergötland, Linköping, Sweden,* [5]*Department of Clinical Genetics, Karolinska University Hospital and Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden,* [6]*Division of Oncology-Pathology, Clinical Sciences, Lund University, Lund, Sweden.*

Background
The life-time risk for colorectal cancer (CRC) in the Swedish population is approximately 5 % with a mortality second only to that of lung cancer. It is estimated that 5 % of all CRC develop in individuals with a Mendelian predisposition for the disease, for example Lynch syndrome (LS), familial adenomatous polyposis (FAP), *MUTYH*-associated polyposis (MAP), juvenile polyposis syndrome (JPS), Peutz-Jeghers syndrome (PJS) or PTEN hamartomatous tumor syndrome (PHTS). However, diagnose-selective genetic screening fails to detect a disease-causing mutation in the majority of patients with suspected hereditary CRC.
Aim
The SWedish Extended genetic analysis of hereditary colorectal Neoplasia (SWEN) is a prospective national study involving researchers and clinically active staff at the cancer genetics clinics in Sweden with the overall aim to improve genetic testing and the care of patients and families with genetic susceptibility for CRC.
Material and Methods
Six hundred adult patients with clinically suspected Mendelian CRC of any type are offered mutation screening of the 11 genes associated with LS, FAP, MAP, JPS, PJS, PHTS and additional selected candidate CRC susceptibility genes. Genetic and clinical data for each family is registered in a national database followed by genotype-phenotype correlation studies.
Current Status
The study is ongoing since February 2014 and inclusion of patients will continue for at least three years.
Significance
The results from the SWEN study should improve genetic testing, personalized risk estimation and effectiveness of surveillance programs for individuals with hereditary predisposition for CRC.

J12.042

Microsatellite instability analysis in sporadic colon cancer patients in Croatia

T. Cacev, *V. Musani, S. Kapitanovic;*
Rudjer Boskovic Institute, Zagreb, Croatia.

Colorectal cancer is a result of accumulation of genetic and epigenetic alterations associated with the transformation of normal colonic epithelium to colon adenocarcinoma. Two major pathways involved in colorectal carcinogenesis, the suppressor and the mutator pathway have been identified, with different clinical behaviors and response to chemotherapy. Approximately 15% of sporadic colorectal carcinomas (CRC) arise from mutator pathway which is characterized by microsatellite instability (MSI) caused by deficient mismatch repair system (MMR) and defects in MMR genes.
In this study we have examined the incidence of MSI using the NCI Bethesda panel of microsatellite markers (Bat-25a, Bat-26, D2S123, D5S346 D17S250) in 200 sporadic CRC patients. Analysis was performed using ABIPRISM 310 genetic analyzer. The sample was denoted as MSI high (MSI-H) if two or more of the markers demonstrated instability. The sample was denoted as low microsatellite instability (MSI-L) if only in one of the analyzed markers the MSI was detected.
The MSI was detected in 11/200 (5,5 %) analyzed samples and 8 tumors with MSI-H and 3 tumors with MSI-L were identified, while the remaining tumors showed no instability and were classified as microsatellite stable (MSS). MSI was detected in the following markers: Bat25a in 8 patients, Bat26 in 7 patients, D2S123 in 10 patients, D5S346 in 6 patients and D17S250 in 8 patients.
There was no statistically significant correlation between the MSI and clinico-pathological characteristics, although MSI was more frequent in larger, poorly differentiated and advanced stage tumors.

Quantitative JAK2^{V617F} mutation and cytogenetic abnormalities in MPNs: Legnano Hospital experience

S. Stioui[1], *R. Busuito*[1], *P. Cozzi*[2], *M. Savarè*[3], *M. Lotzniker*[4], *A. Mazzone*[2], *N. Covini*[4];
[1]*SS Citogenetica Laboratorio Analisi AO Legnano Ospedale Civile, Legnano (MI), Italy,* [2]*Medicina Interna AO Legnano Ospedale Civile, Legnano (MI), Italy,* [3]*Medicina Interna AO Legnano Ospedale Fornaroli, Magenta (MI), Italy,* [4]*Laboratorio Analisi AO Legnano Ospedale Civile, Legnano (MI), Italy.*

The detection of molecular and cytogenetics alterations is important for the diagnosis, prognosis and classification of myeloproliferative neoplasms (MPNs). In our institution bone marrow conventional and molecular cytogenetic and detection of JAK2^{V167F} on isolated granulocytes from blood sample are performed at clinical presentation of suspected MPN. Recently evaluation of JAK2^{V167F}allele burden has been introduced in our diagnostic flow chart. While the V617F acquired mutation in JAK2 gene has been described in a high proportion of MPN patients and allele burden (heterozygosity versus homozygosity) correlates with a higher risk of secondary fibrosis, there is no specific cytogenetic alteration but some recurrent abnormalities in MPNs. Among 34 JAK2 mutated patients since the introduction of quantitative JAK2^{V167F} measurement, 3 patients has also shown an abnormal karyotype. One patient (case 1) presented 2 related clones with trisomy of chromosome 8 and 9, deletion of chromosome 20q has been observed in case 2 and a t(4;20) translocation involving deletion of TET2 gene has been observed in the third case. Prognostic significance of cytogenetics findings at diagnosis and correlation with JAK2^{V167F}allele burden is presented. A specific discussion of trisomy 9 case will be done due to the difficulty of interpretation of the allele burden.

To address clinical and genetic differences between acute lymphoblastic leukaemia in Down syndrome (DS-ALL) and non-DS-ALL and to ascer-

tain prognostic factors in DS-ALL, we reviewed all 128 paediatric DS-ALL diagnosed in the Nordic countries between 1981 and 2010. All had B-cell precursor ALL, comprising 2.7% of such cases. Within the DS-ALL group, platelet counts and the incidence of extramedullary disease were higher in girls. 5-year event-free survival (EFS) and overall survival were significantly poorer for DS-ALL patients with white blood cell (WBC) counts ≥50 x 10^9/l. The DS-ALL and the 4,637 non-DS-ALL patients did not differ as regards sex ratio and WBC counts, but the age distributions varied between the DS and non-DS cases, with age peaks at 2 and 3 years, respectively, and the platelet counts were lower in the DS-ALL group. Abnormal karyotypes were more common in non-DS-ALL, and there was a significant difference in the distribution of modal numbers, with only 2% high hyperdiploid DS-ALL cases. There was no significant difference in 5-year EFS between DS-ALL and non-DS-ALL patients in the recent NOPHO ALL-2000 protocol (0.670 and 0.785, respectively; *P*=0.11). The present study adds further support for increased survival of DS-ALL patients during the last few years.

Allele-specific real-time PCR detection of EGFR exon 19 and 21 mutations in various clinical non-small cell lung cancer specimens

M. Skronski, *R. Langfort, P. Jagus, A. Szpechcinski, K. Maszkowska-Kopij, T. Orlowski, K. Roszkowski-Sliz, J. Chorostowska-Wynimko;*
National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland.

The aim of our study was to evaluate the effectiveness of EGFR gene mutation detection in diverse materials from 707 NSCLC patients using the two ultra-sensitive allele-specific real-time PCR assays in the routine diagnostic procedure.
629 samples were analyzed by PNA-LNA PCR clamp, 164 samples by CE-IVD certified allele-specific PCR assay and 86 samples by both methods. PNA-LNA PCR clamp products were analyzed by Sanger sequencing to confirm rare mutations. NSCLC specimens were characterized by tumor cells content and type of fixation [Table].
62/707 (9%) specimens were positive for EGFR mutations: 32 detected in exon 19, including 4 rare deletions and p.R748K substitution (c.2243G>A); 28 p.L858R (c.2573T>G) mutations, 1 rare variant of p.L858R (c.2572_2573delinsAG) and 1 double mutation p.L858M+p.L861Q (c.2572C>A; c.2582T>A) detected in exon 21. There were 71% women in the EGFR+ group. 98% of EGFR+ were adenocarcinoma samples, thus mutation frequency among adenocarcinoma patients was 9.8% (61/617 patients). Ultrasensitive PNA-LNA PCR clamp assay and allele-specific PCR CE-IVD test presented high results conformity with 95.3% overall percent agreement (95%CI=90.9-99.8) and Cohen's Kappa score of 0.9 (95%CI=0.88-0.92).
Both real-time PCR assays provided reliable and robust detection of most common EGFR activating mutations in various clinical NSCLC specimens.

An investigation of relationships between hypoxia-inducible factor-1a gene polymorphisms and endometrial cancers

L. .. Kafshdooz[1,2], *A. Dastranj*[3], *S. Mohaddes*[4], *T. Kafshdooz*[4];
[1]*medical university Department of Genetics, Tabriz, Islamic Republic of Iran,* [2]*Women's Reproductive Health Research Center Tabriz university of medical sciences, Tabriz, Islamic Republic of Iran,* [3]*Women's Reproductive Health Research Center Tabriz University of Medical sciences, tabriz, Islamic Republic of Iran,* [4]*medical university Department of Genetics, tabriz, Islamic Republic of Iran.*

Background: Endometral carcinoma is the most common malignant tumor of the female genital tract and the fourth most common cancer in women after breast, colorectal and lung cancers. Hypoxia-inducible factor -1 (HIF-1) is a key transcription factor that regulates cellular response to hypoxia. HIF-1 plays important roles in the development and progression of cancer through activation of various genes that are involved in crucial aspects of cancer biology, including angiogenesis ,energy metabolism, vasomotor function, erythropoiesis, and cell survival. The aim of the present study was to investigate the association between *HIF-1* 1772 C/T polymorphisms and endometrial cancer. **Patients and methods**: 75 patients with endometrial carcinoma and 75 patients who underwent hysterectomy for non tumoral reasons selected for evaluation of *HIF-1* 1772 C/T polymorphisms by PCR-RFLP and sequencing. **Results: Our findings** showed that the T allele and genotype TT in *HIF-1* 1772 C/T was significantly associated with endometrial cancer risk in comparision with control group. **Conclusions:** Our results suggest that the C1772T polymorphism of the HIF-1a may be involved in development and progression of endometrial carcinoma.

The EMT gene expression signature and somatic mutations in colorectal cancer with peritoneal carcinomatosis

N. I. Pospekhova, *V. P. Shubin, A. S. Tsukanov, S. A. Frolov, Y. A. Shelygin, D. G. Shakhmatov, O. I. Sushkov, S. I. Achkasov;*
State Scientific Center of Coloproctology, Moscow, Russian Federation.

Colorectal cancer (CRC) often metastasizes even at early stages that is the main cause of death. Epithelial-mesenchymal transition (EMT) is a complex process that is required for dissemination of tumor cells. EMT leads to the transformation of epithelial cells phenotype to mesenchymal phenotype. Tumors with mesenchymal subtype is associated with poor prognosis.
EMT, somatic mutations in *KRAS* and *BRAF*, microsatellite instability were investigated in 17 tumor samples and 20 carcinomatosis nodes from 20 CRC patients with peritoneal carcinomatosis. To determine EMT program gene expression profiling *ZEB1, ZEB2, VIM, SNAIL1, CDH1* by real-time PCR was analyzed. EMT was detected in 5 of 17 tumor samples (29%) and 17 of 20 carcinomatosis nodes (85%). These CRC samples were characterized by high frequency of somatic mutations (11 *KRAS* and 2 *BRAF* mutation, 65%), microsatellite stability (17 MSS and 3 MSI-L tumors) and low grade. We observed a high concordance between tumor and carcinomatosis node for mutations and MSI status, but not for EMT. We suppose the tumors eventually may lose mesenchymal phenotype (mesenchymal-epithelial transition) or intratumoral heterogeneity exists. Our data shows that the most of CRC with peritoneal carcinomatosis undergo EMT process.

J12.048

Role of Dido1 in the progression and development of esophageal squamous cell carcinoma

P. Naeemi Khorasani Zadeh[1], *M. Forghanifard*[2], *M. Abbaszadegan*[1];
[1]*Avicenna Research institute, Mashhad, Islamic Republic of Iran,* [2]*Islamic Azad University, Damghan, Islamic Republic of Iran.*

Background: Bone morphogenetic proteins (BMPs) are implicated in several processes during embryonic development and adult tissues homeostasis. Many cancers are linked to either the BMPs or the molecules functioning in this signaling pathway. Dido1 is a novel BMP-specific Smad-regulated target gene, which is studied in few cancers. However, its expression level has not been yet elucidated in esophageal squamous cell carcinoma (ESCC). To determine this level and its probable clinicopathological consequences, expression of the gene was analyzed.
Methods: Dido1 expression in fresh tumoral and distant tumor-free tissues from 50 esophageal squamous cell carcinoma samples was compared by real-time polymerase chain reaction (PCR).
Results: Dido1 mRNA expression level was overexpressed in 26% of tumors, while its underexpression was detected in 18% of ESCC samples. There was a significant correlation between level of Dido1 mRNA expression and increased depth of tumor invasion (P= 0.043). Furthermore, Dido1 mRNA expression was correlated with the progressed stage of tumor cells in ESCC samples (P = 0.04). Dido1 mRNA expression was inversely correlated with the age of patients (P< 0.05).
Conclusions: These results indicate a relationship between Dido1 expression and depth of tumor invasion and staging. Along with the promising evidences of its role in regulation of BMP signaling pathway which is one of the main involved pathways in tumorigenesis, Dido1 may have a role in progression and invasiveness of ESCC.
Keywords:Esophageal Squamous Cell Carcinoma (ESCC); Dido1 gene; Expressional analysis; Real-time PCR; BMP signaling pathway

J12.049

Impact of HES1 on depth of tumor invasion in esophageal squamous cell carcinoma

S. Taleb, *M. R. Abbaszadegan, M. Moghbeli, M. M. Forghanifard;*
Division of human genetics, immunology research center, Avicenna research institute, Mashhad Univers, Mashhad, Islamic Republic of Iran.

Notch signaling is one of the main involved pathways in cell differentiation and organogenesis and its deregulation may lead to tumorigenesis. In this pathway, targeted to the CSL (CBF1, Suppressor of Hairlesss or Lag-1) complex, notch intracellular domain (NICD) releases corepressors and recruits MAML1 as coactivator triggering the activation of notch signaling transcription complex. HES1 (Hairy enhance of split-1) is one of the notch signaling target genes which is a bHLH transcription factor acting as a proliferation stimulator through the suppression of cell cycle inhibitors such as p27 and p21. HES1 mRNA expression in fresh tumoral tissues from 50 esophageal squamous cell carcinoma (ESCC) samples was compared to their margin normal by real-time polymerase chain reaction (RT-PCR). Thirteen out of 50 cases (26%) had HES1 underexpression while HES1 overexpression was observed only in 4 (8%) samples. HES1 underexpression was significantly

correlated with tumor depth of invasion (P = 0.02). Although we have not observed any significant correlation between the HES1 expression and notch activation in ESCC, this study is the first report that elucidated the HES1 underexpression in ESCC and revealed its correlation with indices of poor prognosis.

J12.050

Clonal genomic changes in progression of multiple myeloma to extramedullary relapse and plasmocellular leukemia - case report

J. Smetana[1,2], *H. Greslikova[1], R. Kupska[1], A. Mikulasova[1,2], M. Almasi[3], L. Pour[3], Z. Adam[3], P. Kuglik[2], R. Hajek[1,3,4];*

[1]Babak Myeloma Group, Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, Brno, Czech Republic, [2]Institute of Experimental Biology, Faculty of Science, Masaryk University Brno, Brno, Czech Republic, [3]Department of Internal Hematooncology, University Hospital Brno, Czech Republic, Brno, Czech Republic, [4]Faculty of Medicine, University of Ostrava and University Hospital Ostrava, Czech Republic, Ostrava, Czech Republic.

Extramedullary relapse (EM) of multiple myeloma (MM) is defined as infiltration of plasma cells (PC) outside of the bone marrow. EM is an aggressive form of the disease with a adverse outcome.

We present a case study of a 52-year-old female diagnosed with MM in 2008. Initial cytogenetic analysis (G-banding) proved hypotriploid karyotype (63-64 chromosomes) with structural and numerical abnormalities. Using cIg-FISH, we detected disruption of IgH gene, t(4;14), gain 1q21 and trisomy of chromosomes 9 and 15. In 2011, patient relapsed twice and progressed in 2011. Peripheral blood was infiltrated by abnormal PC and an extramedullary lesion in the head was formed. At the time of progression, the same chromosomal abnormalities were present in the bone marrow, peripheral blood and the EM lesion: deletion of RB1 and TP53, IgH rearangement, t(4;14), gain(1q21) and non-hyperdiploidy. Array-CGH showed that genome profiles before and after progression were different - during disease progression, hyperdiploid karyotype turned into nonhyperdiploid karyotype together with loss of trisomies of chromosomes 2,3,7,8,9,11,17,18,19,20 and gain of new abnormalities - deletion of 1p, 2p, 4q, 11p, 12p, 13, 14q, 17p and 22p. Similarly, sequencing of TP53 showed different mutations before and after progression.

We suppose that the extramedullary lesion originated by an expansion of one clone of tumor plasma cells from the bone marrow. This is confirmed by identical genome profile of both tested samples.

Work was supported by grants NT13492 and OP VK CZ.1.07/2.3.00/20.0183 project

Germline mutations of apc and myh genes in patients with familial adenomatous polyposis in populations from central western Spain

J. Perez-Garcia[1,2], *J. Buleje[1], E. Sánchez[1], T. Martín[3], E. Lastra[4], A. Sanchez[5], J. Cruz[3,6], R. González[1,2];*

[1]Center of Cancer Research IBMCC (USAL/CSIC), Salamanca, Spain, [2]Institute of Biomedicine Research (IBSAL), Salamanca, Spain, [3]Oncology service, Universitary Hospital, Salamanca, Salamanca, Spain, [4]Oncology service, Hospital General de Yague, Burgos, Burgos, Spain, [5]eComplejo Hospitalario Universitario Insular- Materno Infantil, Las Palmas de Gran Canaria, Spain, [6]Unidad de Medicina Molecular. Facultad de Medicina, Salamanca, Spain.

Germline mutations in APC are asociated with the development of familial adenomatous polyposis (FAP). This syndrome is characterized by the presence of hundreds to thousands of adenomatous polyps in the colon and rectum. An attenuated form of FAP, called attenuated familial adenomatous polyposis (AFAP), is related to mutations in the 5' end, in exon 9 and in the 3' end of the APC. In addition, biallelic mutations in MUTYH gene have also been identified in patients with colorectal adenomas and in APC-negative patients with FAP or AFAP.

Molecular analysis in APC performed to 50 Spanish families diagnosed with FAP (n=38) and AFAP (n=22) has allowed the identification of pathogenic mutations in 85% of FAP families and 21% of AFAP. In total, we found 22 pathogenic mutations: 7 were nonsense and 13 were frameshift (7 deletions, 3 duplications, 2 insertions and a deletion together with an insertion). Ten of these mutations are reported in this work for the first time. We have also detected two novel splicing mutations. In this study, we detected 6 variants of unknow significance and we performed population-based studies, segregation studies and In Silico studies to further define these mutations. In patients who showed no point mutations in the APC gene were analyzed for large rearrangements by multiplex ligation-dependent probe amplification (MLPA).

Analysis of MUTYH revealed 6 pathogenic mutations in 8 unrelated families: 7 biallelic and 1 monoalellic variants.

Thus we have characterized 12 novel mutations in the APC gene involved in Familial Adenomatous Polyposis.

J12.052

FGFR2 K367E mutation is frequently found with low burden in patients with early onset aggressive colorectal cancer

N. Matevska Geshkovska[1], *M. Staninova[1], A. Eftimov[1], M. Panovski[2], M. Panovski[2], T. Josifovski[2,3], A. J. Dimovski[1];*

[1]UKIM Faculty of Pharmacy, Skopje, Macedonia, The Former Yugoslav Republic of, [2]University Clinic for Abdominal Surgery UKIM Faculty of Medicine, Skopje, Macedonia, The Former Yugoslav Republic of, [3]Acibadem Sistina Clinical Hospital, Skopje, Macedonia, The Former Yugoslav Republic of.

We conducted next-generation sequencing using Ion AmpliSeq™ Cancer panel (Life technologies) which covers relevant regions across 46 oncogenes and tumor suppressor genes on 5 primary colorectal tumors. The analyzed patients presented similar clinical features: early onset (39-50yrs), a highly aggressive disease, distal localization, microsatellite stable tumors and a lack of a family history of malignant diseases. The mutations found (Table 1) generally correlate with the most abundant alterations in colorectal cancer. A K367E mutation in exon 9 of the FGFR2 gene was found with low burden (8-11%) in the tumors of 3 patients. This is a novel mutation that results in AA substitution in the extracellular juxtamembrane region and might initiate spontaneous dimerisation of the receptor, leading to factor-independent growth and hyperresponsiveness to ligand, as suggested for similar defects in endometrial cancer and patients
with craniosynostosis syndromes. Having in mind the low burden of the variant, we believe that K367E mutation is a late event alteration in a subclone which may be responsible for the highly aggressive pattern of the disease. This should be clarified by mutational burden analysis of the primary and secondary tumors of these and other patients.

Table 1. Mutations spectrum in the analyzed patients *

patient	PIK3CA	BRAF	TP53	FGFR2	KRAS	APC	FBXW7
CC330			R248F (67%)	K367E (8%)	G13D (55%)		R465C (70%)
CC553			R273C (63%)	K367E (11%)		Q1349X (50%)	
CC562					G13D (10%)		
CC567	G1049R (34%)	V600E (28%)	G245D (50%)	K367E (13%)			
CC571	R88Q (29%)						R465C (26%)

*The mutation burden is presented in parentheses.

FGFR3 and TP53 gene mutations in bladder cancer in the Belarusian population

M. Smal[1], *A. Rolevich[2], S. Krasny[2], S. Polyakov[2], T. Nabebina[2], R. Goncharova[1];*

[1]Institute of Genetics and Cytology NASB, Minsk, Belarus, [2]N.N. Alexandrov National Cancer Centre of Belarus, Lesnoy, Minsk region, Belarus.

Bladder cancer represents the second most common genitourinary tumor, with approximately 390,000 new cases every year worldwide. Mutations in the FGFR3 and TP53 genes have been shown to define two divergent pathways in the pathogenesis of bladder urothelial carcinomas.

The purpose of this study was to perform molecular screening for FGFR3 and TP53 mutations in 243 bladder tumors and to assess the relation of clinicopathological variables with mutation status of these two genes. Mutations in the FGFR3 and TP53 genes were detected by SNaPshot method and PCR-single-strand conformational polymorphism analysis followed by DNA sequencing, respectively.

FGFR3 mutations were identified in 115 (47.3%) specimens and TP53 alterations were found in 46 (18.9%) tumors. In 12 cases (4.9%), FGFR3 and TP53 mutations coexisted; in 94 cases (38.7%), neither mutation was found. Analyses of nonmuscle-invasive and muscle-invasive tumors alone revealed that FGFR3 and TP53 mutations were independent events (p=0.76 and p=0.11, respectivelly). An inverse correlation between mutated FGFR3 and mutated TP53 was observed: FGFR3 mutations were strongly associated with low-stage (p<0.001) low-grade (p<0.001) tumors, whereas the frequency of TP53 mutations was significantly higher in tumors of higher stage (p<0.001) and grade (p<0.001). Moreover, the presence of metastasis was strongly associated with TP53 mutations and the lack of FGFR3 alterations. Our data are consistent with the idea that FGFR3 and TP53 mutations represent two distinct mechanisms of bladder cancer development. In our study, FGFR3 mutations were associated with favorable conventional prognostic factors, whereas TP53 alterations were related to adverse disease parameters.

Association of rs2294008 polymorphism in PSCA gene with gastric cancer susceptibility in Uzbekistan

B. R. Adilov[1], *M. I. Ubaidullaeva[1], S. U. Turdikulova[2], R. S. Muhamedov[1];*

[1]Institute of Bioorganic Chemistry, Academy of Sciences Republic of Uzbekistan, Tashkent, Uzbekistan, [2]Educational-Experimental Centre for High Technologies in Tashkent, Tashkent, Uzbekistan.

Gastric carcinogenesis is a complex, multistep and multifactorial process, in which many factors are implicated. Genetic factors play an important role in the development of gastric cancer(GC). Recent studies have shown that single-nucleotide polymorphisms (SNPs) in several genes are associated with increased GC risk, indicating that genetic variation contributes to gastric carcinogenesis.

Located on chromosome 8q24.2, the prostate stem cell antigen (PSCA) gene encodes a 123-amino acid glycoprotein related to the cell-proliferation inhibition and cell-death induction activity. SNPs in PSCA gene have been found associated with gastric cancer risk in a genome-wide association study. This association has been replicated in several populations, but also there are some conflicting results.

This study aimed to investigate the association between polymorphic variant of PSCA gene(rs2294008) and susceptibility to gastric cancer in Uzbekistan.

105 patients with gastric cancer and the sex and age matched control group of healthy individuals (n=116) were included in this study. DNA samples isolated from these groups were genotyped by means of PCR and RFLP method. Comparative analysis of resulting genotypes showed a statistically significant association between gastric cancer and C/T genotype(p=0.0009, Pearson's χ2 test). The odds ratio (OR) of increased relative risk of developing gastric cancer for CT genotype carriers was 4.75 (CI95% 2.68 - 8.41).

These findings supported that PSCA rs2294008 C>T polymorphism may contribute to the susceptibility to gastric cancer. Genotyping of rs2294008 PSCA gene polymorphism can be recommended as a criterion for identification of high risk groups concerning developing of gastric cancer in Uzbekistan.

Polymorphism of the thymidylate synthase gene and sensitivity of gastric cancer to 5-FU chemotherapy.

A. Udilova, *M. Nemtsova, T. Kchorobrich;*
I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.

Thymidylate synthase (TS) is a key enzyme in nucleotide biosynthesis and is the main intracellular target of 5-FU. There are TYMS polymorphisms in the 5' and 3' untranslated region associated with expression of TS.

We investigated the clinical and prognostic importance of TYMS polymorphisms for gastric cancer patients. We examined of 5' (TSR2/TSR3 and G>C) and 3' (del 6) untranslated region polymorphisms in 80 gastric cancer patients after surgical treatment and chemotherapy with 5-fluorouracil.

We have shown, that the genotype 2R/2R is significantly more often found in patients with regional lymph node metastases (N1-3) (p = 0.0475), genotype -6/-6 is significantly more common in patients with intestinal gastric cancer (p = 0.0375), as well as in patients, who have high/moderately differentiated adenocarcinoma (p = 0.033).

In the study of the effectiveness of chemotherapy we have shown, that genotype 3G/3G was associated with the poor prognosis, development of local recurrence, carcinomatosis, the appearance of distant metastases during the first 3 years after surgery and 5-FU treatment (p = 0.024). Genotype 2G /3C was significantly frequent (p = 0.023) in patients without progression of the disease within the first 3 years after surgery and 5-FU treatment. In the study of the TYMS gene 3'-untranslated region (del 6) polymorphism in the patients after surgical treatment and chemotherapy, we found no significant differences.

We suggest that TYMS 5'UTR and 3'UTR polymorphisms can serve as individual prognostic factors and as predictors of adjuvant treatment effectiveness in patients with locally advanced gastric cancer.

J12.056

Relationship between genetic and protein expression of antifole chemotherapies metabolic enzymes and sensitivity in head and neck cancer cell lines

A. L. S. Galbiatti[1], *H. C. Caldas*[2], *J. V. Maniglia*[3], *É. C. Pavarino*[1], *E. M. Goloni-Bertollo*[1];
[1]Genetics and Molecular Biology Research Unit - UPGEM, FAMERP- São José do Rio Preto Medical School – Brazil., São José do Rio Preto, Brazil, [2]Laboratory of Experimental Immunology and Transplantation / LITEX, FAMERP, São José do Rio Preto, Brazil, [3]Otorhinolaryngology and Head and Neck Surgery Department of São José do Rio Preto Medical School – FAMERP, Brazil, São José do Rio Preto, Brazil.

Introduction: Antifolate chemotherapies disrupt cellular proliferation by blocking folate dependent enzymes. Data show variability in outcomes with antifolate chemotherapies and it can be associated to genetic factors. **Objectives:** To investigate relationship between genetic and protein expression of *MTHFR, DHFR, TYMS* and *SLC19A1* folate genes for 5-fluorouracil (5-FU) and methotrexate (MTX) antifolate chemotherapies response in two head and neck cancer cell lines. **Methods:** HEP-2 (laryngeal cancer) and HN13 (oral cavity cancer) cell lines were treated with 0.25, 25.0, and 75 μM of MTX and 10 ng/ml, 50 ng/ml, and 100 ng/ml of 5-FU, separately, for 24 hours/37°C. Real-time PCR and Western blotting techniques were performed. ANOVA and Bonferroni's post hoc tests were utilized for statistical analysis. P<0.05 was considered significant. **Results:** Regarding to 5-FU treatment, there was increased expression for *TYMS* mRNA in HEP-2 cell line with 100 ng/ml 5-FU, and increased expression for *DHFR* and *TYMS* mRNAs in HN13 cell line with 100 ng/ml (p<0.05). Regarding to MTX treatment, there was increased expression for all mRNAs evaluated in HEP-2 cell line treated with 75 μM MTX. *SLC19A1* gene presented lower expression in HEP-2 cells treated with 0.25μmol of MTX. For HN13 cell line and MTX chemotherapy, there was increased expression for *DHFR* and *SLC19A1* mRNAs in cells with 75 μM MTX (p<0.05). There was not association of protein expression and chemotherapies evaluated. **Conclusion:** Folate genes expression alterations in cell culture model may predict mechanisms of resistance and sensibility for antifolate chemotherapies and give support for studies in clinical practice.

Double knockdown of apoptotic genes and their relationship with other mechanisms involved in tumor cell survival

V. Pileczki[1], *C. Braicu*[1], *L. Pop*[1], *I. Berindan Neagoe*[1,2];
[1]Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania, [2]Ion Chiricuta Institute of Oncology, Cluj-Napoca, Romania.

The simultaneous inhibition of two important genes - p53 and TNF - involved in tumor cell development and evolution, with the siRNA technology, will hopefully bring us new significant and interesting data in triple negative breast cancer (TNBC) cell signaling. TP53 is involved in the intrinsic apoptosis pathway, and the tumor necrosis factor (TNF) is the main inducer of the extrinsic apoptosis signaling mechanisms. In order to evaluate the impact of TNBC dual gene knockdown, we used PCR array technology (qRT-PCR) to analyze the most relevant genes involved in apoptosis along with other staining assays that will unravel important and new data in the tumor cell pathways cross-talk. Our experiments were performed on a triple negative breast cancer cell line (Hs578T) and in relation with untreated cells that serve as control. After analyzing the transcript quantification data we obtained statistical relevant results for 16 genes, of which 12 were up-regulated and 4 down-regulated. By simultaneously inhibiting p53 and TNF genes on Hs578T cells, we observed that they affect the angiogenesis mechanisms by inhibiting the tumor cell network formation and self-degradation of cellular components through autophagy. By integrating the expression profiles of triple negative breast cancer untreated cells with the ones obtained from knocking down p53 and TNF, simultaneously, we obtained a network-based platform, that is important in finding a functional interaction between the networks of intrinsic and extrinsic apoptosis cell signaling pathways and other mechanisms involved in tumor cell angiogenesis, autophagy and cell death in breast cancer.

Genetic profiles' comparative Analysis: Adult glioblastomas vs young adult

S. Trabelsi[1], *D. H'mida-Ben Brahim*[1], *M. Chourabi*[1], *M. L'Adib*[2], *S. Sassi*[1], *M. Haddaji Mastouri*[1], *N. Mama*[3], *M. Mokni*[4], *H. Krifa*[2], *K. Tlili*[3], *M. Yacoubi*[4], *A. Saad*[1];
[1]Department of Cytogenetic, Molecular genetics and Reproductive Biology, Farhat HACHED university Hospital, Sousse, Tunisia., Sousse, Tunisia, [2]Departement of Neurosurgery, Sahloul university Hospital, Sousse, Tunisia., Sousse, Tunisia, [3]Departement of radiology, Sahloul university Hospital, Sousse, Tunisia., Sousse, Tunisia, [4]Departement of pathology, Farhat HACHED Hospital, Sousse, Tunisia., Sousse, Tunisia.

Background : Glioblastomas (GB) are malignant astrocytic tumors, which often occur in patients aged over 55 years. However, younger age (<40 years) was also described in several GB cases. Therefore, GB are newly divided into 2 subtypes according to patient's age: young adult GB (Y.GB) (40 years).

Basically, clinical presentation and histopathological descriptions are similar between the 2 GB subtypes. Nonetheless, the assumption of different tumorogenic pathways was suggested. This hypothesis is supported by molecular alterations differences between Y.GB and A.GB.

Purpose: This study aims to compare the genetic profiles between Y.GB and A.GB in Tunisian glioblastomas.

Methods: 43 samples composed by 40 A.GB and 13 Y.GB were collected during the period of 5 years from 2009 to 2013. In order to investigate discriminative genetic alterations between the 2 GB groups, tumoral DNA was analysed by MLPA (Multiplex Ligation Probe Amplification). We used the 4 SALA MLPA probemix designed for Gliomas analysis: P370, P088, P105 and ME011.

Results: Similarities were observed between the 2 GB groups, concerning tumor size and locations as well as some chromosomal alterations: 10q, 17q and 19q. Interestingly, 1p 19q co-deletion, 1p deletion and CDKN2A (p14)

were only found in A.GB group. While IDH1 mutation was more frequently detected in Y.GB.
Conclusion: GB genetic profile variability noticed in our sample cohort supports the hypothesis of different tumorogenic pathways between A.GB and Y.GB. Despite of the crucial role of clinical and histopathological data in tumor diagnosis, molecular investigations seems of a great importance as well.

J12.059

Association analysis of rs7903146 (C>T) variant of TCF7L2 Gene with Glioblastoma in a Turkish Population

D. Erkoc Kaya[1], *H. Arikoglu*[1], *M. Taspinar*[2], *Y. E. Guner*[3], *F. İscioglu*[4], *H. C. Ugur*[3];
[1]*Selcuk University, Konya, Turkey,* [2]*Yuzuncu Yil University, Van, Turkey,* [3]*Ankara University, Ankara, Turkey,* [4]*Ege University, İzmir, Turkey.*

Glioblastoma (GBM) is the most common malignant brain tumor in the adult population defined as grade IV astrocytoma according to severity of necrosis and vascular proliferation. It can be seen at any age, but commonly between the ages of 45-75. GBM is difficult to treat and presents high morbidity and mortality risks. There is no curative treatment. Patient's genetic structure is a factor as important as the choice of chemotherapeutic agents, dose, time of administration that directly affect the process of chemotherapy. Transcription factor 7-like 2 (TCF7L2) gene, located on chromosome 10q25.3, encodes a transcription factor which is involved in the Wnt/β-catenin signaling pathway. Active nuclear complex which TCF7L2 forms with β-catenin induces the expression of target genes involved in cellular proliferation, evasion of apoptosis and tissue invasion and metastasis. It is demonstrated in association with many cancer types, including breast, prostate, lung and colon cancers. We performed a study to investigate the association between TCF7L2 rs7903146 variant and another cancer type glioblastoma. Forty-three patients who primarily diagnosed as GBM were recruited to this study from Department of Neurosurgery of Faculty of Medicine of Ankara University in Turkey. None of the patients received any chemotherapeutic agents or radiation therapy before surgical resection of the tumor. DNA was isolated using isolation kit from patients' cancerous and their corresponding adjacent non-cancerous tissues. rs7903146 were genotyped by PCR-RFLP. No association was determined between rs7903146C>T and GBM after analyzing carried out using dominant, additive, and recessive models (P>0.05).

Analysis of autophagy polymorfisms in glioblastomas

E. Bueno Martínez[1,2], *I. Rodríguez Hernández*[1,2], *J. L. García*[3], *J. A. Gómez Moreta*[4], *R. González Sarmiento*[1,5];
[1]*Molecular Medicine Unit. Department of Medicine. University of Salamanca, Salamanca, Spain,* [2]*Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain,* [3]*Center for Cancer Research IBMCC (USAL-CSIC), Salamanca, Spain,* [4]*Department of neurosurgery, Virgen Vega Hospital, Salamanca, Spain,* [5]*Institute of Biomedical Research of Salamanca (IBSAL, Salamanca, Spain.*

BACKGROUND
Autophagy is an adaptive and highly regulated response in unfavorable conditions such as starvation. During this process, long-lived proteins and organelles are self-eaten by double membranes vesicles, called autophagosomes, which transport them through the cytosol to the lysosome, where they will be degraded. The resulting macromolecules can be recycled to the cytosol for reuse. Autophagy plays an important role in cellular development and differentiation and it has been reported that its malfunction is implicated in several diseases including cancer. Glioblastoma is a very infiltrating and aggressive heterozygous glioma. Its behavior is directly related to their genetic and chromosomal alterations. Here, we have analysed common polymorphisms in autophagy genes in order to evaluate the role of these variants in modulating glioblastoma risk.
PATIENTS AND METHODS
112 newly diagnosed patients with primary glioblastoma (grade IV) and 189 controls without cancer were included in the study. Genomic DNA was extracted from peripheral blood using phenol/chloroform procedure and genotyped using TaqMan 5'-exonuclease allelic discrimination assays (Applied Biosystems) (table 1). Statistical analysis was performed using SPSS software.
RESULTS
No significant differences were found in genotype distribution for ATG16L1 RS2241880 ATG2B RS3759601 and ATG5 RS2245214 between patients with glioblastoma and control subjects. However, statistical differences in genotype distribution for ATG10 RS1864183 were found. The A allele was associated with increased risk of developing glioblastoma (OR = 2,788, 95% CI 1,40-5,55; p= 0,004).
CONCLUSIONS
ATG10 RS1864183 POLYMORPHISM IS ASSOCIATED WITH SUSCEPTIBILITY TO SUFFER GLIOBLASTOMA, SUPPORTING THE IMPORTANCE OF AUTOPHAGY IN CANCER DEVELOPMENT.

J12.061

Genetic polymorphisms in GSTM1, GSTT1, GSTP1 and the susceptibility to basal cell carcinoma in Iranian population

P. Abbasi Ranjbar[1], *A. Rakhshan*[2], *F. Mashayekhi*[3], *A. Ebrahimi*[4];
[1]*University of Guilan, Rasht, Islamic Republic of Iran,* [2]*Department of Pathology, Skin Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*Department of Biology, faculty of sciences, University of Guilan, Rasht, Islamic Republic of Iran,* [4]*Endocrine Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.*

The glutathione S-transferase (GSTs) are polymorphic supergene family of detoxification enzymes that are involved in the metabolism of numerous potential carcinogens. Several allelic variants of polymorphic GSTs show impaired enzyme activity and are suspected to increase the susceptibility to various cancers. To evaluate the relationship between polymorphisms in the GSTs (GSTT1, GSTM1, GSTP1) and basal cell carcinoma (BCC), 50 BCC patients and 50 healthy controls were studied. Following tissue biopsy and DNA extraction genotypes were analyzed by GAP-PCR and ARMS-PCR. The frequencies of GSTM1 null genotypes in patients and controls were 34% and 6%, respectively. The overall frequency of GSTT1 null was higher in cases as compared with controls (p=0.01, Odds ratio (OR) = 3.78, 95% confidence interval (CI), 1.34-10.63). The GSTP1, Ile/Val genotype and the Val allele were higher in cases than controls (p=0.0001, OR = 12.67% CI = 4.90-32.73; p=0.001, OR = 5.52, CI = 2.56-11.89), respectively. The results obtained demonstrated that presence of two genotypes of GSTM1 null and GSTT1 null and allele GSTP1 Val lead to increase for BCC.

BRIP1 Screening in Spanish Breast and Ovarian Cancer Families

C. Velázquez Pérez[1], *E. M. Esteban Cardeñosa*[1], *M. Durán Domínguez*[1], *M. Tascón Torres*[1], *E. Lastra Aras*[2], *G. Marcos García*[3], *L. Hernández Sanz*[1], *N. Martínez Martín*[1], **M. Infante Sanz**[1];
[1]*IBGM, Valladolid, Spain,* [2]*Servicio de Oncología, Hospital Universitario de Burgos, Burgos, Spain,* [3]*Servicio de Oncología, Hospital Río Hortega., Valladolid, Spain.*

Up to 75% of Hereditary ovarian carcinomas (HOC) are attributed to mutations in *BRCA1* and *BRCA2* genes, whereas DNA mismatch repair genes would cause about 10% of them. Genes involved in FA-BRCA pathway will account for an additional percentage of HOC.
Several studies identify BRIP1 (a FA-BRCA pathway gene) as a moderate-penetrance breast cancer susceptibility gene in BRCA1/2 negative familiar cases. Truncating BRIP1 mutations have been described as cancer susceptibility alleles in families with a great ovarian cancer burden. Thus, we aimed to assess whether BRIP1 alterations may contribute to breast and ovarian cancer (BOC) susceptibility as c.1702_1703delTT mutation has been associated with BOC in Spanish population.
Forty-nine out of 140 families In North West-Central of Spain with family history of breast and ovarian cancer carried a pathogenic mutation in BRCA1 or BRCA2. We performed BRIP1 mutational analysis in 72 BRCA negative families. Mutation screening was performed with High Resolution Melting Curve Analysis (HRMA). Cases displaying abnormal HRM patterns were evaluated by direct Sanger Sequencing.
There is no evidence of pathogenicity in the identified variants. Mutation c.508-31C>G was found in ovarian cases. Mutation c.2755T>C was carried by BOC patients. Around 60% of the samples harbors c.2637A>G and c.3411T>C changes. Variant c.577G>A has been previously reported in a UK study with similar frequency of occurrence.
Although clearly pathogenic mutations have not been identified in the samples screened, BRIP1 polymorphisms may increase ovarian cancer risk, so these findings can be used as a potential tool for improving cancer diagnosis and treatment planning.

J12.063

Analysis of polymorphisms in the EGFR pathway involved in the response and toxicity of treatments in head and neck squamous carcinoma

J. Fernández Mateos[1,2], *E. del Barco Morillo*[3,2], *J. Cruz Hernández*[3,2], *R. González Sarmiento*[1,2];
[1]*Unidad de Medicina Molecular. Facultad de Medicina, Salamanca, Spain,* [2]*Institute of Biomedicine Research (IBSAL), Salamanca, Spain,* [3]*Servicio de Oncología Médica. Hospital Universitario de Salamanca, Salamanca, Spain.*

Head and neck squamous carcinoma (HNSC) is one of the most prevalent cancers in Spain. The classic risk factors strongly associated with developing HNSC are tobacco smoking and alcohol consumption.
The common therapies in HNSC are platinum-based chemotherapy, radiotherapy and/or monoclonal antibodies against EGFR, although the response rates are very variable. We have evaluated the influence of some polymor-

phisms in different genes of the EGFR pathway and antibody dependent cellular cytotoxicity receptors (ADCC) associated with differences in toxicity and responses of these treatments.
Genomic DNA was extracted from peripheral blood samples of 91 Spanish HNSC patients treated with monoclonal antibodies against EGFR. The selected polymorphisms realized by QPCR with TaqMan® probes were: FCGR2A rs1801274, FCGR3A rs396991, EGFR rs28384375, rs2227983, rs17336639 and KRAS lc6 rs61764370.
Statistical analysis was performed comparing the different distribution of the polymorphisms and patients were stratified according to treatment and response.
We found differences in the distribution of FCGR2A A519C (rs1801274) polymorphism (p=0.012), conferring an increased risk of developing dry skin in carriers of two copies of the C allele; OR=4.018 (1.257-12.850). Moreover, we found that carriers of the heterozygous genotype in K-RAS lcs6 polymorphism (rs61764370) exhibit a decrease in global toxicity of anti-EGFR antibodies therapy; p=0.014, OR=0.294 (0.107-0.805).
Our results support the correlation between some germline polymorphisms in some genes in the EGFR pathway and ADCC receptors, and the differences in the toxicity of anti-EGFR antibodies therapy.

J12.064
Conventional cytogenetics and FISH analysis in hematological disorders

C. Ionescu[1], *M. Stoian*[1], *C. Munteanu*[1], *R. Manolache*[2], *A. Rodewald*[1,3];
[1]*Personal Genetics-Medical Genetics Center, Bucharest, Romania,* [2]*Coltea Hospital, Hematology Clinic, Bucharest, Romania,* [3]*Institute of Human Biology, University of Hamburg, Hamburg, Germany.*

Non-random chromosomal aberrations are a common feature of many hematological disorders, making cytogenetic analyzes essential for the most common abnormalities in myelodysplastic / myeloproliferative diseases, leukemias and lymphomas.
Between March 2013 and January 2014, 77 bone marrow samples were analyzed cytogenetically from adults aged between 23 and 82 years. Where possible three independent cultures (direct method, 24 and 48 hours) were established and a minimum of 20 metaphases were analyzed.
The karyotype of 70 patients was analyzed successfully. For 7 patients with insufficient number of metaphases FISH analysis was performed using BCR/ABL1plus probes (MetaSystems). Complementary specific FISH probes (MetaSystems) were used according to clinical hematological diagnosis for 5 patients with normal karyotype.
Among the successfully karyotyped samples, 35 cases of CML, and 3 cases of ALL showed various homogeneous or mosaic chromosome abnormalities. The most common abnormality was the presence of the Philadelphia chromosome (Ph), found in varying percentages (between 9 and 100%) with 2 cases having an additional cell line with double PH chromosome. One case had a complex translocation involving chromosomes 9, 10 and 22. Other common abnormalities were trisomy 8, isochromosome 17, autosomal hyper and hypodiploidy.
Identification of cytogenetic abnormalities by conventional karyotype is important to confirm the diagnosis and provide useful information for classification, staging and prognostic information, for choosing therapy conduct and for signs of remission or relapse. Because some cases show a normal karyotype by conventional banding, FISH and aCGH analysis are valuable techniques recommended for identifying the presence of possible submicroscopic abnormalities.

J12.065
Her-2neu gene in neck squamous cell carcinomas (SCC) a potential target for therapy

M. Neagu;
Nationale Inst. Path.Victor Babes, Bucharest, Romania.

Background: Over-expression of the proto-oncogene cerbB-2 (HER-2/neu) has been shown to be a prognostic marker and also a target for therapy in many cancers but conflicting data exist about the prevalence of HER-2/neu over expression in SCC of the head and neck.
Design: The status of Her-2/neu was evaluated in a series of 36 SCC of the larynx and oro-pharynx to verify the frequency of over-expression of HER-2/neu and evaluate the correlation with traditional diagnostic parameters of this neoplasm. A Hercep test kit was used to detect HER-2 expression, and a Path Vysion kit was used for gene amplification.
Results: On immunohistochemical (IHC) staining HER-2/neu was positive only in 8 cases (8/36) and these were further tested by fluorescent in situ hybridization (FISH) with positive gene amplification in 3 cases (3/8), cep17/Her-2/neu = 4.22 - 4.84. One case with IHC staining 3+ do not have gene amplification and 4 cases with 2+ and 1+ at the IHC evaluation have no amplification (cep17/HER-2/neu = 1.64); tumors with positive gene amplification were grade 3 (4/8) or had basaloid features.
Conclusion: Even there are a small percentage of these tumors that have gene amplification for HER-2/neu, at present, patients who may potentially benefit from molecular targeted therapy targeting HER-2/neu for SCC of head and neck should be identified by gene amplification analysis using FISH in IHC 3+ patients.

J12.066
Colorectal cancer risk in relation to Hypoxia Inducible Factor-1α (HIF-1α) and Von Hippel-Lindau (VHL) gene polymorphisms

P. Tasdemir[1], *S. Demirel*[2], *H. G. Dursun*[2], *I. Cinar*[2], *S. Cetinkaya*[2], *A. B. Turhan*[2];
[1]*Necmettin Erbakan University, Meram Medical Faculty, Medical Genetics Department, Konya, Turkey,* [2]*Necmettin Erbakan University, Meram Medical Faculty, Medical Biology Department, Konya, Turkey.*

Colorectal cancer (CRC) is a multifactorial disease involving environmental and genetic factors. Unhealthy diet habit, smoking, and environmental carcinogenic agents are risk factors of CRC, such as alcohol, low methionine, low folate diets and exposure to white soil stands.
Hypoxia plays a critical role in activating hypoxia-inducible factor-1α (HIF-1α) and leads to numerous metabolic changes such as angiogenesis, anaerobic glycolysis and erythropoiesis. HIF-1α protein level is known to be regulated by von Hippel-Lindau (VHL) ubiquitin-proteasome system but in hypoxic conditions HIF-1α protein level increases. Mutations in VHL ve HIF-1α genes can affect the connection of VHL protein to HIF-1α and cause cancer and cardiovascular diseases.
The aim of this study is to investigate the relation of the C1772T (rs11549465) and G1790A (rs11549467) polymorphisms of HIF-1α gene and the functional rs779805 polymorphism of 5'UTR region of the VHL gene, regulating the oxygen-dependent degradation of HIF-1α, with the risk of colorectal cancer. In the study, 92 patients who have been diagnosed to have colorectal cancer and 101 healthy controls were included. PCR-RFLP ve ARMS-PCR molecular diagnostic methods were used for genotyping.
For statistical analysis student t, chi-square (χ^2), Fisher's exact tests and SNPStats were used. According to genetic models, CT/TT genotypes of HIF-1α C1772T polymorphism were found to increase the risk of colorectal cancer in patients (p=0,049; OR 1,96; 95% CI 1,02-3,77; AOR 4,79 (1,07-21,48). For G1790A ve rs779805 polymorphisms, no significant deviation was observed between patients and controls (p>0,05).

Delineation of high-risk Human papillomavirus genotypes in Iranian breast cancer patients

K. Haratian[1], *A. Mohseni Meybodi*[2];
[1]*Dept. of Microbiology and Immunology, Alborz University of Medical Sciences, Karaj, Islamic Republic of Iran,* [2]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran.*

Contribution of Human papillomavirus (HPV) in tumor-genesis has been proved for a while, but it`s function in the pathogenesis of breast cancer is still not clear. In this investigation we checked the prevalence of main genotypes of HPV and their association with breast cancer in pre/post-operative Iranian patients. 77 formalin fixed paraffin embedded (FFPE) breast invasive ductal carcinoma and their normal adjacent tissues (NAT) were included in the study. L1-born primer pairs applied for amplification and detection of HPVs via nested-multiplex polymerase chain reaction. The HPV positive samples were further genotyped using DNA sequencing. Pretty High percentage of HPV (38%) was detected in breast (core) ductal carcinoma compared to 4% in the NAT. High-risk HPV genotypes 16, 18, 31, 33, 35 and 45 were highly associated with the advanced stages of tumor, while low-risk types 6 and 11 were present in NAT. In malignant tissues, HPV-16 was the most abundant genotype followed by type 18 and 33.The high risk HPV genotypes in breast cancerous tissue may represent its contribution in breast carcinogenesis. Using HPV vaccination program is highly recommended to reduce this type of cancer.

J12.068
Expression of Insulin-Like Growth Factor Binding Protein-2 (IGFBP-2) gene in negative and positive human Cytomegalovirus Glioblastoma multoforme tissues

N. Ahani, *M. Alipour Eskandani;*
University of Zabol, Zabol, Islamic Republic of Iran.

Glioblastoma multiforme (GBM) is the most common and lethal primary brain tumor. The median survival of glioblastoma patients is 12 months. The (possible) relationship between Human Cytomegalovirus (HCMV) infection and cancer has been investigated for decades. Detection of viral DNA, mRNA,

and antigens in tumor tissues suggests that HCMV infection has a role to play in the etiology of several human malignancies. HCMV gene products can promote the various signalling pathways critical to tumor growth, including PDGFR, PI3K/AKT, STAT3 and GSK-3b, that are involved in apoptosis, angiogenesis, invasion and immune evasion. IGFBP2 is a biomarker of the PI3K/AKT pathway so we decided to evaluate the expression of this gene in 3 groups: HCMV-negative glioblastoma multiforme tissues, HCMV-positive glioblastoma multiforme tissues and non tumor tissues. The presence of Human Cytomegalovirus was assessed by cytomegalovirus detection kit. Human Cytomegalovirus was present in %75 of glioblastoma tissues. Then RNA was extracted, cDNA was synthesized and Real-time PCR was performed. Then the rate of increased expression was calculated using the Livac or 2-ΔΔCt. ΔCt of samples in the three groups were compared using ANOVA (Analysis of Variance). The expression of IGFBP2 gene relative to GAPDH gene in HCMV-negative glioblastoma tissues and HCMV-positive glioblastoma tissues, respectively was increased 5.486 and 15.032 times compared to non-neoplastic brain tissues. ANOVA tests showed that the difference of mean ΔCt for IGFBP2 gene between healthy subjects and patients with HCMV positive and HCMV negative glioblastoma tumors statistically significant.

J12.069
2 Novel Somatic Mutations In Exon 15 Of The Apc Gene In Iranian Familial Adeno Polyposis Coli Patient

R. -. Vazifehmand Roodposhtie[1], *D. Saeed Ali*[1], *S. Darakeh*[2];
[1]*Young researchers and elite club ,Azad University,Rasht, Rasht, Islamic Republic of Iran,* [2]*osmania university , nizam college, hyderabad, India.*

Abstract: The adenomatous polyposis coli (APC) gene is considered to be a gatekeeper in colorectal tumorgenesis. 60% of somatic mutations in the APC gene are concentrated in a region called the mutation cluster region (MCR). In this study, our goal was to perform the genetic analysis of 2 patients (index patients) who had been selected by colorectal cancer features, and to identify the genetic changes in the MCR region at the APC gene. **Methods:** Mutation analysis of the MCR, which spans codons 1286-1513, was performed on the paraffin-embedded cancerous tissue samples using macrodissection, nested PCR and direct sequencing of purified PCR fragments. **Results:** In our study 2 new somatic mutations detected in these patients .In one patient we have detected a CGA to TGA as a Nonsense mutation that lead to Arg to premature Stop codon at the 4507 nucleotide position (Codon 1503) and in another patient , we describe a G→A Transition (ACG to ACA) at nucleotide position 4638 in exon 15 (MCR region) which causes a silent mutation since both normal and mutated alleles encode a Thr residue at codon 1546. Thess mutations have not been described previously. **Conclusion:** this observation could suggest differences in the frequency of pathological mutations in APC among different populations; however epidemiological studies must be performed to confirm this theory which it is not the aim of our present work. **Keywords:** APC, Iranian Familial Adenomatousis Polyposis (Iranian FAP), somatic mutations

J12.070
Detection of K-RAS gene activating mutations, an important factor in therapeutic management of CRC Romanian patients

P. Apostol[1], *A. Grigore*[1], *M. Stoicea*[1], *P. Gurban*[1], *M. Gongu*[2], *G. Cardos*[1];
[1]*Personal Genetics - Medical Genetics Center, Bucharest, Romania,* [2]*Gral Medical, Bucharest, Romania.*

Activating mutations in the K-RAS gene, a known oncogene involved in the EGFR signaling pathway, were found in a variety of human tumors, including colorectal carcinoma. These mutations, detected mostly in codons 12 (82%) and 13 (17%), represent an early event in the development and progression of colorectal cancer (CRC), being associated with poor response or resistance to anti-EGFR therapy. K-RAS mutation status is used to predict the response to anti-EGFR therapy.
The aim of our study was to detect the K-RAS activating mutations (in codons 12 and 13) in order to contribute to the selection of CRC patients for anti-EGFR therapy.
DNA was extracted from formalin-fixed, paraffin-embedded samples (tumor cellularity between 10-90%) from 102 Caucasians CRC patients. The patient aged between 21-81 years, and sex distribution was 1:1. The K-RAS mutational status (codons 12 and 13) was identified by PCR-RFLP.
About 35-45% of colorectal tumours have been reported having mutation in the K-RAS gene, that activates cell signalling downstream of EGFR. In our study, such mutations were detected in 43 (42,15%) patients, of which 35 (81,40%) patients with mutations in codon 12 and 8 (18,60%) patients with mutations in codon 13. None of the patients presented mutations in both codons.
Detection of activating mutations in the K-RAS gene is required in all CRC patients, being an important factor for the therapeutic management. Our results were in accordance with international data, contributing to an effective selection of CRC patients for the anti-EGFR- therapy.

Association of IREB2 and FAM13A variants with lung cancer and chronic obstructive pulmonary disease in Poland

I. M. Ziółkowska-Suchanek[1], *M. Mosor*[1], *P. Gabryel*[2], *M. Grabicki*[3], *M. Fichna*[4], *E. Strauss*[1], *H. Batura-Gabryel*[5], *W. Dyszkiewicz*[6], *J. Nowak*[1];
[1]*Institute of Human Genetics, Polish Academy of Sciences, Poznań, Poland,* [2]*Wielkopolska Center of Pulmonology and Thoracosurgery, University of Medical Sciences, Poznań, Poland,* [3]*Allergology and Respiratory Oncology, University of Medical Sciences, Poznań, Poland,* [4]*Department of Endocrinology, Metabolism and Internal Diseases, University of Medical Sciences, Poznań, Poland,* [5]*Department of Pulmonology, Allergology and Respiratory Oncology, University of Medical Sciences, Poznań, Poland,* [6]*Wielkopolska Center of Pulmonology and Thoracosurgery im. Eugenii i Janusza Zeylandów, University of Medical Sciences, Poznań, Poland.*

Several genome-wide association studies (GWAS) have identified loci located at 15q25 (*IREB2*) and 4q22 (*FAM13A*) associated with chronic obstructive pulmonary disease (COPD) and lung cancer (LC). Dysfunctions of *IREB2* gene, as a regulator of iron homeostasis, may lead to oxidative failures, relevant in pathogenesis of lung diseases. *FAM13A* gene is involved in modulation of RhoA molecule activity, suggesting both anti-inflammatory and tumor suppressor function. The aim of our research was to determine the association between *IREB2/FAM13A* polymorphisms and Polish COPD and LC patients. We have examined four variants in *IREB2* (rs2568494, rs2656069, rs10851906, rs13180) and three in *FAM13A* (rs1903003, rs7671167, rs2869967) among 149 COPD, 468 LC patients and 524 controls, using TaqMan® genotyping assays. The frequency of AA genotype/A allele of *IREB2* rs2568494, were significantly higher in LC cases compared with controls (P=0.0081, P=0.0043). The *FAM13A* rs2869967 was significantly associated with COPD and combined COPD with LC+COPD group (CC genotype: P=0.0007, <0.0001; C allele: P=0.0009, 0.0001, respectively). The rs1903003, rs7671167 *FAM13A* variants confers a protective effect on COPD (both P<0.002). Haplotype-based tests identified significant association between the *IREB2* AAAT haplotype and LC cases (P = 0.0021). The *FAM13A* TTC haplotype was associated with an increased risk of COPD and COPD with LC+COPD group (P=0.0013 and P=0.0003, respectively). Results were independent of age, sex, lung function and smoking history. These studies have confirmed that the *IREB2* variants contribute to increased risk of LC, whereas the *FAM13A* predispose to increased susceptibility to COPD.

Genetic Polymorphism of NOS2 -954G/C in Nasal Polyposis. A case Control Study in a Population Group of Northern Romania

A. Catana[1], *R. A. Popp*[1], *A. Maniu*[2], *M. Cosgarea*[2], *M. Petrisor*[1], *I. Catana*[3];
[1]*Department of Medical Genetics, University of Medicine and Pharmacy, Cluj Napoca, Romania, Cluj Napoca, Romania,* [2]*Department of ENT, University of Medicine and Pharmacy, Cluj Napoca, Romania, Cluj Napoca, Romania,* [3]*Department of ENT, University of Medicine and Pharmacy, Cluj Napoca, Romania, Cluj Napoca, Romania, Cluj Napoca, Romania.*

Background Polymorphisms for genes encoding chemosensitive signalling proteins like NOS2, might contribute to the variability in individual susceptibility to nasal polyposis. NO produced by the inducible NO synthase enzyme NOS2A is generated at high levels in certain types of inflammation, so that the role of NOS2 might be important in nasal polyposis etiopathogeny. **Study Design** This is a cross-sectional, randomized, case control study for the evaluation of the frequency of -954G/C NOS2 polymorphism alleles among patients with nasal polyposis. **Subjects** The study included 92 cases of nasal polyposis diagnosed patients (nasal endoscopy and CT scan examination), and 107 healthy unrelated controls. **Methods** -954G/C NOS2 genotyping was carried out using PCR amplification of relevant gene fragment was followed by restriction enzyme digestion. Detection of the variant alleles was determined through analysis of resulting restriction fragment length polymorphism (RFLP) followed by gel electrophoresis. **Results** Molecular analysis revealed an increased frequency of -954G/CNOS2 variant allele in the study group compared to the control group (p=0.043; OR= 1.77; CI=1.02-3.09). **Conclusions** The main finding of our study is that mutant genotype of -954G/C NOS2 is considered to be a risk factor for nasal polyposis development.

J12.073
Clinical features of sebaceous skin lesions and diagnosis of Lynch syndrome: a case series from Genetic Health Queensland

M. J. Boon, *L. Fowles, R. D. Susman;*
Genetic Health Queensland, Brisbane, Australia.

Muir-Torre syndrome is a clinical sub-type of Lynch syndrome which is associated with sebaceous skin lesions and keratoacanthomas in addition to internal malignancies. As established in other Lynch syndrome-associated cancers, these skin lesions demonstrate loss of mismatch repair (MMR) protein expression on immunohistochemical (IHC) staining, allowing targeted germline mutation analysis of the MMR genes associated with Lynch syndrome (*MLH1, MSH2, MSH6, PMS2)*. However, not all lesions with loss of MMR protein expression will result in a molecular or clinical diagnosis of Muir-Torre or Lynch syndrome, as this protein loss may be due to a sporadic mechanism. There is emerging literature that the specific type of sebaceous lesion, along with its location on the body, can provide an indication as to which lesions are more likely to have loss of MMR protein expression and subsequent association with Muir-Torre/Lynch syndrome. In order to assess this theory within the experience of Genetic Health Queensland (GHQ), an internal audit was performed. All patients seen at GHQ between 2005 and 2013 with a primary reason for referral of a sebaceous skin lesion were included in a retrospective analysis. The information reviewed included subtype and location of lesion, age of diagnosis, personal and family history of cancer, IHC results, MMR gene testing results and outcome of assessment. A detailed analysis of this information will be presented, including the proportion of individuals with sebaceous lesions in which a clinical or molecular diagnosis of Muir-Torre/Lynch syndrome was made.

RET proto-oncogene main exons' mutations in Iranian patients with medullary thyroid carcinoma

M. Zarif Yeganeh[1], *S. Sheikholeslami[1], F. Azizi[2], M. Hedayati[1];*
[1]Cellular and Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti Unversity of Medical Sciences, Tehran, Islamic Republic of Iran, [2]Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti Unversity of Medical Sciences, Tehran, Islamic Republic of Iran.

Introduction: Thyroid cancer is the most common endocrine malignancy. Medullary thyroid carcinoma (MTC) account for 5-10% of all thyroid cancer types. It occurs in both hereditary (25%,hMTC) and sporadic (75%,sMTC) forms which are associated with gain of function mutations in the RET proto-oncogene.
Material and methods: We have started MTC genetic screening since 2001. Our study included 360 individuals, including 161sMTC, 39FMTC, 8MEN2A, 3MEN2B, 4pheochromocitoma (215 index cases), and 145 relatives. Genomic DNA was extracted from peripheral blood leukocytes, and the six exons of the RET gene (10, 11, 13, 14, 15, 16) were amplified by PCR and examined by DNA sequence analysis to detect mutations.
Results: A total of 20 different types of missense RET mutations were identified in 78 patients. All of the MEN2A patients had mutations in codon 634. Mutations outside of codon 634 occurred only in FMTCs and sMTCs. A mutation at codon 918 was found in all MEN2B patients. p.C634Y was the most common mutation in our study followed by mutations p.C630Y, p.C634R, p.634S. The G691S/S904S haplotype was identified in 120 patients and 70 relatives. A novel C>T intronic variant (intron 11, chr position 10:43612012) was also detected.
Conclusion: Exon 11 and after that exon 10 were the most frequently mutated exons of RET proto oncogene in MTC patients in our population. As about half of patients with the hot spot mutations had the G691S/S904S haplotype simultaneously, further analysis needs for clarifying the effect of multiple risk alleles in MTC development.

J12.075
Molecular cytogenetic diagnosis of melanocytic lesions

B. Durak Aras[1], *S. Işık[1], F. Canaz[2], M. Özdemir[1], O. Çilingir[1], H. Aslan[1], Ö. Bolluk[3], E. Erzurumluoğlu[1], S. Artan[1];*
[1]Eskisehir Osmangazi University Medical Faculty Dept.of Medical Genetics, Eskisehir, Turkey, [2]Eskisehir Osmangazi University Medical Faculty Dept.of Pathology, Eskisehir, Turkey, [3]Eskisehir Osmangazi University Medical Faculty Dept.of Biostatistics, Eskisehir, Turkey.

Although histopathological analysis is the "gold standard" for melanoma diagnosis, distinguishing potentially lethal melanomas from benign melanocytic nevi with atypical histopathologic features needs further analysis. Most melanomas have chromosome copy number abnormalities. Fluorescent In Situ Hybridization (FISH) is an applicable technique in the diagnosis of these chromosome abnormalities and so its usability is emerging in melanoma diagnosis. The aim of this study was to evaluate the diagnostic role of the FISH in the assessment of malign melanomas and melanocytic nevi. Histologically evaluated most suitable formalin-fixed, paraffin-embedded (FFPE) tissue sections of 25 malign melanoma tumors and 25 melanocytic nevi samples were analysed for copy number abnormalities of CCND1, MYB, RREB1 and centromere of chromosome 6 but no FISH result could be obtained from a tumor tissue. Copy number abnormalities were detected in 20 malign tumors (83.8%) and four melanocytic nevi (16.0%) and statistically significant differences were seen between the tissues for each gene (MYB deletion and RREB1/CEP6 p<0,05 , RREB1 amplification p<0,01 and CCND1 amplification p<0,001). Histopathologic features of the melanocytic nevi tissues with gene copy number abnormalities were similar to the characteristics of malign melanomas and they had had premalignant diagnosis. The CCND1 amplification was the predominantly seen abnormality and its importance as a marker should be evaluated in detail. The study demonstrated that copy number analysis of FFPE tumor samples by FISH is a reliable method in the diagnosis of melanoma and the technique is also informative to understand molecular mechanism of the melanocytic tumors.

Prevalence of *P16* methylation and prognostic factors in plasma cell myeloma of single institution in Korea

H. Kim[1], *M. Kim[2], Y. Kim[2], H. Lee[1], K. Han[2];*
[1]Laboratory Medicine, College of Medicine, The Catholic University of Korea, Seoul, South Korea, Uijeongbu, Korea, Republic of, [2]Laboratory Medicine, College of Medicine, The Catholic University of Korea, Seoul, South Korea, Seoul, Korea, Republic of.

Background: The primary purpose of this study was to investigate the prevalence and characteristics of *p16* methylation and determine the prognostic implications of the clinical data, hematologic data and *p16* methylation changes in plasma cell myeloma (PCM). **Methods:** We reviewed clinical characteristics, laboratory tests and investigated the response to combination chemotherapy, and survival time. DNA methylation of the *p16* gene was tested by methylation specific PCR and evaluated the clinical significance. **Results:** A total of 103 patients were enrolled in this study. The patient median age was 59.0 years at diagnosis and male to female ratio was 1.15:1. According to the International Staging System (ISS), patients were diagnosed as stage: I (n=17, 16.5%); II (n=41, 39.8%); III, (n=39, 37.9%); (not classified 6). Forty five (43.7%) patients and thirty six (35.0%) patients showed abnormal karyotype and complex karyotype on chromosome study, respectively. The*p16*methylation was found in 39 of 103 (37.9%) patients, but there was no significant association of *p16* methylation status with other clinical, laboratory factors and survival outcome. The male gender, albumin and complex karyotype were independent prognostic factors for overall survival by multivariate analysis (P<0.05). **Conclusions:** The male gender, albumin and complex karyotype were independent prognostic factors in PCM. And *p16* methylation was relatively common in PCM, but didn't influence a response to survival outcome.

Analysis of oncogenic mutations in 52 MGUS patients - two case reports of KRAS mutation

A. Mikulasova[1,2,3], *M. Kaiser[4], M. Wayhelova[1], V. Vallova[1,5], J. Smetana[1,2], M. Purgertova[2], V. Sandecka[6], L. Pour[6], P. Kuglik[1,2,5], G. Morgan[4], R. Hajek[2,7,8];*
[1]Department of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic, [2]Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [3]Department of Clinical Haematology, University Hospital Brno, Brno, Czech Republic, [4]Centre for Myeloma Research, Division of Molecular Pathology, The Institute of Cancer Research, London, United Kingdom, [5]Department of Medical Genetics, University Hospital Brno, Brno, Czech Republic, [6]Department of Internal Medicine – Haematooncology, University Hospital Brno, Brno, Czech Republic, [7]Department of Haematooncology, University Hospital Ostrava, Ostrava, Czech Republic, [8]Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic.

Monoclonal gammopathy of undetermined significance (MGUS) is a premalignant condition permanently associated with a risk of progression into malignant disease, especially to multiple myeloma (MM). While in MM, oncogenic mutations have been described in several studies, no mutation study was done in abnormal plasma cells (aPCs) in MGUS. In our study, we performed genetic analysis in 52 samples of aPCs (CD138+CD19-CD56+/-) of MGUS patients by aCGH (SurePrint G3 CGH+SNP, 4×180K, Agilent) together with High Resolution Melting (HRM) followed by Sanger sequencing in HRM positive cases. By HRM, we focused on DNA single nucleotide mutations in 11 hot spots of MYC, NRAS, KRAS, DIS3, BRAF, FAM46C and TP53 genes. We found two cases of KRAS mutations p.Q61L and p.A146T with damaging prediction effect. Both MGUS cases showed positive IGH disruption (in 56% and 85% aPCs) analysed by I-FISH, but only the first case with p.Q61L mutation showed unbalanced chromosomal changes in genome-wide profile: hyperdiploidy (+3, +5, +9, +11, +15, +19), losses of chromosomes 8, 13 and Y, 7 segmental losses (1p34.2-p13.1, 6p23, 6q12-q27, 7q36.3, 12p12.1-p11.23, 12q12, 12q21.2-q23.3) and 4 segmental gains (6p25.3-p23, 6p23-p11.1, 6q11.1-q12, Xq21.33-q28). Interestingly, only this patient has progressed after 6 months to MM. Genome-wide profiling of the second patient with p.A146T mutation did not show any unbalanced chromosomal changes and the patient is still stable for more than 16 months. In our study, we showed that KRAS p.Q61L mutation combinated with chromosomal changes could

be potential markers of MGUS progression. Support: IGA NT13492,OPVK CZ.1.07/2.3.00/20.0183, MH CZ-DRO (FNBr, 65269705)

Gene polymorphisms of microRNAs in Helicobacter pylori- induced high risk atrophic gastritis and gastric cancer

J. Kupcinskas[1], T. Wex[2], R. Steponaitiene[1], S. Juzenas[1], **R. Ramonaite***[1], M. Leja[3], G. Kiudelis[1], L. Jonaitis[1], J. Skieceviciene[1], L. Kupcinskas[1], P. Malfertheiner[2];*
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania, [2]Otto von Guericke University, Magdeburg, Germany, [3]University of Latvia, Riga, Latvia.

Aims: The purpose of this study was to evaluate potential associations between miRNA-related gene polymorphisms (miR-27a, miR-146a, miR-196-a-2, miR-492 and miR-608) and the presence of gastric cancer (GC) or high risk atrophic gastritis (HRAG) in European population.
Methods: Gene polymorphisms were analysed in 995 subjects (controls: n = 351; GC: n = 363; HRAG: n = 281) of European descent. MiR-27a T.C (rs895819), miR-146a G.C (rs2910164), miR-196a-2 C.T (rs11614913), miR-492 G.C (rs2289030) and miR-608 C.G (rs4919510) single nucleotide polymorphisms (SNPs) were genotyped by RT-PCR.
Results: SNPs of miRNAs were not associated with the presence of GC or HRAG. We observed a tendency for miR-196a-2 CT genotype to be associated with higher risk of GC when compared to CC genotype, however, the difference did not reach the adjusted P -value (odds ratio (OR) - 1.46, P=0.032). MiR-608GG genotype was more frequent in GC when compared to controls (OR 2 2.34), but significance remained marginal (P=0.029). A similar tendency was observed in a recessive model for miR-608, where CC + CG vs GG genotype comparison showed a tendency for increased risk of GC with OR of 2.44 (P=0.021). The genotypes and alleles of miR-27a, miR-146a, miR-196a-2, miR-492and miR-608SNPs had similar distribution between histological subtypes of GC and were not linked with the presence of diffuse or intestinal-type GC.
Conclusions: Gene polymorphisms of miR-27a, miR-146a , miR-196a-2, miR-492, miR-492a and miR-608were not associated with the presence of HRAG, GC or different histological subtypes of GC in European subjects.

J12.079

Association of a SNP in miR-576-5p binding site of NHLH2 gene with neuroectodermal tumours in paediatrics

J. Vinklárek*[1], J. Novák[1,2], F. Zlámal[1], Z. Šplíchal[1], D. Ambrozková[1], A. Stejskalová[1], I. Nečesánek[1], D. Kodytková[3], J. Štěrba[3], J. Bienertová-Vašků[1,3,4];*
[1]Department of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, [2]Department of Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic, Brno, Czech Republic, [3]Department of Paediatric Oncology, University Affiliated Hospital, Brno, Czech Republic, [4]Molecular Oncology II, Central-European Technological Institute (CEITEC), Brno, Czech Republic.

Backround: Neuroectodermal tumours represent a large group of tumours of central as well as peripheral nervous system that arise from the cells of neuroectoderm. NHLH2 (nescient helix-loop-helix 2, also known as HEN2 or NSCL2) is a member of basic helix-loop-helix (bHLH) transcription factor family, expressed in neuroectoderm and also involved in tumorogenesis. Hereto, we focus on rs12405792, a single nucleotide polymorphism in the miR-576-5p biding site of the NHLH2 gene.The aim of the study was to investigate the rs12405792 polymorphism in paediatric patients with neuroectodermal tumors and other malignancies.
Material and Methods: The study involved the total of 40 of paediatric patients with neuroectodermal tumors (neuroblastoma, ganglioneuroblastoma, medulloblastoma, pineoblastoma, retinoblastoma, astrocytoma, ganglioneuroma, ependymoma, paraganglioma, glioblastoma, melanoma, dysembryoplastic neuroepithelial tumors), the total of 108 patients with non-ectodermal tumorsand 20 healthy controls.
Results: There were significant differences in genotypes frequencies between the investigated cohorts; the genotype distributions were different in neuroectodermal tumors compared to other groups (p = 0.03), the relative frequency of GG genotype (55 %) being increased in neuroectodermal tumors compared to healthy controls and non-neuroectodermal malignancies.
Discussion: In this study, we observed significant differences in genotype frequencies of rs12405792 between the neuroectodermal and non-neuroectodermal tumors and healthy controls. The functional effect of this SNP in miR-576-5p binding region to NHLH2 expression has to be further elucidated in order to explain possible effects of the SNP in neuroectodermal tumors.

Alterations of miRNA expressions in plasma of AML patients at the time of diagnosis

E. Pazourkova*[1], L. Koutova[2], I. Svobodova[1], S. Pospisilova[1], M. Sterbova[1], A. Horinek[1], M. Korabecna[1];*
[1]Charles University in Prague, 1st Faculty of Medicine and General Hospital in Prague, Prague 2, Czech Republic, [2]Faculty Hospital in Pilsen, Pilsen, Czech Republic.

We studied miRNA expression profiles in patients with acute myeloid leukaemia at diagnosis and in the first remission and we compared them with profiles found in healthy controls. Plasma samples were collected from 8 patients at the first diagnosis of AML and at the first complete remission and from 10 healthy volunteers. Isolated miRNA were transcribed to cDNA and applied on TaqMan Human MicroRNA Array A to find the expression of 381 genes. Relative quantification and statistical analyses were performed with Expression Suite v1.0.3 and with qbase+ v2.4. Relative quantification was calculated using the reference gene miR-16 or the global mean. Both values of miRNA expressions were compared between the patients and controls using Mann-Whitney tests with multiple testing corrections. The differences of various statistical significance were found. Among them there were 12 miRNAs (miR-125a-5p, miR-145, miR-221, miR-652, miR-744, miR-146a, miR-181a, miR-191, miR- 27a, miR-340, miR-134, let-7d) giving the p values < 0.01 with both applied normaliazation methods and another 4 miRNAs (miR-199a-3p, miR-331-3p, miR-324-5p, miR-28-3p) giving p values < 0.01 using reference gene miR-16 and p value between 0.01 - 0.02 using global mean. All these miRNAs were overexpressed in patients at the time of diagnosis only, but not at the first complete remission. With regards to miRNA expression profiles of healthy subjects, we compared the profiles in the morning and the afternoon samples of healthy volunteers and we detected no significant differences refering to circadian rhytmicity. Supported by the Ministry of Health of the Czech Republic, RVO VFN64165.

Investigation of DNA mutations in Mitochondrial D-Loop region at thyroid nodules in Turkish Population-Preliminary findings

R. Bircan*[1], E. Ulu[1], C. Aral[1], D. Yaşar Şirin[1], A. Eren[1], B. Güllüoğlu[2], S. Özçelik[3], H. Ilıksu Gözü[3];*
[1]Namik Kemal University, Faculty of Arts ans Sciences, Department of Molecular Biology and Genetics, Tekirdag, Turkey, [2]Marmara University School of Medicine, Department of General Surgery, İstanbul, Turkey, [3]Haydarpaşa Numune Training and Research Hospital, Department of Endocrinology and Diabetology, İstanbul, Turkey.

Mitochondrial defects have been associated with various human conditions including cancers. However mitochondrial DNA (mtDNA) alterations within the highly variable D-loop control region have been reported as a frequent event in cervical cancer, breast cancer, gastric carcinoma, colorectal cancer, hepatocellular cancer, lung cancer and renal cell carcinoma. Specifically, it was suggested that the D310 region is more susceptible to oxidative damage and electrophilic attack.
Aim of this study to investigate if the accumulation of mtDNA mutations plays a role in tumorigenesis in thyroid nodules in Turkish population. Clinically and pathologically examined 178 tissue samples belonging to the 77 patients; including 58 surrounding healthy tissues, 51 hot thyroid nodules (HTN) and 69 cold thyroid nodules (CTN), were enrolled to the study. DNA extraction from tissue samples was done by using phenol-chloroform methodology. D-Loop region between 15-484. nt and 15971-16411. nt were amplified by PCR. DNA sequencing reaction of D-Loop region between 15-484. nt was performed on Bekcmann Coulter Genomelab Automated DNA Sequencer.
The same polymorphisms were detected in both healthy and nodular tissue samples belonging to the same patients. But two different polymorphisms (A73G; T89G) were detected as heteroplasmically in HTN tissue of 31th patient different from healthy tissue. Beside this in HTN tissue of 33th and CTN tissues of 13th patient D310 polymorphisms were also detected as heteroplasmically different from healthy tissues.
As a result, the obtained data indicates that mtDNA alterations in the D-loop region could happen before tumorigenesis in thyroid, and they might also accumulate during tumorigenesis.

J12.082

The occurrence of *EZH2* mutations in patients with *BCR-ABL*-negative myeloproliferative neoplasms

L. Polushkina*, E. Petrova, L. Martynenko, M. Ivanova, N. Cybakova, E. Shabanova, M. Fominykh, V. Shuvaev, K. Abdulkadyrov, I. Martynkevich;*
Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation.

Recent studies have revealed a number of epigenetic alterations that contribute to myeloproliferative neoplasms (MPNs) pathogenesis and determine the clinical outcome. According to the published data, mutations involving *EZH2*, which encodes a histone methyltransferase, are founded in 6% cases of primary myelofibrosis (PMF), 1% of polycythemia vera and 1-3% of essential thrombocythemia regardless of the presence of mutations in *JAK2* or *MPL*. *EZH2* mutations may be of prognostic value in MPN's at the time of

transformation to the blastic phase. The goal of our research was to determine the frequency of mutations in *EZH2* in two groups of patients with different chromosomal aberrations. We examined 47 patients with *BCR-ABL*-negative MPNs. The first group included 20 patients with normal karyotype, and 16 patients with the isolated chromosomal aberrations del(13)(q22), del(20)(q12),-Y associated with favorable prognosis, and add(22)(q13), del(1)(p32), del(6)(q15), t(10;12)(q22;p13) that are referred to as intermediate risk. The second group included 11 patients with complex abnormalities and the chromosomal aberrations of unfavorable prognosis +8, +7, inv(7)(p11;q21). Mutations in 8,10,17,18,19 exons of *EZH2* were defined by sequence analysis. The Ile713Thr mutation in *EZH2* gene was detected in 2.1% (1/47 cases). The patient with mutation had a del(6)(q15) karyotype which is associated with an intermediate risk, and he subsequently underwent transformation from PMF to myelodisplastic syndrome in 9 months after the disease onset. Conclusions: mutations in the *EZH2* gene could be preliminarily assessed as additional prognostic markers of unfavorable prognosis in patients with *BCR-ABL*-negative MPNs and with different chromosomal aberrations. Further studies are needed.

Presence of RET Proto-oncogene mutations and polymorphisms in Iranian families with multiple endocrine neoplasia type 2A

M. Nasiri Aghdam[1,2], *M. R. Abbaszadegan*[2,1], *A. Tafazoli*[1,2], *z. Moosavi*[3];
[1]*Medical Genetics Research Center, Department of Medical Genetics, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran,* [2]*Division of Human Genetics, Immunology Research Center, Avicenna Research Institute, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran,* [3]*Endocrinology Research Center, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran.*

Introduction Multiple Endocrine Neoplasia type 2A (MEN 2A) is a complex autosomal dominant inherited syndrome characterized by medullary thyroid carcinoma (MTC), pheochromocytoma and primary parathyroid hyperplasia. In patients with only one or two clinical features, identification of a germ line RET (**RE**arranged in **T**ransfection) mutation on chromosome 10 or the identification of the clinical features of MEN 2A in other first degree relatives is required to make the diagnosis. **Methods** We analyzed blood DNA from 4 Iranian families with three generations of MEN2A including 22 affected persons with MTC and 10 with pheochromocytoma. RET hotspots were amplified in probands and sequenced for mutation detection. RFLP test was used for identification of mutations in family members. For fidelity analyzing of used RFLP test, all members sequenced. **Result** The causative mutation in all families was found to be Cys634Tyr missense substitution. The simultaneous presence of a functional SNP resulting in Gly691Ser was also detected in exon 11 of all the affected cases. Two known silent substitutions and one new silent mutation was also detected in exons 10 and 13. RsaI restriction endonuclease can detect all carriers of Cys632Tyr mutations. **Conclusion** Simultaneous presence of Cys634Tyr mutation in cysteine rich region and Gly691Ser polymorphism in trans-membrane domain of RET tyrosine kinase have been detected in all patients. This study shows that Cys634Tyr mutation is recurrent in Iranian patient with MEN2A and suggest the RFLP method for detection of this mutation. All asymptomatic carriers of mentioned high risk activating mutation were recommended for prophylactic thyroidectomy.

Coordination of expression of cell cycle related genes in Multiple Myeloma and Plasma Cell Leukemia

P. Nemec[1,2], *F. Kryukov*[3,4], *I. Ihnatova*[2], *R. Hajek*[4], *P. Kuglik*[1];
[1]*Faculty of Science, Masaryk University, Brno, Czech Republic,* [2]*Faculty of Medicine, Masaryk University, Brno, Czech Republic,* [3]*Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic,* [4]*University Hospital Ostrava, Ostrava, Czech Republic.*

In multiple myeloma (MM), malignant cells retain the self-renewing potential. Majority of myeloma cells stay in the G1 phase, however after leukemic transformation in plasma cell leukemia (PCL) myeloma cells become highly proliferative. We anticipate that complex "re-setting" of cell cycle gene expression coordination during leukemic transformation creates required background for proliferation restoration. The aim of this study was to define and describe complex "re-setting" of cell cycle gene expression coordination in MM and PCL. Gene expression profiling was performed in 7 healthy donors, 6 MM and 7 PCL patients utilizing Affymetrix GeneChip Human Exon 1.0 ST Arrays. Genesets, connected with cell cycle regulation (GO:0045786; GO:0045787) and regulation of apoptotic process (GO:0043065; GO:0043066) together with all descended direct connected genesets were taken for the GSEA analysis and Gene Set Differential Coordination Analysis. Comparison of PCL, MM and healthy donors revealed coordinating expression changes between regulation of mitosis, apoptosis and cell cycle arrest for both positive and negative regulation genes. In MM, co-expression changes were associated with early phase of cell cycle, whereas in PCL with both - early and late phase of cell cycle. We anticipate that expression of cell cycle positive regulators is in dynamic equilibrium with cell cycle negative regulators. We suppose that this equilibrium serves as a compensatory mechanism to oncogenic events. Despite compensation mechanisms activation, whole regulatory complex seems to be imbalanced by growing "oncogenic stress" during MM to PCL progression. Supported by grants NT12130, NT13190 and OPVK CZ.1.07/2.3.00/20.0183.

MYCN oncogene amplification in advanced neuroblastoma patients from Republic of Macedonia

S. A. Kocheva[1], *G. Bozinovski*[2], *K. Martinova*[1], *B. Coneska-Jovanova*[1], *A. Acevska*[1], *D. Plaseska-Kanfilska*[3];
[1]*University Childrens Hospital, Skopje, Macedonia, The Former Yugoslav Republic of,* [2]*Research Center for Genetic Engineering and Biotechnology „Georgi D.Efremov" Macedonian Academy of Sciences and Arts, Skopje, Macedonia, The Former Yugoslav Republic of,* [3]*Research Center for Genetic Engineerin and Biotechnology „Georgi d.Efremov, Macedonian Academy of Sciences and Arts, Skopje, Macedonia, The Former Yugoslav Republic of.*

Neuroblastoma is characterized by striking clinical heterogeneity, including subsets that show spontaneous tumor regression. Several acquired genetic alterations such as amplification of the MYCN oncogene, deletions of chromosome bands 1p36 and 11q23 and unbalanced gains of 17q regions have been well-characterized and shown to be correlated with tumor behavior, including response to treatment. Amplification of the MYCN oncogene identifies a group of patients who have a poor prognosis. The aim of our study was to evaluate the prognostic role of MYCN oncogene amplification in our cohort of children with neuroblastoma. Ten children (age 9 months to 4 years) with previously untreated neuroblastoma, were evaluated at diagnosis for MYCN gene amplification. Fresh surgical specimens were obtained during excision of the tumor or during bone marrow fine needle aspiration and analyzed using MLPA P252 kit. MYCN amplification was observed in 8 patients (4 with stage IV and 4 with stage III disease), and it was not present in the two patients with stage 2A disease. The disease was lethal in six patients with MYCN amplification with overall median survival of 10 months. The other two patients with MYCN amplification are alive, but with a recurrent disease. In conclusion, MLPA analysis is simple, fast and cost-effective method that enabled accurate detection of MYCN amplification in our patients with neuroblastoma. Our study also shows that MYCN amplication is frequent event in patients with an advanced neuroblastoma and confirms it as a poor prognostic factor

Elucidation of genetic changes associated with a rare form of familial myelodysplastic syndrome

R. M. Gillett[1], *D. Gaston*[1], *M. Nightingale*[1], *C. MacGilivray*[2], *O. Hayne*[3,4], *S. Couban*[3,4], *C. V. Fernandez*[5,6], *C. R. McMaster*[7], *W. Greer*[1], *K. Bedard*[1];
[1]*Department of Pathology, Dalhousie University, Halifax, NS, Canada,* [2]*Department of Ophthalmology, Capital Health, Halifax, NS, Canada,* [3]*Department of Medicine, Dalhousie University, Halifax, NS, Canada,* [4]*Capital District Health Authority, Halifax, NS, Canada,* [5]*Department of Pediactrics, Dalhousie University, Halifax, NS, Canada,* [6]*IWK Health Centre, Halifax, NS, Canada,* [7]*Department of Pharmacology, Dalhousie University, Halifax, NS, Canada.*

BACKGROUND Myelodysplastic syndrome (MDS) is a clonal proliferative disorder of the bone marrow characterized by ineffective hematopoiesis, peripheral blood cytopenias, and increased risk of developing acute myeloid leukemia (AML). Identifying predisposing gene mutations is critical for effective diagnosis, assessment of prognosis, and therapeutic counselling. A Caucasian family with an autosomal dominant inheritance pattern of early onset MDS was identified. No common exposures to potential carcinogens were present and clinical genetic testing indicated that regions 5q31 and 7q22, frequently associated with sporadic MDS, were not causal, suggesting an inherited predisposition. **METHODS/RESULTS** In-depth genetic analysis was undertaken. Six samples were acquired, including four clinically affected males across 2 generations (age of onset 25-69; one RAEB MDS, two unclassified MDS, one unknown MDS), a suspected unaffected female family member (aged 40), and an unaffected spouse (aged 72). Single-nucleotide polymorphism genotyping was performed on the suspected unaffected and three affected individuals. Data was analyzed using a haplotype mapping technique for autosomal dominant disorders. Using a cut-off of 3cM, affected individuals were found to share 89 genomic regions. Whole-exome sequencing on two affected individuals, combined with the mapping data, revealed 1904 shared variants in those regions. **FUTURE DIRECTIONS** Whole-exome sequencing on a third affected individual is underway to reduce the list of potential causative variants. After analysis, variants will be prioritized based on the genes known function and mutation severity. Top candidate genes will be sequenced in all available family members to determine which variant(s) track with the disease.

NAT2 acetylation polymorphisms in bladder cancer risk

N. Ersoy Tunali, *Y. Ozger, N. O. Tiryakioglu;*
Halic University, Istanbul, Turkey.

Bladder cancer is known to be modulated by environmental carcinogens. Polymorphisms in the genes coding for the enzymes involved in the metabolism of carcinogens are considered as susceptibility factors for bladder cancer. N-acetyltransferase 2 (NAT2) is a Phase II enzyme of the xenobiotic metabolism pathway, which is involved in detoxification of arylamines and heterocyclic amines. Therefore, polymorphisms of the NAT2 gene and its related acetylation status may confer a risk factor for the development and progression of bladder cancer. In this study, we have investigated NAT2 481C>T, 590G>A and 857G>A polymorphisms, corresponding to NAT2*11A, NAT2*6B and NAT2*7A alleles, in terms of bladder cancer risk. For this purpose, genomic DNA samples of 129 bladder cancer and 148 healthy subjects were genotyped by PCR-RFLP upon their informed consent. We have shown that NAT2*11A allele have a trend for protection against bladder cancer (p=0.059; OR=0,761), and significance of protection increases (p=0,005; OR=0,539) when non-smokers are excluded. We also categorized the individuals according to their acetylation status as slow, intermediate and fast acetylators, however, we could not find a statistically significant asscociation between bladder cancer and acetylation status.

Evaluation of genotoxic risk of Tunisian hospital workers exposed to low levels of ionizing radiation (IR)

S. Bouraoui[1], *S. Mougou*[1], *F. Tabka*[2], *A. Drira*[2], *D. Hmida*[1], *O. Mamai*[1], *N. Mrizek*[2], *H. Elghezal*[1], *A. Saad*[1];
[1]*Department of Cytogenetic and Reproductive Biology, Farhat Hached University Teaching Hospital, Sousse, Tunisia,* [2]*Department of occupational and environmental medecine, Farhat Hached University Teaching Hospital, Sousse, Tunisia.*

Over the years, (IR) has become a universal diagnostic and therapeutic tool, making the largest man-made contribution to the population dose. Thus, medical personnel represent the group most consistently exposed to low doses of IR.
Many cytogenetic studies have been conducted among hospital workers exposed to IR.
The cytokinesis-blocked micronucleus (CBMN) assay is widely used, since it represents a reliable test to assess radiation-induced chromosme damage and it's a valuable biomarker in many biomonitoring studies on human populations exposed to IR.
The aim of our study is to assess chromosomal damage in Tunisian hospital workers occupationnally exposed to low levels of IR.
The CBMN in peripheral lymphocytes of 67 exposed workers compared to 43 controls.
The clastogenic/aneugenic effect of IR was evaluated using the CBMN assay in combination with flurescence in situ hybridization (FISH) with pan-centromeric DNA in all the exposed subjects and controls.
The centromere analysis performed in our study showed that MNs in hospital staff were predominantly centromere negative and the mean negative labeled micronucleus (C-MN) frequency was significantly higher in the exposed subjects than in the controls (9.04±4.57‰ vs. 1.17± 0.77‰). The multivariate regression analysis showed that only the time of exposure ti IR had a significant effect on the level of MNs and C-MN.
The results of the study confirm the well-known clastogenic properties of IR.

J12.089

The detection of mutations in gene PTEN in patients with ovarian cancer from Bashkortostan Republic of Russia

Z. Takhirova[1], *M. Bermisheva*[1], *O. Urkina*[2], *E. Khusnutdinova*[1,2];
[1] *Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [2]*Bashkir State University, Ufa, Russian Federation.*

PTEN (phosphatase and tensin homolog) localized on chromosome 10q23.3 is tumor suppressor, which mutations cause both hereditary and sporadic forms of malignancies, including ovarian cancer (OC). The first germinal mutations in this gene have been identified in the study of hereditary syndromes: Cowden, Bannayan-Riley-Ruvalcaba and Lhermitte-Duclos. PTEN is negative regulator of the PI3K/AKT/mTOR pathway by dephosphorylating phosphatidylinositol 3,4,5-triphosphate to phosphatidylinositol -4,5-bisphosphate thus counteracting PI3K function. The operation of PTEN is necessary to control apoptosis, migration and proliferation of cells in the organism.
We carried out an analysis of structural changes in the PTEN in 250 patients with ovarian cancer from different ethnic groups of the Republic of Bashkortostan. The detection of mutations was performed by high resolution melting curve analysis (HRM) and confirmed by direct sequencing. The study of nucleotide sequence of the PTEN in patients with OC were detected changes: c.904A>C (Ser302Arg), c.217G>A (Glu73Lys), previously described polymorphism c.132T>C (Gly44Gly), and changes in introns: c.209+9G>C, c.209+10T>C.
Using the program Polyphen-2, we have found that the change c.904A>C, located in exon 8 of PTEN, is not pathogenic, and therefore does not contribute to the development of ovarian cancer. Mutation c.217G>A (Glu73Lys), located in exon 4 of PTEN, is found in phosphatase domain of protein PTEN that may possibly affect the impaired function of the protein and subsequently lead to tumor formation.

microRNA expression in circulating samples of pancreatic ductal adenocarcinoma patients

B. Alemar[1,2], *C. Gregório*[1,2], *P. Izetti*[1,2], *A. Osvaldt*[1], *U. Matte*[1,2], *P. Ashton-Prolla*[1,2];
[1]*Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil,* [2]*Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.*

Pancreatic ductal adenocarcinoma (PDAC) is a rare disease, whose incidence rates are very close to mortality rates, due to its difficult and late diagnosis. Noninvasive diagnostic biomarkers emerges as a possibility to perform a safe diagnosis, preferably early in the disease course. Recently, microRNAs (involved in the initiation and maintenance of tumors, and able to discriminate the presence or absence of certain diseases) were discovered as stable molecules in circulating samples. We evaluated the expression levels of six miRNAs (miR-21, -34a, -155, -196a, -200b and -376a) in serum (24 PDAC and 9 healthy patients) and saliva (10 PDAC and 10 healthy patients) samples. The aim of our study was to investigate the presence of diagnostic and/or prognostic biomarkers. Expression levels were measured by relative quantification using qRT-PCR. In serum, miR-21 and miR-34a were significantly more expressed in samples from patients with PDAC (P<0.001 and P=0.001) and both were able to distinguish patients with and without disease with clinically acceptable sensitivity and specificity (AUC for miR-21 and miR-34a of 0.894 and 0.865). We also found a strong and positive correlation between the expression levels of these two miRNAs in serum (r_s=0.681; P<0.001; Kappa-tests: 0.477; P=0.022). However, the mechanism related to this correlation remains unknown. In salivary samples, generally, miRNA levels were very low. No difference in miRNA expression levels was seen between cases and controls. These findings suggest that the chosen miRNAs are not adequate as diagnostic biomarkers in saliva, although these findings require confirmation in a larger series of cases.

Association of Platelet Derived Growth Factor-B (PDGF-B) and Human Epidermal Growth Factor Receptor -2 (HER-2/neu) Single Nucleotide Polymorphisms (SNP's) with Gallbladder Cancer

K. Mishra[1], *A. Behari*[2], *V. K. Kapoor*[2], *S. Agrawal*[3], *M. Khan*[4];
[1]*Department of Surgical Gastroenterology,Sanjay Gandhi Post-graduate Institute of Medical Sciences (SGPGIMS), Lucknow, India,* [2]*Department of Surgical Gastroenterology, Sanjay Gandhi Post-graduate Institute of Medical Sciences (SGPGIMS), Lucknow, India,* [3]*Department of Medical Genetics, Sanjay Gandhi Post-graduate Institute of Medical Sciences (SGPGIMS), Lucknow, India,* [4]*Department of Bio-Sciences, Integral University, Kursi Road, Lucknow, India.*

Purpose: Gall bladder cancer (GBC), a highly malignant gastrointestinal tumour, is very common in north India. Platelet derived growth factor-B (PDGF-B) at chromosome 22q12.3-q13.1 and Her-2/neu at 17q12-q21 play an important role in tumour angiogenesis. PDGF-B and Her-2/neu overexpression has been found in many cancers. We studied PDGF-B and Her-2/neu single nucleotide polymorphisms (SNPs) in GBC and gall stone associated benign diseases viz. chronic cholecystitis (CC) and xantho-granulomatous cholecystitis (XGC).
Methods: DNA was extracted from blood in patients with GBC (n=195), CC (n=140), XGC (n=47) and normal controls (n=300). PDGF-B polymorphisms were investigated using ARMS PCR for +286A>G and +1135A>C, and for Her-2/Neu Ile^{655}Val by PCR-RFLP method.
Results: +286A>G polymorphism homozygous GG genotype, and +286G allele was found to be risk associated for GBC (OR=5.25 P=<0.0001 and OR=2.02 P=<0.0001). Recessive model (GG vs. AA+GA) of +286A>G polymorphism was risk associated (OR=4.78, P=<0.0001) whereas dominant model (AA vs. GG+GA) was risk protective (OR=0.56, P=0.003) with GBC. +1135A>C polymorphism CC genotype and +1135C allele was risk associated (OR=3.19, P=<0.0001 and OR=1.81, P=<0.0001) with GBC. Recessive model (CC vs. AA+AC) was risk associated (OR=2.75, P=0.0003) whereas dominant model (AA vs. CC+AC) showed protective association (OR=0.56, P=0.0024) with GBC. In HER-2 Ile^{655}Val polymorphism, dominant model and Val allele of this polymorphism was risk protective for XGC. In haplotype

analysis, haplotypes ACIle (OR= 1.48), GAVal (OR=1.70) and GAIle (OR=2.00) were risk associated with GBC.
Conclusion: PDGF-B polymorphisms may play a role in carcinogenesis of GBC and need further evaluation.

'3-Phosphoglycerate Dehydrogenase Polymorphism in male patients with thyroid gland cancer

M. Ristanovic[1], *J. Dotlić*[2], *J. Grbović*[1], *N. Popovac*[1], *J. Trifunović*[3], *V. Živaljević*[4];
[1]*Institute of Human genetics, University of Belgrade, Belgrade, Serbia,* [2]*Institute of Obstretics and Gynecology, Clinical Center of Serbia, Belgrade, Serbia,* [3]*Department of Pathology, Departmant of Central Laboratory, KBC Bezanijska kosa, Belgrade, Belgrade, Serbia,* [4]*Center for Endocrine Surgery, Clinical Centre of Serbia, University of Belgrade, Faculty of Medicine, Belgrade, Serbia.*

Introduction: Thyroid gland cancer (TC) is considered a rare malignancy, accounting up to 2% in males. Recent studies suggest important role of both environmental and genetic factors in cancerogenesis. 3-Phosphoglycerate dehydrogenase (3-PHGDH) gene overexpression is assosiated with patogenesis of human cancer and contributes to cell proliferation.
Aim: The objective of our study was to assess the association of PHGDH gene polimorphism in group of males with thyroid gland cancer and control group of healthy men.
Methods: The survey was carried out in the Department of Human Genetics-Medical School, University of Belgrade. The study has encompassed 80 man diagnosed with thyroid gland cancer in Center for Endocrine Surgery, Clinical Center of Serbia Serbia and 100 health males volonteers. The DNA was isolated from the periferal blood with solting out method. The genotypes 3-PHGDH polimorphism were determined by Polimerase Chain Reaction and Restriction Fragment Lenght Polimorphism. Gel-electrophoresis was used to separate DNA fragments.
Results: There was a significant difference in frequency of TT, CT and CC between
experimental and control groups of rs541503 polymorfism (Hi2= 38.924; p=0.001). There were
significantly more TT in experimental group, while in control group there were more CT (Hi2=33.186; p=0.001) and CC (Hi2=21.734; p=0.001). Conclusion: In our study we found TT genopype as the most frequent in patients with thyroid gland cancer. The results of our study also suggest that C allele might be factor of risk associated with thyroid gland cancer. It is necessary to undergo further testing with more adequate test groups.

J12.093
Incidence of PIK3CA mutations in breast cancer correlated with histopathological characteristics of the tumor

A. Mendelova[1,2], *V. Holubekova*[1], *P. Zubor*[2], *L. Plank*[3], *J. Danko*[2], *Z. Lasabova*[1];
[1]*Comenius University in Bratislava, Jessenius Faculty of Medicine, Department of Molecular Biology, Martin, Slovakia,* [2]*Comenius University in Bratislava, Jessenius Faculty of Medicine, Clinic of Gynecology and Obstetrics, Martin, Slovakia,* [3]*Comenius University in Bratislava, Jessenius Faculty of Medicine, Department of Pathological Anatomy, Martin, Slovakia.*

Gain-of-function mutations in PIK3CA have been found in breast cancer, but prognostic value of PIK3CA mutation status is controversial. The goal of the study is the analysis of PIK3CA hotspot mutations and their correlation with clinicopathological parameters. Paraffin-embedded tissue sections were obtained from biopsy specimens of 95 breast cancer patients characterized histologically and immunohistochemically including histological grade, regional lymph node status (pN), estrogen receptor, progesterone receptor and HER2 status. We investigated exon 9 and exon 20 of PIK3CA gene in 95 breast tumor samples by DNA sequencing. We observed mutations in 27.3% (26/95), all with exception of 2 cases were mutually exclusive. Mutations in exon 9 represent 16.8% (16/95); mutations in exon 20 represent 12.6% (12/95). We observed associations between mutations and the histopathological characteristics of the disease. In exon 9, we detected E542K (5/16), E545K (9/16), Q546K (2/16) missense changes. These mutations showed significant correlation with lower grade (p=0.0074) and pN status without metastases (p=0.0415). Mutations in exon 20 H1047R, H1047Y and G1049R were associated with higher age of patients (p=0.0249). The E545K mutation correlated with lower grade (p=0.0013) and with pN status (p=0.0232) particularly; the H1047R mutation was significantly more frequent in lobular type of breast cancer (p=0.0354). We have shown that the mutations in exon 9 of PIK3CA were associated with favorable prognostic factors. The PI3K signaling pathway plays a critical oncogenic role in the development of human breast cancer and the prevalence of its dysregulation advocates its potential as a feasible therapeutic target.

J12.094
Molecular subtyping of three aggressive PCa patients from Bulgaria in correlation with clinic-histological data

A. Tsvetkova[1,2], *A. Todorova*[1,2], *T. Todorov*[2], *G. Georgiev*[3], *I. Drandarska*[4], *V. Mitev*[1];
[1]*Department of Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria,* [2]*Genetic Medico-Diagnostic Laboratory Genica, Sofia, Bulgaria,* [3]*Department of Urology, Military Medical Academy Sofia, Sofia, Bulgaria,* [4]*Department of Pathology, Military Medical Academy Sofia, Sofia, Bulgaria.*

Prostate cancer (PCa) is among the most prevalent neoplasms worldwide, whereas metastatic PCa is one of the leading causes of death in men. Here we report three Bulgarian patients with strongly aggressive, hormone-refractory PCa. The application of the following molecular markers: DD3 overexpression, GSTP1 promoter hypermethylation, TMPRSS2-ERG gene fusions and mutations in androgen receptor (AR) gene for diagnostic purposes was assessed. We attempt to correlate the molecular data to both histological and clinical data. The obtained molecular profile in the three Bulgarian patients coincides with the clinical and histological data of aggressive, hormone-independent PCa. There was no association between the tumor stage (assessed by TNM as T2) and the detected molecular profile of aggressive cancer behaviour. None of our cases was with positive family history and no somatic mutations were detected in the AR gene. The rest of the markers: DD3 overexpression, GSTP1 gene promoter hypermethylation and TMRSS2-ERG fusion were positive in fresh prostatic tissues and biopsies from all three patients, whereas only one blood sample showed triple positive result. The appearance of PCa specific molecular markers in blood was considered as a predictor for a pronounced migration and dissemination of prostatic tumor cells in circulation. The GSTP1 promoter hypermethylation is the earliest epigenetic fluctuation, which indicates cancerous changes in the gland the first and long-lasting marker, in the blood circulation. The molecular profile during cancer treatment could be used to predict the individual response
Acknowledgements: the study was supported by the grants №4-D/2011 and 26-D/2012, Medical University Sofia, Bulgaria.

Analysis of the *PCA3*, *TMPRSS2-ERG*, *TERT* genes expression in biopsy samples and urine sediments as potential markers for diagnostics of prostate cancer

D. S. Mikhaylenko[1,2], *N. Y. Safronova*[1], *D. V. Zaletayev*[2], *D. A. Roschin*[1], *G. D. Efremov*[1], *A. V. Sivkov*[1];
[1]*State Federal Institute of Urology of the Health Ministry of Russia, Moscow, Russian Federation,* [2]*Research Centre for Medical Genetics RAMS, Moscow, Russian Federation.*

Prostate-specific antigen (PSA) concentration in the blood can be increased in hyperplasia or adenoma, analysis of biopsies due to the heterogeneity of prostate cancer (PCa) requires highly skilled pathologist. Search of new molecular markers for noninvasive diagnostics of PCa is an actual oncourology problem. The aim of this study is analysis of *PCA3*, *TMPRSS2-ERG*, *TERT* expression in biopsies and urine sediments as potential markers for the diagnostics of PCa. We have analyzed 72 biopsies, which included 21 adenocarcinoma, 29 prostate intraepithelial neoplasia (PIN) and benign prostatic hyperplasia (BPH), 22 cases of inflammatory lesions; 10 urine sediments obtained after prostatic massage. Genes expression was analyzed by real-time PCR with endogenous *GAPDH* and tissue-specific *KLK3* controls. There was a correlation between the grade in normal/low- /high PIN/adenocarcinoma and expression of *PCA3* (r = 0,691). The threshold ΔCt(PCA3-KLK3) 3,9 provided optimal sensitivity and specificity in biopsy: 86% and 96%, respectively. *TMPRSS2-ERG* expression was detected in 48% of adenocarcinomas and 11% of high PIN, *TERT* - 71% and 22%, respectively. Combination of *PCA3*, *TMPRSS2-ERG*, *TERT* has detected PCa in biopsies with 95% sensitivity and 97% specificity. Analysis of 10 urine sediments has classified correctly 9 cases. The high PIN is a precancerous stage, more than 50% of it proceeds in adenocarcinoma. This fact explains the difficulties in diagnosis of high PIN versus PCa using markers of carcinogenesis. Thus, analysis of *PCA3*, *TMPRSS2-ERG*, *TERT* expression could be useful for PCa detection in the biopsies and urinary sediments of patients with elevated PSA.

J12.096
Vitamin D receptor gene BsmI, FokI, ApaI and TaqI polymorphisms and the risk of prostate cancer among men of Russian, Tatar and Bashkir ethnic origin.

G. Kunsbaeva[1], *I. Gilyazova*[2], *A. Amenova*[1], *A. Izmailov*[3], *A. Papoyan*[3], *I. Sultanov*[3], *R. Ishemgulov*[3], *A. Itkulov*[3], *R. Kalmurzin*[3], *A. Pushkarev*[3], *V. Pavlov*[3], *E. Khusnutdinova*[1,2];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Establishment of the Russian Academy of Sciences Institute of Biochemistry and Genetics, Ufa, Russian Federation,* [3]*Bashkir Medical State University, Ufa, Russian Federation.*

Prostate cancer (PCa) is one of common tumors among men in Russia. Low levels of vitamin D are implicated as a potential risk factor for PCa development, and vitamin D receptor (VDR) gene may be important in the on-

set and disease progression. In this study, SNP variants rs2228570 (FokI), rs1544410 (BsmI), rs7975232 (ApaI), rs731236 (TaqI) in the VDR gene were investigated in PCa patients and controls of Russian (N=122 and N=95, respectively), Tatar (N=70 and N=170), and Bashkir ethnic origin (N=42 and N=82) to determine whether they are associated with PC risk. We evaluated the association between these SNPs in the VDR gene and PCa risk as well as clinical characteristics (prostate-specific antigen level, clinical stage, pathological stage) in men (237 PCa patients who underwent a prostatectomy and orchectomy) using logistic regression.

We did not observe significant differences for either the VDR BsmI, ApaI and TaqI genotype and allele frequencies in PCa patients and healthy individuals. However, the frequency of the VDR *T/*T genotype of rs2228570 (FokI) was statistically different between PCa patients and controls of Tatar ethnic origin (OR = 1.88, 95%CI=1.22-2.58, p=0.0023). There wasn't association of the studied VDR BsmI, ApaI and TaqI polymorphisms with clinical characteristics of PCa patients. We found linkage disequilibrium between the BsmI *A and ApaI *C alleles (D'=84%). Our study indicates that VDR FokI variant might increase PCa risk in Tatars. However, current limitation for small cohorts might have false positive effects; therefore it should be overcome via further large-scale validating studies.

Expression of Zn^{2+} metabolism genes in prostate cancer

J. Mares[1], *D. Krupicova[1], M. Cerny[1], L. Stepanek[1], S. Vesely[2], J. Soukup[2], M. Klabanova[3], L. Jarolim[4], M. Schmidt[4];*

[1]2nd Faculty of Medicine Charles University, Prague, Czech Republic, [2]2nd Faculty of Medicine University Hospital Motol Charles University, Prague, Czech Republic, [3]Diana Lucina, Prague, Czech Republic, [4]2nd Faculty of Medicine University Hospital Motol Charles University, Prague, Czech Republic.

During prostate carcinogenesis prostate tumor cells lose the ability to accumulate Zn^{2+} ions in high levels. The aim of this study was to investigate the expression of four genes ZIP1, ZIP7, MT1-F and MT2 involved in the maintenance of homeostasis of zinc cations in prostate cells in tumor tissue and in benign prostate hyperplasia (BPH) by RT-PCR and determine whether there is an correlation between the mRNA expression of four genes and the TNM classification, Gleason score, PSA level and age and thus evaluate its diagnostic and prognostic potential.

Isolation of mRNA from prostate cancer in 65 patients has been performed in period 2011 - 2013. As a control group, 27 patients with BPH were used. Statistically significant lower relative expression of MT1-F and ZIP1 genes was detected in prostate cancer tissue than in BPH ($p<0.00048$, $p<0.0082$, resp.). The PSA level correlated positively with the ZIP7 expression ($p<0.0099$). Decreased expression of all four genes correlated with higher age. No correlation of the gene expression with the TNM classification and Gleason score was observed.

According to our results, it is possible to consider that the genes MT1-F and ZIP1 may be candidate tumor suppressor genes for prostate cancer. **Supported by Diana Lucina, the Ministry of Health project for conceptual development of research organization 00064203** and by grant MSM 0021620808.

Association between the RAD50 rs17166050 polymorphism and risk of childhood leukemia and adult cancers

M. Mosor, *I. Ziółkowska-Suchanek, A. Dzikiewicz-Krawczyk, D. Januszkiewicz-Lewandowska, J. Nowak;*

Institute of Human Genetics Polish Academy of Sciences, Poznań, Poland.

The RAD50 gene encode one of the protein of the MRE11-RAD50-NBN complex involved in cellular response to DNA damage and the maintenance of genome stability. The aim of this study was to answer the question whether the RAD50_rs171660505 polymorphism may be associated with childhood leukemia or adult cancers. We estimated the frequency of RAD50_rs171660505 polymorphism in the group of 220 children diagnosed with leukemias and in the 280 non-selected breast cancer (BC) patients, 175 with a single laryngeal cancer (LC) and 115 with multiple primary tumors but one malignancy (primary or second primary) localized in the larynx (MPT-LC) and 68 multiple primary tumors localized in the head or neck (MPT) and controls (n=504). The analysis was performed by multi-temperature single-strand conformation polymorphism technique. We performed two molecular tests to examine any potential function of the detected the c.551+19G>A SNP in RAD50 gene. The frequency of either the AA genotype or A allele of RAD50_rs17166050 were significantly different in controls compared to childhood leukemia group (ALL+AML) ($P<0.0019$ and $P<0.0019$, respectively). In MPT group, heterozygous genotype GA was significantly more frequent, even after multiple testing correction, than in controls ($P=0.0205$). The cDNA analysis of AA or GA genotypes carriers has not revealed evidence of splicing abnormality of RAD50 pre-mRNA. We measured the allelic-specific expression of G and A alleles at c.551+19G>A and the statistically significant overexpression of the G allele has been observed. This data demonstrate that some specific alternations of the RAD50 gene may be associated with childhood ALL.

Research of association between the SNP309 of MDM2 gene and the occurence retinoblastoma in Algerian population

A. M. Boubekeur[1], *L. Louhibi[1], K. Mahmoudi[2], R. K. Abderrahmane[1], F. Z. Moghtit[1], M. Aberkane[3], N. Mehtar[1];*

[1]University of science and technology, Oran, Algeria, [2]Pediatric hospital of Canastel, Oran, Algeria, [3]Faculty of medecine, Oran, Algeria.

Retinoblastoma is an intraocular malignant tumor that usually affects the child in the first months of life. The gene responsible for this disease is an anti concogene called RB1. Retinoblastoma is due to the biallelic inactivation of RB1 gene. The loss of this gene does not confer a growth advantage due to the activation of p53 pathway. Events that would block or attenuate this pathway seem necessary for the development of retinoblastoma as the proto-oncogene MDM2 that negatively regulates p53. Indeed, the close relationship between MDM2, P53 and RB1 in retinoblastoma tumorigenesis makes the SNP 309 T > G of MDM2 gene as a good candidate for the development of this cancer.

This study is based on the search for a possible association between the polymorphism 309 T>G MDM2 gene and the occurrence of retinoblastoma in the Algerian population. We performed a case control study including 73 patients and 100 controls. The 309 T > G polymorphism was determined by PCR-RFLP method.

Our results show that there is a significant increase of the G allele in cases compared to controls ($p = 0.0002$). Therefore, this allele seems to decrease susceptibility to retinoblastoma in our population.

Atypical *RUNX1* rearrangements in patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS)

I. Sarova[1,2], *J. Brezinova[1], S. Ransdorfova[1], S. Izakova[2], Z. Zemanova[2], E. Malinova[2], K. Svobodova[2], L. Pavlistova[2], J. Cermak[1], K. Michalova[1,2];*

[1]Institute of Hematology and Blood Transfusion, Prague 2, Czech Republic, [2]Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General Faculty Hospital and 1 st Faculty of Medicine of Charles University, Prague, Czech Republic.

The *RUNX1* (*AML1*) gene is a key regulator of hematopoiesis which is frequently rearranged in acute leukemias and myeloid malignancies. More than 55 different translocations of *RUNX1* have been described. However, majority has been reported rather sporadically and as complex *RUNX1* rearrangements they remain undefined at the molecular level. A series of 21 adult patients with uncommon structural abnormality of 21q21-q22 detected by conventional cytogenetic/multicolor FISH methods and diagnosis of AML or MDS was collected. Three patients with no further available material were excluded from the study. All the others were tested for involvement of the *RUNX1* using FISH analysis with Vysis LSI TEL/AML1 or LSI AML1/ETO probe (Abbott). The split signal of *RUNX1* gene was confirmed in four patients with: 1) t(8;21;7)(q22;q22;p13); 2) t(3;21)(q12;q22); 3) der(21)ins(21;10)(q22;q?)t(14;21)(q11;q22); 4) der(12)t(12;22)(p11.2;?)t(12;21)(q13;?),der(21)t(5;21)(?;q21)t(5;12)(?;q13). Further FISH analyses have been focused on the reciprocal translocation t(3;21)(q11;q22) and have been performed with BAC probes located at 3q11-12. The breakpoint has been specified between clones RP11-138C11 and RP11-153N1. In conclusion, four until now unreported *RUNX1* alterations with the new potential fusion partners are described. One of them was specified into 293 kbp region at 3q12. Two protein and three RNA coding genes have been mapped at this interval. The description and identification of atypical *RUNX1* fusions on the larger cohort of patients is an important tool for understanding and characterization of the pathogenic mechanisms of *RUNX1* rearrangements. Supported by MHCR for conceptual development of research organization 00023736, RVO-VFN64165/2012, GACR-P302/12/G157, RVOUK-/27/LF1/1.

SALL4 as a new biomarker for early colorectal cancers

S. Ardalan Khales[1], *M. Forghanifard[2], M. Abbaszadegan[1];*

[1]Division of Human Genetics, Immunology Research Center, Avicenna Research Institute, Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran, [2]Department of Biology, Damghan Branch, Islamic Azad University, Damghan, Islamic Republic of Iran.

Colorectal cancer (CRC) is one of the most commonly diagnosed cancers in the world. SALL4, newly identified oncogene, is a member of family of zinc finger transcription factors. Our aim in this study was evaluation of SALL4 mRNA absolute copy number in the peripheral blood of CRC patients, to in-

troduce a probable new prognostic or diagnostic molecular marker for CRC. Method: Peripheral mononuclear cells from 51 blood samples of CRC patients and 60 healthy controls, as well as 21 serum samples from the same patients were examined using absolute quantitative real-time RT-PCR to evaluate the exact copy number of SALL4 mRNA. Results: The blood copy number of SALL4 in recruited CRC patients was significantly higher in comparison with the healthy controls (p = 0.0001). This high copy number was not only inversely associated with the depth of tumor invasion (p=0.045), but also was significantly correlated with the higher grade of tumor differentiation (p=0.029). Furthermore, the copy number of SALL4 was also found to be elevated in all serum samples of CRC patients where high copy number of SALL4 was significantly associated with the higher grade of tumor differentiation (p = 0.026). Discussion: Our results emphasize the potential of SALL4 as a biomarker for detection of early stages (I/II) of CRC which are not invaded to the adventitia. Since early detection of CRC is correlated to improved outcomes, SALL4 may be introduced as a critical biomarker for efficient screening of patients, who are in early stages of CRC tumorigenesis.

CDH1 intronic mutation c.2440-6C>G misclassification: not confirming earlier described splicing aberration.

*L. Grodecká[1,2], **P. Lockerová**[1,2], M. Kramárek[2], B. Ravčuková[1], R. Richterová[3], K. Kyselová[3], J. Indráková[3], T. Freiberger[1,2,4];*
[1]Molecular Genetics Laboratory, CKTCH, Brno, Czech Republic, [2]Molecular Immunology and Micrbiology, CEITEC MU, Brno, Czech Republic, [3]Laboratory of medical genetic – department molecular biology, AGEL Research and Training Institute – Nový Jičín Branch, AGEL Laboratories, Nový Jičín, Czech Republic, [4]Institute of clinical immunology and allergology, FNuSA, Brno, Czech Republic.

E-cadherin, encoded by the gene named CDH1, is a protein important for cell-to-cell adhesions. Germinal mutations in the gene trigger hereditary diffuse gastric cancer (HDGC). In this work, we have investigated c.2440-6C>G transversion found in our patient with a family history of gastric carcinomas. The mutation that is located in acceptor splice site of the last exon was previously described as pathogenic, affecting splicing of the mutated intron (1). However, the identity of aberrant splicing variant (detected by RT-PCR from patient's blood) and even the segregation of mutation in family was not so obvious. Recently, other research group found no aberrant mRNA in their patient carrying the same mutation (2). In our patient, we did not detect any splicing aberration in the blood-derived mRNA, nor we did see any difference in splicing when using our hybrid minigene system specialized for the analysis of the last introns/exons splicing. Furthermore, the mutation does not clearly co-segregate with the disease in our patient's family, being detected in the unaffected father's side of family whereas the mother's affected side could not have been examined. In conclusion, we propose that this mutation should be regarded rather as benign or with uncertain effect on gene expression and HDGC development. Nonetheless, further investigations of mRNA from the affected tissue might be helpful.

Correlation between amplification and expression status of ERBB1, MYC, Her2/neu, and TOP2A oncogenes in Iranian women with sporadic breast cancer and their relationship with Clinical and Immunohistochemistry prarameters

F. Behjati[1], *R. Pazhoomand[1], E. Keyhani[1], M. Banan[1], M. Karimlou[2], F. Khodadadi[3], K. Majidzadeh-A[4], S. Abedini[1], H. Najmabadi[1];*
[1]Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, [2]Department of Biostatistics and Computer, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, [3]Department of Surgery, Mehrad Hospital, Tehran, Islamic Republic of Iran, [4]4-Cancer Genetics Research Group, Breast Cancer Research Center, ACECR, Tehran, Islamic Republic of Iran.

ERBB1, *MYC*, *Her2/neu*, and *Top2A* oncogenes are known to be involved in the development, prognosis and response to the therapy in breast cancer. We extracted DNA and RNA of 81 primary sporadic breast cancer tumor tissues and 30 normal breast tissues. IHC, MLPA, RT-PCR and FISH techniques were used. The *Her2/neu* gene showed the most significant correlation between amplification and overexpression in 23 patients. The concurrent increase in amplification and overexpression for *Top2A* gene was statistically significant. *ERBB1* and *MYC,* showed no correlation between their amplification and overexpression. Significant concordance between co-amplification of *Her2/neu* and *Top2A* genes was detected. The amplification of *Her2/neu* gene was associated with negative progesterone receptor state, higher grade of the tumor, and increase in MVD; the overexpression of the gene was concordant with negative hormone receptor state and higher grade and stage of the tumor. The amplification of *MYC* was seen more in younger patients (<50yr) and was correlated with higher cell proliferation factor (KI-67). The amplification of *TOP2A* was detected more in stage 3 tumors. Co-amplification of *MYC-HER2* genes and co-overexpression of *TOP2A-HER2* genes were detected more in higher grade and stage tumors; co-overexpression of *TOP2A-HER2* genes were related to higher MVD. The rate of co-amplification of *MYC-ERBB1* genes was higher in tumors greater than 5 cm. In conclusion, besides *HER2* gene, the amplified *TOP2A* and *MYC* genes have crucial role in predicting the prognosis of the patients; the co-amplification and co-overexpression of these genes with *HER2* gene have significant prognostic roles.

J12.104

Evaluation of HER2 status in sporadic breast cancer amongst Iranian women using IHC, FISH, MLPA, and Real time RT-PCR techniques

R. Pazhoomand[1], *E. Keyhani[1], M. Banan[1], H. Najmabadi[1], M. Karimlou[2], F. Khodadadi[3], K. Majidzadeh-A[4], A. Iranparast[5], F. Feiz[6], A. Muhammadnejad[7], S. Abedini[1], F. Behjati[1];*
[1]Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, [2]Department of Biostatistics and Computer, University of Social Welfare and Rehabilitation Sciences, Tehran, Islamic Republic of Iran, [3]Department of Surgery, Mehrad Hospital, Tehran, Islamic Republic of Iran, [4]Cancer Genetics Research Group, Breast Cancer Research Center, ACECR, Tehran, Islamic Republic of Iran, [5]School of Medicine, Shiraz University of Medical Sciences, Shiraz, Islamic Republic of Iran, [6]School of Medicine, Shiraz university of Medical Sciences, Shiraz, Islamic Republic of Iran, [7]Cancer Research Center, Cancer Institute of Iran, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Objectives: Human epidermal growth factor receptor (HER) status is an important prognostic factor in breast cancer. There is no globally accepted method for determining HER2 status, and which method is most precise is still a matter of debate.
Methods: A total of 93 Iranian women with sporadic invasive breast cancer were studied. We analyzed *HER2* mRNA expression by quantitative reverse transcription-PCR (qRT-PCR) and *HER2* DNA amplification using multiplex ligation-dependent probe amplification (MLPA). To assess the accuracy of the RT-PCR and MLPA techniques, a combination of IHC and FISH was used, substituting FISH when the results of IHC were ambiguous (2+) and for those IHC results that disagreed with MLPA and qRT-PCR and named it IHC-FISH.
Results: The correlations between IHC-FISH and qRT-PCR or MLPA were 0.945 and 0.973, respectively. The ASCO/CAP guideline IHC/FISH correlation with MLPA was (0.827) and with RT-PCR was (0.854).
The correlations between the IHC results (0, 1+ as negative, and 3+ as positive) and qRT-PCR and MLPA techniques were 0.743 and 0.831, respectively.
Conclusion: Given the shortcomings of IHC analysis and greater correlations between MLPA, qRT-PCR, and FISH methods than IHC analysis alone with each of these three methods, we propose that MLPA and real-time PCR are good alternatives to IHC. However a suitable cut-off point for qRT-PCR is a prerequisite for determining the exact status of HER2.

J12.105

Clinical Utility of Measuring Expression Levels of Stanniocalcin 2 in Patients with Colorectal Cancer

M. Asghari Estiar[1], *E. Sakhinia[2], A. Arabzadeh[3], S. Hashemzadeh[3], L. Emrahi[2];*
[1]Students' Scientific Research Center and Department of Medical Genetics, School of Medicine, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran, [2]Department of Medical Genetics, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran, [3]Department of General Surgery, Tabriz University of Medical Sciences, Tabriz, Islamic Republic of Iran.

Stanniocalcins (STC) are glycoprotein hormones which were originally found in the endocrine gland of bony fish. Recently, Microarray expression data revealed that the expression level of Stanniocalcin was higher in tumors. Regarding the need for novel prognostic biomarkers, in place of the existing routine histopathological methods in early screening and the choice of therapy options in Colorectal Cancer (CRC), we examined Stanniocalcin 2 expression levels in patients with CRC and assessed their association with clinicopathogical data. We examined the mRNA expression levels of Stanniocalcin 2 in CRC in 48 tumor tissues and 48 marginal tissue samples using real-time reverse transcription-polymerase chain reaction (RT PCR). Clinicopathological data of patients were collected after fulfilling criteria and the pathological evaluation of their tissue samples. STC2 mRNA expression levels were higher in tumor tissues than the control marginal groups. (r=0.36, p=0.02). The median expression level in tumor groups was 31829 and the minimum and maximum levels were 2366 and 25183989, respectively, with the median expression level in marginal groups, 7303.5 and the minimum and maximum levels, 681 and 1296806, respectively. The mRNA expression level of STC2 was significantly associated with tumor size (p=0.04) and the histology of tumors (p=0.03). Taking into account the results of this study, high levels of STC2 expression were seen to be associated with larger tumour sizes with poor histological characteristic. We also showed that STC2

can be as a marker (indicator) to differentiate between tumor borders and margins, potentially improving accuracy during surgery.

Characteristics of hematologic malignancies with coexistence of t(9;22) and inv(16)

H. Choi[1], *J. Kim*[1], *A. Kwon*[1], *E. Han*[1], *H. Lee*[2], *M. Kim*[1], *Y. Kim*[1], *K. Han*[2], *S. Lee*[3], *H. Kim*[3], *D. Kim*[3];

[1]*Catholic University of Korea, Seoul, Korea, Republic of,* [2]*Catholic Genetic Laboratory Center, Seoul, Korea, Republic of,* [3]*Department of Hematology, Seoul, Korea, Republic of.*

Background : The coexistence of the t(9;22)(q34;q11.2) and inv(16)(p13q22) is one that has been described in chronic myeloid leukemia (CML) mainly in myeloid blast phase (BP), de novo acute myeloid leukemia (AML) and a few therapy-related AML (t-AML). In this study, we evaluated 7 cases of hematologic malignancies with coexistence of t(9;22) and inv(16) and tried to characterize their laboratory and clinical findings.

Materials and Methods : We found 7cases with coexistence of t(9;22) and inv(16) in data of the Catholic Blood and Marrow Transplantation Center. We reviewed available data including clinical informations and peripheral blood smears, bone marrow (BM) aspirates, cytochemical stains, core biopsy specimens and chromosomal analyses. And we analyze the mutations of genes including IKZF1, NPM1, FLT3, N-RAS,K-RAS, c-KIT and TP53.

Results : 4 CML (1 chronic phase, 2 accelerated phase, 1 blast phase) and 3 AML (1 de novo AML, 2 AML) were identified. The percentage of circulating blasts and BM eosinophils were higher in AML than in CML (53% vs. 5%, 30% vs. 5.5%, respectively). The proportion of each chromosomal abnormality and follow-up karyotype were informative to identify which was a secondary change. The BCR-ABL1 a p210 fusion transcript was associated with CML and a p190 fusion was associated with AMLs. One patient with AML revealed two mutations; c-KIT D816V and TP53 E11Q.

Conclusion : Our experience demonstrated that BM morphology, initial and follow-up cytogenetics and type of BCR-ABL1 and CBFB-MYH11gave us valuable information to characterize CML and AML with coexistence of t(9;22) and inv(16).

J12.107

Extended RET proto-oncogene screening in medullary thyroid cancer

S. Sheikholeslami[1], *M. Zarif Yeganeh*[1], *F. Azizi*[2], *M. Hedayati*[1];

[1]*Cellular and Molecular Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [2]*Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Tehran, Islamic Republic of Iran.*

Introduction: Medullary thyroid carcinoma (MTC) is accounts for 5-10% of all thyroid cancers. The molecular pathology of MTC is constitutive of *RET* proto-oncogene. *RET* mutations have an important role for diagnosis and confirming MTC. The most common mutation follow in the exons 10, 11,and 14-16. In this study some others exons examined in MTC patients. **Material and methods:** 298 participants were included, 196 patients (111 female, 85 male) and 112 relatives (58 female, 54 male). Genomic DNA was extracted from peripheral blood leucocytes and nucleotide change detection of exons 2, 3, 5, 8, 12, 17, 18 of the *RET* gene was performed by PCR and direct DNA sequencing methods. **Results:** A total of 10 different nucleotide substitutions were identified. There was not found any SNP in exons 5 and 8. One missense mutation (R982C) in exon18 and three synonymous mutations (A45A, V125V, G733G) were found in exons 2, 3, and 12 respectively. A novel C>T intronic variant (intron17, chr position 10:43620286) was also found. **Conclusion:** This study was focused on some *RET* gene exons that did not consider comprehensively before. It seems, molecular screening of the *RET* gene in MTC patients should not be limited to hotspot exons. Probable deleterious, protective, and/or additive effects of these SNPs with or without *RET* hotspot mutations in MTC development remained to be clarified.

TP53 Arg72Pro and MDM2 SNP309 polymorphisms and colorectal cancer risk: a West Algerian population study

R. Abderrahmane[1], *louhibi L, F. Moghtit*[1], *A. Boubekeur*[1], *F. Fodil*[2], *M. aberkane*[1], *N. Mehtar*[1];

[1]*Université des Sciences et de la Technologie d'Oran, Oran, Algeria,* [2]*Université des Sciences et de la tTchnologie d'Oran, Oran, Algeria.*

The tumor suppressor gene *TP53* and its regulator *MDM2* are both key players involved in multiple pathways including apoptosis, cellular transcriptional control, and cell cycle regulation. Common germline polymorphisms in these genes may affect colorectal cancer susceptibility. An arginine-to-proline substitution at codon 72 in the p53 gene is reported to decrease apoptotic potential, while a thymine-to-guanine polymorphism at nucleotide 309 (named SNP309) of murine double minute 2 *MDM2* gene increases its transcription. These two polymorphisms therefore may be of importance in colorectal carcinogenesis. The relation of these polymorphisms to colorectal cancer in the Algerian population was addressed in this study.

DNA samples from 121 controls and 116 cases were genotyped for these two polymorphisms by PCR/RFLP then confirmed by sequencing.

Unexpectedly no significant association was found between this potential marker *TP53* Arg72Pro and CRC (p>0.05). However, our findings reveal that individuals with the *MDM2* SNP309 GG genotype have a low risk of CRC (OR=0.49; 95% CI, 0.24- 0.98, p=0.04) relative to the TT genotype and with more significance in females (OR= 0.16; 95% CI,0.06-0.41, p<0.05). Moreover, no significant association was observed between the combined *TP53* and *MDM2* genotypes and colorectal cancer.

Contrary to initial expectations that the GG genotype with high *MDM2* levels will increase cancer risk, our results demonstrate that the *MDM2* SNP309 GG genotype is associated with decreased risk of colorectal cancer. This is suggesting that other mechanisms independent of increased *MDM2* levels can influence cancer susceptibility.

J12.109

Acquired uniparental disomy (UPD) involving the short arm of chromosome 17 in patients with myelodysplastic syndromes (MDS) and complex karyotype

K. Svobodova[1], *Z. Zemanova*[1], *H. Lhotska*[1], *M. Belickova*[2], *M. Novakova*[1], *A. Berkova*[1], *K. Michalova*[1,2];

[1]*Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General University Hospital and 1st Faculty of Medicine of Charles University, Prague, Czech Republic,* [2]*Institute of Hematology and Blood Transfusion, Prague, Czech Republic.*

Acquired uniparental disomy (UPD), which can be an important step in cancer development and progression, are found in various subtypes of haematological malignancies including myelodysplastic syndromes (MDS). The aim of the study was to evaluate the frequency of 17p UPD in bone marrow cells of patients with newly diagnosed MDS and complex karyotypes and to assess correlation of 17p UPD with mutations of tumour suppressor gene TP53 located at 17p13.1.

Bone marrow samples from 49 patients were analyzed by aCGH/SNP (BlueGnome) and UPD of 17p was found in 7 of them (14%). All cases had deletion of 5q and additional recurrent chromosomal aberrations: 7q deletion (4x), monosomy 7 (1x), or 12p deletion involving ETV6 gene (5x). Average extent of 17p UPD was 14-20 Mb involving TP53 gene. In all 7 cases with 17p UPD, two copies of TP53 gene were detected by FISH (Abbott). DNA isolated from bone marrow cells of 5/7 patients was NGS-sequenced (Roche) and in all of them homozygous TP53 mutations were found.

Our study confirmed that acquired UPD 17p is a recurrent cytogenetic defect in patients with MDS with complex karyotypes and is strongly associated with homozygous mutations of TP53 gene. This lesion is cryptic unless analyzed by SNP array. UPD might have a fundamental role in tumorigenesis, therefore further characterization of 17p UPD will lead to better understanding of the initiation and progression of MDS.

Association between polymorphism of glutathione S-transferase genes (GSTM1) and uterine leiomyoma in Iranian population

S. Mostafavi[1], *M. Sadat*[2], *M. Aghasadeghi*[2], *F. Davari Tanha*[3], *G. Bahramali*[2], *M. Safarpour*[4], *A. Ebrahimi*[4];
[1]*Islamic Azad University Ahar Branch, Tabriz-Ahar, Islamic Republic of Iran,* [2]*Department of Hepatitis and AIDS, Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [3]*Tehran University of Medical Science, Tehran, Islamic Republic of Iran,* [4]*Cellular and Molecular Endocrine Research Center, Obesity research center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Introduction: Uterine leiomyoma is one of the most common benign smooth muscle tumors, occurring in 20-40% of women in their reproductive years. Although, the initiator/initiators of uterine leiomyoma are unknown, several predisposing factors such as age, nulliparity, obesity and genetic factors have been identified to be contributed to the pathogenesis of the disease. In regards to genetics factors contributing to uterine leiomyoma, a few studies have investigated the role of GSTM1 gene polymorphisms and incidence of uterine Leiomyoma. However, further studies are needed to clarify the effects of genetic variations in uterine leiomyoma. Therefore, this study was carried out to investigate the associations between GSTM1 null genotype and uterine leiomyoma in Iranian population.
Methods: In this case-control study, blood samples were collected from 50 women with uterine leiomyoma and 50 healthy controls. Genomic DNA was extracted and GSTM1 gene polymorphisms were detected using Gap-PCR. Allelic and genotypic association was evaluated by Chi-square and Fisher's exact tests.
Results: The frequency of GSTM1 null genotype was significantly different (p = 0.01) in cases (42%) compared to controls (18%). In addition, the results indicated that the presence of GSTM10/0 genotype increased risk of uterine leiomyoma in case group compared to control group (OR: 3.56; CI 95%: 1.35-9.37; p = 0.01).
Conclusion:
This study would be important to report the first data on the relationship between GSTM1 gene polymorphisms and risk of uterine leiomyoma in Iranian population.The findings revealed the association between the GSTM1 null genotype and uterine leiomyoma among Iranian population.

J12.111

Study of thrombosis factors related polymorphisms including PT (rs1799963), FGB (rs1800790) and PAI-1(rs1799889) in Iranian affected women with uterine myoma

M. Arabnejad[1], *A. Ebrahimi*[2], *M. Nasiri*[1], *M. Karimi*[3], *A. khalili*[4];
[1]*Arsanjan Branch, Islamic Azad University, Department of Biology, Arsanjan, Islamic Republic of Iran,* [2]*Endocrine research center, Shahid Beheshti University, Tehran, Islamic Republic of Iran,* [3]*Hematology Research Center. Shiraz University of Medical Sciences, Shiraz, Islamic Republic of Iran,* [4]*Zeinabieh Hospital, shiraz, Islamic Republic of Iran.*

Introduction: Myomas are benign, solid, monoclonal tumors of the smooth muscle cells of the endometrium. Myomas occur in 20%-40% of women in their reproductive years. Venous thromboembolism (VTE) is a common complication cancers. Although several thrombosis genetic risk factors related to cancer are known; however, their contributions to thrombotic tendency in cancer patients have conflicting results. However, the association of venous thrombosis with large uterine myoma has been reported previously, the influence of thrombosis related factors polymorphism on incidence risk of uterine myoma is unclear.
Material and methods: In the present study, three selected thrombotic factors gene polymorphisms have been evaluated by ARMS-PCR method. We have focused on the prevalence of PT G20210A, FGB -455G/A and PAI-1 4G/5G polymorphisms in 70 women with clinically diagnosed uterine myoma and 70 healthy controls. The data were analyzed by SPSS19 software and using χ 2 test.
Results: The results of this study demonstrated that the PT (rs1799963), FGB (rs1800790) and PAI-1 (rs1799889) polymorphisms were not correlated with an increased risk of uterine myoma in the study population (p>0.05).

In about 50 % of „sporadic „ cases of Retinoblastoma no constitutive *RB1* mutations can be identified. Recent research suggests that, at least in some of these cases, somatic mosaicism of *RB1* can be found. The increased availability of Next Generation Sequencing (NGS) technology improves our ability to detect the exact percentage of patients with *RB1* mosaicism. Using NGS we re-tested a series of 42 patients with sporadic Retinoblastoma. Twelve patients had constitutive mutations, in apparent heterozygosis, that were identified according to traditional techniques, whereas 30 patients had no mutations. Among the 30 patients with no mutations, NGS identified the mutation in a „mosaic state", varying between 8 and 27% in 3 cases. Among the cases with apparent heterozygosis according to traditional methods, mutations in a mosaic state -varying from 3 to 28%- were found in 100 % of cases when, in addition to blood samples, it was possible to test more than 3 tissues ,i.e. ocular tissue, urine and/or oral mucosa. Present results confirm that 10 % of patients with sporadic retinoblastoma with no apparent mutations in RB are actually cases with low-rate mosaicism. In addition, our results show for the first time that many sporadic cases with 50% mutations in blood -that have been interpreted up to now as de novo mutations occured at gametogenesis- could actually be postzygotic events.

XPD Lys751Gln and Arg156Arg Polymorphisms and Acute Myeloid Leukemia risk

C. Bănescu[1], *C. Duicu*[1], *A. Trifa*[2], *E. Lazar Benedek*[1], *I. Macarie*[1], *A. Todoran Butila*[1], *V. Moldovan*[1], *M. Dobreanu*[1];
[1]*University of Medicine and Pharmacy, Tîrgu Mureș, Romania,* [2]*"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania.*

Defects in repair pathways are involved in cancer pathogenesis. Therefore, DNA repair genes might be involved in acute myeloid leukemia (AML) susceptibility. Some studies have shown an associations between risk of de novo acute myeloid leukemia and XPD (XPD Lys751Gln) gene polymorphisms. In the present study, we investigated the possible association between single nucleotide polymorphisme in two key regions of XPD, codons 156 and 751 and LAM in a Romanian population. The study included a total of 102 patients with AML and 153 heathy control subjects without any malignancy. The findings of our study suggest that XPD Arg156Arg polymorphism is not significantly associated with AML risk. In our study the XPD 751Lys/Gln variant heterozygous genotype was significantly associated with a increased risk of developing AML (p - value = 0.005). In the case of XPD 751, the heterozygous and homozygous variant genotypes were significantly enriched in AML cases compared to controls (OR = 2.08; 95% CI = 1.237-3.498; p-value = 0.006). There was a significantly better overall survival among AML patients with wild-type homozygous compared to those with at least one variant allele, in the case of XPD Lys751Gln polymorphism. Our preliminary results show that XPD Lys751Gln genetic polymorphism may be a genetic risk factor for acute myeloid leukemia.

J12.114

Clinical, hematological and molecular-genetic variability of acute myeloid leukemia

E. Petrova, *G. Chubukina, L. Polushkina, L. Martynenko, M. Ivanova, N. Cybakova, E. Kleina, E. Shabanova, S. Gritsaev, K. Abdulkadyrov, I. Martynkevich;*
Russian Research Institute of Haemotology and Transfusiology, St.-Petersburg, Russian Federation.

The aim of the study was to determine the heterogeneity of AML patients with FLT3-ITD mutation and CD7 aberrant expression.
Mutation FLT3/ITD was detected by PCR in 21/101 (20.8%) patients. The cytogenetic analysis revealed 13 pts with normal karyotype (NK) and 8 pts with different chromosomal aberrations. A high WBC count was found to be significantly associated with FLT3/ITD mutation (p=0.049). CD34 expression in control group and group with FLT3-ITD was 83.3% against 90.0% (p=0.635). We found the significant association of FLT3/ITD mutation with aberrant expression of HLA-DR (50.0% cases with FLT3/ITD against 5.6% without FLT3/ITD) and CD7 (100% samples with FLT3/ITD mutation and 55.6% of samples without FLT3/ITD) markers.
The expression of CD7 in the group of 31 patients is varied over the range from 20 to 97.7% (average 70.4%). We formed 2 comparative groups: 13 pts with CD7 expression below the average and 18 – above. Patients with high level of CD7 expression were older than patients with lower expression:

57.5 vs 44 years, respectively (p=0.011). There was no significant difference between these two groups in respect of FAB and karyotype variants, the presence of FLT3/ITD mutation and CD34 expression.
Summary. Leukocytosis, aberrant expression of CD7, and/or hyperexpression of HLA-DR on blast cells are probable markers for the detection of FLT3-ITD mutations in AML patients with NK. Patients with AML and CD7 aberrant expression are heterogeneous in morphological, cytogenetic and molecular characteristics. CD7 expression in AML blasts is not an independent prognostic factor.

Tailored Targeting of Inflamed, Regenerative, and Mutated K-RasG12D Upregulated cDNA Microarray Gene Signatures in Pancreatic Ductal Cells

G. P. Botta[1,2], *M. Reichert*[2], *M. J. Reginato*[1], *S. Heeg*[3], *A. K. Rustgi*[2], *P. I. Lelkes*[4];
[1]Department of Biochemistry and Molecular Biology, Molecular and Cellular Biology and Genetics Program, Drexel University College of Medicine, Philadelphia, PA, United States, [2]Division of Gastroenterology, Departments of Medicine and Genetics, Abramson Cancer Center, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, United States, [3]Department of Hematology and Oncology, University of Freiburg Medical Center, Freiburg, Germany, [4]Department of Bioengineering, Temple University, Philadelphia, PA, United States.

Pancreatic ductal adenocarcinoma (PDAC) harbors a universal K-RasG12D mutation that incites extracellular matrix (ECM) invasion and metastasis. Importantly, human Pancreatic Ductal Cells (PDCs) recapitulate ERK2 phosphorylation and gene upregulation only within a 3D ECM. By differentiating PDCs with stepwise p53, Rb/p16INK4a, and K-RasG12D mutations, we present a model that readily permits high-throughput cDNA microarray analysis of invasive gene signatures for personalized targeting. Specifically, populations of human PDCs in different chronologic and phenotypic stages of neoplastic formation and murine PDCs isolated ex vivo from inflamed, regenerative, or neoplastic Pdx1-Cre;LSLKrasG12D/+ pancreata were acquired. RNA was extracted and its cDNA was analyzed on genotypically-focused, invasion-specific microarray plates. As expected, K-RasG12D was the overwhelming driver of upregulated, invasive genes within the phenotypic and histologic neoplastic populations. Indeed, genes associated with cancer stem cells and necessary for PDCs to escape the ECM (metalloproteinases, tenascin-c, vitronectin and CD44) were induced 2.5 to 35-fold based distinctly on unrestricted K-Ras signaling. Uniquely however, when PDCs were stratified to pathologic stage (inflamed, regenerating, neoplastic) or mutational iteration (p53 ± Rb/p16INK4a ± K-RasG12D), there was substantial variation in the gene signatures regulating invasive potential. Indeed RNAi, shRNA, and pharmacologic inhibition of invasive genes and proteins successfully inhibited invasion or ceased neoplastic formation only if tailored to unique genes uncovered in that PDC population's gene signature. As the majority of patient's with PDAC ultimately die of metastasis, 'personalizing' the targeting of gene products is necessary to effectively attenuate each PDC population's invasive potential.

J12.116

Rare complex chromosomal aberrations in CML: A report on 300 cases

B. B. Ganguly[1], *S. Mandal*[1], *T. K. Dolai*[2], *M. Bhattacharyya*[2], *R. De*[2];
[1]Genetics Center, Navi Mumbai, India, [2]NRS Medical College, Kolkata, India.

CML is characterized by *BCR-ABL* mutation in over 90%, which indicates a favorable prognosis. Involvement of third or more chromosome(s) has been reported in 5-10% of CML. The presence of additional abnormalities is rarely reported and thus merely been discussed for prognostication. However, management of leukemia varies considerably with the involvement of additional chromosome(s). We present data on 300 CML patients of which 30 (10%) appeared with additional rearrangements in addition to *BCR-ABL* mutation. Conventional G-banding analysis was the first step followed for chromosomal characterization of leukemic condition. In cases with cryptic rearrangements, FISH was employed for confirmation of CML. PHA-stimulated lymphocyte culture was performed in all cases carrying additional translocation for differentiation of acquired or constitutive pattern. Complex and rare abnormalities observed in 10% CML are presented in bold in the table below. Cases with only trisomy 8, i(17q) and extra Ph chromosome have been excluded in this classification. Of these, constitutive aberrations were of important concern for family members of blood-lineage. Half yearly follow-up study of these cases showed secondary clones and no response to imatinib. Presence of complex aberrations might have played a different mechanism of imatinib action. The study highlights the pattern of rare rearrangements in CML and its importance for molecular investigation of such complex situation and pharmaceutical alteration of TKI for understanding prognosis of *BCR-ABL* in a complex situation.

Common genetic variants in NEFL influence gene expression and neuroblastoma risk

M. Capasso[1], *S. Diskin*[2], *F. Cimmino*[1], *F. Totaro*[1], *G. Petrosino*[1], *L. Pezone*[1], *M. Diamond*[2], *L. McDaniel*[2], *H. Hakonarson*[2], *A. Iolascon*[1], *M. Devoto*[2], *J. Maris*[2];
[1]University of Naples Federico II, Napoli, Italy, [2]Children's Hospital of Philadelphia, Philadelphia, PA, United States.

The genetic etiology of sporadic neuroblastoma is still largely unknown. Using genome-wide association study, we identified single nucleotide polymorphisms (SNPs) associated with neuroblastoma at the LINC00340, BARD1, LMO1, DUSP12, HSD17B12, HACE1 and LIN28B gene loci, but these explain only a small fraction of neuroblastoma heritability. Other neuroblastoma susceptibility genes are likely hidden among signals discarded by the multiple testing corrections.
Eight genes were selected based on their proven involvement in neuroblastoma differentiation. Here, we tested SNPs at the eight candidate genes for association with disease susceptibility in 2101 cases and 4202 controls. We replicated the associations of the identified gene in an independent cohort of 459 cases and 809 controls. Replicated associations were studied for cis-effect using gene expression, transient overexpression and cellular differentiation assays.
NEFL showed three SNPs associated with neuroblastoma (rs11994014; Pcombined=0.0050; OR=0.88, rs2979704; Pcombined=0.0072; OR=0.87, rs105911; Pcombined=0.0049; OR=0.86). The protective allele of rs1059111 correlated with increased level of NEFL expression and we observed significant growth inhibition upon over-expression of NEFL, specifically in neuroblastoma cells carrying the protective allele. We also demonstrated that NEFL expression enhanced differentiation and impaired proliferation and colony growth in soft agar of cells with protective allele and basal NEFL expression while impairing invasiveness and proliferation of cells homozygous for risk genotype. Finally, high NEFL expression in diagnostic primary neuroblastomas was associated with better overall survival (P=0.03; HR=0.68). Our study shows that common variants of NEFL influence neuroblastoma susceptibility and indicates that NEFL likely has a role in disease initiation and progression.

Characterization of the rs2802292 SNP identifies FOXO3A as a modifier locus predicting cancer risk in patients with PJS and PHTS hamartomatous polyposis syndromes

C. Simone[1], *G. Forte*[1], *V. Grossi*[1], *G. Lucisano*[2], *M. Scardapane*[2], *F. Pellegrini*[2], *R. Bagnulo*[1], *D. Loconte*[1], *D. Varvara*[1], *M. Patruno*[1], *N. Resta*[1], *A. Petracca*[3], *S. Giglio*[3], *L. Giunti*[3], *M. Genuardi*[3];
[1]DIMO - Università degli Studi di Bari ,Aldo Moro', Bari, Italy, [2]FMNS, Santa Maria Imbaro (CH), Italy, [3]Dipartimento di Scienze Biomediche, Sperimentali e Cliniche, University of Florence, Florence, Italy.

Hamartomatous polyposis syndromes (HPS) are inherited conditions associated with high cancer risk and frequently carrying mutations in the LKB1 or PTEN genes. Estimation of cancer risk is crucial in order to optimize surveillance, but no prognostic markers are currently available for these conditions. Our study is based on a 'signal transduction' hypothesis relying on the crosstalk between LKB1/AMPK and PI3K/PTEN/Akt signals at the level of the tumor suppressor protein FoxO3A. Of note, the FOXO3A rs2802292 G-allele was shown to be associated with longevity, improved insulin sensitivity and increased expression of FoxO3A mRNA.
Thus, we typed this polymorphism in 150 HPS unrelated patients. We found a significantly higher risk for malignancies in female patients and TT genotype carriers compared to those having at least one G-allele. Indeed, subgroup analysis for each HPS syndrome revealed a G-allele-associated beneficial effect on cancer risk occurring mainly in males.
Our results suggest an inverse correlation between the copy number of the protective allele (G) and the risk of cancer and might be useful to optimize

surveillance in HPS patients. Further investigations will be needed to confirm our hypothesis and to ascertain whether differences exist in terms of therapeutic response across genotypes

Gene expression of MMP9 and its prognostic role in patients with gliomas

G. Stancheva[1,2], *T. Goranova*[2], *M. Laleva*[3], *M. Kamenova*[4], *A. Mitkova*[2,1], *N. Velinov*[3], *G. Poptodorov*[3], *R. Kaneva*[1,2], *V. Mitev*[1,2], *N. Gabrovsky*[3];
[1]Dept. of Medical Chemistry and Biochemistry, Sofia, Bulgaria, [2]Molecular Medicine Center, Medical University, Sofia, Bulgaria, [3]Department of Neurosurgery, University Multiprofile Hospital for Active Treatment and Emergency Medicine "N.I.Pirogov", Sofia, Bulgaria, [4]Department of Pathology, University Multiprofile Hospital for Active Treatment and Emergency Medicine "N.I.Pirogov", Sofia, Bulgaria.

Background: Brain tumours, especially glioblastoma multiforme is an aggressive cancer characterized by extensive glioma invasiveness. Matrix metalloproteinase (MMP)-9 have been implicated to play a critical role in this process. **Methods**: In the present study we analyzed the expression of MMP9 mRNA in 59 gliomas (astrocytomas and oligodendrogliomas) and 14 nonneoplastic brain tissues. MMP9 gene expression was detected by real-time quantitative RT-PCR assay. **Results:** The expression level of MMP9 mRNA in glioma tissues was significantly higher than that in corresponding nonneoplastic brain tissues. MMP9 was observed with high expression level in 36 out of the 59 (61%) glioma tumours. Overall survival rates of patients with high MMP9 mRNA expression were obviously lower (12 months) than the patients in the other two groups - the median survival was 48.7 and 22.9 months for the down-regulated and normal MMP9 mRNA expression, respectively (p< 0.001). The increased expression of MMP9 mRNA was also significantly correlated with low Karnofsky performance score (p= 0.001). Multivariate analysis showed that high MMP9 mRNA expression was an independent prognostic factor for glioma patients (p= 0.002). **Conclusion:** Our results indicate that the overexpression of MMP9 mRNA is closely associated with poor clinical outcome. It may be used as specific prognostic biomarkers and for the future could be molecular targets in the treatment of malignant gliomas. Acknowledgements: This work was supported by: Infrastructural Grant DUNK01/2/2009 and Grant No.49/2009 funded by National Science Fund, Ministry of Education and Science, Bulgaria; Grant No.25-D/2012 by the Science Fund, MU-Sofia, Bulgaria;

Individual variability in escape from nonsense mediated decay may influence the clinical severity of patients with nonsense mutations in the upstream region of the hMLH1 gene

M. Staninova[1], *N. Matevska Geshkovska*[1], *A. Eftimov*[1], *M. Panovski*[2], *T. Josifovski*[2,3], *A. Dimovski*[1];
[1]Faculty of Pharmacy, Skopje, Macedonia, The Former Yugoslav Republic of, [2]Clinic for Abdominal Surgery, UKIM Faculty of Medicine, Skopje, Macedonia, The Former Yugoslav Republic of, [3]Acibadem Sistina Clinical Hospital, Skopje, Macedonia, The Former Yugoslav Republic of.

We previously reported the MLH1 S131X as founder mutation in patients with the Lynch syndrome from Macedonia. The mutation has a high penetrance with different time of disease onset ranging from 32 to 55 years. We speculated that this variability might in part result from a leaky nonsense mediated decay (NMD) of mutant transcripts, which results in a truncated protein and dominant-negative effect in patients with a more severe disease. Herein, we present in vivo expression data of the S131X mutation in PBMCs and 3 tumors of 2 patients with the time of onset at the age of 33 and 49. Since both patients were also heterozygotes for the common I219V polymorphism, the output from each allele was analyzed by measuring the relative amounts of transcripts containing either I219 or V219 by direct sequencing of PCR amplified cDNA. The mutant transcripts in the patient with the later onset of the disease were completely absent in the 2 synchronous tumors (stomach and colon), whereas in the patient with an early onset of the disease they were present in a significant amount (50%) both in the tumor and in PBMCs, indicating the presence of leaky NMD. Having in mind that we previously detected a variable amount of normal transcripts from alleles with splicing mutations in patients with β+-thalassemia, we suggest that inter-individual variability in the capacity for posttranscriptional processing of mutant transcripts is a general mechanism which influences the clinical severity of inherited diseases resulting from truncating mutations.

Genetic alterations in breast cancer patients from Saudi Arabia by FISH

M. S. Aly[1,2];
[1]Faculty of Science, Jazan University, Jazan, Saudi Arabia, [2]Faculty of Science, Beni-Suef University, Beni-Suef, Egypt.

Breast cancer remains a worldwide public health concern. The incidence and mortality of breast cancer varies significantly in ethnically and geographically distinct populations. In the Kingdom of Saudi Arabia, it ranks number one in terms of incidence as well as cancer related mortality in females. Although the age-standardized incidence rate for breast cancers in Saudi Arabia is 3.4 fold lower compared to United States, the median age of onset is 47 years, significantly lower than 62 years observed in patients from United States. Amplification of the two oncogenes: Her-2/neu and c-myc and deletion of the tumor suppressor gene p53 are frequently encountered in breast carcinomas. Our objective was to evaluate the association between Her-2/neu, c-myc, p53, and clinicopathologic variables in breast cancer patients using fluorescence in situ hybridization (FISH). FISH analysis for Her-2/neu, c-myc, and p53 was performed on 60 samples with breast carcinomas and 22 samples with benign breast lesions. Amplification of HER-2/neu was seen in 7/60 (11.7%) cases and amplification of c-myc was seen in 11 of 60 (18.3%) cases; neither was associated with adverse clinicopathologic variables or survival. Deletion of p53 was seen in 29/60 (48.3%) cases and was associated with poor histologic grade, compared to the benign group. There was impact of genetic alterations on overall survival and disease-free interval. The results indicate that the p53 gene plays a significant role in breast carcinogenesis and the early onset of the disease among Saudi female individuals.

J13.02
Hemolysis to Red Blood Cell

C. Murugaiah;
Newcastle University Medicine Malaysia, Nusajaya, Malaysia.

Hemolytic due to hemolysis, the abnormal breakdown of red blood cell (RBCs), either in the blood vessels (intravascular hemolysis) or elsewhere in the human body (extravascular). It has numerous possible causes, ranging from relatively harmless to life-threatening. The general classification of hemolytic is either inherited or acquired. Treatment depends on the cause and nature of the breakdown. Symptoms of hemolytic anemia are similar to other forms of anemia (fatigue and shortness of breath), but in addition, the breakdown of red cells leads to jaundice and increases the risk of particular long-term complications, such as gallstones and pulmonary hypertension. In the present study, the *V. cholerae* were tested for their ability to cause hemolyis. The WT caused an excessive destruction of RBCs. However, several *V. cholerae* mutants did not hemolyse the chicken RBCs as the WT did. The genes that caused the reduction of hemolytic activity could not be determined as the mutant strains carried multiple gene mutation. In the previous study, hly gene was reported to cause hemolyis. Hly gene is repressed by hap, which is expressed late in infection.

Postreplicative semihistonal form of the chromatin is cause of education and disappearance of chromosomes during cell cycle

A. Rafailov, *M. Rafailova;*
Departament of Biology, Institute of Natural Sciences, M.K. Ammosov North-Eastern Federal University, Yakutsk, Russian Federation, Russian Federation.

It is suggest a hypothesis, that replication creates a new form of chromatin, which exists from G2 period of interphase to telophase. The replication doubles of DNA, but the amount of nucleosomic histones in the nucleus remain the same as before replication in G1 period. Therefore daughter nucleofilaments of G2 period have twice less histones than before replication. This is a new post-replicative semihistonal form of chromatin, „semichromatin". Helix formation and condensation are important structural properties of semichromatin. They are responsible for the formation and development of the chromosomes. It is known that helix formation and condensation latst in the chromosomes during of prophase - metaphase.
Consequently, the chromosomal material is represented semichromatin of the nucleus all this time. The hypothesis shows that the nucleus doesn't contain a stock of free histones, and a nuclear pores can't pass quickly all histones of cytoplasm in a nucleus. The cytoplasmal histones reach of semihromatin of chromosomes only after the destruction of the nuclear membrane in prometaphase. They gradually double the number of histones of semichromatine of chromosomes in a anaphase - telophase and return it into full for histones threadlike chromatin, ie nucleofilamenty. Thus, replication creates a semihistonal form of chromatin and it is the reason of formation of chromosomes. Synthesis of new histones in cytoplasm fills histones semichromatin and return in full histones chromatin, i.e. synthesis of new histones is the reason of disappearance semichromatin and chromosomes from view a light microscope.

Alkyl Mercury chloride compounds induced genotoxicity in human blood cultures and corrective role of Ascorbic acid (Vitamin C)

R. M. A. Abdel Kader;
the National research center, Cairo, Egypt.

Methyl mercury chloride is a xenobiotic metal that is a highly deleterious environmental pollutant. The biotransformation of mercuric chloride (HgCl2) into methyl mercury chloride (CH3HgCl) in aquatic environments is well-known and humans are exposed by consumption of contaminated fish, shellfish and algae. The genotoxicity induced by mercury compounds remains controversial. Therefore we have investigated the genotoxic effect of methyl mercury chloride (MMC; CH3HgCl) at two concentrations (100, and 1000 µg/L) and the role of ascorbic acid (Vitamin C) at a single concentration of (9.734 mm) on MMC-treated short-term human lymphocyte cultures. We assessed the chromosomal aberrations (CAS), sister chromatid exchange (SCE) and COMET assay in control and MMC-treated lymphocyte cultures with and without Vitamin C supplementation. The results showed that MMC has increased the frequency of CAS and SCE/cell in a dose-dependent manner than control values. CH3HgCl also, induced DNA damage in determined by COMET assay. These effects were prevented by the addition of Vitamin C to MMC-treated lymphocyte cultures. Data revealed that, mutagenic activity of MMC and the protective role of Vitamin C on mercury compounds-induced genotoxicity in human lymphocyte cultures is probably due to its strong antioxidant and nucleophilic nature

Departament de Biologia Cel•lular, Fisiologia i Immunologia. Universitat Autònoma, Barcelona, Spain,* [3]*Unitat d'Antropologia Biològica. Departament de Biologia Animal, Biologia Vegetal i Ecologia. Universitat Autònoma de Barcelona,, Barcelona,, Spain.*

The evolution of the world demand will make that Algeria will develop, in a near future; nuclear energy .This will require a competence in this field, and particular in the evaluation effect of the radiations emitted in the event of radiobiology accidents. The importance of the effects of ionizing radiation is to increase the risk of cancer or genetic defects. The most reliable method of biological dosimetry, is analysis of chromosomal modifications radiation-induced, particularly, the dicentric chromosomes, in lymphocytes of peripheral blood. For this purpose, we established two calibration curves Dose/effect, by the methods of cytogenetic in uniform staining. The selected experimental conditions are the same as those used by the team of Pr J,F. BARQUINERO (University Autonomy, Barcelona, SPAIN). The first was established like witness, from the blood of a Spanish person. As for the second, it was conceived for the Algerian laboratory from a blood sample of an Algerian person, without history to exposure to radiations. The frequency of dicentric chromosomes increases as dose and the statistical analysis shows that the values obtained follow a Poisson distribution revealing thus that the irradiations were correct and homogeneous. The two curves obtained from the dicentric analyses, obey the quadratic linear model and the relation Dose/effect is expressed by the equation: $Y = C + \alpha D + \beta D2$.
This study has allowed us, in Algeria to establish a dose effect curve for biodosimetry laboratory, which could in the future be part of an international biodosimetry network

Dysgonosomies at University Hospital Hassan II Fes: Cytogenetic and molecular aspects

K. Belhassan;
CHU FES, genetics department, Fes, Morocco.

Abstract. The dysgonosomies are represented by all the anomalies of the X and Y sexual chromosomes.
The main dysgonosomies are represented by Klinfelter syndrome which includes the presence of at least one extra X chromosome in a masculine karyotype 46, XY and Turner syndrome, which is linked to the complete or part absence of X chromosome. Monosomy X is not the only form of this syndrome. In half cases we find mosaic and / or structural abnormality of the X chromosome and sometimes the Y. Other less frequent dysgonosomies are represented by Double Y, Triple XXX , Men XX and Women XY. We report our first series collated between October 2009 and Marsh 2014 at the unit of medical genetics and Oncogenetics CHU Hassan II Fes. Many abnormalities found: Klinfelter syndrome (n: 9), Turner syndrome (n: 21), 12 cases with chromosomal formula (45, X), 3 cases of mosaic, 4 cases of isochromosome of the X long arm and 2 cases of Turner syndrome with the Y. Finally a patient with double Y (n: 1). The cytogenetic investigations used: metaphase karyotype; FISH (Fluorecent In Situ Hybridization) used „probe SRY Region (LSI SRY (Yp11.3) Spectrum Orange / CEP X Spectrum Green)", and multiplex PCR SRY / DXS1684.Through this communication we will display our different dysgonosomies (Klinfelter syndrome, Turner syndrome, double Y) in all their aspects: circumstances of discovery, clinical aspect, management and genetic counseling. The classical and molecular cytogenetic diagnostic of dysgonosomies allows better medical and surgical care and proper genetic counseling.

Genetic heterogeneity of Fanconi anemia (FA)-A in Egyptian patients

G. Y. El-Kamah[1], *H. T. El-Bassyouni*[1], *A. M. Salem*[2], *W. A. Zarouk*[1], *M. M. Eid*[1], *R. M. Mosaad*[1], *A. A. Sayed*[2], *S. A. Temtamy*[1];
[1]*National Research Centre, Cairo, Egypt,* [2]*Ain Shams University, Cairo, Egypt.*

Fanconi anemia (FA)-A is the most frequent complementation group and is detected in approximately two-thirds of studied FA patients in most countries. The aim of the study was to screen the common mutations previously reported in the international literature within exons 27, 34, 38, and 43 of the FANCA gene among Egyptian FA patients. **Patients and methods** The study included 24 Egyptian FA patients of unrelated consanguineous pedigrees and diagnosed by positive chromosomal breakage studies using diepoxybutane. Ten healthy unrelated individuals matching age and sex were included as the control group. Genomic DNA amplification, sequencing of exons 27, 34, and 43 of the FANCA gene, and restriction enzyme analysis for the exon 38 3788-3790del mutation were performed for patients and controls. **Results** No mutations were detected within the studied FANCA gene exons. **Conclusion** This is the first molecular study of FA in Egyptian patients that proved absence of the common mutations previously reported in other countries this may denote molecular heterogeneity in Egyptian patients. Further studies are recommended to establish the underlying mutations responsible for Egyptian FA cases as an important step in disease control.

Over expression of the glycoprotein P human in chemoresistance

S. Seddiki, *F. El Kebir;*
University of Oran, Oran, Algeria.

The "Multidrug resistance" (MDR) is an important obstacle to the success of the chemotherapy of many human cancers. The cellular multi chemoresistance is due to the over expression of the glycoprotein P, which confers the phenotype MDR to the cells. The aim of these researches if the localization of the fixation site of the steroid chemosensitizing in order to prepare efficacious modulating molecules of the MDR "phenotype". The first object has consisted in increasing the expression level of the Pgp in the R7 cells born of (descended from) a patient attacked by an erthroleuchaemis expressing concentrations of doxorubicin. The characterization of the Pgp presence has been realized by affinity photomarking with azidopine tritiée. An augmentation of the Pgp concentration is observed in the membranous fractions of the R7 cells treated by the doxorubicin. The second aim has consisted in preparing different radio active chemomarkers by peptidic coupling of bromo acetic [14C] the terminal amine of the progesterone derivatives substituted on the carbon 11 but the introduction of different hydrophobic chains, and in testing these chemomarkers with the membranous fractions of the R7 cells treated with the doxorubicin.

The diversity of MED12 gene mutations in uterine fibroid cells

N. S. Osinovskaya, *T. E. Ivashchenko, I. U. Sultanov, V. F. Bezhenar, V. S. Baranov;*
Ott's Institute of Obstetrics and Gynecology, St.Petersburg, Russian Federation.

Uterine myoma (UM) is a benign and most common tumor that affects 20-45% of women of fertile age. Previously it was shown that somatic mutations in the MED12 gene occur in most women with uterine myoma. We analyzed exon 2 nucleotide sequence of MED12 gene from 94 DNA samples extracted from fibroids, endometrium, myometrium cells and peripheral blood leukocytes of 17 women with uterine leiomyoma. Twenty-four samples exhibited various MED12 gene mutations. No mutations were found in DNA from myometrium cells and peripheral blood leukocytes. Two mutations have been identified in codon 44 from endometrial tissue sample. In 22 of the 47 samples (47%) isolated from fibroids we found different mutations of the MED12 gene. Each fibroid is characterized by its MED12 mutation. Up to five different mutations per individual patient could be identified depending on the amount of fibroids. Altogether we identified 18 mutations in codon 44 and 5 deletions of varying lengths. A single nucleotide substitution c.92T>A was also found within the area of alternative splicing. MED12 gene mutations were identified in 12 of the 17 women (70%). Mutations of MED12 gene could make substantial contribution in UM progression by modifying the activity of other genes that encode proteins involved in cell

proliferation and blast transformation.

Serotonin effects on NDUFS2 gene expression, a schizophrenia animal model research

A. Haghighatfard, *A. Rahimpour, M. Amini fasakhodi;*
Islamic Azad university-science and reasearch branch, Tehran, Islamic Republic of Iran.

Schizophrenia is a chronic and disabling psychiatric disorder with unknown cause that affects about 1% of the population worldwide. In last researches we have seen a significant higher expression of ndufs2 in schizophrenic mouse models in compare with normal controls. we have studied expression changes of 200 schizophrenic mouse models with and without serotonin treatment. Based on sex and treatments program, Mouse models have separated to four groups. Group A(male) and B(female) have been treated with serotonin(40 microg/kg body weight/day) for 6 weeks , and group C (male) and D(female) did not treated with serotonin. All mouse models were in the same age (15-16 weeks old) and all situations including air, light, feeding and etc were completely similar to four groups. After this period, mouse models killed and RNA isolated from prefrontal and hypo camp of their brains. We have investigated ndufs2 expression by using qRTPCR. Results shown significant lower expression of ndufs1 in models of group A and B in compare with models of group C and D. Also normal control group results confirmed our last researches output about increasing expression of ndufs2 in schizophrenic mouse models. Control group gene expression rate was lower than all other four groups. This research shown a significant relation between serotonin treatment and ndufs2 expression in brain but Since the neurotransmitter does not easily cross the blood-brain barrier the mechanisms of serotonin effect to genes expression in prefrontal and hypo camp are not clear and needs more studies.

Extended expression of promyelocytic leukemia (PML) during in vitro neural differentiation process of mouse embryonic stem cells (mESCs) purposes the importance of PML in cellular pluripotency and nervous system development

K. Karbalaie[1,2], *S. Vallian*[1], *H. Baharvand*[3], *M. Nasr-Esfahani*[2];
[1]Division of Genetics, Department of Biology, Faculty of Science, University of Isfahan, Isfahan, Islamic Republic of Iran, [2]Department of Cellular Biotechnology at Cell Science Research Center, Royan Institute for Biotechnology, ACECR, Isfahan, Islamic Republic of Iran, [3]Department of Stem Cells and Developmental Biology at Cell Science Research Center, Royan Institute for Stem Cell Biology and Technology, ACECR, Tehran, Islamic Republic of Iran.

Pro-myelotic leukemia (*PML*) is one of the major proteins in promyelotic leukemia nuclear bodies (*PML*-NBs). *Pml* gene has located on 9B mouse chromosome. Retinoic acid (RA) exerts its tumor growth suppressor activity and terminal myeloid differentiation of granulocyte\monocyte progenitor (GMP) cells via *PML*-NBs in RA pathway. In addition, RA as a natural morphogen guides posterior patterning in embryo neural development. Based on these two scenarios the aim of this study was to define if there was any revenue for PML-NBs in RA dependent neural development. For this reason, RA was used as a neural inducer for *in vitro* neural differentiation of mouse embryonic stem cells (mESCs). In mESCs, neural precursor cells (NPCs) and neural cells (NCs) obtained from this differentiation process *Pml* mRNA and protein levels were assessed by quantitative real time RT-PCR (q-RT-PCR) and western blotting. qRT-PCR results showed that *Pml* had a maximum expression in mESCs and this expression clearly had decreased in NPCs and NCs, although no significant differences existed between two latter groups. Interestingly, three un-foresight protein bands about 170, 130 and 70 kDa similarly were detected in these cell types on western blots. Based on qRT-PCR results, PML expression may have an important role in cellular pluripotency. However, the appearance of three similar bands in western blots from ESCs, NPCs, and NCs led us to assumption that PML might be necessary in cellular pluripotency and nervous system development. Although till now these protein bands were not reported.

The effect of carvacrol on prostatic cancer cells line PC3, Using comet assay technique

J. Saffari[1], **M. Nikoukar***[1], *E. Heidarian*[1], *M. Keloshadi*[2], *P. Ghasemi*[3], *M. Gholami*[3];
[1]Clinical Biochemistry Research Center Shahrekord University of Medical Sciences., Shahrekord, Islamic Republic of Iran, [2]Medical Plants Research Center Shahrekord University of Medical Sciences., Shahrekord, Islamic Republic of Iran, [3]Cellular & Molecular Research Center Shahrekord University of Medical Sciences., Shahrekord, Islamic Republic of Iran.

Background and aims: Nowadays, cancers are one of the biggest concerns of human societies. Polyphenolic compounds and antioxidants are a key factor in the prevention or treatment of various cancers. In this study, the effects of carvacrol on prostatic cancer cells line PC3 were investigated using comet assay technique.
Methods: 130, 230, and 360 µM concentrations of carvacrol were selected according to IC_{50} using MTT assay on cells line PC3. Then, alkaline electrophoresis was done and 100 comet pictures were analyzed with CASP software and all results were analyzed by SPSS statistical software.
Results: The IC_{50} for carvacrol was determined at 360µM by MTT test. Rate of tail to head in alkaline electrophoresis at 130, 230, and 360 µM of carvacrol concentrations were 15.9±2.1, 38.7±4.2, and 65.3±2.0 percent, respectively.
Conclusion: Carvacrol is one of the effective polyphenolic compounds in treatment the cancers and has destructive effects in prostatic cancer cells line PC3. The genomic destruction effects of carvacrol on cells line PC3 is more effective in near the IC_{50} concentration.

Random Aneuploidy in Amniocytes from Aneuploidic Pregnancies

A. Amiel[1], *M. Liberman*[1], *R. Sukenik Halevy*[1], *M. D. Fejgin*[2], *T. Biron-Shental*[3];
[1]Genetic Institute, Kfar Saba, Israel, [2]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel, [3]Department of OBGYN department, Meir Medical Center, Kfar Saba, Israel.

Aneuploidy may represent genetic instability. Amniocytes of fetuses with aneuploidy carry characteristics of genetic instability. Individuals with chromosomal aneuploidies may develop various types of malignancies. In this study, looking for random aneuploidy, we applied FISH technique, using different probes, to amniocytes from pregnancies with trisomies 21 and 18, and 47,XXY (study group) and compared them to amniocytes from pregnancies with normal karyotypes (control group). A significantly higher rate of random trisomy and more triploidies were observed in trisomy 21 and 18 cases. However, in the 4 cases of 47, XXY higher rates of random trisomies, but not triploidy were observed. Monosomies appeared in both study and control groups, which could be the result of technical problems. The observed differences in the random aneuploidy rates between the somatic and sex chromosome aneuploidies might reflect different mechanisms of random aneuploidy between the two types. Triploidy was significantly higher in the somatic aneuploidies compared to the sex aneuploidy and control groups. As previously shown in CML patients, triploidy, which occurred more often in the study group, probably reflects an increased predisposition to develop malignancy compared to random aneuploidy. In most aneuploidies, malignancy will develop as a result of an oncogenic event that occurs in addition to the existing genetic instability. Occurrence of triploidy may reflect such an event.

J13.14

Small Supernumerary Marker Chromosome Originating From Chromosome 10 Associated With an Apparently Normal Phenotype

T. Roberta[1], *R. Santacroce*[1], *A. Pansini*[2], *M. Gentile*[2], *M. Margaglione*[1];
[1]Laboratory of Human Genetics, Foggia, Italy, [2]Cytogenetics Laboratory, Bari, Italy.

A normal 40-years old Italian woman was referred for cytogenetic evaluation before having undergone controlled ovarian hyperstimulation, in vitro fertilization and embryo transfer. Family history was noncontributory except for her long-term infertility. QFQ-banding revealed a karyotype 47,XX,+mar[49]/46,XX[51] with one sSMC. Studies by aCGH and FISH confirmed that the marker originated from chromosome 10, with duplication of 10p11.21p11.1 segment. Molecular cytogenetic characterization in her parents, sister and brother defined a normal karyotype 46,XY for father and brother while the mother was 47,XX,+mar[61]/46,XX[39] and sister was 47,XX,+mar[77]/46,XX[23] with sSMC derived from chromosome 10. Chromosome 10 is rarely involved in the formation of marker chromosomes. Eight cases have been reported in literature and in six out of these, sSMCs were associated with an increased risk of abnormal phenotype. In our case, there was an apparently normal phenotype, probably associated with minimal involved material and gene content. Some sSMCs derived from the same chromosome, but in spite of this, a great variation in phenotype was observed, probably due to the degree of mosaicism that may vary in different patients as well as in different tissues in the same patient. Furthermore, most sSMCs were ascertained in phenotypically abnormal subjects, but it isn't always possible to correlate the phenotype with sSMC; so it is difficult to predict the precise phenotype-karyotype correlation and phenotypic outcome. This report shows the importance of cytogenetic characterization in patients with comparable chromosome defects, giving the possibility of identifying similarities in the clinical picture that will benefit the counseling of future cases.

AvaII-TaqI-HindIII represents a novel informative haplotype at the β-globin gene cluster: Application in carrier detection and prenatal

diagnosis of beta-thalassemia in the Iranian population

S. Givi, *T. Moradi, S. Vallian;*
University of Isfahan, Isfahan, Islamic Republic of Iran.

Thalassemia is one of the common monogenic disorders, with a high demand for carrier detection and prenatal diagnosis in the Iranian population. In view of the presence of a large number of mutations associated with the disease, the polymorphic markers present in the β-globin cluster region were commonly used in linkage analysis of the disease. Markers usually show a population dependent base haplotype frequency. Among the polymorphic markers, five markers including AvaII, RsaI, HinfI, TaqI and Hind III were genotyped in 150 unrelated healthy individuals from the Iranian population. The haplotype frequency was estimated using PHASE program and linkage disequilibrium (LD) was analyzed by MIDAS program. Among the 31 possible haplotypes, seven haplotypes showed relatively high frequencies ≥ 5%. The haplotype AvaII-TaqI-HindIII could be suggested as an informative haplotype for possible carrier detection and prenatal diagnosis of beta thalassemia in the Iranian population. Moreover, RsaI and HinfI (located in the hotspot region) were not associated with the 5' sub-haplotypes or 3' sub-haplotypes. The data suggested that RsaI and Hinfl markers might be excluded as strong molecular diagnostic markers in beta-thalassemia carriership and prenatal diagnosis in the Iranian population.

Study of cytogenetic stability of induced pluripotent stem cells (iPSCs) using karyotyping and comet assay techniques

P. Ghasemi-Dehkordi[1], *M. Allahbakhshian-Farsani*[2], *N. Abdian*[1], *H. Jafari-Ghahfarokhi*[1], *J. Saffari-Chaleshtori*[3], *M. Sadeghiani*[1], *A. Mirzaeian*[1], *M. Hashemzadeh-Chaleshtori*[1];
[1]*Cellular and Molecular Research Center, Shahrekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran,* [2]*Department of Hematology and Blood Banking, Faculty of Allied Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran,* [3]*Clinical Biochemistry Research Center, Shahrekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran.*

Induced pluripotent stem cells (iPSCs) have capability to undergo unlimited self-renewal and differentiation into all cell types in the body. In order to use iPS cells and apply studies in therapeutic applications, the stability of these cells is essential step. In present experimental study HDF cells were isolated from human foreskin samples and cytogenetic stability of these cells were evaluated in early passages (1-3) using karyotype test and alkaline comet assay. The HDF cells treated with hydrogen peroxide were used as a positive control for alkaline comet assay. The iPS cells with low passage (4-7) derived from reprogrammed HDFs were cultured on MEF feeder layer and cytogenetic stability of these cells were evaluated by karyotype test and alkaline comet assay technique. After karyotype test and comet assay, the results showed that the iPS cells in early passages (4-7) had normal karyotype (46, XY) and DNA damage and comet in these cells were not observed. In addition, HDF cells showed normal karyotype in early passages (1-3) but using comet assay, abnormality and DNA damages in positive control (HDF cells treated with H2O2) was observed. The parameters of alkaline comet assay of iPS cells and HDFs compared with positive control group were statistically significant ($p<0.05$). These findings indicated that comet assay is a sensitive technique and should before performing the functional experiments on iPS cells, cytogenetic stability of these cells must be study. Therefore, for precise evaluation of DNA damage and cytogenetic stability of these cells, both techniques could complete each other.

The assessment of lentiviral vectors appliction for gene transformation in human dermal fibroblasts (HDFs)

P. Ghasemi-Dehkordi[1], **M. Allahbakhshian-Farsani**[1], *N. Abdian*[1], *S. Khosravi-Farsani*[1], *A. Mirzaeian*[2], *M. Nasri*[1], *A. Karimi-Taghanaki*[3], *G. Mardani*[3], *S. Amiri*[1], *M. Hashemzadeh-Chaleshtori*[1];
[1]*Cellular and Molecular Research Center, Shahrekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran,* [2]*Clinical Biochemistry Research Center, Shahrekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran,* [3]*Medical Plants Research Center, Shahrekord University of Medical Sciences, Shahrekord, Islamic Republic of Iran.*

Induced pluripotent stem cells (iPSC) are primary undifferentiated cells that are able to create almost any type of cells in the body. The purpose of the present study was production and transmission of TetO-FUW-OSKM lentiviral vector to human dermal fibroblast cells (HDFs) and investigation the application of this vector. In this experimental study after isolation and culture of HDF cells, TetO-FUW-OSKM lentiviral vector containing the reprogramming genes (as transfer vector) and psPAX2 and pMD2.G vectors (as packaging plasmids) were transfected to HEK-293T cell line for virus production. The supernatants of packaging cells were harvested in 48h and 72h after transfection. Then, these viruses were transducted to HDF for reprogramming these cells. The results of this study demonstrated the successful production of TetO-FUW-OSKM lentiviral vector and suitable expression of the transcription factors in HDF cells after transduction. According to these findings lentiviral vectors could be used for gene transmission and reprogramming of adult cells such HDF to generate iPS cells in future studies.

J13.18

A rare case of a 12-year-old boy with a 45,X karyotype: cytogenetic and molecular genetic

M. Police, *C. Rosania, A. Pedicini, G. Cerbone, M. Ventruto, C. Rosania, A. Frieri, M. Del Gaudio, I. De Maggio, A. Colucci;*
aosgmoscati, avellino, Italy.

We report the case of a 12 years-old boy of non consanguineous parents. He was born by uterine-incision delivery, weighting 2480kg and measuring 47 cm.. The present height was of 139 cm (height SD score -2.2)< to parental target of 176 cm and weight of 26.3 kg, BMI of 13.61 (SD score-2.98 DS) and head circumference of 52 cm (10°percentile). At physical examination he presented long face, sharp chin, prominent ears, malar hypoplasia, pectus excavatum, joint laxity, cubitus valgus and severe scoliosis. The genitalia were normal for male phenotype but the left testicle were not yet in scrotum He presented mild mental retardation, motor and speech delay The ultrasound examination of heart was normal .
Standard cytogenetic analysys showed a 45,X karyotype. Y microdeletion analysis showed the presence of an intact SRY homeobox region and the ZFY region, instead the regions AZF a,b,c are delete.
Fluorescence in situ hybridation (FISH) with chromosome paints for chromosome Y and with subtelomeric probe for 10q, showed the presence of a rare aberration with an unbalanced karyotype constituted by 45 chromosomes including a der(10) deriving from the Y/10 traslocation. Finally it results a monosomy of the region 10q26.3-qter and a deletion of Yp11.2-qter. The breakpoints were, later, by molecular genetic analysis (Agilent 8x60k array-CGH), ascertained.
The karyotype is:
45,X,der(10)t(Y;10)(q26.3;p11.2).arr Yp11.2 (9,394,173-28,548,485) x0,10q26.3 (131,561,314-135,404,523)x1

Developmental role of NF-Y as an epigenetic element on regulatory region of *SALL4* gene in human embryonic carcinoma cells

F. Moeinvaziri[1,2], *M. Shahhoseini*[2], *R. Favaedi*[2];
[1]*University of Science and Culture, Tehran, Islamic Republic of Iran,* [2]*Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Islamic Republic of Iran.*

Introduction
During development epigenetic mechanisms have key roles in molecular regulation of gene transcription. Through various epigenetic mechanisms, NF-Y act as a histone substitute protein, which precisely binds to the CCAAT box of promoter and has a significant role in chromatin remodelling of their target genes. *SALL4*, spalt-like transcription factor 4, is a coding gene with CCAAT box, play a crucial role in maintaining the properties of embryonic stem (ES) cells and governing the cellular fate. Embryonal carcinoma (EC) cells derived from testicular tumors are worthwhile models for elucidating molecular and cellular genetic and epigenetic functions involved in developmental process due to its similarities with embryonic stem (ES) cells.
Material and Method
In this study, the chromatin immunoprecipitation (ChIP) coupled with real-time PCR was performed using anti-NF-Y antibody, on chromatin extract from a human embryonal carcinoma cell line, named NT2/NTera2, to evaluate incorporation levels of NF-Y on the regulatory region of *SALL4* gene.
Results
The results of ChIP real-time PCR analysis clearly showed a considerable incorporation of NF-Y complex on the regulatory region of *SALL4* in NTera2 cells.
Conclusion
According to the presence of NF-Y protein on *SALL4* regulatory region, it can be concluded that NF-Y has a dynamic epigenetic role in regulation of *SALL4*, a master gene in controlling the molecular pathway of pluripotency during development.

An automatic algorithm to extract mid-sagittal plan of fetus in first trimester from 3D volumes

P. Tsai;
Department of Obstetrics and Gynecology, National Cheng Kung University Medical College and Hospital, Tainan, Taiwan.

Background:
In first trimester, there are many important ultrasound examinations during

prenatal care. In evaluation the fetal structure in utero, the three-dimensional ultrasound is the most convenient and powerful tool. However, accuracy image (e.g. mid-sagittal plan) is extremely important. Thus, we proposed an automatic algorithm to extract mid-sagittal plan of fetus in first trimester from 3D volumes.
Materials and Methods:
3D volumes with gestational ages of 11 to 13 weeks were used in the study. We plan a registration method based on the selected feature points. After finishing the registration of image and model with affine transform, we adjusted the scale of model to obtain the optimal size, which is similar to the object in the image. The process to put the statistic shape to the testing volume image is similar to the adoption of all training shapes in the statistic model construction. The following step was to make the geometric information of the statistic shape model was used to avoid the excessive distortion caused
Result:
The measurement results were compared with those manually obtained by an expert. The experimental results show that the proposed method overcomes the difficulties and achieves good consistency between the automatic method and manual measurements.
Discussion:
Due to the difficulties in treating highly-noise US images, the fully automatic image segmentation tool for the fetal ultrasound is lack. The proposed system precisely detected mid-sagittal plan of fetus using 3D US in the first trimester, making it useful for clinical service.

J14.02
Genetic diagnosis of Bardet-Biedl syndrome by MiSeq exome sequencing

E. N. Suspitsin[1,2], *A. P. Sokolenko*[1,2], *L. V. Lyazina*[3], *E. N. Imyanitov*[1,2,4];
[1]*St.-Petersburg State Pediatric Medical University, St.-Petersburg, Russian Federation,* [2]*N.N. Petrov Institute of Oncology, St.-Petersburg, Russian Federation,* [3]*Center of Medical Genetics, St.-Petersburg, Russian Federation,* [4]*I.I. Mechnikov North-Western Medical University, St.-Petersburg, Russian Federation.*

Bardet-Biedl syndrome (BBS) is a rare autosomal-recessive ciliopathy characterized by obesity, postaxial polydactily, retinitis pygmentosa, mental retardation and kidney abnormalities. At least 18 genes have been shown to be associated with BBS, therefore genetic testing for this disease is highly complicated. We consulted a family with strong clinical features of BBS in 2 children. While considering the labor and consumables costs for analysis of at least 7 "common" BBS genes (BBS1, BBS10, BBS2, BBS6, BBS9, BBS12 and BBS13), we opted for exome sequencing as a viable alternative to multiple single-gene tests. Using Illumina MiSeq platform, we identified homozygous BBS7 L656fsX673 (c.1967_1968delTAinsC) mutation in 2 affected sibs; both parents and their healthy son were heterozygous for this allele. Presence of an identical gene defects in non-consanguineous parents is uncommon for BBS, however Russian population was repeatedly shown to have an unusually pronounced founder effect. We are currently examining whether the above mutation is indeed recurrent in Russia: at the time of abstract submission, we genotyped 1817 healthy donors and identified 1 (0.06%) additional carrier of BBS7 c.1967_1968delTAinsC.
We conclude that even medium-throughput next generation sequencing platforms may facilitate clinical diagnosis of genetically heterogeneous disease.

J14.03
Detection of Borna Disease Virus in peripheral blood cells of a number of obese patients in Iran via Nested RT-PCR

R. Sonboli;
Mazandaran University ,babolsar, Babolsar, Islamic Republic of Iran.

Worldwide prevalence of obesity trends attentions toward the multiple origins of it. The most overlooked one is infectious factor, and among them viruses are the most noticeable. Borna Disease Virus is a nonsegmented, single-stranded RNA virus, usually causes sporadic neurological disease in horses and sheep as its natural host. Although BDV is considered as a non-human virus, recently Serological and molecular evidences investigated the possible association of BDV with specific psychiatric diseases in humans. But the point that we choose it as an etiology of human obesity is that BDV is identified as a cause of rapid increase of body weight with development of an obesity syndrome without obvious neurological signs in Experimental intracerebrally infected Lewis rats. In this study which was done for the first time in Iran, by using nested RT-PCR technique, we demonstrated that BDV RNA was present in peripheral Blood Mononuclear cells of a number of obese patients. 43 subjects took part in this study. The BMI in kg/m2 of the obese subjects were over 30.the detection rate is about 16/2%.sequenceing of positive samples confirmed our finding. These results illustrated the adiposity-promoting effect of BDV occurs in Human being.

Reliable and cost effective screening of 16 breast cancer gene panel using sequence capture method coupled with next-generation sequencing in clinical settings

J. Kósa[1], *K. Árvai*[1], *B. Balla*[1], *P. Horváth*[2], *M. Dank*[2], *A. Tőkés*[3], *B. Tóbiás*[1], *I. Takács*[2], *P. Lakatos*[2];
[1]*Semmelweis University PentaCoreLab, Budapest, Hungary,* [2]*Semmelweis University 1st Department of Internal Medicine, Budapest, Hungary,* [3]*Semmelweis University 2nd Department of Pathology, Budapest, Hungary.*

BRCA1 and BRCA2 are two well-known genes in the background of hereditary cancer syndromes. There is also evidence that several other genes play an important role in the pathogenesis of these type of diseases. Latest population-scaled studies showed that certain mutations in different genes could cause as high risk elevation as BRCA2 mutations. In this study we present a reliable and cost-effective method to analyse the risk assessment of different types of cancer. Using Haloplex, a novel sequence capture method combined with benchtop non-optical next-generation sequencing we were able to achive short turn around time with the screening of 16 genes that could be associated with an increased risk of breast, ovarian and other types of cancer. The analysis of this 16-gene set can explain the inherited background of almost 30% of hereditary and familiar cases of breast and ovarian cancers. Thus, it opens up a high-throughput approach with fast turnaround time to the genetic diagnostics of these disorders and may be helpful to investigate other familial genetic disorders as well.

The clinical utility of cell-free DNA analysis for non-small cell lung cancer diagnostics and radical therapy effectiveness monitoring

A. Szpechcinski, *R. Struniawski, M. Skronski, J. Chorostowska-Wynimko, B. Poplawska-Wisniewska, W. Kupis, P. Rudzinski, K. Maszkowska-Kopij, J. Zaleska, E. Radzikowska, E. Puscinska, R. Langfort, P. Sliwinski, T. Orlowski, K. Roszkowski-Sliz;*
National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland.

Objective: The presence of cell-free DNA (cfDNA) in plasma/serum of non-small cell lung cancer (NSCLC) patients demonstrates promising clinical implications as the minimally-invasive liquid biopsy for diagnostic, prognostic and predictive applications. To date, we performed quantitative evaluation of cfDNA in plasma of NSCLC patients and non-malignant controls. **Methods:** Plasma cfDNA concentration and integrity index (DII) were measured by real-time PCR in 60 NSCLC patients (stage I-IIIA), 100 patients with chronic respiratory inflammation (COPD, sarcoidosis, asthma), 15 patients with non-malignant lung nodules (hamartoma, fibrosis, tuberculoma) and 40 healthy volunteers. **Results:** NSCLC patients presented significantly higher plasma DNA levels (8.0 ng/ml) than patients with chronic respiratory inflammation (3.4 ng/ml) and healthy controls (2.3 ng/ml; p<0.0000), but not than patients with non-malignant lung nodules. The ROC analysis provided 90% sensitivity and 80.5% specificity in discriminating NSCLC from healthy individuals, while 56% specificity and 90% sensitivity in distinguishing NSCLC from any non-NSCLC subjects (p<0.0001). Similarly, the mean DII in NSCLC (4.0) significantly differed from healthy control values (1.0; p=0.000), but not from DII in chronic respiratory inflammation (3.7) and non-malignant nodule group (4.0). During 3-6 month follow-up plasma DNA level were significantly reduced in relapse-free NSCLC patients (2.8 ng/ml), while in relapsed subjects were higher than at baseline. Conclusions: The plasma DNA quantification, though insufficient for routine NSCLC detection, is still superior to diagnostic accuracy of conventional serological markers. Epi-/genetic alteration analysis might improve the diagnostic power of cfDNA. Long-term post-operative plasma DNA level follow-up might prove promising in monitoring of radical NSCLC therapy.

J14.06
Chitotriosidase as a biomarker for the diagnostic approach of lysosomal storage disorders in Colombia

N. Pacheco-Fernández, *A. Uribe;*
Universidad de los Andes, Bogota, Colombia.

Lysosomal storage disorders (LSDs) are a group of disorders that enclose the damage of an enzyme and its pathological consequences due to the accumulation of substrate in lysosomes. In Colombia, LSDs are misdiagnosed because many of them are not widely known. A biomarker is defined as a molecule that works as an indicator of disease, being useful for a diagnostic approach. Chitotriosidase (ChT) is a chitin hydrolyzing enzyme that cleaves the 1,4-β linkage of chitin. In human its function has not been entirely elucidated, but its increase has been associated with inflammation, fungal/parasitic infection or LSDs. We propose ChT as a reliable biomarker for the diagnostic approach to LSDs in Colombia. We took DBS samples from 240 patients (112 females and 128 males) with Pompe, Fabry, Metachromatic Leucodystrophy, Mucopolysaccharidosis, Mucolipidosis, Gaucher, Niemann Pick (NP), Gangliosidosis GM1 or Sialidosis, who were previously dia-

gnosed by enzymatic assays in leukocytes. Also 48 patients with symptoms suggestive of LSD and 87 control subjects were analyzed by a fluorometric assay using 4MU-triacetylchitotrioside. While most patients with LSDs showed an increase in ChT (range: 1,1-3118,0 nmol/ml/h), Morquio A patients showed no increase (n=30, range: 5,6-78,1 nmol/ml/h) in relation to the reference value (<96 nmol/ml/h). Gaucher and NP patients showed the highest values (3118 and 1649,6 nmol/ml/h, respectively). Although ChT is not an specific biomarker, it can be used for an LSD diagnosis approach as long as the clinical symptoms strongly suggest it.

Chromosomal microarray analysis as first-tier clinical diagnostic test: Estonian five years experience

O. Zilina[1,2], *P. Tammur[1], K. Kuuse[1], T. Mölter-Väär[1], M. Yakoreva[1,3], R. Teek[1,4], E. Vaidla[1], T. Reimand[1,4,3], A. Kurg[2], K. Õunap[1,4];*
[1]Department of Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia, [2]Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia, [3]Department of Biomedicine, Institute of Biomedicine and Translation Medicine, University of Tartu, Tartu, Estonia, [4]Department of Pediatrics, University of Tartu, Tartu, Estonia.

Chromosomal microarray analysis (CMA) is now established as the first-tier cytogenetic diagnostic test for fast and accurate detection of chromosomal abnormalities in patients with developmental delay/intellectual disability (DD/ID), multiple congenital anomalies (MCA), and autism spectrum disorders (ASD). We present our experience with using CMA for postnatal and prenatal diagnosis in Estonian patients during 2009-2013. Since 2011 CMA is on the official service list of the Estonian Health Insurance Fund and is performed as the first-tier cytogenetic test for patients with DD/ID, MCA or ASD. A total of 1902 patients were analyzed, including postnatal [1692 (89%) patients and 106 (6%) family members] and prenatal referrals [104 (5%) fetuses]. Abnormal results were reported in 500 (26%) patients, with a total of 585 findings (1-5 per individual): 217 (37%) deletions, 174 (30%) duplications, 176 (30%) long contiguous stretches of homozygosity (LCSH) events (>5 Mb), and 18 (3%) aneuploidies. Of all findings, 230 (39%) were defined as (likely) pathogenic; for 271 findings (46%), most of which were LCSH (159), the clinical significance remained uncertain; 80 (14%) reported findings were classified as likely benign. Clinically relevant findings were detected in 201 (11%) patients. However, the proportion of variants of uncertain clinical significance was high (46% of all findings) demonstrating that the interpretation of CMA finding remains a rather difficult task. Close cooperation between clinicians and cytogeneticists, as well as further data sharing with colleagues are the cornerstones of successful CMA application in clinical practice.

Clonal evolution in prospective analysis of chronic lymphocytic leukemia patients detected by FISH and conventional cytogenetics after stimulation with CpG oligonucleotides and interleukin-2

M. Stoklasova[1], A. Burdova[1], **L. Dostalova**[1], *B. Drevojankova[1], T. Sablaturova[1], A. Strnkova[1], V. Hodslavska[1], K. Horka[1], R. Sitkova[1], Y. Brychtova[2], A. Panovska[2], K. Stepanovska[2], G. Vankova[2], K. Plevova[2,3], A. Oltova[2], S. Pospisilova[2,3], J. Mayer[2,3], M. Doubek[2,3], M. Brejcha[4];*
[1]AGEL Research and Training Institute, Novy Jicin, Czech Republic, [2]University Hospital and Faculty of Medicine, Masaryk University, Brno, Czech Republic, [3]Central European Institute of Technology, Masaryk University, Brno, Czech Republic, [4]Hospital Novy Jicin, Novy Jicin, Czech Republic.

Introduction: Chromosomal abnormalities are important prognostic factors in chronic lymphocytic leukemia (CLL). During the course of the disease clonal evolution (CE) may occur. CE, defined as acquisition of new cytogenetic aberration, is associated with shorter overall survival. In the majority of published analyses to date, CE has been monitored using FISH. Therefore, the aim of our study was to prospectively assess CE frequency using a combination of FISH and conventional chromosome banding (CBA) after stimulation with CpG oligonucleotides and interleukin-2 (IL-2). The role of other prognostic factors and therapy in development of poor-prognosis CE (new deletion 17p, new deletion 11q or new complex karyotype) was also evaluated. Methods: Betweeen 2008 and 2012, 140 patients with previously untreated CLL were evaluated by FISH (deletion 11q, 13q, 17p, trisomy 12, rearrangement 14q32) and CBA after stimulation. Peripheral blood samples of each patient were provided for baseline and follow-up testing. Mutation status of IGVH gene and expression of CD38 and ZAP70 were also analysed. Results: CE was detected in 15.7 % (22/140) of patients using FISH, in 28.6 % (40/140) using CBA, and in 34.3 % (48/140) of patients by combining both methods. Poor-prognosis CE was detected in 15 % (21/140) of patients and was significantly associated with previous CLL treatment (p = 0.013). Conclusions: CBA after stimulation with CpG oligonucleotides and IL-2 provides more complex information about cytogenetic abnormalities in CLL than FISH. Many patients can acquire new abnormalities during the course of their disease in a relatively short time period.

Submitting biomedical data to the European Genome-phenome Archive (EGA)

J. P. Almeida-King, *J. Kandasamy1, I. Lappalainen1, I. Medina, G. Saunders, V. Kumanduri, S. Ur-Rehman, D. Spalding, J. Paschall;*
European Bioinformatics Institute, Cambridge, United Kingdom.

The European Genome-phenome Archive (EGA), a service of the European Bioinformatics Institute (EBI), is a permanent archive for all types of potentially identifiable genetic and phenotypic data that has been consented for use in biomedical research, but not for open public distribution. The EGA includes major reference data collections for rare and common diseases, including data derived from the UK10K project, Wellcome Trust Case Control Consortium (WTCCC) and International Cancer Genome Consortium (ICGC), as well as control sets that can be used in addition to the public reference panels such as the 1000 Genomes project. Accepted submissions include manufacturer raw data from genome sequence, transcriptome, epigenome or proteomics experiments. The EGA also stores called variants, genotypes, study summary statistics and associated sample phenotypes. Submission tools designed to facilitate the secure upload of data files and associated metadata are accessible for each submitter using a single log-in and may be run as graphical interface or from the command line. The functionality of the submission tools may be incorporated into submission pipelines for large-scale submitters. The EGA follows strict protocols for information management, data storage, security and dissemination. Authorized access to the data is managed in partnership with the data providing organizations. Future plans include expanding the EGA into a distributed network of data archive and distribution services. A pilot project has already started in collaboration with the Centre for Genome Regulation (CRG) in Barcelona, Spain. The EGA is currently available at www.ebi.ac.uk/ega/.

Detection of EGFR gene amplification in head and neck squamous cell carcinoma with paralogue ratio test

B. Zagradišnik, **A. Erjavec Skerget**, *Š. Stangler Herodež, D. Krgović, N. Kokalj Vokač;*
university Medical Centre Maribor, maribor, Slovenia.

Introduction: EGFR signaling pathway has an important role in the development of head and neck squamous cell carcinoma (HNSCC). Therefore any mutation that affects its components, may influence the course and management of the disease. The amplification of the EGFR gene is such significant event that is present in HNSCC. We compared the efficacy of a targeted detection of the EGFR gene amplification with the paralogue ratio test (PRT) to results obtained with the array comparative genomic hybridization (aCGH).
Methods: Samples of genomic DNA extracted from tumors of 50 patients with various stages of HNSCC were first analyzed with the aCGH method. An oligonucleotide pair that maps inside the amplified EGFR region was selected from a collection at www.prtprimer.org and used for PRT analysis.
Results: The aCGH analysis identified EGFR amplification in 7 samples, with EGFR gene copy number ranging from 3 to 6 copies. Subsequent PRT analysis also identified all 7 EGFR amplifications and it produced concordant results in all remaining samples which were without EGFR gene amplification.
Conclusion: Paralogue ratio test can be adopted for a rapid, targeted detection of gene amplification, such as EGFR amplification present in HNSCC, The method may be applicable as a screening tool and for conformation of aCGH results.

J14.11
Molecular evaluation of carbapenemases and Metallo beta lactamases production among Gram-negative bacteria with carbapenem resistance

H. Ghafarzadeh[1,2], *S. Nobary[1], S. Zeinali[2], F. Shahcheraghi[1];*
[1]Department of microbiology, Institute Pausteur of Iran, Tehran, Islamic Republic of Iran, [2]Kawsar human genetics research center, Tehran, Islamic Republic of Iran.

Emerging multidrug resistant (MDR) microorganisms among hospital isolations have been limited the effective drugs to treat or prevent bacterial infections. This study was performed to determine the rates of antibiotic resistance in Gram-negative isolates from clinical samples and to identify carbapenemases and Metallo beta lactamases genes variation in the strain. Identification and assessment of gram negative bacteria with Carbapenem resistant sensitivity to 11 antibiotic was done through biochemistry and disk diffusion methods, respectively. 11 isolates were checked by PCR for identification of blaVIMI,II blaIMP blaSPM blaGES blaNDM blaKPC blaOXA-48 genes MHT and DDST tests were used assessment for Carbapenemases and Metallo beta lactamases production in these strains. The iden-

tified genes were confirmed by sequencing technique.
In this study, a total of 134 isolates were studied, including 57 Escherichia coli (E.Coli) strain, 26 Klebsiella strain, 21 Acenitobacter strain, 17 Pseudomonas strain, 8 Citrobacter strain, 3 Proteus strain, 2 Enterobacter strain. Confirmatory tests showed that 44 strains were EDTA positive and 17 strains were H-Test positive. A PCR based screening revealed the presence of the blaIMP-1 gene in 4 isolates. E.coli showed the highest level of resistance to imipenem. Most of positive H-test (41.17%) and positive DDST (39.13%) strains were Acenitobacter.
Owing to the presentation of blaIMP-1 gene in Klebsiella, Citrobacter, Acenitobacter and E.coli and feasibility of horizontal gene transfer among bacteria, but also due to the importance of Metallo beta lactamase production strains in hospital, change in antibiotic prescription policies are required.

J14.12
Improved methods for preparing high quality genomic libraries from challenging FFPE tumour samples for use on Illumina® sequencing systems

R. Sanches-Kuiper, *H. McGarvey, A. Jackson, T. James, O. Mead, S. McArthur, S. Berri, S. Humphray, V. Smith;*
Illumina Cambridge Ltd., Essex, United Kingdom.

The research community needs robust and rapid sample preparation workflows for high-throughput sequencing to unlock challenging samples and generate high quality sequence data. These include samples with low input amounts of genomic DNA and highly degraded tumour samples extracted from formalin-fixed paraffin embedded (FFPE) material.
The quality of the libraries and ultimately the sequencing data depends on the integrity of the genomic DNA extracted from FFPE samples. The formalin fixation and paraffin embedding of tissues affects this through fragmenting, cross-linking, and otherwise damaging DNA through various chemical modifications. It is essential to assess the extent of the damage, adjust the DNA extraction procedure to compensate for the damage as much as possible, and adapt the sample preparation workflows to the quality of these samples.
We have developed flexible FFPE-specific sample preparation workflows analysis solutions for tumour/normal low coverage copy number analysis and deep whole-genome sequencing. The end-to-end workflow from sample preparation to answer includes an upfront sample QC step enabling sample triage into three different quality bins (high, medium and low). Depending on the sample quality bin, different input DNA and size selection conditions are recommended for the sample preparation. We have also developed software solutions in BaseSpace and tested third party tools for the detection of somatic variants from tumour/normal analysis, including single nucleotide variants (SNV), structural variants (SV) and copy number aberrations (CNA) data analysis.
We present results obtained with FFPE samples from different qualities sequenced on several Illumina® sequencing systems.

J14.13
Importance Of Poliaspectual Prenatal Diagnostics Of Congenital Malformation

E. Paladi[1], *M. Sprincean*[1,2];
[1]*Institute of Mother and Child, Chisinau, Moldova, Republic of,* [2]*State University of Medicine and Pharmacy "N. Testemitanu", Chisinau, Moldova, Republic of.*

Background: Congenital pathology is the leading cause in Republic of Moldova of infant morbidity and mortality. Invasive techniques of prenatal diagnosis (amniocentesis) are very important in efficient medico-genetic counseling for determining caryotipe, used in diagnosis of many chromosomal abnormalities (Down syndrome, Patau and Edwards syndromes etc.).
Object of study. Efficient diagnosis and prevention of chromosomal abnormalities and congenital malformation can be assured only by medico-genetic, pedagogical, psychological theory and practice as wide interdisciplinary knowledge on genetic diseases and hereditary pathologies.
Methods. In this research were used a number of practical methods such as gathering of anamnestic data, conversation, questioning, observation, psychological and psycho-pedagogical testing as well as a complex of cytogenetic and molecular-genetic methods. Clinical-genealogical examination of pregnant women from genetic risk group was provided at the beginning of the study.
Results obtained. The diagnosis of chromosomal abnormalities and congenital malformation was provided during medico-genetic counseling and during sessions of qualified psychological assistance, to 74 pregnant women of risk group. Results of the study can be used in family planning and counseling for prophylaxis of congenital pathology as well as to increase the level of awareness of people of risk group on prevention of genetic diseases.
Conclusions. This study stated the necessity of implementation in Moldova of a diversity of medico-genetic strategies during counseling of pregnant women of risk group, for improve the efficiency of diagnosis of chromosomal abnormalities and congenital malformation, which can be achieved by close cooperation between specialists of many fields as genetic physicians, psychologists, pedagogues.

Seroprevalence Of Helicobacter Pylori In Children In A Rural Area

T. Sabbi;
Pediatric Unit, Rome, Italy.

BACKGROUND Helicobacter pylori (Hp) infection has been recognized as a cause of chronic gastritis, peptic ulcer, atrophic gastritis and gastric cancer. **AIM** To analyzed the seroprevalence of Helicobacter pylori in pediatric age in rural area and to evaluate some epidemiologic characteristics. **PATIENTS AND METHODS** the study included 100 patients (80 males; age range 5-13 years) suffering from different gastrointestinal complaints. Blood serology and stool antigen testing were used for the diagnosis of infection due to H. pylori. We interviewed the children with questionnaire about socioeconomics factors, hygiene, living conditions and their dietary habits. **RESULTS** 20 (20%) of the 100 patients were positive for Helicobacter pylori and this positivity had a significantly increasing correlation with age ($p<0.001$). A lower frequency of fermented dairy food, fruits and vegetable consumption was registred among infected children. Among infected patients were noted low socio-economic markers such as croweded living conditions and unclean water. **CONCLUSIONS** Might decrease the risk of Hp infection the use of vitamin C and antioxidants contained in fruit and vegetables. Risk factors for Hp infection are low socioeconomics factors, hygiene and living conditions.

J14.15
Comparison of clinical performances among Roche Cobas HPV, RFMP HPV Papillo Typer and Hybrid Capture 2 assays for detection of high-risk types of human papillomavirus

S. Yu[1], *M. Kwon*[1], *E. Lee*[2], *H. Woo*[1], *H. Park*[1];
[1]*Kangbuk Samsung Hospital, Seoul, Korea, Republic of,* [2]*Green Cross Reference Laboratory, Yongin, Korea, Republic of.*

High-risk types of human papillomavirus (HR-HPV) is an important cause of cervical cancers. Current cervical cancer screening guidelines suggest that early detection of HPV-16 and HPV-18 may prevent the progression of cervical cancer. We evaluated and compared three HPV DNA tests, Roche Cobas HPV, RFMP HPV Papillo Typer and Hybrid Capture 2 (HC2). Roche Cobas HPV specifically identifies HPV-16 and HPV-18 with concurrently detecting other 12 HR-HPV types and RFMP identifies 74 HPV genotypes. A total of 861 cervical swab specimens from women over 30 years of age were classified into groups of high grade squamous intraepithelial lesion (HSIL) and non-HSIL according to cervical cytology results and analyzed by three assays. The results of direct sequencing or Linear array HPV genotyping test were considered true when three assays presented discrepancies. Concordance rates between Roche Cobas HPV *vs.* RFMP, RFMP *vs.* HC2, and HC2 *vs.* Roche Cobas HPV were 94.5% (814/861), 94.2% (811/861), and 95.8% (825/861), respectively. In 71 specimens with discrepant results, concordance rates between each assay and direct sequencing or Linear array were as follows: Roche Cobas HPV, 35.2%; RFMP, 93.0%; HC2, 25.4%. Clinical sensitivities and specificities for detecting HSIL were 80.3% and 95.8% with Roche Cobas HPV, 83.6% and 95.1% with RFMP and 90.2% and 94.8% with HC2. In conclusion, Roche Cobas HPV, RFMP and HC2 showed high agreement rates each other. Although Roche Cobas HPV and RFMP showed lower clinical sensitivity in detecting HSIL compared to HC2, they would be clinically useful since both provide HPV genotypes.

J14.16
Absolute quantification of transcripts in single leukaemic cells

E. Ghayoor Karimiani;
Mashhad University of Medical Sciences, Mashhad, Islamic Republic of Iran.

We and others have shown that the BCR-ABL mRNA expression is higher in the CD34+ cellular population, representing an enrichment of BCR-ABL+ cells in the progenitor fraction or a higher expression of the fusion gene. Primitive progenitor BCR-ABL+ cells isolated from CML patients will maintain their functionality after Imatinib treatment. Therefore, CML progenitor cells appear to be more insensitive to Imatinib than more mature cells suggesting that TKIs are unable to inhibit the function of the primitive leukaemic stem cells. During the assessment of minimal residual disease (MRD) by RT-qPCR, some of the early leukaemic progenitors of malignant cells with significantly higher levels of BCR-ABL transcript cannot be differentiated from other groups of homogeneous cells. This fact may cause a failure to perform personalised monitoring of MRD; while the sensitivity and reliability of the

assay are directly affected by bulk measurements where the number of normal cells that do not express the target genes. In this study, K562 cells were grown in suspension and a small fraction of these cells was noted to have adhered to the plastic dish after the removal of the media. These adherent cells (K562/Adh) were passaged serially. The FACS separated individual K562 cells into PCR wells with a fixed amount of qPCR buffer. Optimized amplification RT-qPCR was performed on single cells to reveal the nature and significance of cellular heterogeneity with the measurement of BCR-ABL levels in K562 cells was investigated.

J14.17
Novel methods for phenotyping mice pups during the first few hours after birth

E. Durand;
PhenoPups SAS, Evry, France.

Mice are the preferred species to study the biological function of mammalian genes through mutation but there are still specific challenges to solve in order to characterize their phenotype. As early lethality is common in genetically engineered mice, an important proportion of homozygous mutant mice cannot be phenotyped. When the corresponding heterozygous mice have no phenotype, the effects of this mutation remain unknown. Unfortunately, studies in newborn mice face major difficulties due to the small size of the pups and their sensory and motor immaturity. In order to gain access to the early post-natal phenotype, we developed three dedicated non-invasive devices, suitable for high-throughput screening: - PhysioPups (patented device) is used to assess vital functions: breathing patterns, electrocardiogram (ECG), body temperature, gross body mov ements, and ultrasonic vocalizations. Four animals can be tested simultaneously under controlled conditions of temperature and gas composition. - NeoGAIT is used to assess gait ontogeny. It uses infrared detection of the animal's contact patterns with the floor and custom image analysis software. - MemoryPups is used to assess memory and associative learning abilities. The tests are based on olfaction and thermotactile sensitivity, the only sensory functions operating at birth. This platform has no equivalent worldwide. It allows phenotyping mice pups from the first few hours after birth until weaning. It is currently used to characterize genetically engineered mice, including models of genetic diseases (autism, Prader-Willi, Ondine's syndrome) and to study the toxicity of anti-infectious drugs used in neonates (eg. European TINN project).

J14.18
A comparative study of MPCR analysis for deletion detection within DMD gene using different sets of primers

V. Scurtu, *V. Sacara;*
Institute of Mother and Child, Chisinau, Moldova, Republic of.

Background: Duchenne/Becker muscular dystrophy is X-linked recessive, progressive muscle-wasting disease affecting 1 in 3500 boys, caused by mutations within DMD gene. The patients exhibit pathological deletions in approximately 60% of cases. Since 1988 existing reactions for the multiplex PCR amplification of exons in the dystrophin gene have been modified. We aimed to verify the reliability of the multiplex PCR amplification using two different primers sets in order to define the borders of the deletions. Methods: The patients were diagnosed using standard clinical diagnostic criteria including: EMG and serum creatine kinase (CK) level. Three MPCR assays were performed on 80 DNA samples of patients to amplify 24 DMD gene exons using combined sets of primers designed by Chamberlain and Ashton. Results: All the patients showed a raised serum CK level than normal. MPCR analysis in 4 patients showed deletions of 45 and 48 exons using Chamberlain's primers set. Deletions weren't confirmed by Ashton analysis. The length of 45 and 48 exons amplified using Chamberlain's primers are more extended than Ashton's primers and overlap them. Conclusions: A comparative study of 4 patients showed discrepancies between the results obtained by using primers designed by Chamberlain and Ashton for 45 and 48 exons. MPCR analysis is a reliable method for deletion detection but a noncontiguous and single-exon deletions within DMD gene should be interpreted with caution and confirmed with another technique or using alternative sets of primers to exactly mapping the end point of deletions.

J14.19
NGS targeted resequencing of multiple genes for rare diseases in Bulgaria

R. V. Vazharova[1,2], *S. Ivanov*[2], *L. Balabansky*[2], *D. Serbezov*[2], *M. Malinov*[2], *N. Yaneva*[3], *S. Bichev*[3], *A. Savov*[3], *D. Toncheva*[4,2];
[1]*Department of Biology, Medical genetics and Microbiology, Faculty of Medicine, Sofia University „St. Kliment Ohridski", Sofia, Bulgaria,* [2]*Hospital „Malinov", Genomic laboratory, Sofia, Bulgaria,* [3]*National Genetic laboratory, UHOG „Maichin dom", Sofia, Bulgaria,* [4]*Department of Medical Genetics, Medical University of Sofia, Sofia, Bulgaria.*

During last years the next generation sequencing (NGS) technologies have significantly enhanced the discovery of causative genetic alterations and identification of mutations in rare diseases. The diseases with locus heterogeneity are still a challenge in clinical practice and sometimes patients remain for years with unknown genetic status.
In order to accelerate the establishment of proper genetic status of patients with rare diseases we analyzed exons of 552 genes underlying rare monogenic recessive disorders using TruSight Inherited Disease Sequencing Panel (Illumina). As model we used diseases with clear unequivocal phenotype (CF, DMD) and included in the study patients in whom routine DNA testing was insufficient to obtain genetic diagnosis. The study included 4 patients: 2 with CF with identified only one mutation, 1 with DMD without deletions/duplications in DMD gene and 1 with polymalformative syndrome including Dandy-Walker anomaly, AVSD, hypoplastic genitalia, MR and facial dysmorphism. NGS revealed CFTR: p.Gly1349Asp as second pathogenic mutation in one patient with CF and DMD: p.His2921Arg in patient with DMD. Both mutations are reported for first time in patients of Bulgarian descent. In one patient with CF NGS revealed only one causative mutation and MLPA showed a large deletion encompassing exons 18-20 of CFTR gene. A homozygous in-frame deletion p.Ser372del in MKS1 gene was found in the patient with polymalformative syndrome.
The NGS technology has the potential quickly and cost-effectively to point out disease causing mutations in patients with rare genetic diseases and gives us the opportunity for better genetic counseling and prophylaxis in affected families.

J14.20
Non-invasive prenatal testing of chromosomal aneuploidies by massively parallel sequencing of circulating free DNA

E. Contini[1], *M. Benelli*[1], *C. Pescucci*[1], *G. Marseglia*[1], *F. Gerundino*[1], *C. Giachini*[1], *F. Sbernini*[1], *F. Marin*[1], *S. Frusconi*[1], *E. Periti*[2], *L. Rosignoli*[2], *E. Pelo*[1], *F. Torricelli*[1];
[1]*SOD Diagnostica genetica, AOU Careggi, Florence, Italy,* [2]*Centro Unico Diagnosi Prenatale, Ospedale Palagi, Florence, Italy.*

Background: cell free fetal DNA (cffDNA) circulates in low concentration in maternal plasma and is a source of genetic material for safe non-invasive prenatal testing (NIPT) by parallel massive sequencing techniques. Aims: validation of a protocol for NIPT and optimization of a method for fetal fraction detection. Methods: low coverage whole genome sequencing was performed on plasma DNA samples from 175 pregnant women (8 - 10 weeks of gestation) for the detection of aneuplodies. Digital PCR assay was used for fetal fraction detection by quantification of RASSF1A, TERT and beta-actin genes. Sequenced reads were mapped against the human reference genome hg19 by BWA. Duplicated reads were removed and unique mapped reads were counted (mapping quality > 20 was required). Read count for each chromosome was normalized based on library size and GC content. Chromosomal aneuploidies were detected by using a z-score statistics. Reference dataset was built by including euploid samples selected on the basis of the correlation between z-scores and coverage in 5 aneuploid cases. This allowed us to estimate the best trade-off between coverage (> 0.4) and sample size (= 140). In the male fetuses, fetal fraction was detected by measuring normalized read count on chromosome Y. Results: sequencing of 175 euploid samples allowed us to set up the experimental protocol and to create the reference dataset. The performance of the dataset was assessed by blinded analysis of twenty pregnancies. Five trisomy 21 and fifteen euploid fetuses were correctly identified by our analysis.

J14.21
FISH and methylation studies in Egyptian children with Prader-Willi syndrome

A. A. Khedr[1], *S. R. Ismail*[2], *A. M. Mohamed*[3], *N. A. Mohamed*[3], *N. A. Nazmy*[4];
[1]*National Research Center Cairo, Dokki, Egypt,* [2]*Medical Research Institute,Alexandria university, Alexandria, Egypt,* [3]*national research center cairo, dokki, Egypt,* [4]*Medical Research Institute, Alexandria University, Alexandria, Egypt.*

Prader -Willi syndrome (PWS) is a complex, multisystem disorders of genetic origin due to lack of paternally active genes on critical area on chromosome (15) (q11-13) . PWS is almost always sporadic and is the most common syndromal cause of human obesity with an estimated incidence of 1 in 25,000 Material and methods:Conventional G-banding, FISH using an SNRPN Prader-Willi /Angelman chromosome region probe by Appligene-Oncor and methylation specific-PCR studies were conducted on 23 patients (13 males and 10 females age ranged from 6.5 months to 20 years selected according to suggested criteria proposed by Gunay- Aygun et al, 2001. Aim: This study aims at confirming/ excluding PWS in clinically suspected patients through a sensible strategy of investigations on the cytogenetic level, FISH technique and molecular level using DNA methylation tests for phenotype/ genotype correlation, early diagnosis and proper counseling. Results: On the cytogenetic level, 10 out of 23 cases showed deletion of 15q (11-

13). FISH confirmed the deletion in in 6 cases with mosaicism in one case (50%); detected deletion in 4 cases with normal cytogenetic findings, and excluded deletion in 13 cases. Molecular methylation studies conducted on 17 patients (6 cases spared upon request) confirmed diagnosis in 10 cases detected 1 new case and excluded PWS in 6 cases. In conclusion: we reinforce the necessity of analysis of DNA methylation within the chromosome 15q 11-13 region, which is an important tool for the correct diagnosis and for detecting etiology among children presenting with neonatal hypotonia, mental deficiency and obesity.

J14.22
Procalcitonin Gene Expression is a Real Biomarker of Aging Process

M. A. Soylemez;
Marmara Medical School, Istanbul, Turkey.

Objective: Inflammation is the single greatest precipitator of aging and age-related diseases such as, diabetes, heart disease, alzheimer, arthritis. Inflammation, which takes place on a cellular level, is triggered by a wide variety of factors such as the oxidative stress, hormonal changes and eating a pro-inflammatory diet (Hyperglycemic diet). The procalcitonin gene has promoter sites for NF-kappaβ and AP-1, factors induced under inflammatory conditions. Hyperglycemia is associated with oxidative stress and elevation of advanced glycation end products (AGEs). AGE's interacts the receptor for advanced glycation end products (RAGE) and, RAGE activation is caused by elevation of transcriptional factors NF- kappaβ and AP-1. These factors induce procalcitonin gene expression. The aim of this study was to determine whether or not procalcitonin is a specific marker of aging process. **Research Design and Methods:** 14 type II Diabetes Mellitus (DM) patients within hyperglycemia were studied along with age and sex matched with normal normoglycemic subjects(NNS). Blood samples were taken for measurements of procalcitoninin and analized with kryptor analizator. Procalcitonin levels were elevated in DM patients within hyperglycemia when compared with NNS. There was a statistically significant difference in serum procalcitonin of DM patients within hyperglycemia versus NNS($P<0.01$). **Conclusion:** Our study revealed a raise in serum procalcitonin in DM patients within hyperglycemia. Hyperglycemia associated with increased circulating concentrations of procalcitonin may be a mechanism which explains many of the clinical and biochemical features of aging process. Procalcitonin is a new aging biomarker which can help for discover new drugs to combat aging.

J14.23
Targeted DNA sequencing analysis reveals heterogeneity of single-cell somatic mutations

P. Chen, *L. S. Weaver, D. Wang, K. Szulwach, J. Wang, L. Xi, D. Ruff, R. Ramakrishnan, M. A. Unger, R. C. Jones;*
Fluidigm Corporation, South San Francisco, CA, United States.

Research linking genetic variants to disease has been challenging in the past, because traditional approaches are commonly limited to detecting high frequency variants within a bulk sample. This approach assumes that the sample is comprised of identical cells with the same variants. However, in the case of cancer genomics, somatic mutations accumulate over time and a single tumor can give rise to multiple sub-clones. Employing a multi-cell based DNA sequencing strategy to heterogeneous samples can mask low abundant variants and make it difficult to distinguish them from sequencing errors. Sequencing the genome of individual cells, however, circumvents the problem and provides deeper insight into the molecular heterogeneity within the cell population. The existing single cell whole genome amplification methods and library preparation are costly, laborious, and subject to handling errors. We have developed a method for whole genome amplification (WGA) of single cells using an integrated microfluidic system to automate the capture, lysis, and DNA amplification from up to 96 individual cells in a single workflow. Amplified products harvested from the system are ready for downstream library preparation and targeted, whole exome or whole genome sequencing. Whole genome sequencing results of a few cells indicate improvement in genome coverage, uniformity and GC bias over state-of-the-art WGA methods. We also demonstrate targeted sequencing performance of over 100 single cells compared to bulk unamplified genomic DNA, and show single nucleotide variant distributions in normal/disease-paired breast cancer cells.

J14.24
Interpretation of sex chromosome abnormalities by SNP-array analysis

D. Svaneby, *A. Bojesen, J. Graakjaer;*
Department of Clinical Genetics, Vejle Hospital, Vejle, Denmark.

Sex chromosome abnormalities represent a special challenge in the analysis of SNP-array data. Data analysis is complicated by the complex structure of the sex chromosomes (PAR regions, interfering homologous regions and only one of each sex chromosome in males). At present, no guidelines can help interpretate the analysis of sex chromosome abnormalities identified by SNP array.
In this study we analysed SNP-array data from 25 samples with known sex chromosome abnormalities.
We present the results from this study and present a general guideline for SNP-array interpretation of sex chromosomes. Hopefully this will aid others in the interpretation of sex chromosome abnormalities identified by SNP-array.

J14.26
NextGen Sequencing: a tool for deciphering the BRCA1/2 and TNBC relationship

R. M. Petric[1,2], *L. Pop*[1], *I. Berindan Neagoe*[1,3];
[1]*Iuliu Hatieganu University of Medicine and Pharmacy, Cluj Napoca, Romania,* [2]*Babes Bolyai University, Cluj Napoca, Romania,* [3]*The Oncology Institute „Prof. Dr. I. Chiricuta", Cluj Napoca, Romania.*

Although during recent years science and technology have generated a great deal of progress in medicine, breast cancer still is the most common malignancy and the leading cause of death by cancer in women. Triple negative breast cancer (TNBC), characterized by the absence of Estrogen and Progesterone receptors and Her2/neu, affects 15-20% of breast cancer patients, has a more aggressive phenotype and occurs at younger ages. Because of its therapeutic limitations, TNBC needs to be investigated in more detail with the help of new technologies. This is why our study focuses on exploring the mutation status of BRCA1/2 genes involved in hereditary breast cancer, and with known mutations in TNBC. This retrospective study on 30 TNBC patients who underwent surgery at The Oncology Institute "Prof. Dr. I. Chiricuta" Cluj-Napoca was conducted with the help of the next generation sequencing platform Ion Torrent PGM. After sequencing the DNA extracted from FFPE tissue, we observed that 20 of the 30 patients presented germline BRCA1/2 mutations, of which seven in BRCA2, 10 in BRCA1, and three in both genes. We identified two mutations that are frequent in patients of European descent with hereditary breast cancers, two that are similar to mutations identified in families of Swedish origin, and several other new mutations. This is the first study that investigates BRCA1/2 mutations in TNBC patients in Romania, and proves that NextGen Sequencing is a competitive and cost-effective BRCA screening method especially in low-income countries where patients cannot afford early breast cancer diagnosis.

Comparison of variant calling from whole exome and transcriptome sequencing using CLC Cancer Research Workbench

A. Arens, *A. Joecker, A. K. Hein, P. Dekker, U. Appelt, A. Joecker, S. Mønsted, B. Knudsen, N. Thomson, R. Lussier, C. Boysen, R. Forsberg;*
CLC bio - A QIAGEN company, Aarhus, Denmark.

Some of the major reasons for high throughput sequencing being more and more frequently applied in cancer research and cancer diagnostics today, are the significant improvements in accuracy, throughput, and speed. In the past, sequencing was clearly the bottleneck but the most time consuming step currently is the data analysis - more precisely the identification and characterization of variants in tumor samples. Whole exome and genome sequencing protocols are commonly used and allow for the identification of SNPs and InDels in protein coding regions. However, both methods fail to show which allele variants are actually expressed in the tumor tissue. Contrariwise transcriptome sequencing (RNA-seq) reveals the expressed alleles and can in addition provide insight into the transcript expression levels, expressed isoforms, and instances of fusion transcripts. Here, we illustrate the benefits of combining the analysis of whole exome sequencing and RNA-seq using CLC Cancer Research Workbench. This software suite includes algorithms for quality control, read mapping, variant calling, and RNA-seq analysis, as well as numerous tools for the comparison and annotation of variants. The analysis is carried out with ready-to-use workflows and the results are visualized in a track based genome browser. In the present work differences found between the variants identified in exome and in RNA-seq data from uveal melanoma samples will be highlighted.

J14.28
Molecular-genetic analysis of predisposition to ovarian cancer among women of Uzbekistan

S. Nurmatova[1], *B. Adylov*[1], *S. Turdikulova*[1], *D. Nabiyeva*[2], *M. Isamuhamedova*[2];
[1]*Educational-Experimental Centre for High Technologies in Tashkent, Tashkent, Uzbekistan,* [2]*Tashkent Institute of Postgraduate Medical Education, Tashkent Regional Oncological Dispenser, Tashkent, Uzbekistan.*

Ovarian cancer is the 9th most common cancer, with an estimated 22240 new

cases in 2013. Most women aren't diagnosed until the cancer has spread, leading to a poor five-year survival rate of 43%. Only 10-15% of malignant epithelial ovarian tumors are genetically determined.
The most significant genes associated with ovarian cancer include BRCA1, BRCA2, CHEK2. These genes produce tumor suppressor proteins which help repair damaged DNA and play a role in ensuring the stability of the cell's genetic material. When either of these genes is mutated, DNA damage may not be repaired properly. As a result, cells are more likely to develop additional genetic alterations that can lead to cancer.
This study aimed to investigate the contribution mutations of BRCA1, BRCA2 and CHEK2 genes to ovarian cancer cases in Uzbekistan.
66 patients with ovarian cancer were included in this study. By means of real-time allele-specific PCR we analyzed DNA samples of above mentioned group for the presence of 5382insC mutation in BRCA1, 6174delT - in BRCA2 and IVS2+1G>A - in CHEK2. 6 unrelated samples (9.1%) were found to be positive for the heterozygous 5382insC mutation representing a possible founder mutation in the Uzbek population. We didn't find 6174delT and IVS2+1G>A mutations. The presented data confirm contribution of BRCA1 5382insC mutation for ovarian cancer development in Uzbek people and taking into account a high disease penetrance in carriers of BRCA1 mutation, it seems reasonable to suggest inclusion of 5382insC mutation test in screening programs for breast cancer prevention in Uzbekistan.

J14.29
Multiple genes of small effect and their interactions with environmental factors explain variation in personality traits

A. Kazantseva[1], *Y. Kutlumbetova*[2], *S. Malykh*[3], *R. Kanzafarova*[2], *T. Traks*[4], *S. Koks*[5], *M. Lobaskova*[6], *E. Khusnutdinova*[1,2];
[1]Institute of Biochemistry and Genetics Ufa Scientific Center of Russian Academy of Sciencies, Ufa, Russian Federation, [2]Bashkir State University, Ufa, Russian Federation, [3]Psychological Institute, Russian Academy of Education, Moscow, Russian Federation, [4]Department of Physiology, University of Tartu, Tartu, Estonia, [5]Department of Pathophysiology, University of Tartu, Tartu, Estonia, [6]Udmurt State University, Izhevsk, Russian Federation.

Personality traits are thought to be endophenotypes (high Harm Avoidance (HA), low Self-directedness (SD)) for most psychiatric disorders and predictors of life outcomes. Genetic influences on personality traits are attributable to many genes of small effect and are modulated by environmental factors.
We aimed to examine gene-environment (GxE) and gene-gene (GxG) interaction models based on neurotrophic factor (NGF, BDNF, NTRK2, NTRK3), serotoninergic (SLC6A4, TPH1) and dopaminergic system (DRD2, SLC6A3) gene polymorphisms contributing into personality traits variation in healthy individuals.
In total, 1018 healthy individuals (68% women) from Russia (mean age±SD: 19.81±2.65 years) without any history of psychopathologies were subjected to personality traits assessment via TCI-125 (Cloninger et al., 1993). Involved individuals are Caucasians from Russian (N=409), Tatar (N=290), Bashkir (N=130) and Udmurt populations (N=189). Socio-demographic data including gender, ethnicity, order and season of birth (SOB), place of residence, level of income, childhood maltreatment were obtained. Genotyping of 70 SNPs was performed with SNPlexTM platform (Applied Biosystems). Statistical analysis was conducted with PLINK v.1.07 corrected via FDR-procedure for multiple comparisons.
The present study revealed GxE models demonstrated BDNF Val66Met*SOB (PFDR=0.036), BDNF rs1519479*ethnicity (PFDR=0.042) and 5-HTTLPR*SOB (PFDR=0.05) interactions affected HA. Moreover, variations in SD were caused by interactions between BDNF Val66Met (PFDR=0.048), BDNF rs2030323 (PFDR=0.035) and ethnicity. Accordingly, genetic testing for BDNF and 5-HTT gene polymorphisms assuming gender, ethnicity and SOB confounding is necessary for psychopathologies prevention at early stages.
This work was supported by Russian foundation for humanities grant 13-06-00583a.

J14.30
Validation of a CE marked tool (SEQPRO LIPO RS) based on Next Generation Sequencing for diagnosis of Familial Hypercholesterolemia

M. Stef[1], *L. Palacios*[1], *D. Arteta*[1], *J. Nieves*[2], *B. Sanz*[2], *N. Aizpuru*[1], *A. Martinez*[1], *D. Tejedor*[1];
[1]Progenika Biopharma - a Grifols company, Derio, Spain, [2]Deustotech Computing, Bilbao, Spain.

Familial Hypercholesterolemia (FH) is an autosomal dominant disorder caused by mutations in the LDLR, APOB and PCSK9 genes. A recessive form is caused by mutations in the LDLRAP1 gene. More than 1500 mutations have been described worldwide, with a mutation spectrum varying depending on the countries. In order to screen any population, we decided to develop a kit (SEQPRO LIPO RS) based on Next Generation Sequencing (NGS). In 2013 we launched a NGS Roche 454 based product with CE mark. We describe here part of the validation of this product in order to obtain the CE mark.
Around 300 patients previously sequenced by Sanger sequencing were used to determine the analytical specificity and sensitivity of the method for point mutation (substitutions and indels), while more than 500 patients previously screened by MLPA were used to verify the ability of the method to detect Copy Number Variations (CNVs) in the LDLR gene.
Reliable variant detection for up to 20 FH patients per run was achieved, with accuracy, specificity and sensitivity similar to Sanger sequencing and MLPA. This algorithm has been fully integrated in software that names the variants according to the HGVS nomenclature, and performs a search in our mutation database, while providing the variants' pathogenicity status.
The SEQPRO LIPO RS tool is feasible for FH detection. Moreover, it serves as a proof of principle for the development of genetic diagnostic tests for any other disease caused by both point mutations and CNVs, cardiovascular or not.

J14.31
DNA microchips for the diagnostics of monogenic hereditary disease in Yakuts

M. Turdieva, *N. Maksimova;*
North Eastern Federal University, Yakutk, Russian Federation.

Yakuts belongs to the monogenic populations with ethnicity specific forms of pathology, with the frequency significantly more higher than in other populations in the world.The genetics research on high frequency diseases in the Republic of Sakha showed the presence of major mutations in the genes specific and often found among people of Yakut origin.One of the major problems for now is to do a heterozygosity screening for found mutations and to organize preventive care program. Until now there are 20 hereditary diseases can be diagnosed in the Republic of Sakha by routine methods such as PCR and restriction.Unfortunately these methods are very time consuming. Alternative method that has been emerging rapidly is a DNA microarray.This main advantage of this method is a possibility to screen thousands of mutations at once making the diagnostic simple and fast. In collaboration with our colleagues from Busan National University(South Korea) there was established a testing system based on DNA microarray for the diagnostic of five high frequency diseases: Enzymopathic methemoglobinemia (OMIM 250800, Pro269Leu mutation in DIA1 gene), 3 M syndrome(OMIM 273750,4582insT in Cul7 gene), SOPH syndrome (OMIM 614800, G5741 A in NAG gene),Nonsyndromic hearing loss 1A type (OMIM220290, IVS1+1G>A in GJB2 gene), Tyrosinemia type1 (OMIM 276700 1090G>C mutation in FAH gene). Since the microarray is well known and rapidly developing, the heterozygocity screening itself using the microarray rather than then microarray establishment have the significance. It will allow reducing the frequency of these diseases in the Republic and the risk of diseased child birth.

Pitfalls in molecular genetic testing of m.8344 A>G (MERRF) mutation

K. Pentelenyi, *V. Remenyi, V. Harsfalvi, Z. Balogh, M. Molnar;*
Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary.

For identification the common mitochondrial 8344 A>G mutation resulting in MERRF (myoclonus epilepsy with ragged red fibers) syndrome a worldwide used molecular diagnostic method is a PCR-RFLP method, using the BanII restriction enzyme. So far it was not a matter of common knowledge, that it is not a trusty technique.
Methods. Mitochondrial 8344 A>G mutation was investigated by PCR-RFLP using BanII restriction enzyme on DNA samples (n=1073). In cases with abnormal restriction pattern mitochondrial tRNA lysin gene region (nt 8105-8536) was sequenced bidirectionally (n=14).
Results. PCR and BanII RFLP analysis detected abnormal restriction pattern indicating m.8344 A>G mutation in 14 cases. Sequence analysis of tRNA lysin gene verified the presence of the m.8344 A>G substitution only in 6 cases. Unexpectedly the m.8347 A>C substitution was present in 8 cases with 9-bp triplication (8272-8280) in 3 samples. The gelphoto showed nearly the same pattern in cases with m.8347 A>C mutation or 9-bp triplication. The BanII cleaves samples with m.8347 A>C and m.8344 A>G substitutions on the same way. The 8347 A>C mutation was prevoiusly not described as pathogenic alteration, however it is a highly conserved nucelotid and has similar effect on the tRNALys as the 8344 A>G mutation. The 9-bp triplication is a polymorphism, its anthropological interest is controversial.
Conclusion. The PCR-RFLP method using BanII restriction enzyme is not a solid method for detecting m.8344 A>G mutation. It may result in pseudo positivity. We suggest to use it only as a screening method, which must be validated always by Sanger sequencing.

J15.01

Brain-derived neurotrophic factor Val66Met polymorphism and cardiac stress reactivity

A. A. Chis[1], *L. G. Crisan*[2], *B. Blaj*[2], *R. Vulturar*[1], *A. C. Miu*[2];
[1]*University of Medicine and Pharmacy, Cluj-Napoca, Romania,* [2]*Cognitive Neuroscience Laboratory, Department of Psychology, Babes-Bolyai University, Cluj-Napoca, Romania.*

Twin studies indicated that heart rate variability (HRV) and particularly its high frequency (HF) spectral component show significant heritability, and their genetic variance is amplified by mental stress. This genetic association study investigated the influence of the brain-derived neurotrophic factor (BDNF) Val66Met polymorphism and the triallelic serotonin transporter gene promoter (5-HTTLPR) polymorphism on state anxiety and time and frequency measures of HRV reactivity to mental stress. In comparison to BDNF Val homozygotes, the Met allele carriers showed larger cardiovagal withdrawal during stress. The triallelic 5-HTTLPR did not significantly influence any of the psychophysiological measures. Although BDNF Val66Met only explained a small part of the variance of cardiovagal withdrawal during stress, this polymorphism may be part of a complex genetic pathway underlying the comorbidity of autonomic dysfunctions and emotional vulnerability.

J15.02

Heterogeneity of Tumors - comprehensive biomarker-panels to decipher cancer

R. Loewe;
GeneWake GmbH, Neuried, Germany.

Personalized cancer treatment increasingly enters into clinical routine. Due to the fact that each tumor is individual regarding its genomic structure, the screening for these changes on DNA and RNA level in tumor tissue is becoming increasingly crucial for an individually effective therapy. Drugs like EGFR-Inhibitors in particular and tyrosine kinase inhibitors in general have proven to benefit greatly from companion diagnostics. Despite this fact, however, expectations of clinical impact on the well being of patients were bigger than what was truly observed. Vast improvements were merely seen in a fraction of treated individuals, making a general assumption less than relevant. Even in patients exhibiting great initial response subsequent relapse was quick to follow. Hence a broader approach of analyzing comprehensive biomarker-panels by various techniques should be taken into consideration to account also for heterogeneity and predict maybe the next phase of tumor expansion. After a short overview of high throughput techniques like next generation sequencing and its combination with routine methods like pathological examination, micro-dissection and purification of DNA/RNA, mutation analyses via high resolution melting (HRM), gene expression profiling and epigenetic analysis, the combination of these multiple approaches for personalized cancer therapy are highlighted. The clinical use of this novel and comprehensive approach for an improved diagnostics and thus more effective treatment is demonstrated on the example of prostate and colorectal cancer.

J15.03

The investigation of *BRCA1* and *BRCA2* expression in colorectal cancer

V. P. Shubin, *Y. A. Shelygin, A. S. Tsukanov, S. I. Achkasov, O. I. Sushkov, S. A. Frolov, N. I. Pospekhova;*
State Scientific Center of Coloproctology, Moscow, Russian Federation.

BRCA1 and *BRCA2* genes are suppressor of malignant tumor and predictive markers sensitivity to platinum-drugs. Malignant transformation and carcinogenesis accompanied by alters the expression of tumor-suppressor genes. Loss of any of these genes expression is associated with positive response on treatment by platinum-drugs. Tumor and normal tissue samples of colon among 30 patients with colorectal cancer were investigated. High level (3 and more time) of *BRCA1* and *BRCA2* expression was found in 22/30 (70%) tumors and 24/30 (80%), respectively. As well high expression of both genes was detected in 19 tumors. The expression of *BRCA1* was not changed in 7 of 30 (23%) tumors and in one tumor was decreased in 7 times. The expression of *BRCA2* was not changed in 4 of 30 (13,3%) tumors and was decreased (in 7 times) in two tumors. The expressions of both the genes were not altered in two cases. However *BRCA1* and *BRCA2* expression was not a coordinately decreasing in neither case. We obtained information about change *BRCA1* and *BRCA2* expression in tumor for Russian patients with colorectal cancer. These data can improve the therapy for colorectal cancer patients by platinum-drugs.

The effects of hypericin on p53 and ADAMTS gene expression in MCF-7 breast cancer cell line

M. Acar[1], *Z. Ocak*[2], *K. Erdogan*[1], *E. N. Cetin*[1], *O. F. Hatipoglu*[1], *U. Uyeturk*[3], *E. Gunduz*[1], *M. Gunduz*[4];
[1]*Turgut Ozal University, Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey,* [2]*Abant Izzet Baysal University, Department of Medical Genetics, Bolu, Turkey,* [3]*Abant Izzet Baysal University, Department of Medical Oncology, Bolu, Turkey,* [4]*Turgut Ozal University, Faculty of Medicine, Department of Medical Genetics and Otolaryngology, Ankara, Turkey.*

Our objective was to determine the effects of hypericin on MCF-7 breast cancer cells, as it is known to have an anti-tumor effect on the expression and regulation of ADAMTS1, 3, 10 and the P53 gene in breast cancer cells. MFC-7 cells were cultivated and subjected separately to various doses of 1, 5 and 7.5 µg/mL hypericin. After 24 h, RNA was isolated and transcribed into cDNA. Expression analysis was performed by real-time RT-PCR and cell survival was determined by XTT assay. While expression of ADAMTS1 in MFC-7 cells decreased to 0.04 fold after exposure to 1 µg /mL hypericin, expression increased by 5.6- and 36-fold at 5 mg/mL and 7.5µg/mL, respectively. Furthermore, ADAMTS3 expression in MCF7 cells were increased 3.9 fold with the use of 5 µg /mL of hypericin. These concentrations of hypericin did not lead to significant changes in the expression of ADAMTS10 and the P53 gene. XTT tests have shown that hypericin concentration of 7.5 µg /mL lead to significant death of cancer cells. The increase in ADAMTS1 expression may prevent metastasis or facilitate development of an adjuvant factor with tumor-suppressive effects. Hypericin may therefore exert its anti-tumoral and apoptotic effects in MFC-7 cells via ADAMTS1 and ADAMTS3.

J15.05

Effect of Hypericin on the ADAMTS-8 and ADAMTS-9 gene expression in MCF7 breast cancer cells

Z. Ocak[1], *M. Acar*[2], *E. Gunduz*[2], *M. Gunduz*[3], *U. Uyeturk*[4], *T. Ozlu*[5];
[1]*Abant Izzet Baysal University Faculty of Medicine, Department of Medical Genetics, Bolu, Turkey,* [2]*Turgut Ozal University, Faculty of Medicine, Department of Medical Genetics, Ankara, Turkey,* [3]*Turgut Ozal University, Faculty of Medicine, Department of Medical Genetics and Otolaryngology, Ankara, Turkey,* [4]*Abant Izzet Baysal University, Department of Medical Oncology, Bolu, Turkey,* [5]*Abant Izzet Baysal University, Department of Obstetrics and Gynecology, Bolu, Turkey.*

Our aim was to investigate the effects of hypericin which is obtained from the plant Hypericum perforatum on the expression and the regulation of ADAMTS8 and ADAMTS9 genes in MCF7 breast cancer cells and on the viability of these cells. MCF7 cells were cultured and were separately exposed to 2, 10 and 50 µl/mL of hypericin. After 24 hours, RNA was isolated from these cells and converted to cDNA. The expression levels of ADAMTS8 and ADAMTS9 genes were evaluated using the real-time RT-PCR. XTT (2,3-bis-(2-methoxy-4-nitro-5-sulfophenyl)-2H-tetrazolium-5-carboxanilide, disodium salt) cell viability assay was used to determine cytotoxicity. ADAMTS9 expression in MCF7 cells were increased 1.8 and 3.6 fold with the use of 2 and 10 µl/mL of hypericin, respectively; and decreased 0.7 fold with the use of 50 µl/mL of hypericin. There was no significant change in the ADAMTS8 expression. Rapid cell death was observed in the cancer cells when hypericin was used at a dose of ≥ 50 µl/mL. The increase in ADAMTS9 expression can be a useful factor in the prevention of possible metastasis in breast cancer and for the occurrence of a tumor suppressive effect. Hypericin increases the expression of ADAMTS9, therefore, it may show its antitumoral and antiapoptotic effects by means of ADAMTS9.

Effects of tomatine in breast cancer

B. Ozmen Yelken[1], *S. Yilmaz Susluer*[1], *C. Kayabasi*[1], *T. Balci*[1], *C. Caliskan*[1], *B. Goker*[1], *Z. Mutlu*[1], *C. Biray Avci*[1], *P. Ballar Kirmizibayrak*[2], *C. Gunduz*[1];
[1]*Ege University Medical School, Department of Medical Biology, İzmir, Turkey,* [2]*Ege University, Faculty of Pharmacy, Department of Biochemistry, İzmir, Turkey.*

Metastasis in breast cancer is still a complicated issue and matrix metalloproteinase family has a significant role in metastasis showing the link between MMP members and tumor development. Tomatine is a secondary metabolite synthesized by tomatoes and has a role in natural defenses against plant fungi, viruses and bacteria. Besides, it is known to disrupt cell membranes and be a strong inhibitor of human cancer cells. In this study, it was aimed to evaluate the effect of tomatine on cytotoxicity and apoptosis on MCF-7 cell line. Firstly, IC50 dose of tomatine was measured as 7.07 µM by using xCELLigence system. Further, it was shown that tomatine induced apoptosis is 3 times greater than control cells with by Annexin V labeling on Flow Cytometry . Additionally, miRNA expression profiles of breast cancer cells were determined by qRT-PCR and 22 downregulated and 15 upregulated miRNAs were found. Active and zymogen forms of MMP-2 and MMP-9 were detected by zymography method and the activations of MMP2 and

MMP9 were decreased significantly. In conclusion, these results show the suppression of matrix metalloproteinase activity on metastasis.

J15.07

Aberrant miRNA Expression by Ellagic Acid Alters Apoptosis and Cell Cycle Regulation in Breast Cancer Cells and Breast Cancer Stem Cells

S. Yilmaz Susluer[1], *H. O. Caglar*[2], *S. Kavakli*[3], *B. Erturk*[4], *C. Gunduz*[1], *F. Ozkinay*[4], *A. Haydaroglu*[5];

[1]*Ege University Medical Faculty Department of Medical Biology, Izmir, Turkey,* [2]*Ege University, Institute of Health Science, Dept. of Stem Cell, Izmir, Turkey,* [3]*Ege University, Faculty of Agriculture, Izmir, Turkey,* [4]*Ege University Medical Faculty Department of Medical Genetics, Izmir, Turkey,* [5]*Ege University, Cancer Control Research and Application Center, Izmir, Turkey.*

Breast cancer has still been the most important subject with other cancer types. This cancer is the most common and second leading cause of death among women. It is known that various plant extracts, including ellagic acid, have anti-proliferative and pro-apoptotic effect on breast cancer cells. However, miRNAs which are associated with tumor initiation for estrogen dependent breast cancer are suppressed by ellagic acid treatment. In this study, it was aimed that ellagic acid could induce apoptosis related mechanism in breast cancer cells and this induction could be trigged by altered expression profiles of miRNAs. Cytotoxic effects of ellagic acid on MCF-7 breast cancer cells and breast cancer stem cells were examined by WST-1 reagent test. Apoptosis and cell cycle analysis were detected by flow cytometry analysis. After ellagic acid treatment, miRNA expression profiles of breast cancer stem cells were determined by RT-PCR. While ellagic acid had no any cytotoxic effect on MCF-7 breast cancer cells, cytotoxic value of ellagic acid for breast cancer stem cells was detected as 24.8 µM dose. Ellagic acid did not induce apoptosis in both cell groups and increased living cells. In the cell cycle, S arrest was observed in MCF-7 breast cancer cells as well as breast cancer stem cells. When analyzed in terms of miRNAs profiles, ellagic acid generally suppressed expression of miRNAs and expression profiles were associated to oncogenic effect. It was suggested that ellagic acid may not be chemo-preventive agent because of miRNA profiles, have oncogene effect.

Development of targets for colorectal cancer treatment on a base of small interfering RNA and functional genomics

A. Korotaeva, *A. Bavykin, A. Karpukhin;*

Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.

The significance of genes for tumor cell viability and understanding of the cell genetic features under which high apoptotic effect of gene silencing will observed - both are important in development of targets. We were searching of genes, silencing of that will increase sensitivity of colorectal cancer cells to oxaliplatin. The panel of genes was formed using of expression data bases and publications analysis. The expression gene profile was determined in dependence on the dose and the time of oxaliplatin action for two colorectal cancer cell lines: HT-29 and HCT-116 $p53^{-/-}$. The over expressed and demonstrating dose dependence under different period of incubation genes have been identified. It was interesting that the identified genes - *c-IAP2* and *Livin* - were the same for both cell lines, although the lines are different genetically. The silencing of genes was performed by small interfering RNA (siRNA). Joint silencing of the gene found has led to a substantial (70-80%) suppression of the cell viability and increase of 5 -10 times the sensitivity of cancer cells to small oxaliplatin doses (5 - 10 µM). Common for HT-29 and HCT-116 is mutation in *TP53* gene. Possibly, this feature is responsible for the similarity of response to oxaliplatin genetically different cancer cells. In conclusion, there were found the genes silencing of that by siRNA gives the possibility to reduce approximately of 10 times the standard dose of chemotherapeutic drug with reaching a high apoptotic effect on genetically different colorectal cancer cells.

The CYP2E1 gene encodes a member of the cytochrome P450 superfamily enzymes, which play a key role in the metabolism of inhaled anaesthetics as worldwide used sevoflurane. Potentially nontoxic anaesthetics are converted into simple organic compounds, inorganic fluoride and also vinyl ether, a product of sevoflurane breakdown, which may cause nephro- and hepatotoxicity. Investigations on genetic variability of CYP2E1 gene and the possibility to associate the results with clinical effect of metabolized sevoflurane provide the basis for the development of personalized anaesthesia.

The aim of this study was to establish a simple and economical method for analysis of whole coding sequence of the CYP2E1 and to determine the prevalence of sequence variations in this gene among the Polish patients under sevoflurane anaesthesia. Here we present the molecular test based on multiplex HRMA. The entire coding sequence of the CYP2E1 gene was successful amplified using 14 pairs of primers in the 7 multiplex reactions using the Rotor-GeneQ equipment [Qiagen].

We have analyzed DNA from 41 individuals. After HRMA screening, selected samples with different melting profiles, were sequenced. Among the tested samples we observed relatively high diversity of low-frequency changes. We found 5 different sequence variations, where two are novel changes: p.Gln75Leu (1.2%) and p.His226Tyr (1.2%). The frequencies of known polymorphisms (p.Gly173Ser, rs60452492 - 1.2%; p.Val179Ile, rs6413419 - 1.2%; p.Phe421Phe, rs2515641 - 9.8%) are similar to the other Caucasian populations.

Epigallocatechin gallate as inducer of cell death and apoptosis in human oral squamous carcinoma cell line

A. Irimie[1], *C. Braicu*[2], *I. Berindan-Neagoe*[3,4,5], *R. Campeanu*[1];

[1]*Faculty of Dentistry, University of Medicine and Pharmacy Iuliu Hatieganu, Cluj-Napoca, Romania,* [2]*Research Center for Functional Genomics, Biomedicine and Translational Medicine, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania,* [3]*Research Center for Functional Genomics, Biomedicine and Translational Medicine, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania, Cluj-Napoca, Romania,* [4]*Department of Functional Genomics and Experimental Pathology, Institute of Oncology "Prof. Dr. I Chiricuta",, Cluj-Napoca, Romania,* [5]*Department of Immunology, Faculty of Medicine, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania.*

The antitumor effects of the green tea compound epigallocatechin-3-gallate (EGCG) have not been studied in detail previously in oral squamous cell carcinoma cells. Expression of the proapoptotic protein (p53) occurs frequently in oral squamous carcinoma as being overexpressed as mutant or oncogene or knockdown as suppressor gene, which is an adverse prognostic factor. Therefore, we examined in detail the molecular effects of EGCG on focusing on the apoptosis signaling pathway, in SSC-4 cell line. Human oral squamous cell carcinoma is a form of cancer that presents a poor prognosis, therefore is an urgent need to determine the molecular mechanisms involved in tumor cell survival and invasion. EGCG is a natural phytochemical previously indicated as chemopreventive and chemotherapeutic agent in multiple cancer types. In the case of treatment with low doses of EGCG, we observed increased apoptosis as and reduced proliferation and invasion as displays the xCELLigence data on SSC-4 oral squamous carcinoma cells. This may be due to the inhibition of pro-survival genes and the activation of cell death mechanisms as results from the qRT-PCR evaluation. EGCG has been shown to exhibit antitumor activities in the case of SSC-4 cell line, and this finding supports the therapeutic implication in oral squamous carcinoma.

Epigallocathechin-3-gallate and zoledronic acid induce apoptosis via down-regulation of miR-17-5p and miR-20a-5p in chronic myeloid leukemia

B. Goker[1], *Z. Mutlu*[1], *C. Caliskan*[1], *C. Kayabasi*[1], *B. Erbaykent Tepedelen*[2], *B. Kaymaz*[1], *C. Gunduz*[1], *G. Saydam*[3], *M. Korkmaz*[4], *C. Biray Avci*[1];

[1]*Department of Medical Biology, School of Medicine, Ege University, Izmir, Turkey,* [2]*Department of Molecular Biology and Genetics, Faculty Of Science And Letters, Avrasya University, Trabzon, Turkey,* [3]*Department of Hematology, School of Medicine, Ege University, Izmir, Turkey,* [4]*Department of Medical Biology, School of Medicine, Celal Bayar University, Manisa, Turkey.*

Chronic myeloid leukemia (CML) is a clonal disorder of hematopoietic stem cells. Epigallocathecin-3-gallate (EGCG) is a major flavonoid of green tea. Zoledronic acid (ZA) is a nitrogen-containing bisphosphonate. MicroRNAs (miRNAs) are small, single strand, non-coding RNA molecules that are responsible for post-translational gene regulation. The aim of this study is determine expression changes of miRNAs related with leukemogenesis with the treatment of EGCG and also define cytotoxic and apoptotic effects of EGCG in K562 human CML cell line. The cytotoxic effects of EGCG on K562 cells were determined in time and dose dependent manner. Total RNA, including miRNAs, was isolated from K562 cells treated with EGCG and ZA 24h and untreated cells as control group. Reverse transcription procedure was performed for cDNA synthesis. Apoptosis assays were performed by using ApoDIRECT Assay. miRNA expressions were showed by RT-qPCR. Expression results were analyzed by using miScript miRNA PCR Array Data Analysis. IC50 value of EGCG and ZA were determined as 50, 60µM, respectively. EGCG

and ZA induced apoptosis 10.9, 2.3 fold and down-regulated miR-17-5p and miR-20a-5p 2.5758, 20.3332 fold according to the control cells, respectively. Up-regulation of miR17-92 cluster, the best defined oncomir group, was associated with a lot of cancer types. Our findings showed that treatment of EGCG and ZA triggered down-regulation of miR-17-5p and miR-20a-5p expression levels which are member of miR17-92 oncomir cluster in K562 CML cells. These novel findings can be valued by exploring the targets of these aberrated oncomirs in leukemia progression.

J15.12

The Effect of Fluoride Agents on the Expression Levels of Pro and Anti-apoptotic Genes in Human Gingival Fibroblasts

B. Kocanali[1], C. Kayabasi[2], C. Gunduz[2], **D. Cogulu**[1];
[1]Ege University School of Dentistry, Department of Pedodontics, Izmir, Turkey, [2]Ege University School of Medicine Department of Medical Biology, Izmir, Turkey.

Fluoride is widely used to prevent dental caries in dentistry. It is cytotoxic and produces inflammatory responses in human. The aim of this study was to investigate the effect of fluoride usage on expression levels of BCL-2, BAX, BAD, FASL, P53, CASPASE 3, CASPASE 8, CASPASE 9. Five different fluoride agents [1.23% Acidulated Phosphate Fluoride (APF) and 2% Sodium Fluoride (NaF) gels, 1% Titanium Tetrafluoride (TiF4) and 38% Silver Diamine Fluoride (SDF) solutions and Duraphat Fluoride Varnish containing %5 NaF] were used in human gingival fibroblast cell lines which were obtained from healthy individuals. Gene expressions were analyzed by using real time RT-PCR. No significant change was detected in the expression levels of those genes in NaF group. The expression levels of BAD did not significantly change in all study groups as well. The ratio of pro-apoptotic BAX to anti-apoptotic BCL-2 was greater than 1 which demonstrates that those fluoride agents cause induction of apoptosis. In conclusion we suggest to protect the soft tissues during the application of the fluoride agents, to be careful for patients not to swallow the fluoride agents and to avoid unnecessary usage of fluoride in clinics..

Implication of HLA B27 and ITPA polymorphisms in treatment response of HCV infected patients

P. Gurban[1,2], *S. Spandole[1,3], G. Cardos[1], S. A. Florescu[4], C. Oprea[4], A. Kosa[4], S. Ruta[5], Collaborative Team of the HepGen Project, M. Ecobici[6], M. Voiculescu[6], G. Oprisan[7];*
[1]Personal Genetics-Medical Genetics Center, Bucharest, Romania, [2]Faculty of Biology, University of Bucharest, Bucharest, Romania, [3]Department of Genetics, University of Bucharest, Bucharest, Romania, [4]"Dr Victor Babes" Hospital of Infectious and Tropical diseases, Bucharest, Romania, [5]St. S. Nicolau Institute of Virology, Bucharest, Romania, [6]Fundeni Clinical Institute, Bucharest, Romania, [7]"Cantacuzino" National Institute of Research - Developement for Microbiology and Immunology, Bucharest, Romania.

Evolution of Hepatitis C virus (HCV) infection is influenced by interactions between viral and host factors. Inosine-Triphosphate-Pyrophosphates (ITPA) gene polymorphisms 21A>C and 94C>A may have a protective role in treatment-induced anemia. Human Leukocyte Antigen B27 (HLA-B27) alleles were associated with spontaneous viral clearance in HCV infection. The aim of our study was to identify HLA-B27 and ITPA genotypes in order to assess the implication of these two human genetic factors in treatment response of HCV patients from Romania. DNA extracted from blood samples of 100 HCV-infected patients was used for genotyping both host factors using PCR-based methods
The study led to the following results:

Patients with HLA-B27 present	ITPA 21 A>C polymorphisms			ITPA 94C>A polymorphisms		
	Homozygous 'wild type' AA	Heterozygous AC	Mutant homozygous CC	Homozygous 'wild type' CC	Heterozygous CA	Mutant homozygous AA
6	76	23	1	88	12	0
	A allele frequency	87.50% (0.875)		C allele frequency	94% (0.94)	
	C allele frequency	12.50% (0.125)		A allele frequency	6% (0.06)	

The HLA-B27 allele frequency (6%) obtained in our study is similar to corresponding data reported in literature for Caucasian populations (8%). Up to now, we found neither association between the ITPA markers and Pegylated Interferon-Ribavirin treatment induced anemia, nor between the presence of HLA-B27 allele and spontaneous viral clearance. To find any correlation between these two genetics human factors and response to Pegylated Interferon-Ribavirin therapy, more HCV-infected patients will be included in our ongoing study.

Cytogenetic monitoring of response and karyotype evolution in low-risk MDS patients treated in the leMon5-study

K. Shirneshan[1], *U. Platzbecker[2], F. Nolte[3], F. Braulke[1], J. Schanz[1], U. Germing[4], D. Haase[1], LeMon5 study group;*
[1]Department of Hematology and Oncology, Goettingen, Germany, [2]Medical Clinic I, University Hospital, Dresden, Dresden, Germany, [3]University Medicine Mannheim, Mannheim, Germany, [4]Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany.

Besides a more reliable and frequent measurement of cytogenetic response, it was our aim to find out whether lenalidomide treatment in patients with IPSS low- or intermediate I-risk MDS can foster karyotype evolution (KE) and thus increase the risk of leukemic transformation. In this study, only lower risk MDS patients with an isolated del(5q) are included.
We performed a initial screening of bone marrow aspirates by chromosome banding as well as FISH-analysis to ensure an isolated del(5q). For initial screening and frequent cytogenetic follow-up every two to three months (FISH analysis of CD34+ peripheral blood cells), we used panels of 8 to 13 FISH probes. From the initially examined 145 MDS patients, 84 could be included in the study according to the study inclusion criteria. Currently, follow-up data are available for 53 patients. A complete cytogenetic response was observed in 35 patients (66%) after a median follow-up of 15.5 months. In eleven patients (20%) the size of the del (5q) clone did not change. A cytogenetic response was observed after a median of 6 months after initiation of therapy for a median duration of 10 months. In 8 of 53 patients a true karyotype evolution occurred after a median time of 12 months. Conclusion: Our previous cytogenetic results demonstrate the rapid effect of lenalidomide on clones with del(5q) in 66% of patients. The rate of karyotype evolution was 15% and thus does not appear to be significantly increased. Gain of additional abnormalities does not always result in leukemic transformation.

J15.15

The effect of Centaurea lydia on MDM2 gene expression in human acute lymphocytic leukemia cells via transfection of miR-150 by MATRA

T. Balci, *S. Yilmaz Süslüer, Ç. Kayabaşi, B. Özmen Yelken, C. Çalişkan, B. Göker, Ç. Biray Avci, C. Gündüz;*
Medical School, Izmir, Turkey.

Acute lymphocytic leukemia (ALL) arises from the clonal proliferation of lymphoid progenitors in the bone marrow. It accounts for nearly a quarter of all childhood cancers. *Centaurea lydia* has shown anticancer activity in vitro. miRNAs are single strand, non-protein-coding small RNA molecules that have role in the regulation of gene expression and cell growth, development, apoptosis and hematopoiesis. In recent years, Magnet assisted transfection (MATRA) is one of the most effective non-viral transfection methods. We aimed to evaluate the effect of methanol extract of *C.lydia* (CLM) on apoptosis and MDM2 gene expression levels in CCRF-CEM cells (ALL) via transfection of miR-150 by MATRA.
Cytotoxic effects of CLM in CCRF-CEM cell line was detected in time and dose dependent manner with XTT assay. We determined effects of CLM, miR-150 and the combination of miR-150 with CLM (miR150-CLM) on apoptosis by using ApoDIRECT with FACS and MDM2 gene expression levels with real-time qRT-PCR (TaqMan) in the course of 48 hours. GAPDH was used as "housekeeping" gene.
IC_{50} dose of CLM is detected as 14.95 µM in CCRF-CEM. miR-150 and miR150-CLM were no apoptotic effects on CCRF-CEM cells while CLM induced 10 fold compared to control cells. MDM2 gene expression in CCRF-CEM were found as up-regulated (CLM) 2,44 fold and down-regulated (miR-150) 224,41 (miR150-CLM) 1,34 fold, respectively, according to the control cells. Down regulation of MDM2 gene following the treatment with combination and CLM apoptosis effects, provide evidence that these compounds may serve as potentially effective in leukemia cells via transfection of miR-150.

Testing of EGFR mutations, ALK and ROS1 rearrangements, and KRAS-LCS6 polymorphism in Non-Small Cell Lung Carcinoma (NSCLC) in Czech patients

D. Konvalinka[1], *J. Šímová[1,2], J. Žmolíková[1,2], S. Pitronová[1], B. Kubová[1,2], R. Měch[1], I. Urbanovská[1,2], M. Uvírová[1], A. Hopenštoková[1], M. Rafajová[1], L. Trombik[1], I. Žebráková[1], J. Mazurová[1], J. Dvořáčková[1,2];*
[1]CGB laboratoř, a.s., Ostrava, Czech Republic, [2]Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic.

Introduction: Activating EGFR mutations are associated with good response for tyrosin kinase inhibitors (TKIs) therapy (gefitinib, erlotinib). Also ALK and ROS1 rearrangements are connected with therapeutic options (crizotinib). KRAS is one of the very frequently mutated genes in many various

cancers, including NSCLC. A germline single nucleotide polymorphism (SNP; rs61764370), located in the let - 7 complementary site 6 (LCS6) within the 3`UTR of the KRAS gene, affects the binding affinity of microRNA let-7 to the KRAS mRNA and thus gene expression. It was published that KRAS-LCS6 SNP is associated with the higher risk of NSCLC development, especially in moderate smokers. **Material and methods:** DNA was isolated from biopsy and cytology specimens with verified histological diagnosis. Mutation detection was done by real-time PCR. EGFR patients with no detected mutation were tested for ALK and ROS1 gene rearrangements using the FISH method. SNP (rs61764370) analysis was performed using PCR and RFLP. **Results:** Numbers of positive/tested samples were: Activating EGFR mutations: 50/658 (7,5 %); ALK gene rearrangement: 39/405 (9,6 %); ROS1 gene rearrangement: 1/159 (0,6 %). KRAS-LCS6 NSCLC patients (G-allele): 23/160 (14,3 %) and KRAS-LCS6 healthy controls (G-allele): 61/387 (15,7 %), respectively. **Discussion and conclusions:** Activating mutations of the EGFR gene, ALK and ROS1 genes rearrangements predict possible therapeutic response to TKIs or other small molecules. Our results correlate with generally known findings. No statistically significant difference between frequency of KRAS-LCS6 G-alleles in NSCLC patients and healthy controls was found.

Particularities of ATRA therapy in pediatric patients with acute promyelocytic leukemia

I. E. Jurca- Simina[1,2], *R. M. Jurac*[2], *M. Cucuruz*[1,2], *C. Jinca*[1,2], *E. Boeriu*[1,2], *C. Popa*[1,2], *S. Arghirescu*[1,2], *M. Puiu*[1,2];
[1]*"Victor Babes" University of Medicine and Pharmacy, Timisoara, Romania,* [2]*"Louis Turcanu" Emergency Hospital for Children, Timisoara, Romania.*

Acute promyelocytic leukemia (APL) is defined by an error in myelopoiesis. Translocation (15;17) giving PML/RARA fusion gene represents the classic molecular disorder found in 92% of patients with APL. Addition of ATRA induces apoptosis and differentiation of promyelocytes acting at multiple molecular levels. We present three pediatric patients (P1, P2, P3) which were diagnosed with APL in our hospital's Oncopediatric department between 2010 and 2013. At admission, they all presented severe bleeding disorders, gingival hypertrophy, thrombocytopenia, anemia, inflammatory syndrome. Bone marrow smear and immunophenotyping established diagnose, later supported by FISH and PCR analyses that detected PML/RARA fusion gene. They received treatment according to the AML BFM 2004 protocol. P2 was allergic to Etoposide, which was withdrawn later from therapy. In later evolution, he was diagnosed with pulmonary aspergillosis presenting massive pleurisy and exudative pericarditis needing surgical drainage. Both P2 and P1 developed ATRA syndrome with complete remission under dexamethasone. Immunophenotype profiles were significantly different for the 3 patients. PCR analysis and FISH were repeatedly performed showing the absence of the fusion gene at the end of the induction therapy for P2 and P1, but not for P3 which needed a supplementary reinduction chemotherapy course. Currently, all three patients are in hematological and molecular remission, being closely monitored. The addition of ATRA to chemotherapy was efficient to our patients, who were early treated and received proper supportive care. ATRA syndrome was manageable, but it still represents a potentially serious complication that has to be confronted.

J15.18

Resveratrol regulates apoptosis by targeting mir-181 family in chronic myeloid leukemia cells

Z. Mutlu, *C. Caliskan, B. Göker, C. Kayabasi, S. Yılmaz Susluer, T. Balci, B. Ozmen Yelken, C. Gunduz, C. Bıray Avcı;*
Ege University Medical School Department of Medical Biology, Izmir, Turkey.

Chronic myeloid leukemia (CML) is a malignant disorder of the haematopoietic stem cell arisen from the reciprocal translocation between the breakpoint cluster region (BCR) gene on chromosome 22, and the Abelson (ABL) murine leukemia virus gene on chromosome 9, t(9;22)(q34;q11), resulting in the formation of Philadelphia chromosome which has constitutive tyrosine kinase activity, leading to leukemogenesis. Resveratrol is a naturally occurring phytoalexin with apoptotic and growth inhibitory effects in leukemic cells. MicroRNAs play a pivotal role in normal hematopoiesis. In this study we aimed to evaluate the cytotoxic and apoptotic effect of resveratrol in CML cells by questioning miRNA expression levels associated with CML progression. K562 cells were treated with the IC50 dose (100 µM) of resveratrol for 72 hours. Cytotoxicity analyses were conducted by WST-1 analysis. Apoptosis was evaluated by AnnexinV-enhanced green fluorescent protein (EGFP) and by ApoDIRECT In Situ DNA Fragmentation Assay Kit. The RT-qPCR is used for miRNA expressions analysis. miRNA expression levels were evaluated by using miScript miRNA PCR Array. miRNA expression levels was analyzed by using miScript miRNA PCR Array Data Analysis. Log2 transformation was applied. Significant increase in miR-181 family was observed in K562 cells treated with resveratrol according to control. Resveratrol up-regulated miR-181a, miR-181b, miR-181c and miR-181d expressions as 8.96, 6.42, 10.15, 17.19 fold according to the control cells, respectively. Resveratrol upregulated tumor suppressor miR-181 family in K562 cells through induction of apoptosis and this effect can be used for alternative detection of chronic myeloid leukemia progression.

J15.19

Zoledronic acid inhibits glioma cell growth and induces apoptosis by up-regulating miR-22 expression

C. Caliskan, *B. Göker, Z. Mutlu, C. Kayabasi, S. Yılmaz Susluer, T. Balci, B. Ozmen Yelken, C. Gunduz, C. Bıray Avcı;*
Ege University Medical School Department of Medical Biology, Izmir, Turkey.

Glioblastoma multiforme (GBM) is the most extensive and malignant type tumors of central nervous system. These lethal brain tumors seen in adults and have no-response to standard treatment. Zoledronic acid (ZA) demonstrates anti-tumor activity in various cancers. MicroRNAs are small (19-24 nucleotides) and non-coding RNAs that regulate post-transcriptional gene expression. miRNAs serve as oncogenes and tumor suppressors through unlighted mechanisms in human.
The aim of the study was to evaluate the effect of zoledronic acid on the expression of 84 miRNAs. In our experiments, U87-MG cell line (Human glioblastoma-astrocytoma) is used as an in vitro model of human glioblastoma cells to investigate the cytotoxic and apoptotic effect of ZA towards glioma cells. U87-MG cells were treated with 25 µM (IC50) ZA during 72 hours. Apoptosis assays were performed by using ApoDIRECT In Situ DNA Fragmentation Assay. The RT-qPCR is used for miRNA expressions analysis. miRNA expression levels were evaluated by using miScript miRNA PCR Array.
Results showed that IC50 dose of ZA induced apoptosis 4.25 fold when compared to control cells that untreated with ZA. Also IC50 dose of ZA of miRNA expression results showed that; mir-22 expression level was upregulated 3,08 fold according to control group .
In conclusion, these novel findings showed that ZA can be important in prognosis of glioma and it is necessary to question whether it can be used as a drug candidate in glioma treatment with further research on miR-22 and its target gene expression.

Nicotine and Cotinine Dependent Regulation of P-glycoprotein Expression in Caco-2 Cells

N. Samarov, *V. Shupletsova, M. Goeva, A. Voloshina, A. Pankina, A. Korzhenkov, S. Babak;*
Immanuel Kant Baltic Federal University, Kaliningrad, Russian Federation.

P-glycoprotein (P-gp), encoded by the multidrug resistance gene 1 (*MDR1*), acts as an efflux pump that exports a wide spectrum of drugs across the membrane out of the cell. P-gp is expressed in a number of barrier tissues such as apical membranes of the lower GI tract, blood-brain barrier, liver, kidney, placenta and testis. Therefore, the expression of P-gp is one of the most important factors regulating bioavailability of a wide spectrum of orally administrated drugs.
Previously it was shown that tobacco smoking changes the bioavailability of several P-gp substrates. It's also known that nicotine is metabolized mostly by CYP2A6 and transformed into a cotinine which has an extremely long half-life in comparison to nicotine (about 20 hours versus 2 hours). In the present study we have shown dose-dependent up/down-regulation of P-gp expression in Caco-2 cells by nicotine and cotinine exposure. Cells were treated with three different concentrations of nicotine (5ng/ml, 15ng/ml, 50ng/ml) and cotinine (50ng/ml, 250ng/ml, 750ng/ml) for 96 hours.
P-gp expression was estimated by real-time RT-PCR. We recognized that P-gp expression was increasing in a nonlinear manner. It was shown that the intermediate concentrations of nicotine and cotinine had a lower effect on P-gp mRNA level compared to other concentrations including the lowest one which matched passive smoker's plasma concentrations. Low concentrations lead to 1,5-fold increase of P-gp expression in comparison with untreated cells. It was also shown that cotinine has a role in regulation of P-gp mRNA level in the case of prolonged smoking abuse.

J15.21

The impact of Oncotype DX testing on chemotherapy prescribing patterns in a tertiary referral centre

L. M. Hughes, *T. P. McVeigh, K. J. Sweeney, M. Keane, M. J. Kerin;*
National University of Ireland Galway, Galway, Ireland.

Introduction: The use of chemotherapy in node-negative, ER-positive breast cancer has changed dramatically since the introduction of OncotypeDX to determine systemic recurrence risk based on tumour genomic signature. **Aims**: This study aims to 1. Document longitudinal changes in chemotherapy use 2. Assess the impact of new evidence on local protocol **Methods**:

A cohort study was undertaken, including consecutive patients with early node-negative, ER-positive breast cancer diagnosed between 2006 and May 2013. Data was collected regarding clinico-pathological features, OncotypeDX use, recurrence score, and chemotherapy use. All therapeutic decisions followed multidisciplinary discussion, with adherence to guidelines and consideration of trial protocol and OncotypeDX recurrence scores. **Results**: The study group included 476 consecutive patients, of whom 240 (50%) underwent OncotypeDX testing, 96 as part of TAILORx trial. OncotypeDX has been used in 84%(n=125) patients since being made available for use in the public sector (see table).

Time Period	2006-2007	2007-May 2010	June 2010-October 2011	October 2011-May 2013
OncotypeDX test availability	Oncotype Not Available	Oncotype Available on Trial only	Oncotype not publicly reimbursed	Oncotype in Clinical use
Number of patients treated	55	199	73	149
OncotypeDX use (n(%))	0 (0)	96 (48)	19 (26)	125 (84)
Chemotherapy Use (n(%))	34 (62)	101 (51)	33 (45)	48 (32)

Chemotherapy use changed in inverse proportion to the availability of the genomic assay. Of patients undergoing genomic profiling, 138(58%) were spared chemotherapy. A multivariate analysis found factors influencing chemotherapy use to include recurrence score (OR 1.33 per unit increase, p<0.001), and time period of treatment (p=0.04). Traditional factors such as size and grade did not influence chemotherapy use in patients undergoing genomic assessment (p=0.59 and 0.24). **Conclusion**: This study validates the use of molecular testing in the rationalisation of systemic therapy.

J15.22
F8 gene mutations and inhibitor development in hemophiliac patients from West Algeria

M. ABDI[1], *F. Zemani-Fodil[1], M. Fodil[1], N. Saidi-Mehtar[1], H. Touhami[2], A. Boudjema[1];*
[1]Laboratoire de Génétique Moléculaire et Cellulaire, Université des Sciences et de la Technologie d'O, Oran, Algeria, [2]Service d'hématologie, Centre Hospitalo-universitaire d'Oran. Algeria., Oran, Algeria.

Neutralizing inhibitors development toward factor VIII is one of the most challenging complications in the treatment of hemophilia A. Several studies have suggested that genetic factors influence the development of factor VIII inhibitors such as mutations in the factor 8 gene. The aim of the present study was to analyze the relationship between inhibitor development and F8 gene mutations in a sample of hemophiliac patients from West Algeria.
To study the genetic predisposition for inhibitor development, we genotyped 24 hemophiliac patients with and without inhibitors. Inhibitor detection for all patients was performed using the Bethesda assay once every 3 months. A conventional Fisher's exact test was used for statistical analysis; p-value <0.05 indicate statistical significance.
A total of seven patients had developed inhibitors. Six patients with inhibitors were classified as low responder; whereas, one patient was categorized as high responder. In the present study, we showed that there was any association of the F8 gene mutations and the inhibitor development in our study-group. However, these findings should be confirmed in a larger group of patients.

J16.01
Association of DNA methylation of tumor suppressor genes and histopathological features of breast cancers

K. Popovska-Jankovic[1], *M. Jakimovska[1], I. Maleva[1], K. Kubelka[2], L. Stojanovska[3], A. Arsovski[3], M. Karagjozov[2], D. Plaseska-Karanfilska[1];*
[1]Research Center for Genetic Engineering and Biotechnology, Skopje, Macedonia, The Former Yugoslav Republic of, [2]Acibadem Sistina, Hospital, Skopje, Macedonia, The Former Yugoslav Republic of, [3]Re-Medika, Hospital, Skopje, Macedonia, The Former Yugoslav Republic of.

Breast cancer (BC) represents a heterogeneous disease in which many different genetic, epigenetic and environmental factors are involved. The aim of our study was to investigate the association of DNA methylation of tumor suppressor genes and histopathological profiles of BCs. The methylation status of 24 tumor suppressor genes was determined in 124 BCs using MS MLPA001 kit. Methylation of more than 15% was regarded indicative for gene hypermethylation. SPSS statistics was used for statistical analysis. A total of 103 BCs (87.5%) showed a methylation of at least one tumor suppressor gene. Seventeen of the 24 analyzed genes showed methylation. The most frequently methylated genes were RASSF1 (66.1%), APC2 (41.9%), CDH13 (35.5%), GSTP1 (25%), DAPK1 (15.3%), and CASP8 (8.1%). Triple negative BCs showed positive association with ESR1 (p=0.006), BRCA1 (p=0.006) and TIMP3 methylation (p=5x10-5) and negative association with RASSF1 (p=0.003) and GSTP1 methylation (p=0.02). Similar associations showed the BCs with BRCA1ness profiles, determined by MLPA analysis. Estrogen (ER) and progesterone (PR) positive BCs were positively associated with RASSF1 (p=0.001 and p=0.003, respectively) and DAPK1 methylation (p=0.018 and p=0.027, respectively). ESR1, CDH13, BRCA1 and TIMP3 were less frequently methylated in ER+ tumors. RARB1 and CD44 showed positive association with tumor size (p=0.008 and p=0.006, respectively). Herceptine, p53 and Ki-67 positive BCs were more frequently non-methylated at any of the analyzed genes (p=0.05, p=0.022 and p=0.008 respectively). In conclusion, our study shows that DNA methylation is a frequent event in BC and that different genes are methylated in BCs with different histopathological features.

J16.02
Investigation of the promoter hypermethylation in ILC and IDC of the breast

O. Eroglu[1], *M. Erci Baysak[2], B. Durak Aras[2], S. Artan[2], M. Ozdemir[2], O. Cilingir[2];*
[1]Bilecik Seyh Edebali University, Science and Art Faculty, Molecular Biology and Genetics Department, Bilecik, Turkey, [2]Eskisehir Osmangazi University, Medical Faculty of Medical Genetics, Eskisehir, Turkey.

Backround: IDC and ILC are the most common invasive breast cancer tumor types. About 80% and 10% of invasive breast cancers are infiltrating ductal and lobular carcinomas respectively.
Method: In this study the promoter methylation levels of TWIST, RARβ2, ESR1, GSTP1 and CDH1 genes which are associated with breast cancer were investigated by Quantitative Methylation Sensitive High Resolution Melting Analysis (QMS-HRM). We analysed primary tumor core biopsies from 80 high-risk primary breast cancer patients (tumors ≥2 cm and/or lenfatic metastase and/or distant metastases and/or under 40 years) and their histopathologic types were associated with the methylation levels.
Results: In our study the promoter hypermethylation status were observed at different rates; TWIST, RARβ2, ESR1, GSTP1 and CDH1 methylation frequencies were 25%, 88,75% 72,5%, 82% and 95% respectively. When comparing the promoter hypermethylation of tumor types of the breast, RARβ2, ESR1, GSTP1 and CDH1 genes found to be significant with invasive ductal carcinomas (IDC). RARβ2 and CDH1 genes promoter hypermethylation is found to be significant with invasive lobular carcinomas (ILC). Also the promoter hypermethylation levels of the genes found to be significant with lymph node positivity, ER positivity and HER2/neu negativity.
Conclusions: Our study is important as being the first study that analyzes the association between IDC and ILC tumor types of breast cancer and TWIST, RARβ2, ESR1, GSTP1 and CDH1 genes promotor methylation status in Turkish population.

J16.03
Presenting the genomic cipher adenine = 0, guanine =1, cytosine = 2, thymine = 3 derived directly from the DNA to convert nucleotide names/letters to numbers to study patterns of unique identifiers to detect command genes in the human genome

L. B. Scheiber II, *L. Scheiber;*
Osteoporosis & Arthritis Center, Trenton, MI, United States.

Presented is a cipher to convert each DNA nucleotide to a specific number to reveal patterns of unique gene identifiers in the human genome. The cipher was developed by converting tRNA anticodons to 5'-3', then reverse transcribing 5'-3' RNA anticodons to 5'-3' DNA anticodons to facilitate construct of a 4x4x4 prime genomic cube; where the first letter of the anticodon is positioned along the 'x' axis of the cube, second letter positioned along the 'y' axis and third letter positioned along the 'z' axis. Assigning adenine the value of '0', guanine value of '1', cytosine value of '2' and thymine value of '3' places methionine, considered the START anticodon, on one end of the cube and the three STOP anticodons on the opposite end of the cube. The three dimensional image of this arrangement of DNA anticodons demonstrates an orderly stepwise progression of the triplicate DNA anticodons AAA, GGG, CCC, and TTT through the cube. A secondary pattern is demonstrated if the triplicate anticodons nullify anticodons in their rows and anticodons numbering three or more elements are neutral, then there are zero free anticodons in the 'A' 4x4 panel, one free anticodon in the 'G' 4x4 panel, two free anticodons in the 'C' 4x4 panel, three free anticodons in the 'T' 4x4 panel. Analysis produces the cipher Adenine=0, Guanine=1, Cytosine=2, and Thymine=3. Utilizing this cipher to convert nucleotide elements to numbers facilitates study of the human genome to detect command genes that cannot be determined by conventional analysis techniques.

Evaluation of New Epi-panel Markers SPG20,ITGA4 and ALX4 in Plasma for Early Detection of Colorectal Cancer

R. Foroughi[1,2], *S. Chavoshi[1], S. Mohammad Ganji[3], M. Tavallaie[1];*
[1]Human Genetics Research Center,Baqiyatallah Medical Sciences University, Tehran,

Islamic Republic of Iran, [2]Islamic Azad University, Damghan, Islamic Republic of Iran, [3]Department of Biomaterials and Tissue Engineering, National institute of genetic Engineering and Biotechnology (NIGEB), Tehran, Islamic Republic of Iran.

Colorectal cancer (CRC) is the 3rd most common cause of cancer death in the world.Introducing a suitable method for screening and early detection of CRC will be one of the most important strategies. The presence of cancer-specific DNA methylation biomarkers in the body fluid of CRC patients will provide a simple, non-invasive screening test for colorectal cancer. This study was designed to evaluate methylated SPG20, ALX4, ITGA4 genes as a novel epi-panel for screening and detection of CRC. In the first step 90 blood samples were collected from diagnosed cases as colorectal cancer and 40 samples were collected from healthy volunteers as control from Baqiatalah University of Medical Sciences, Tehran, Iran.DNA from plasma samples was extracted by using Qiagene DNA purification protocol following Bisulfite modified DNA was amplified by using specific primers for Methylation Specific PCR(MSP).Finally the MSP evaluation was performed on the patients and control groups.The results up to now showed that ITGA4, SPG20, ALX4 were hypermethylated in between 30 to 50% of CRC and polyp patients whereas normal samples were rarely methylated. These candidate markers can be considered for further evaluation in screening or diagnostic applications for colorectal cancer.Our findings suggest this epigenetic panel is suitable for screening and early CRC detection. Furthermore, we showed our epi-panel performed better than the individual DNA methylation biomarkers when analyzed in the same plasma samples.

Epigenetics, aging and cancer

G. Belaaloui;
Faculty of Medicine. Hadj Lakhdar University, Batna, Algeria.

Epigenetics is a fast-growing branch of biology. It consists in the study of reversible and transmissible modifications of gene expression without changing DNA sequences. Epigenetic modifications are contributing to the regulation of many physiologic phenomena such us embryonic development, X chromosome inactivation in female and parental imprinting. These modifications are regulated by several mechanisms, the most frequent are: DNA methylation, histones post-translational modifications and non coding RNAs. They are influenced by genetic, environmental as well as stochastic factors.

It has been shown that physiologic aging depends not only on genetic factors but also on „epigenome" modifications, and several age-related diseases such as cardio-vascular diseases, type II diabetes, Alzheimer, auto-immune diseases and cancer have been associated to epigenetic changes. Cancer is, so far, the most studied disease in this context, making „epigenetics" a plausible explanation to the increasing rate of cancer in old. Cancer epigenetic modifications lead to expression alteration of genes regulating neoplastic phenotypes such us cell proliferation and metastasis.

A best knowledge of epigenetic mechanisms gave a possibility to a targeted cancer therapy (epigenetic therapy) and opened many preventive, diagnosis and prognosis perspectives.

Gene expression profiles in uranium industry workers of Stepnogorsk city occupationally exposed to ionizing radiation.

A. Abilmazhinova[1], *M. Zhabagin[1], A. Akhmetova[1], D. Erezhepov[1], S. Rakhimova[1], M. Bakhtin[2], P. Kazymbet[2], A. Akilzhanova[1], Z. Zhumadilov[1];*
[1]Center for Life Sciences, Nazarbayev University, Astana, Kazakhstan, [2]Radiobiology Research Institute, Astana Medical University, Astana, Kazakhstan.

Ionizing radiation (IR) imposes risks to human health and the environment. Taking into account the fact that Kazakhstan is one of the world's leading uranium producer, and considering the magnitude of the damage from Semipalatinsk nuclear test site, the study of radiation effects on genes has always been a priority. It is known that LIG3 and XPA genes may serve as biomarkers for sensitive methods of dosimetry. The purpose of this study is to determine the impact of the IR on gene expression in uranium industry workers of Stepnogorsk city, Kazakhstan.

Peripheral blood samples (n=20, n=19) were collected from workers who were exposed to different radiation doses (50mSv, 20mSv). To examine gene expression profiles of radiation exposed workers quantitative real-time PCR were used. We used B-actin gene as an endogenous control for our study. The expression of LIG3, XPA genes were analyzed and compared between two groups.

Gene expression analysis showed statistically significant difference in expression of DNA repair genes (LIG3, XPA) between two groups exposed to different doses of radiation. The greater the delivered dose of IR, the greater the expression level of DNA repair genes.

Altered expression profiles in this study can be used as biomarkers of dosimetry for uranium industry workers. This strategy on risk assessment should be considered in the construction of industrial safety and health of workers occasionally exposed to IR.

Whole genome sequencing of Mycobacterium tuberculosis in Kazakhstan: first sequence results of two clinical isolates

A. Molkenov[1], *U. Kairov[1], U. Kozhamkulov[1], S. Rakhimova[1], A. Askapuli[1], M. Zhabagin[1], Z. Abilova[1], A. Akhmetova[1], D. Yerezhepov[1], A. Abilmazhinova[1], V. Bismilda[2], L. Chingisova[2], Z. Zhumadilov[1], A. Akilzhanova[1];*
[1]Center For Life Sciences, Nazarbayev University, Astana, Kazakhstan, [2]National Center of Tuberculosis Problems of the Republic of Kazakhstan, Almaty, Kazakhstan.

The project is aimed to create the prerequisites for a personalized approach to the diagnosis and treatment of tuberculosis by identifying and comparing the whole genome sequences of M.tuberculosis strains, isolated in Kazakhstan. Analysis for whole genome sequences obtained using NGS technology will clarify the factors cause of the formation of highly virulent strains of M.tuberculosis, the evolution of local strains, and genetic markers of drug resistance.

Material collection from 50 patients, sputum extraction and determination of drug sensitivity was performed in the reference-laboratory "National Center of Tuberculosis Problems", Almaty, Kazakhstan. DNA libraries for whole genome sequencing were prepared from DNA extracted from the isolates. The sequencing was performed on Roche 454 GS FLX+ NGS platform at the Center for Life Sciences, Nazarbayev University, Astana, Kazakhstan. The sequencing reads from two isolates were assembled into contigs using GS De Novo Assembler. All alignments were done against the M.tuberculosis reference strain H37Rv using GS Reference Mapper.

The sequencing has performed for two M.tuberculosis isolates MTB-476 and MTB-489. 96 M bp with an average read length of 520 bp, approximately 21.8X coverage and 104.2 M bp with an average read length of 589 bp and approximately 23.7X coverage were generated for the MTB-476 and MTB-489, respectively. The genome of MTB-476 consists of 257 contigs, 4204 CDS, 46 tRNAs and 3 rRNAs. MTB-489 has 187 contigs, 4183 CDS, 45 tRNAs and 3rRNAs. The results of genome assembling have been submitted into NCBI GenBank, available for public access under the accession numbers AZBA00000000, AZAZ00000000.

J16.08
Correlation of O6-Methylguanine DNA methyltransferase promoter methylation and clinicopathological parameters in bladder cancer

O. Cetin[1], *V. Caner[2], N. Sen Turk[3], V. Okur[1], O. Can[2], S. Eskicorapci[4], L. Tuncay[4], L. Elmas[2], G. Bagci[1];*
[1]Pamukkale University, School of Medicine, Department of Medical Genetics, Denizli, Turkey, [2]Pamukkale University, School of Medicine, Department of Medical Biology, Denizli, Turkey, [3]Pamukkale University, School of Medicine, Department of Medical Pathology, Denizli, Turkey, [4]Pamukkale University, School of Medicine, Department of Urology, Denizli, Turkey.

Bladder cancer is the one of the most common cancers worldwide and O6-Methylguanine DNA Methyltransferase (MGMT) promoter methylation might be contributing to clinicopathological features of the disease. We analyzed formaline-fixed, paraffin-embedded bladder tissue samples from 101 patients with urothelial carcinoma. All samples were analyzed by real-time methylation-specific PCR. MGMT promoter methylation was detected in 15 (14.9%) of the samples and was not significantly different between any of the groups, although the number of high grade tumors with MGMT promoter methylation was twice the number of low grade tumors. Methylation of MGMT in high grade tumors might play a role in aggressive proliferation of the tumor cells and a poor prognosis.

J16.09
PRKCDBP downstream hypermethylation and its influence on gene expression in squamous intraepithelial lesions and carcinomas

V. Holubekova[1], *A. Mendelova[1,2], I. Svecova[2], I. Kapustova[2], A. Vanochova[1], P. Zubor[2], Z. Lasabova[1];*
[1]Commenius University in Bratislava, Jessenius Faculty of Medicine, Department of Molecular Biology, Martin, Slovakia, [2]Commenius University in Bratislava, Jessenius Faculty of Medicine, Clinic of Gynecology and Obstetrics, Martin, Slovakia.

Protein kinase C delta binding protein (PRKCDBP) is a potential tumor suppressor although molecular basis of its action has been poorly understood. PRKCDBP gene is inactivated in colorectal, lung and breast cancer by genetic or epigenetic alteration which leads to down-regulation of PRKCDBP expression. The purpose of this primary study was to examine PRKCDBP hypermethylation in 7 CpG sites (assays predesigned by QIAGEN) by pyrosequencing and to find out the expression in squamous intraepithelial lesions and carcinomas. A total of 51 cervical specimens were divided into groups with a diagnosis of normal cervix (n=21) and squamous intraepithe-

lial lesion or carcinoma (n=30). Downstream hypermethylation was found significantly hypermethylated in two CpG sites in intron (p=0.0033; 95% CI: -3.26 to -0.69 and p=0.0015; 95% CI: -4.07 to -1.03) and one in exon 2 (p=0.0222; 95% CI -5.06 to -0.41) when compared to group with normal cervix. PRKCDBP gene expression was also reduced in group with cervical lesion or carcinoma. Downstream hypermethylation has been reported as widespread phenomenon with different effect on the gene expression and promoter hypermethylation. These results could indicate the potential impact of downstream hypermethylation on reduced PRKCDBP expression during cervical carcinogenesis.

Short runs of homozygosity as an underappreciated mechanism for imprinting disorders

I. Y. Iourov[1,2,3], *S. G. Vorsanova*[1,2,4], *M. A. Zelenova*[1,2], *O. S. Kurinnaia*[1,2,4], *S. A. Korostelev*[5], *Y. B. Yurov*[1,2,4];
[1]*National Research Center of Mental Health, RAMS, Moscow, Russian Federation,* [2]*Institute of Paediatrics and Paediatric Surgery, Ministry of Health, Moscow, Russian Federation,* [3]*Department of Medical Genetics, Russian Medical Academy of Postgraduate Education, Ministry of Health, Moscow, Russian Federation,* [4]*Moscow City University of Psychology and Education, Moscow, Russian Federation,* [5]*The State Educational Institution of Professional Training under the Federal Agency of Health Care and Social Development, Moscow, Russian Federation.*

Runs of homozygosity (ROH) are epigenetic changes encompassing relatively large genomic loci and presenting as stretches of consecutive homozygous genotypes scattered through the genome. Usually, ROH exceeding 5-10 Mb in length are only considered to have an effect on phenotype. On the other hand, heterozygosity losses of a single imprinted gene can produce an epigenetic change leading to imprinting disorders. Therefore, such epigenetic changes have not necessarily to encompass large genomic loci. Studying ROHs in 115 children with intellectual disability and congenital malformations by Affymetrix 2.7M SNP/array, we have found that 1-Mb-long-ROHs are associated with imprinting disorders. In a case of atypical Angelman syndrome a ROH at 15q11.2 (size 1.16Mb) was detected. Furthermore, two cases of atypical Beckwith-Wiedemann associated with ROHS at 11p15.5p15.4 (size: 1.36Mb and 1.15Mb) were identified. In addition, a long ROH at 7p14.2p12.1 (14.95Mb) affecting GRB10 (an imprinted candidate gene for Silver-Russell syndrome) was detected in a child with severe growth retardation, microcephaly and intellectual disability. Three children (2.6%) demonstrated overall ROH burden typical for offspring of a consanguineous relationship. Retrospectively, consanguinity was confirmed by genealogical analysis. Thus, our observations show that 3.5% of intellectual disability cases can be attributed to ROH. Moreover, ROHs can be as short as 1Mb, which are usually overlooked, when SNP/array assays or other methods for epigenetic analysis are applied. We conclude that these epigenetic mutations are a relatively common mechanism for imprinting disorders. Supported by the Russian Federation President Grant (MD-4401.2013.7).

The review od epigenetic modification in human thyroid cancer

B. Faam[1], *M. Ghaffari*[2], *A. Gadiri*[3], *A. Amouzegar*[4], *A. Fanaii*[5], *F. Azizi*[6];
[1]*Cellular and Molecular Research Center, Research Institute for endocrine sciences Shaheed Beheshti University of Medical Science, Tehran, Iran/ Cellular and Molecular Research Center, Jondishapur University, Ahvaz, Iran, Tehran, Islamic Republic of Iran,* [2]*Cellular and Molecular Research Center, Department of Biochemistry, School of Medical, Jundishapur University of Medical Sciences, Ahvaz, Iran., Tehran, Islamic Republic of Iran,* [3]*Department of Immunology, Faculty of Medicine, Jundishapur University of Medical Sciences, Ahvaz, Iran., Ahvaz, Islamic Republic of Iran,* [4]*5) Endocrine Research Center, Endocrine Research Institute, Shahid Beheshti University of Medical Sciences, Tehran, Iran., Tehran, Islamic Republic of Iran,* [5]*6) Baqiyatallah University of Medical Science, Tehran, Iran., Tehran, Islamic Republic of Iran,* [6]*Endocrine Research Center, Endocrine Research Institute, Shahid Beheshti University of Medical Sciences, Tehran, Iran., Tehran, Islamic Republic of Iran.*

Thyroid cancer is the most common endocrine malignancy worldwide. However, there is not a definite treatment for advanced thyroid cancer, which comprises poorly differentiated, anaplastic and metastatic or recurrent differentiated thyroid cancer that do not response to radioiodine; treated patients had not a complete response. Biological therapies have been proposed on the basis of the recognition key oncogenic mutations and these treatments could be effective in stabilizing progressive disease. Epigenetic abnormalities are present in almost all cancers and together with genetic variations led to tumor progression. Epigenetic modification is mostly occur in genes, which play role in the control of cell proliferation and invasion such as RASSF1A, PTEN, DAPK, RAP1GAP, and specific genes of thyroid are mostly epigenetically silenced in thyroid cancer. Rap1, a member of RAS family of small GTPase has been implicated in regulation of mitogenic and oncogenic pathways in thyroid, and its CpG island methylation is reported in some kind of tumors. In addition, miRNAs play important role in cell differentiation, proliferation and survival. They considered as the regulators of gene expression at posttranscriptional level. Deregulation of miRNAs expression is suspected to be an important regulator of tumor development and progressive. Epigenetic modification pattern is different not only between normal and tumors tissues, but also between different stage of malignancy and between primary and metastatic tumor. Therefore these variations may become useful novel biomarkers for diagnostic and treatment tumors.

J16.12
Epigenetics, maternal responsibility and neurological development

K. Hens;
Maastricht University, Maastricht, Netherlands.

It is believed that epigenetics can partly explain the development of neurological conditions. As epigenetic changes often happen in utero, maternal behavior may affect brain development. This raises questions regarding the responsibility of the pregnant woman. To which extent is she responsible for the neurological status of the future child? Should she, for example, avoid all stress, if this is shown to lead to molecular changes increasing the chance of the child to develop ADHD later in life? Should she ensure that she takes optimum nutrition for development of synaptic plasticity of her fetus? With of this talk I demonstrate first that epigenetics complicates the question of the responsibility of the pregnant woman. To which extent does the increasing knowledge about epigenetics influences in utero further complicate this responsibility, if even behavior of years before the conception may influence a fetus? Is this an individual responsibility or also a collective one? Second, by using the examples of autism and extreme intelligence, I demonstrate that , although discussions about parental responsibility towards future children have centered on duties to prevent suffering or to maximize welfare or 'the chance of a good life', the distinction between prevention and enhancement is difficult to maintain in the context of neurological conditions. By analyzing arguments from the neurodiversity movement, whose members often insist that their neurological condition is not a disease, but an integral part of their identity, I shall demonstrate that there is a need for a revisiting of the concept of maternal responsibility.

Anchored Assembly: Comprehensive variant detection using NGS data

J. Bruestle, *B. Drees, Ph.D.;*
Spiral Genetics, Seattle, WA, United States.

Characterization of large indels, inversions, and multi-nucleotide variants is important for disease studies. These are often undetected by standard pipelines. Spiral Genetics has developed Anchored Assembly, a novel method using direct, *de novo* read overlap assembly to accurately detect variants from next-generation sequence reads. We detect, on average, over 90% of indels and structural variants ≤ 30 kbp in non-repetitive regions. The ability to detect deletions and structural variants is undiminished by variant size, and the ability to accurately detect and assemble insertions continues well into the 30 kbp range.
Anchored Assembly was evaluated against Pindel and BWA + GATK using simulated read data. Datasets were generated by populating chromosome 22 of the human genome reference sequence with a set of SNPs, indels, inversions, and tandem repeats. Anchored Assembly detected, on average, over 90% of SNPs, indels, and structural variants up to 50 kbp with false discovery rates well below 1%. In comparison, Pindel and BWA + GATK had false discovery rates of 10% and 9%, respectively.
Anchored Assembly's range of detection and low false discovery rates may benefit cancer and rare disease studies. The ability to accurately detect structural differences will be useful for characterizing tumor vs. normal samples and analyzing and comparing whole human trio data to identify risk-associated variants.

Hidden parts of whole exome sequencing data: non-coding variants and copy number variations

S. Fahiminiya[1], *F. Rauch*[2], *L. Jerome-Majewska*[3], *J. Majewski*[1];
[1]*Department of Human Genetics, Faculty of Medicine, McGill University and Genome Quebec Innovation Center, Montreal, QC, Canada,* [2]*Shriners Hospital for Children and McGill University, Montreal, QC, Canada,* [3]*Department of Pediatrics, McGill University, Montreal Children's Hospital, Montreal, QC, Canada.*

Sequencing of protein coding regions of human genome (Whole Exome Sequencing; WES) has been wildly used to unravel the mystery behind various inherited human genetic diseases, in the past few years. Despite its great success in the identification of causal mutations for such disorders, a subset of them remained still unsolved. Here, we present the result of our WES studies where analyzing only rare variants in coding regions was not conclusive but further investigation revealed the involvement of non-coding

variants and copy number variations (CNV) in etiology of the diseases. Whole exome sequencing and bioinformatics analyses were performed at Genome Quebec Innovation Center, Montreal, Canada. We successfully identified disease-causing mutations in coding regions of several human rare diseases (e.g. SCARF2: Van den Ende-Gupta syndrome and SNAP29: 22q11.2 deletion syndrome). Additionally, we showed that variants in non-coding regions and CNV have also important value and should not be ignored during bioinformatics analysis of WES data. For instance, in patients with osteogenesis imperfecta type V and in patients with glucocorticoid deficiency, we identified variants in 5'UTR, resulting in the production of longer or truncating non-functional proteins. Furthermore, CNVs were identified as the main cause of the diseases in patients with metaphyseal dysplasia with maxillary hypoplasia and brachydactyly and in patients with osteogenesis imperfecta type VII. Our results highlight that non-coding variants and CNVs can be crucial and they should be considered during WES data analysis, as they can be the only cause of the disease under investigation.

J16.15
An automated benchmarking toolkit for structural variation calling using Next Generation Sequencing data

W. Leung[1], T. Marschall[2], L. Falquet[3,4], S. van Leeuwen[1], Y. Paudel[5], H. Mei[1], **A. Schönhuth**[2]*, T. Moss[6];*
[1]Leiden University Medical Center, Leiden, Netherlands, [2]Centrum Wiskunde & Informatica, Amsterdam, Netherlands, [3]University of Fribourg, Fribourg, Switzerland, [4]Swiss Institute of Bioinformatics, Fribourg, Switzerland, [5]Wageningen University, Wageningen, Netherlands, [6]Weizmann Institute of Science, Rehovot, Israel.

Structural variations (SVs), such as insertions, deletions and duplications are found to be one of the major genetic causes of cancer. Identifying and characterizing these events is becoming increasingly important in cancer genomics. Next Generation Sequencing (NGS) technology has made it possible to detect SV events at base pair resolution. Many different computational SV detection tools have been developed, based on information sources such as read depth, discordant paired-end reads, split alignments, and de novo assembly. While some approaches make similar predictions, some approaches disagree in their predictions and deliver rather complementary sets of SV calls. The current challenge for researchers, when being confronted with myriads of tools, is to make a good selection, so as to generate a set of SV calls that is both most reliable and most comprehensive.
To appropriately guide researchers in comparing and selecting most appropriate SV detection tools, we have developed an open source toolkit (available also in a downloadable virtual machine) that allows us to systematically benchmark and evaluate SV detection tools. We have generated realistic, simulated datasets based on comprehensive sets of real SVs from several different genomes. We have put forward the performance statistics of different SV calling methods and created a pipeline for their optimal usage. If desired, more SV detection tools can be added to this pipeline, whose workflow is generic in the choice of tools. Results are summarized in a PDF file where precision, recall and also other useful detection statistics referring to the tools selected are displayed.

Angiotensin-I converting enzyme I/D polymorphism gene in Moldavian population

D. D. Dulap, *N. Sirocova, N. Usurelu, S. Gatcan, V. Sacara;*
Institute of Mother and Child, Chisinau, Moldova, Republic of.

Background: The angiotensin-converting enzyme (ACE) gene in humans has an insertion-deletion (I/D) polymorphic state in intron 16 on chromosome 17q23. This polymorphism has been widely investigated in different diseases. In this study we aimed to investigate the ACE I/D genotype frequency in Moldavian population with others populations.
Materials and Methods: Have been investigated DNA of 100 healthy children aged up to 17 years, in order to make a comparative analysis of ACE I/D polymorphisms in Moldova with other countries. PCR methods were used for polymorphisms determination of ACE I/D allele. The distribution of genotypes was tested for deviation from Hardy-Weinberg Equilibrium (HWE).
Results: There was no significant difference in the distribution of DD, II and I/D genotypes of ACE polymorphism in Moldavian population (21.3, 28.8, and 48%) and their ethnically matched control from Italian population (36, 16, and 48%), respectively. There two groups also presented with very similar allelic frequencies and were also found to be in Hardy-Weinberg equilibrium, when ($\chi 2=2,05, p<0.15$) indicate statistic confirmation of similarities. The same similarities were found in North Indian, Dutch and Turkish populations and total differences with Kyrgyz population ($\chi 2=13.69, p=0.002$) .
Conclusion: The polymorphism of ACE I/D genotypes frequency in Moldavian population are statistical similar with Italian, Dutch, North Indian and Turkish populations.

Establishment of the most common of autosomal dominant spinocerebellar ataxias (ADSCA's) in Bulgarian patients

I. Dimitrova, *M. Chergova, S. Bichev, A. Savov;*
National Genetic Laboratory, Sofia, Bulgaria.

Background: The autosomal dominant spinocerebellar ataxia (ADSCA) is large and genetically heterogeneous group of neurological disorder characterized by cerebellar dysfunction. Today are known more than 30 types of SCA's. The most common ADSCA's (SCA1, SCA2, SCA3, & SCA6) are associated with the expansion and instability of CAG trinucleotide repeat (CAG) n encoding polyglutamine proteins.
Aim: The aim of this study was to investigate the most common Spinocerebellar ataxia from SCA1, SCA2, SCA3 and SCA6 in patients from Bulgarian families, and to implement fast and reliable workflow for diagnosis of this disease.
Materials and methods: Our group consists of 63 patients from 50 Bulgarian families with clinical symptoms referred to those of the disease. DNA was extracted from the periferal blood with salting out method. Polymerase chain reaction (PCR) and triplet repeat primed PCR (TP-PCR) were used to confirm the diagnosis.
Results: From 63 analyzed patients SCA was established in 16 patients from 15 out of 50 kindreds (7.5%) . We have determined that SCA1 is found in 5 (2.5%) and SCA2 in 10 (5%) of all families. From all genetically confirmed patients 66% were diagnosed with SCA2 and 33% with SCA1.
CONCLUSIONS: The frequency of SCA2 is substantially higher than that of SCA1, 3, 6 and 7 in patients with SCA from Bulgarian families, unlike the worldwide investigations showing that SCA1 and SCA 3are reported to be most common. TP- PCR proved to be reliable method for routine diagnosis

CCR5del32, CCR2-64I та SDF-1 3'A mutations of chemokine receptors genes in West-Ukrainian population

H. Makukh, *M. Tyrkus, H. Akopyan;*
State institution "Institute of Hereditary Pathology of Academy of Medical Science of Ukraine", Lviv, Ukraine.

Ukraine has one of the highest speeds of HIV-1 infection spread in Europe but Western region is the most "trouble-free": 7 compare to 100 - 300 cases of HIV per 100 thousand inhabitants in other regions. A speed of epidemic depends on correlation between susceptible and resistant individuals in single population.
The purpose of study to set up the frequency of allelic variants of genes, which lead to higher resistance to HIV-1 among people of the Western region of Ukraine.
It was used the DNA samples of 200 healthy people (50% men and 50% women). The PCR products were digested with the restriction enzymes and subjected to agarose electrophoresis.
Heterozygote mutations CCR5del32 was detected in 17.0% and homozygote CCR5del32 in 0.5% people with same frequency in both sexes. Heterozygous mutation CCR2-64I was revealed in 14.5% people and homozygotes in 1.5%. This mutation was found in women almost twice often than in men. Heterozygote mutation SDF-1 3'A in studied group was found in 30.5% of people, homozygote - in 3% of all with same frequency in both sexes.
The CCR5del32 was combined with CCR2-64I (1 sample), with SDF-13'A (8), CCR2-64I with SDF-1 3'A (9) and combination of homozygotes mutation CCR2-64I and heterozygotes mutation SDF-1/3'A (1 person). The number of people who do not have any protective genotype is 33%.
Thus, the frequency of mutations in chemokine receptors gene in people of Western region of Ukraine is indicate about the high genetic resistance to HIV-1 infection compared with other ethnic groups.

J17.04
Determination of allele frequencies, duplication and mutation of 17 Y-STR loci in UAE population

H. B. Turkiah, *S.H.Sanqoor, M. Jarrar, S. Behl, S.Gaur, M.S.Nazir;*
University of Modern Sciences, Dubai, United Arab Emirates.

Determining the allelic frequencies and an inconsistency of the transmitted alleles of Y-STR haplotype among different populations is crucial for the correct interpretation of DNA profile matches in paternity and kinship analysis. In this research, STR allele duplications, mutations and the allelic frequencies of the 17 Y-STR loci in the UAE population, will be determined. Cheek swabs samples will be collected randomly from 200 unrelated male individuals. Donors will be UAE citizens, whom ancestors' have long-lived in the country. DNA will be extracted using Genomic DNA Isolation Kit, (NORGEN Biotek CORP, Canada). The quality of the extracted DNA samples will be assessed using agarose gel electrophoresis (AGE). DNA quantification will be carried out using Quantifiler® Duo DNA Quantification Kit followed by

multiplex PCR amplification using AmpFlSTR® Y-filer® PCR Amplification Kit (Applied Biosystems, USA). Capillary electrophoresis (CE) of amplified multiplex PCR will be performed using an ABI 3130 Prism® Genetic Analyzer (Applied Biosystems). The data obtained from capillary electrophoresis will be analyzed and the allelic frequencies of Y-STR loci will be determined using a population-genetics-software called "ARLEQUIN". This study will provide an additional information to the framework of variation involving 17 Y-STR loci in forensic case work samples as well as a further contribution to the Y-STR database for UAE male population. This study will also help to determine allele duplications and mutations plus an inconsistency of the transmitted alleles appeared in the UAE population.

Hemoglobin H (HbH) Disease in Khuzestan Province

M. Hamid[1,2], *L. Dawoody Nejad*[1], *G. Shariati*[3,2], *H. Galehdari*[4], *A. Saberi*[4], *M. Mohammadi –Anaei*[2];
[1]*Pasteur Institute of Iran, Tehran, Islamic Republic of Iran,* [2]*Narges Medical Genetics & PND Laboratory, Ahvaz, Islamic Republic of Iran,* [3]*Department of Medical Genetic, Faculty of Medicine, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Islamic Republic of Iran,* [4]*Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Islamic Republic of Iran.*

Background and Purpose: We studied the α-globin gene genotypes, hematologic values, and transfusion dependency of patients with hemoglobin H (HbH) disease in Khuzestan Province, Southwest of Iran.
Methods: We detected alpha globin gene mutation by Using gap-polymerase chain reaction (gap-PCR) and direct DNA sequencing.
Results: We identified 44 patients with hemoglobin H disease. Of these patients, 15 (34%) had deletional form of HbH disease, 29 (66%) had different form of nondeletional HbH disease. The most frequently observed HbH genotypes were --Med/ -α3.7 in 14 patients (31.8%), αpoly A6α/ αpoly A6α in nine patients (20.5%),and αpoly A4α/ αpoly A4α in five patients (11.3%). Some persons with HbH disease required blood transfusion, whereas some others with the same alpha globin genotype were not transfusion-dependent.
Conclusions: Our data show diversity in the genotype and clinical presentation of deletional and nondeletional HbH disease. This discrepancy between similar genotypes with different phenotypes may be due to other modifying factors. Therefore, we cannot describe a general conclusion regarding the need for blood transfusion in the patients with HbH disease

J17.06
Prevalence of alpha-1-antitrypsin deficiency among Polish patients with lung or liver disorders

R. Struniawski[1], *B. Poplawska-Wisniewska*[1], *A. Szpechcinski*[1], *P. Kuca*[1], *M. Czajkowska-Malinowska*[2], *J. Kozielski*[3], *P. Sliwinski*[1], *K. Gorska*[4], *P. Korczynski*[4], *R. Krenke*[4], *J. Chorostowska–Wynimko*[1];
[1]*National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland,* [2]*Regional Center of Pulmonology, Bydgoszcz, Poland,* [3]*Silesian Medical University, Zabrze, Poland,* [4]*Medical University of Warsaw, Warsaw, Poland.*

Background: In Poland, the overwhelming majority of individuals with alpha-1-antitrypsin (AAT) deficiency still remains undiagnosed. We estimated the AAT gene frequency and prevalence in a large cohort of Polish chronic lung or liver disease patients eligible for AAT testing.
Methods: Blood samples were collected prospectively from 419 respiratory patients (COPD, emphysema, bronchiectasis, asthma) and 281 patients referred for liver transplantation due to cirrhotic and non-cirrhotic chronic disease. AAT serum concentration was measured by nephelometry and PI-phenotype identified by isoelectrofocusing. The PI*S and PI*Z alleles were confirmed by real-time PCR; rare phenotypes were identified by DNA sequencing.
Results: 53 (12.6%) lung disease patients and 18 (6.4%) liver disease patients demonstrated AAT deficiency phenotypes. Calculated frequencies expressed per 1000 were for PI*Z 46.6 (95% CI: 32.3-60.8), PI*S 20,3 (95% CI: 10.8-29.8) in respiratory patients and PI*Z 19.6 (95% CI: 8.1-31), PI*S 10.7 (95% CI: 2.2-19.2) in liver disease patients. The AAT gene prevalence calculated by Hardy-Weinberg equilibrium were: 1/1.16 for MM, 1/26 for MS, 1/2429 for SS, 1/11 for MZ, 1/530 for SZ and 1/462 for ZZ in respiratory patients and 1/1.07 for MM, 1/48 for MS, 1/8773 for SS, 1/26 for MZ, 1/2393 for SZ and 1/2610 for ZZ in liver disease patients.
Conclusion: Our results show relatively high frequency of AAT deficiency among Polish patients with chronic obstructive respiratory disorders. Estimated frequency for PI*Z and PI*S allele in respiratory group was about two-fold higher than in liver disease patients and four-fold higher than estimated prevalence in healthy Polish population.

J17.07
The epidemiology of anorectal malformations in Russia in 2000-2012

J. Vydrych[1], *A. Asanov*[1], **N. Demikova**[2];
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation,* [2]*Research Clinical Institute of Pediatrics of Pirogov Russian National Research Medical University, Moscow, Russian Federation.*

The aim of this study was to investigate the epidemiological characteristics of anorectal malformations (ARM) in Russia.
Material and methods. We analyzed data from 36 regional birth defects registries of Russia for 2000-2012. The epidemiological analysis included such factors as sex of affected cases, birth outcome, birth weight, maternal age and number of births. Total prevalence per 10,000 births was defined as the total number of cases among live births, stillbirths and induced abortions divided by the total number of all births.
Results. Among participating registries total number of ARM cases was 970 with prevalence of 1.84 per 10,000 births. Most of them (85.26%) are isolated and 14.74% cases are combined with other anomalies. Among isolated cases 47,76% were cases of congenital anomalies of anus (CAA) without fistula (code Q42.3), 33,25% - CAA with fistula (Q42.2), 11,12% - congenital anomalies of rectum (CAR) without fistula (Q42.1) and 7,87% - CAR with fistula (Q42.0). Among the combined cases CAA without fistula were 42%; CAA with fistula - 25,1%; CAR without fistula - 21%; CAR with fistula - 11,9%. The male affected more frequently than female (1,6:1). Among infants with all kinds of ARM are more common the infants with the low birth weight.
Conclusions. On average ARM affected 1 in 5435 births. There are no changes in prevalence of ARM during research period. The regular monitoring of congenital malformations allows the study of the epidemiological characteristics of even the rare birth defects.

J17.08
Status of RANK and MMP9 gene polymorphism in beta-thalassemia patients of Indian origin

M. M. Singh, *K. Singh, S. R. Phadke, S. Agarwal;*
Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India.

β-thalassemia is an autosomal recessive, commonest hematological disorder found in India. Regular transfusion to sustain life in thalassemia major leads to iron overload. The Cardiac complications and bone deformities are very well documented as outcome of regular transfusion in thalassemics. To evaluate the genetic predisposition for these two important clinical complications, RANK and MMP9 gene prevalence in transfusion dependent cases have been studied. Receptor activator of nuclear factor (RANK) is one of the proteins in regulation of osteoclastogenesis via RANK/RANKL/OPG pathway. In a recent GWAS study RANK was found to be associated with osteoporotic fractures and variations could alter the expression so the two polymorsphisms were studied in beta thalassemia patients. Seventy-five patients of thalassemia major were selected and the genotyping of RANK (G -> A) polymorphism was performed in thalassemia major patients. High prevalence of G allele [86%] was observed compared to 13% prevalence of A allele. Second RANK (insdel C) polymorphism showed 88.6% of insertion cases while remaining were deletions. Matrix metallopeptidase 9 (MMP9) plays a pivotal role in early atherosclerosis, vascular remodeling and development of atherosclerotic lesion. The potentially functional MMP-9 gene polymorphism may contribute to the susceptibility of acute coronary syndrome (ACS). This study includes -1556C>T polymorphism of MMP9 gene in β-thalassemia major patients where 75.3% allele C was found in thalassemia major patients. The present study reports the higher prevalence of wildtype alleles of RANK (+34901G>A, +35966insdelC) & MMP9 (-1556C>T) polymorphism in Thalassemia patients of Indian origin.

J17.09
FTO (rs17817449 and rs9939609) mutations in a Romanian obese children population

O. Marginean, *C. Duicu, V. Moldovan, A. Crauciuc, F. Tripon, C. Banescu;*
University of Medicine and Pharmacy Tg. Mures, Romania, Tg. Mures, Romania.

Background: Obesity is a disorder with increasing freaquency in children and adolescents, directly linked with various diseases such as type-2 diabetes, hypertension and atherosclerosis. Variants in the FTO gene have been associated with Body Mass Index in Western European and North American populations.**Aim:** In this research the authors examine the association between the FTO gene variants rs17817449 respectevly rs9939609 and overweight and obesity in a Romanian population.**Subjects and methods:** A total of 292 children, 178 obese and
214 non-obese individuals, were included in this case-control study. Genotyping of FTO gene (rs17817449 and rs9939609) polymorphism for all subjects was performed by the PCR-RFLP method. We measured weight, height,

waist circumference, and triceps and subscapular skinfolds; body mass index (BMI [calculated as weight in kilograms divided by height in meters squared]). **Results:** The rs9939609 A allele was strongly associated with overweight and obesity in this population. The A allele of the *FTO* polymorphism was significantly associated with higher BMI and higher waist circumference.No significant association between FTO rs 17817449 genotype and adiposity was found.**Conclusions:** This study replicated the genetic association of SNP of FTO (rs9939609) with obesity in a romanian population and, to the authors' knowledge; this is the first such association study in a Romanian population. Acknowledgement This work was financially supported by Internal Research Grants of the University of Medicine and Pharmacy Tîrgu Mureș, România (grant number 1/30.01.2013).

J17.10

The effects of chemical mutagens on the chromosomes of the population living in the area of the oil and petroleum industries

G. Svyatova, *G. M. Berezina, K. A. Koshkarova, D. N. Salimbayeva;*
The Scientific Center of obstetrics, gynecology and perinatology, Almaty, Kazakhstan.

One of the major problems facing the world is the pollution of the environment and the study of its effect on the rate of mutation and inheritance rights. Petroleum products and petroleum industries affect pollution.
Aim: To evaluate the effects of prolonged exposure to chemical mutagens on chromosome population Zhylyoi district of Atyrau region, living in ecologically unfavorable regions.
Material for cytogenetic analysis: the culture of peripheral blood lymphocytes from 71 residents living in the area with the development of the oil industry. Culturing lymphocytes, cooking preparations, coloring G-method performed by standard methods. The control group consisted of 25 people in an ecologically clean region.
The results of the study. We studied the frequency and spectrum of chromosomal aberrations in the groups studied. Found a higher incidence of aberrant cells (1.75 per 100 cells) and the total frequency of chromosomal aberrations (1.9 per 100 cells) in affected individuals compared with controls (p <0,05).
Frequency paired fragments were 0,10±1,99 per 100 cells, dicentric 0,01,±0,23, ring chromosomes 0,14±0,38 frequency of stable chromosome aberrations 0,02±1,17 100 cells in people living in Zhylyoi area. The frequency of chromatid type aberrations was 0,87±0,01 100 metaphases and is represented mainly by single fragments. Findings suggest the influence of chemical factors on the chromosome of people living close to the oil companies and petroleum industries.
Conclusion. Cytogenetic studies of the population will be used to define a group of families of „high risk" for the prevention of genetic disorders in ecologically unfavorable regions.

J17.11

Association between C282Y and H36D mutations of the HFE gene with hepatic cirrhosis in Lithuanian population

S. Juzenas[1], *L. Kucinskas[1], J. Sumskiene[2], V. Petrenkiene[2], J. Kondrackiene[2], I. Valantiene[3], J. Skieceviciene[1], L. Kupcinskas[1];*
[1]Institute for Digestive research, Lithuanian University of Health Sciences, Kaunas, Lithuania, [2]Department of Gastroenterology, Lithuanian University of Health Sciences, Kaunas, Lithuania, [3]Institute for Digestive Research, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction: Liver cirrhosis is one of the major gastrointestinal diseases. Cirrhosis is commonly caused by alcohol use, viral hepatitis B and C and many other possible causes. The search for epidemiological, biological or genetic factors that could help to select patients at higher risk of developing cirrhosis is necessary. Among these factors, the influence of excessive liver iron overload and HFE gene mutations have been debated over the past few years and up to now there is limited data on association between HFE gene mutations and cirrhosis.
The aim of this study: To determine the association between HFE gene C282Y and H63D mutations and liver cirrhosis.
Methods: A cohort of cirrhosis patients consisted of 209 participants. The diagnosis of cirrhosis was confirmed by clinical features, liver biopsy and radiological imaging tests. Control samples were randomly obtained from 1005 blood donors. HFE gene mutations were detected using PCR-RFLP method. Statistical analysis were performed using statistical software for genetic association studies PLINK v2.050.
Results: C282Y allele was associated with liver cirrhosis (5,02%, OR-2.074, p=0.00510) when compared with controls (2,49%). C282Y/wt genotype was linked with cirrhosis comparing with wt/wt genotype (OR-2.002, p=0.01239). A similar situation was observed in dominant model for C282Y mutation (wt/wt vs. C282Y/wt + C282Y/C282Y) which showed increased risk of liver cirrhosis (OR-2.065, p=0.00766). H63D mutation was not associated with cirrhosis in Lithuanian population.
Conclusion: HFE gene C282Y mutation is associated with liver cirrhosis and might cause a higher risk for progression of liver cirrhosis in Lithuanian population.

J17.12

Associations of genetic variants of CNR1 and CNR2 with hypertension or dislipidemia in the Chinese post-menopausal women

M. Lin[1,2], *F. Jian[1], H. Wu[3], L. Hsiao[4], C. Hwu[4];*
[1]Institute of Public Health, National Yang-Ming University, Taipei, Taiwan, [2]Department of Medical Research, Taipei Veterans General Hospital, Taipei, Taiwan, [3]IDepartment of Radiology, Taipei Veterans General Hospital, Taipei, Taiwan, [4]Section of Endocrinology and Metabolism, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.

Metabolic syndrome may occur in 40% of postmenopausal women and is largely determined by overweight and obesity. Obesity in menopause women occurs as a result of genetic background, hormonal changes and acquired changes in eating behavior and physical activity. Evidence showed that the endogenous cannabinoid system (ECS) plays a role in obesity and related metabolic disorders. To investigate the association between *CNR1* and *CNR2* gene polymorphisms and metabolic risk factors in the Chinese postmenopausal women, five hundred and fifteen post-menopausal women were recruited. Anthropometric measures (body mass index (BMI), waist circumference (WC)), blood pressures, and metabolic parameters were determined. Four SNPs from *CNR1* gene and 1 SNP from *CNR2* gene were selected for genotyping on these post-menopausal women. We found that post-menopausal women carrying TT+TC genotype of *CNR1* rs2023239 had increased risk of metabolic syndrome (p=0.047). We also found two SNPs were significantly associated with pre-hypertension or hypertension (OR= 1.72, 95% C.I.: 1.12-2.63 for rs806381 and OR= 1.77, 95% C.I.: 1.00-3.11 for rs1049353, respectively). We further observed that *CNR2* rs2229579 was significantly associated with hyper-triglycerides in our post-menopausal women (OR= 1.85, 95% C.I.: 1.06-3.23). Haplotype analysis also revealed that those women carry the CGTA haplotype of *CNR1* gene were less likely to develop pre-hypertension or hypertension (aOR= 0.67, 95% C.I.: 0.47-0.96). Our findings provide initial evidence that the *CNR1* gene variants may contribute to pre-hypertension or hypertension and *CNR2* gene variant may predict hyper-triglycerides in post-menopausal women in Taiwan.

J17.13

A study on the association of ERCC1 Asn118Asn polymorphism and colorectal cancer risk in West Algerian population

F. Moghtit[1], *M. Aberkane[2], V. Lemorvan[3], L. Louhibi[1], R. Bellot[3], A. Bousahba[4], A. Megaiz[4], J. Robert[3], N. Mehtar[1];*
[1]University of science and technology of Oran Mohamed BOUDIAF, Oran, Algeria, [2]Department of pharmacy, University of Oran, Oran, Algeria, [3]Laboratory of Pharmacology of Anticancer Agents Inserm VINCO U916, Institut Bergonié and Victor Segalen University Bordeaux 2, Bordeaux, France, [4]Regional Anti-Cancer Center (El Emir Abdelkader), Oran, Algeria.

Colorectal cancer (CRC) is one of the most common causes of death due to cancer in both men and women throughout the world. It has been suggested that sporadic CRC is most likely caused by lowpenetrance genes, including those involved in DNA repair mechanisms. Furthermore, the accumulation of DNA damage may contribute to colorectal carcinogenesis. Many epidemiological studies have explored the association between ERCC1 Asn118Asn (C/T, rs #3177700) polymorphism and colorectal cancer risk in various populations, its role in colorectal carcinogenesis in Algerian population has not been established. Therefore, we conducted this case-control study in a West Algerian population to assess the potential role of this genetic polymorphism on the risk of colorectal cancer. Peripheral blood samples of 90 sporadic CRC patients and 100 normal controls were collected, DNA extracted genotyped using pyrosequencing technique. The distribution of genotypes of ERCC1 Asn118Asn genotype and allele frequencies among CRC cases was not significantly different from those among controls (P>0,05). The variant genotype combinations did not show any significant association with CRC susceptibility risk suggesting that the ERCC1 codon 118 polymorphism does not convey moderate increase in susceptibility to CRC in West Algerian population. This is the first study on ERCC1 gene polymorphism in our population suggesting that the Asn118Asn polymorphism may not be associated with the colorectal cancer risk in West Algerian population. Further research with a larger sample size is needed to reveal more information about this polymorphism and the appearance of colorectal cancer in our population.

Cystic Fibrosis in Arab populations: Identification of novel mutations and complex allele in Egyptian and Lebanese Patients

A. EL-Seedy[1,2], *R. Farhat*[2], *M. Pasquet*[2,3], *H. Shafiek*[4], *T. Morsi*[4], *M. EL-Komy*[1], *A. Megarbane*[5], *A. Kitzis*[2,3], *V. Ladeveze*[2];
[1]*Department of Genetics, Alexandria University,, Alexandria, Egypt,* [2]*Université de Poitiers - Pôle Biologie Santé, Génétique de Maladies Rares, Université de Poitiers, Poitiers, France,* [3]*CHU de Poitiers, Poitiers, France,* [4]*Department of Chest diseases, Alexandria University, EL-Sultan Hussein St.-Azarita,, Alexandria, Egypt,* [5]*Unité de Génétique Médicale, Faculté de Médecine, Université Saint-Joseph, Beirut, Lebanon.*

Background: Cystic fibrosis occurrence in Arab populations is not common and still remains unidentified. Furthermore, the lack of disease awareness and diagnosis facilities mislead the identification of Cystic Fibrosis (CF) during many decades. The knowledge about cystic fibrosis (CF) in Egypt is very limited, and a few reports have draw attention to the existence of CF or CFTR-related disorders in Egyptian population as well as in Lebanese population. Therefore a comprehensive genetic analysis of the CFTR gene was realized in the Egyptian and Lebanese patients.
Methods: DNA samples of 56 Egyptian and 17 Lebanese patients were screened for the CFTR gene mutations. The 27 exons and their flanking regions of the CFTR gene were amplified by PCR using the published primer pairs and were studied by automated direct DNA sequencing to identify disease-causing mutations.
Results: CFTR screening revealed the identification of seven mutations: including two novel (c.3718-24G>A; c.2782G>C) and five previously reported mutations (c.1418delG, c.2997-3000delAATT, c.902 A>G, c.2620-15C>G, c.3877G>A). Furthermore, six polymorphisms were found: c.1408A>G, c.3870A>G, c.2562T>G, c.1584G>A, c.4389G>A, c.869+11C>T. These mutations and polymorphisms were not previously detected in the Egyptian population except for the c.1408A>G polymorphism. Whereas Lebanese patients have a complex allele c.[869+11C>T;3909C>G] not previously described, no other novel mutations were identified.
Conclusion: Identification of CFTR mutations will become increasingly important in undocumented populations. The current findings will help us to establish a panel of the CFTR gene mutations in the Egyptian and Lebanese populations for designing an appropriate strategy for future genetic diagnosis of CF.

J17.15

Is Elucigene CF30 Kit effective in detecting CFTR mutations on Algerian patients?

F. Z. Sediki[1], *A. Radoui*[2], *F. Cabet*[3], *F. Zemani-Fodil*[1], *M. Fodil*[1], *N. Mehtar*[1], *A. Boudjema*[1];
[1]*Laboratoire de Génétique Moléculaire et Cellulaire. Université des Sciences et de la Technologie d'O, Oran, Algeria,* [2]*Service de Pneumologie et Allergologie Pédiatriques, Etablissement Hospitalier Spécialisé (EHS) Canastel- Oran- Algérie., Oran, Algeria,* [3]*Service d'Endocrinologie Moléculaire et Maladies Rares, Hôpital Femme-Mère-Enfant, Bron-Lyon-France., Bron- Lyon, France.*

Introduction: Cystic Fibrosis (CF) [MIM # 219700] is the most common autosomal recessive genetic disease, in Caucasian populations [1].
In Algeria, no information is available about the incidence of CF. In the Maghreb, there are few data about the molecular basis of CF, probably due to an under diagnosis.
This study evaluated the effectiveness of the ELUCIGENE CF30 Kit in a sample of Algerian CF patients.
Patients and methods: Subjects: Twenty four (24) unrelated CF patients were recruited from the Pneumology and Allergology Department of the specialized Hospital Center in Canastel Oran (Algeria).CF diagnosis was based on a clinical findings and repeated positive sweat chloride tests (>60 mmol/l).
DNA extraction and genotyping
- 10 ml of whole blood was collected from all participants in EDTA tubes.
- Genomic DNA was extracted using standard Salting Out procedure [2].
- Mutations were explored by the ELUCIGENE CF 30 Kit (Tepnel Diagnostics, Oxon, United Kingdom) which is base d on a PCR/ARMS technique.
In screening the twenty four CF patients (48 chromosomes) for 30 mutations available in ELUCIGENE CF30 kit, only five mutations were found:
- c.1521_1523delCTT (F508del).
- c.579+1G>T (711+1G>T).
- c.1624G>T (G542X).
- c.3909C>G (N1303K).
- c.1652G>A (G551D).
All the mutations found were validated.
„ The Elucigene CF30 detected 5 mutations in our sample, which is about 16.66%.
„ The detection rate seems low compared to European populations. **Conclusion:** The most interesting is to develop in collaboration with ELUCIGENE one specific Maghreb Kit and inclued mutations which frequency higher than 2%.

J17.16

Notification of death from cystic fibrosis in Brazil during 30 years from 1981 to 2010

V. Cury, L. F. P. Longui, A. Zanolla, V. G. Carvalho, S. R. Middleton, **C. L. A. Paiva**;
Universidade Federal do Estado do Rio de Janeiro (UNIRIO), Rio de Janeiro, Brazil.

The aim of this work was to evaluate the notification of cystic fibrosis (CF) as primary cause of death in Brazil, from 1981 to 2010, and to compare with developed countries. The Brazilian data was obtained from SIM-Data/SUS and the American from the CDC WONDER. The Brazilian median age at death (MAD) was 3.9 years in 1981 and 12.4 years in 2010 for typical severe CF. In 1994, the Brazilian MAD was much lower (7.2y) than that (21y) of seven developed countries reported by Forgarty et al, 2000. We found no increase in MAD in Brazil from 1981 to 1985; from 1986 to 2010 it showed a three-fold increase. From 1981 to 1990, there were few deaths over 25 years of age in Brazil, mostly concentrated in younger age groups. During the sample period there was an increase in deaths in higher age groups in Brazil, which may reflect better patient survival rates due to increased knowledge of the disease, with repercussions for its diagnosis and treatment. We also observed an increase in the reported cases of CF deaths per 100.000 inhabitants in Brazil over the years, possibly due to the better knowledge of the disease and consequently more accurate death notification, since this increase is not typical of a genetic disease. For the USA we observed a decrease in notified CF deaths, despite the population increase which may be a reflection of a smaller number of people born with CF, due to appropriate genetic counseling and prenatal diagnosis.

J17.17

SERPINA1 gene polymorphism frequency in clinically confirmed cystic fibrosis patients

G. Taurina[1,2], *L. Piekuse*[1], *I. Kempa*[1], *Z. Krumina*[2], *L. Kornejeva*[2], *V. Svabe*[3], *A. Krumina*[4];
[1]*Scientific Laboratory of Molecular Genetics, Riga Stradins University, Riga, Latvia,* [2]*Medical Genetics Clinic, Children's Clinical University Hospital, Riga, Latvia,* [3]*Department of Pulmonology and Allergology, Children's Clinical University Hospital, Riga, Latvia,* [4]*Latvian Biomedical Research and Study center, Riga, Latvia.*

Background - *SERPINA1* gene is known to be one of cystic fibrosis (CF) modifier gene. Patients who carry the Z allele are at greater risk of developing severe liver disease. The aim of this study - to assess whether PIZ (rs28929474), PIS (rs17580) M1 ala/val (rs6647) or M2 (rs709932) alleles are associated with liver disease in patients with CF. Materials and methods - 61 clinically confirmed cystic fibrosis patients (enrolled 1998- 2013) and 61 control patients (without confirmed cystic fibrosis) were analysed for M, S and Z alleles in *SERPINA1* gene. The methods used were multiplex PCR and RFLP. Results - M2 allele was more common in CF patients comparing to the control group, (MAF affected=0.2449, MAF controls = 0.123, p=0.018, OR=2,314, CI95%=1,138-4.705). Analysing haplotype rs28929474-rs17580-rs6647-rs709932 frequency in the *SERPINA1* gene in patients and controls significant association was found in CF patients with haplotypes N-N-val-M2 (MAF affected=0.244, MAF controls=0.123, p=0.0198) and N-N-val-wt (MAF affected=0.516, MAF controls=0.647, p=0.051). Comparing CF patients with confirmed liver damage (n=6) and CF patients without it statistically significant association was not found. Conclusions - Haplotypes in the *SERPINA1* gene do not predispose cystic fibrosis patients to liver disease/damage. M2 allele and its containing haplotypes are more common in cystic fibrosis patients than in control group.

J17.18

Population data of 11 DNA markers from a sample taken from South Romania

A. Alexiu[1], *M. L. Toma*[2,1], *S. Spandole*[1], *I. Radu*[1], *C. Cristescu*[2], *D. Cimponeriu*[1];
[1]*Department of Genetics, Bucharest, Romania,* [2]*Titu Maiorescu University, Bucharest, Romania.*

In this work, were typed in 100 unrelated individuals (sex ratio 60:40) from South Romania eight DNA markers. Aim was to analyze the genetic variability and to establish the relation between this region and other European populations. We establish Hardy-Weinberg equilibrium, gene diversity, genetic distances and tree topology by PHYLIP 3.68 package. Polymorphism's frequencies were similar to the mean frequencies calculated for the whole set of populations included in the study. The mean value of Ht was 0,201, and for Hs was 0,18. The most affiliated population with our lot are Italy, Spain, Poland, Germany, Greece and Turkey the most distant population are United Kingdom, Sweden, Croatia and Slovacia.

A new variant of Ehlers-Danlos syndrome with inborn errors of mucopolysaccharide metabolism in the mother and son

E. V. Bugaeva, *Y. B. Grechanina, E. Y. Grechanina;*
KSMGC, Kharkiv, Ukraine.

Background: Connective tissue dysplasias are characterized by the clinical polymorphism and genetic heterogeneity. Each new patient with Ehlers - Danlos syndrome, according to our observations is potentially a new variant of the syndrome.
Care report: Family V. has been followed-up for 13 years. Proband V. Clinical manifestations - coarse facial features, a disproportionate body, keeled chest deformity, kiphoscoliotic spinal deformity, wing-like scapulas, an increased skin extensibility, its softness, velvet, hypotonia, hypermobility of joints, varicose veins, swelling of the lower extremities. Proband's mother M. - disproportionate body, coarse facial features, kiphoscoliotic spinal deformity, a soft, doughy, hyperelastic skin, hypermobility of joints, varicose veins, lymphatic edema of the lower extremities.
The examination echografically revealed hepatosplenomegaly, metabolic, dysplastic changes in the kidneys, mitral valve prolapse, an additional chord of the left ventricle. Biochemically - signs of an increased collagen degradation, daily urine oxyproline - 155.4 mg/day, increased urinary glycosaminoglycans up to 148 CPC U/g creat., hyperprolinemia, hyperglycinemia, hyperprolinuria, hyperhomocysteinemia - 26.6 µmol/l. Pedigree analysis showed that the pedigree is burdened by cardiovascular disease.
MTHFR G1793A/MTRR A66G polymorphism was revealed in the proband and his mother by the study of gene polymorphisms of folate cycle system.
Conclusion: A new variant of Ehlers-Danlos syndrome has been diagnosed in the mother and son with the phenotype associated with metabolism errors of mucopolysaccharides, hypermobility of joints, hepatosplenomegaly, an early common varicose disease, muscular hypotonia due to lower activity of MTHFR G1793A/MTRR A66G enzymes.

Multidisciplinary study of Endometriosis as a common complex disorder

V. S. Baranov, *Yarmolinskaya M.I., Ivaschenko T.E.;*
Ott's Institute of Obstetrics&Gynecology, St.-Petersburg, Russian Federation.

Endometriosis (E) is a common multigenetic disorder affecting almost 10% of women of reproductive age. Comparative molecular, genetic, immunological analysis and endocrinology tests were applied in the studies of 257 women with E and in 117 women in the control. Participation of the genes responsible for steroid hormone activity, their receptors, inflammation, proliferation, cell migration, apoptosis, intercellular adhesion, angiogenesis as well as the genes regulating their activity have therefore been suggested as plausible candidates. A handful of very interesting new candidate genes involved in oncogenesis, metaplasia of endometrium cells and embryonic development of female reproductive system were identified by GWAS technology. In addition to alterations in the DNA sequence itself, differential expression levels of the candidate genes might be caused by different epigenetic modifications including methylation, heterochromatization, miRNA regulation etc. Complex genetic net of E, implies participation of epigenetic landscape of E. Origin of E could be provoked by any combination of both genetic and epigenetic risk factors with subsequent canalization of pathological processes (reverse epigenetic landscape), which become irreversible soon after it starts.

Asthma related FCER2 variant in Roma and Hungarian populations

P. Matyas[1,2], *R. Szalai[1,2], L. Magyari[1,2], B. Duga[1,2], E. Kovesdi[1,2], Z. Banfai[1,2], A. Szabo[1,2], B. Melegh[1,2];*
[1]Department of Medical Genetics, University of Pecs, Pecs, Hungary, [2]Szentagothai Research Centre, University of Pecs, Pecs, Hungary.

Asthma is a complex respiratory disease, which can be caused by environmental factors and genetical predisposition. It is one of the most widespread diseases in the world; it has a high presence in most ethnic group. The low-affinity IgE receptor (FcεRII /CD23) encoded by the FCER2 gene (Fc fragment of IgE) plays important role in the regulation of IgE responses and inhaled corticosteroids (ICS) therapy in asthma. Corticosteroids influence FCER2 expression and FcεRII receptor function. The intronic rs28364072 polymorphism (T2206C) of FCER2 gene associated with elevated IgE levels, severe asthmatic exacerbations and decreased gene expression. The variation in the FCER2 gene contributes to variation in ICS treatment response in asthmatics. Our aim was to investigate the ethnic differences, allele and genotype frequencies of intronic variant of FCER2 in average Roma and Hungarian population. We examined 458 Roma (206 males, 252 females, mean age: 46.4±18.4) and 397 Hungarian subjects (222 males, 175 females; 37.8 mean age±12.6 years) with PCR-RFLP method. We found more than twofold increased homozygous CC genotype frequency in Hungarian group compared to Roma samples (5.8% vs. 2.8%, p<0,05). The C allele frequencies were similar in each group (24.8% in Romas and 24.6% in Hungarians). The current study demonstrated that unfavourable variants can diversely occur in Hungarian and Roma individuals. Genetic test of FCER2 variant are likely necessary to assess the outcome of asthma treatment. Homozygous 2206C allele carrier Hungarians have higher chance for insufficient response to corticosteroids compared with Roma subjects due to genotype higher risk frequency. This research was supported by TÁMOP-4.2.3-12/1/KONV-2012-0028.

Common MEFV gene mutation profiles in Familial Mediterranean Fever patients in Canakkale Population

F. Silan[1], *N. Topaloglu[2], M. Urfali[1], C. AKURUT[1], M. G. K. KOCAK[3], D. Kankaya[1], E. ARI[1], O. Ozdemir[1];*
[1]Department of Medical Genetics, Canakkale, Turkey, [2]Department of Pediatrics, Canakkale, Turkey, [3]Department of Nephrology, Canakkale, Turkey.

Objective:In the current results it was aimed to find out of the current study is to determine the frequency of common MEFV gene point mutations in 741 patients who preliminary diagnosed as FMF Method:The genomic DNA was isolated by spin-colon method(Roche, Germany) from peripheral blood samples with EDTA and buccal smears. The MEFV gene profiles for the current FMF cohort were genotyped by Pyrosequencing and direct Sanger sequencing techniques for the target common point mutations. Results: Twenty-two different point mutations were identified in 363(49%) patients and no mutation was detected in 378(51%) current patients suspicious for FMF. The most frequent mutations were M694V(32.7%), E148Q(15.1%), R202Q(11.8%), M680I(9.9%), V726A(7.4%), P369S(6.3%) and K695R(4.4%) in the current FMF cohort. The M694V/E148Q mutation was the most frequent compound point mutation that detected in the current FMF cohort. The most common clinical finding was abdominal pain in the all MEFV mutation types that detected in the current mutated FMF patients. Median attack frequencies of untreated patients are ; 3.14 for M694V, 2.8 for E148Q, 2.75 for R202Q, 2.71 for P369S and 1.44 for K695R. Although attack frequencies were less than patients with M694V, all of the patients from Canakkale region with mutations E148Q, R202Q, P369S and K695R had FMF clinical diagnostic criterias. Conclussion:The current results showed that the R202Q point mutation frequency was higher than the other sub-populations that reported from different reigions of TURKEY. It was seen that the initiation of clinical symptoms were delayed in patients with R2020Q mutation when compared to the others.

The association analysis of polymorphism the metabolism of lipids genes with bmi, waist circumference and blood lipidogramma's parameters at women before and after the Menopause

O. S. Glotov[1,2,3], *I. V. Tarkovskaya[1,4], M. M. Danilova[1], E. S. Vashukova[1,2], A. S. Glotov[1,2], V. S. Pakin[1,2,4], M. V. Aseev[1,2,3], T. E. Ivashchenko[1,2], A. B. Maslennikov[1], V. S. Baranov[1,2];*
[1]St-Petersburg State University, St-Petersburg, Russian Federation, [2]FSBI «The D.O.Ott Research Institute of Obstetrics and Gynecology» NWB RAMS, Saint-Petersburg, Russian Federation, [3]Saint Petersburg State Establishment of Health Care City Hospital No 40, Saint-Petersburg, Russian Federation, [4]Genetic Laboratory, Ltd BioGlot, Saint-Petersburg, Russian Federation.

Using the PCR-RFLP method we have studied polymorphism of 36 genes involved in lipid metabolism in 212 women residents of the North-West Region of Russia (St. Petersburg) at the age of 18 to 77. We found the association of polymorphisms in several candidate genes with body mass index, waist circumference, total cholesterol level, low density lipoprotein cholesterol level and very low density lipoprotein cholesterol level. We proposed a model for the prediction of examined parameters based on logistic regression method. Our findings confirm the possibility of primary assessment of body mass index, waist circumference, total cholesterol level, low density lipoprotein cholesterol level and very low density lipoprotein cholesterol level in women based on genetic markers. It is shown that women before and after a menopause have a contribution of genetics to determination of body mass index, waist circumference, total cholesterol level, low density lipoprotein cholesterol level and very low density lipoprotein cholesterol level is various.

Genetic epidemiological study of hereditary disorders in Tatarstan Republic (Russia)

R. A. Zinchenko, *T. A. Vasilyeva, E. K. Ginter;*
Research Center for Medical Genetics, Moscow, Russian Federation.

Tatars - are the second sized ethnos of the Russia. The load and genetic diversity of monogenic hereditary disorders (HDs) in three major ethnographic groups of Tatars from Tatarstan Republic were analyzed (Kazan Tatars-3 Districts, Mishars-2 Districts and Teptyars-3 Districts. The size of the investigated populations was more than 270,000 inhabitants (213,000 Tatars). The total population was examined by standard protocol of medical

genetic research elaborated in laboratory of genetic epidemiology, Research Centre for Medical Genetics. About 3500 HDs of OMIM could be identified by this protocol. Clinical investigations were performed by neurologists, ophthalmologists, orthopedic, otolaryngology's, dermatologists, pediatricians and clinical geneticists, focused on diagnostic of HDs. Genetic diversity of HDs in the investigated population consisted of 256 disorders (1597 affected): 135 AD, 97 AR and 24 X-linked recessive. Genetic differentiation of load of Mendelian HDs between populations of different ethnographic groups was found. The average prevalence rates were 1:172 persons in Kazan Tatars; 1:120 persons in Mishars and 1:150 persons in Teptyars. Variation of prevalence of all HDs in districts was from 1:350 persons to 1:85 persons. Significant differences in the load and diversity of HDs was found between groups "Kazan Tatars- Mishars" and "Teptyares - Mishars".

Medical and population genetic characteristics of the population genodermatosis Rostov region, Russia

S. Amelina[1], *N. Vetrova[1], E. Degtereva[2], M. Amelina[1], R. Zinchenko[3];*
[1]Research Institute of Biology, Rostov-on-Don, Russian Federation, [2]Rostov Medical Institute, Rostov-on-Don, Russian Federation, [3]Research Centre for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation.

Genodermatosis is a genetic disorder of the skin usually generalized.
The medical and population genetic studies genodermatosis population 12 districts of the Rostov region were conducted. The total size of the investigated population was 497,460 persons, 20% of whom are children (101,845 children).
Data collection and processing were done according to the protocol of Genetic Epidemiology Laboratory of Research Centre for Medical Genetics in Moscow.
The total prevalence rate among the population genodermatosis Rostov region was 1:1709 and 1:1047 for the child population, respectively.
The incidence of autosomal dominant (AD) genodermatosis was high (5,15±0,32) and incidence of autosomal recessive (AR) and X-linked genodermatosis was low (0,28±0,08 and 0,84±0,18, respectively). The same tendency was among children (the incidence of AD, AR and X-linked genodermatosis, 7,81±0,90, 0,72±0,27, 2,05±0,65, respectively). Incidence was calculated per 10,000 populations.
Significant differences in the different districts of the incidence rates of AD and AR disorders were reviewed. The correlation with one of the main population genetics factor is genetic drift was found.
Spectrum genodermatosis represented 22 nosological forms, 15 of them with AD, 5 with AR and 2 with X-linked inheritance types. The «nucleus» of genodermatosis spectrum in Rostov region population are ichthyosis vulgaris (1:5025), palmoplantar keratoderma with autosomal dominant inheritance (1:13818), multiple lipomatosis (1:31091), neurofibromatosis type 1 (1:9212), tuberous sclerosis (1:29262), X-linked ichthyosis (1:15546) and anhidrotic ectodermal dysplasia (1:49746). The prevalence rate of these diseases has been frequently than 1:50000.
Foci accumulation such genodermatosis as neurofibromatosis type 1, vulgar and X-linked ichthyosis was determined.

Allelic heterogeneity of GJB2 gene in Romanian population with congenital isolated hearing-loss

C. Dragomir[1], *A. Stan[1], D. T. Stefanescu[1], L. Savu[1], E. Severin[2];*
[1]Genetic Lab, Bucharest, Romania, [2]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania.

Aimes: Different alleles within the same gene can cause a similar variant phenotype. Previously published studies showed the allelic heterogeneity of GJB2 gene as main genetic cause of isolated congenital hearing-loss phenotype. The proportional distribution of the different mutations within GJB2 gene varies in different ethnic groups. The aim of the present study was to provide a complete and updated spectrum of mutations in GJB2 and GJB6 gene and to identify the most prevalent mutations in Romanian population.
Material and Methods: To overcome our aims, we used clinical data from 80 unrelated persons with congenital hearing-loss and performed ARMS-PCR and DNA sequencing techniques for detection of known mutations and identification of mutations within GJB2 gene. Analysis of del(GJB6-D13S1830) and del(GJB6-D13S1854) was performed by multiplex PCR.
Results: Most prevalent mutation was c.35delG (40.0%) in both homozygotic and heterozygotic forms. The second mutant allele was W24X (8.75%) also founded in homo- or heterozygotic forms, followed by c.-23+1G>A originally named IVS1+1G>A and R127W mutations with lower frequencies.
Conclusions: The study reveals c.35delG mutation as most prevalent one, absence of GJB6 gene deletions, genetic background of congenital hearing-loss in local population and supports improvement of genetic counselling services.

Alleles analysis of *GSTA1* and *GSTP1* genes in the Polish population

O. Zakerska-Banaszak[1,2], *M. Skrzypczak-Zielinska[3], B. Tamowicz[4], I. Sobieraj[2], N. Drweska-Matelska[5], M. Szalata[5], R. Slomski[5,3], A. Mikstacki[4];*
[1]The NanoBioMedical Centre, Poznan, Poland, [2]University of Life Sciences, Department of Biochemistry and Biotechnology, Poznan, Poland, [3]Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland, [4]Department of Anaesthesiology and Intensive Therapy, Regional Hospital, Poznań, Poland, [5]University of Life Sciences, Department of Biochemistry and Biotechnology, Poznań, Poland.

Glutathione S-transferases A1 and P1 are the main enzymes involved in the biotransformation of drugs, carcinogens and toxins. Their activity may influence drug response as well as susceptibility to diseases. *GSTA1* and *GSTP1* genes coding for these enzymes, are important objects of many studies due to their genetic variability which may affect enzymes activity. The aim of our study was to determine the alleles *GSTA1*A/*B*, *GSTP1*A, *B, *C* distribution in the Polish population. We performed our analyses on the DNA of 160 subjects from the Polish population. In the *GSTP1* gene we have genotyped two polymorphisms (I105V and A114V) with pyrosequencing method and the *GSTA1* gene was screened for the changes in the promoter region using sequencing. The detected variants were subjected to the haplotype analysis. We found alleles *GSTP1*A* (c.313A, c.341C), **B* (c.313G, c.341C) and **C* (c.313G, c.341T) with 65.3%, 23.8% and 10.9% frequency, respectively. As a result of *GSTA1* gene promoter sequencing we detected 8 SNPs located in sites: G-52A, C-69T, C-115T, A-513G, T-567G, G-631T, A-1066T, G-1142C, G-1245A. The allele *GSTA1*B,* associated with the decreased enzyme activity was observed in our study with frequency of 43.1%. Finally, 4 haplotypes have been determined in 160 Polish individuals. Our study demonstrated that the distribution of the alleles *GSTA1*A/*B* and *GSTP1*A, *B, *C* in the Polish population corresponds to data for Caucasians. Furthermore, we found novel SNPs, excluding three well known changes (G-52A, C-69T, T-567G), which are linked to the alleles *GSTA1*A/*B* affecting enzymes activity.

J17.28

Genome-wide association analysis identifies a locus on DMD (dystrophin) gene for power athlete status in Russians

V. A. Naumov[1], **I. I. Ahmetov**[2], *A. K. Larin[1], E. V. Generozov[1], N. A. Kulemin[1], E. A. Ospanova[1], A. V. Pavlenko[1], E. S. Kostryukova[1], D. G. Alexeev[1], V. M. Govorun[1];*
[1]Research Institute for Physical-Chemical Medicine, Moscow, Russian Federation, [2]Volga Region State Academy of Physical Culture, Sport and Tourism, Kazan, Russian Federation.

Power athlete status is a heritable trait: around two-thirds of the variance in this phenotype is explained by genetic factors. Since power and endurance are located at the opposite extremes of a muscle performance continuum, a genome-wide association study (GWAS) of elite Russian power-oriented athletes (sprinters and strength athletes) and endurance-oriented athletes as controls was performed to identify common genetic variants associated with elite power athlete status. 102 sprinters, 86 strength athletes and 178 endurance-oriented athletes were genotyped using the Illumina® HumanOmni1-Quad BeadChips. When comparing sprinters and endurance-oriented athletes, the most significant association (P=6.2∗10-7) was shown for the rs939787 polymorphism. Interestingly, this association was replicated (P=2.9∗10-6) by comparing strength athletes and endurance-oriented athletes (P=3∗10-8 when sprinters and strength athletes were combined). The rs939787 is located in the DMD (dystrophin) gene which plays an important role in muscle contraction and strength, linking the intracellular cytoskeleton to the extracellular matrix. In conclusion, our data suggest that the DMD gene rs939787 polymorphism is associated with elite power athlete status in Russians.

J17.29

Human longevity and Alu-polymorphism

V. V. Erdman, *T. R. Nasibullin, I. A. Tuktarova, D. S. Karimov, O. E. Mustafina;*
Institute of Biochemistry and Genetics, Ufa, Russian Federation.

It is assumed that genome instability can affect the lifespan. Alu-insertion is one of the causes of such instability.
The aim of study was to search association between age and polymorphic Alu-elements, localized within introns of PLAT, COL13A1, ACE, LAMA2 and TEAD1 genes.
DNA of 1611 unrelated individuals from 21 to 109 years, ethnic Tatars from Russia, was genotyped. Age dynamics of the genotype and allele frequency was estimated using logistic regression analysis (SPSS18.0).
Associations between age and polymorphic Alu-elements localized within introns of COL13A1 (Ya5ac1986), LAMA2 (Ya5-MLS19) and TEAD1 (Ya5ac2013) genes was found for females. Chances of achievement of longevity age above for females with COL13A1*I/*I (range 57 - 109 years, OR=1.046, P<0.001), LAMA2*I/*I (range of 56-109 years, OR=1.059, P<0.001), LAMA2*I/*D (range of 56-109 years, OR=1.016, P=0.002) and TEAD1*I/*I (range of 78-109

years, OR=1.055, P=0.012) genotypes. Chances of achievement of longevity age below for females with COL13A1*I/*D (range 57 - 109 years, OR=0.948, P<0.001) and LAMA2*D/*D (range of 56-109 years, OR=0.981, P<0.001) genotypes. Association between age and a polymorphic Alu-element within an intron 16 of ACE gene (Ya5ACE) was detected for males and females. Decrease of ACE*D/*D genotype frequency was observed among long-livers females (range of 77-109 years, OR=0.953, P=0.006) and long-livers males (range of 76-109 years, OR=0.935, P=0.040).
Thus, Alu-polymorphism of COL13A1, ACE, LAMA2 and TEAD1 genes, possibly, are associated with attainment of longevity age. And besides, positive association with age is traced for insertional allele of Alu-elements.
Supported by grants RFBR 13-04-01561a, 14-04-97094a, 14-04-01169a.

Formation of the genetic structure of Uigurs in Kazakhstan
A. Baysbekova[1], *G. M. Berezina*[2], *G. Svyatova*[2];
[1]*The Institute of Molecular Medicine, Almaty, Kazakhstan,* [2]*The Scientific Center of obstetrics, gynecology and perinatology, Almaty, Kazakhstan.*

The study of genetic structure of modern human population is one of key problems of human genetics. Genetic and demographic parameters of uighurs is presented. Marriage and migration structure of fourteen rural regions were studied. The mean value of ethnic assortative marriage was 1.68. Analysis of marriage structure suggests genetic differentiation of rural districts uighur region and is characterized by a high proportion of mononational marriages (86-97%), low intensity and radius of migrations, the share of external migration to an average of 0.99%, high level of inbreeding from 0.0005 in Chundzha rural district to 0.00946 in Kolzhat. Positive assortative mating on a national basis was 4.2. High index of endogamy found in Kolzhat districts (72%).
The mean number of children per woman constituted 3.98. Crow index of total selection (Itot) and its components (Im, If) were 0.25, 0.04 and 0.20 respectively. The size of the portion of the population before reproduction (40.4% of the total), the prevalence of reproductive parts of the population (43.8% of total), and family size is 4.0 allow us to classify the type of growing population of uighurs.
Recent social and economic changes have led to an increase in differentiation of rural districts uighurs of Kazakhstan. Thus, detected subdivision uighur rural population on number of interacting subpopulation units, the main insulating factor that is positive assortative mating on national basis, set growing type of reproduction, described nature of migration processes, analysis of components as possible of potential population screening for uighurs in Kazakhstan.

Random Inbreeding in Karachay
G. I. Elchinova[1], **A. Ivanov**[2], *L. Elkanova*[2], *R. Zinchenko*[2];
[1]*Research Centre for Medical Genetics, Moscow, Russian Federation,* [2] *Research Centre for Medical Genetics, Moscow, Russian Federation.*

Karachays live compactly in 4 regions of Karachay-Cherkessia (Russia). Karachays are one of the Turkic-speaking North Caucasian peoples. Values of Wright random inbreeding (a quarter of the sum of squares of frequencies of surnames) are counted on the basis of distribution of adults surnames for rank of „district" population and „Village Council" population. Both of thees assessments are necessary for carrying out various types of analysis. District population rank F_{st} values are: 0.0035 (Malokarachaevsky district), 0.0014 (Prikubansky district), 0.0016 (Ust-Dzhegutinsky district), 0.0015 (Karachaevsky district). The average-weight values F_{st} for "Village Council" population rank are counted separately for rural and urban populations (where urban present) and make: 0.0056 (Malokarachaevsky, rural), 0.0033 (Prikubansky, rural), 0.0042 and 0.0010 (Ust-Dzhegutinsky, rural and urban), 0.0084 and 0.0016 (Karachaevsky, rural and urban), thus the general assessment of the average-weight F_{st} value for these areas without division into urban and rural people make: 0.0056, 0.0033, 0.0024, 0.0059, respectively.

J17.32
An early manifestation of LBSL syndrome, case description
E. P. Zdubskaya;
KSMGC, Kharkiv, Ukraine.

Background :Leukoencephalopathy with brain stem and spinal cord involvement and lactate elevation is an autosomal recessive disease. Mutation in gene DARS2 is associated with this syndrome. The gene is located on the long arm of chromosome 1 (1q 25.1), the disease is associated with deficiency of mitochondrial aspartyl - tRNA synthetase.
Care report: 1 year and 5 month old boy T., with static kinetic and psycho-speech development delay, excess body weight (16kg). The child is from I pregnancy against the background of threatened miscarriage. Delivery at 36-37 weeks by cesarean section. Birth weight - 3300g. At the time of examination we paid our attention at the decreased muscle tone, muscle strength tendon and periosteal reflexes are not observed, nystagmus, ataxia. ENMG - the neuropathic type of changes, myopathic syndrome. MRI of the brain - using T1, T2 and FLAIR- modes - white matter lesions of the brain and cerebellum. The karyotype - 46,XY. Amino acid levels, blood lactate are unchanged. Partial analysis of the DARS gene by sequencing: in 5 gene locus - mutation c492+2T-C in the heterozygous state.
Conclusion: The disease manifests in the age of 3-15 years. Cerebellar ataxia, spastic tetraparesis and cognitive impairment develop. Before the onset of the disease, psychomotor and speech development corresponds to age, movement disorders develop further, patients become disabled by the second to fourth decade of life. In our case, the disease manifested in the heterozygous carrier by one year of life and was accompanied by obesity.

J17.33
Association analysis of haplotypes of the leptin gene promotor region with BMI in Roma population
M. Zajc Petranović, *Ž. Tomas, A. Barešić, A. Ivankov, S. Petrić, M. Peričić Salihović, N. Smolej Narančić, B. Janićijević, T. Škarić-Jurić;*
Institute for Anthropological Research, Zagreb, Croatia.

Leptin, an adipocyte-derived protein, plays a key role in regulating energy intake and consumption. Increased circulating leptin levels, commonly found in obesity, indicate a failure to signal satiety and halt the progression of obesity. Aim of this study was to investigate the association of single nucleotide polymorphisms (SNP) and haplotypes of the leptin gene promotor region with body mass index (BMI) in Roma (Gypsy), a population known to be vulnerable to developing obesity presumably due to both their life-style and genetic background.
We sequenced 1500 bp region of leptin gene promotor in the sample of 377 Roma individuals from Croatia and identified 9 polymorphic sites. Haploview software was used to assess linkage disequilibrium (LD) among polymorphic loci as well as the Unphased version 3.0.13 software for haplotype association analysis.
All nine SNPs were grouped into single LD block due to their proximity. None of the single markers (rs1349419, rs146378188, rs13245201, rs185230264, rs791614, rs12535708, rs10487506, rs11770725 and rs12535747) showed individual statistically significant association with BMI. However, two haplotypes, A-A-G-G-A-C-G-T-C and G-A-A-G-G-A-A-T-A, showed significant association with BMI (p=0.005061 and p=0.03214). Both p-values remained significant after 1000 permutation tests.
Our data showed that haplotype association analysis provided advantage over individual SNPs analysis. Haplotypes spanning the leptin gene promotor region were found to be significant predictors of BMI in Croatian Roma.

J17.34
Germline variants of ARID5B as possible risk factors for childhood acute lymphoblastic leukemia in Latvia
M. Kreile, *L. Piekuse, D. Rots, A. Zarina, E. Cebura, Z. Kovalova;*
Riga Stradins University, Riga, Latvia.

Background. Acute lymphoblastic leukemia (ALL) is the most common childhood malignancy but etiology of pediatric ALL remains poorly understood. Data from GWAS provided convincing evidence that inherited genetic variation in ARID5B contributes to childhood ALL predisposition, the strongest association was found with SNP rs10821936, some studies show strong association with whole intron. **Aim.** To detect possible association of SNPs in intron 3 of gene ARID5B and ALL predisposition to childhood ALL in Latvia. Material and Methods. In study were enrolled 34 ALL patients and their biological parents. In study group were detected rs10821936 and 6 other SNPs as a closest three from both sides to SNP rs10821936, where MAF > 1%. Analyses were performed using PCR, RFLP and sequencing. **Results.** By TDT test strongest association were found with rs10821936 (OR=10, CI95% 1.28-78.12, p=0.0066), rs10821937 (OR=0.667, CI95% 1.172-8.735, p=0.0164) and almost significant with rs7908445 (OR3.333, CI95% 0.917-12.11, p=0.0522) Haplotype analysis TDT test - with sliding window 5 - rs7923074-rs77918077-rs10821936-rs12246030-rs10821937 (AGCCC) (transmitted frequency 5.959, untransmitted frequency 0.0284, p=0.0153); rs77918077-rs10821936-rs12246030-rs10821937-rs7896246 (GCCCA) (transmitted frequency 8.761, untransmitted frequency 1.042, p=0.0137). Haplotype analysis TDT test -with sliding window 4 - rs77918077-rs10821936-rs12246030-rs10821937 (GCCC) (transmitted frequency 5.929, untransmitted frequency 0.0279, p=0.0156); rs10821936-rs12246030-rs10821937-rs7896246 (CCCA) (transmitted frequency 6.917, untransmitted frequency 1.038, p=0.037). **Conclusions.** 1. We have found an association with SNP rs10821936 C allele and increased predisposition

to childhood leukemia. 2. We detected risk haplotypes of childhood ALL composed of 7 SNPs located in intron 3 of ARID5B gene.

J17.35
Genetic polymorphism and mRNA levels of TNFα and TGFβ genes in patients with chronic lower limbs infections

M. Zagozda[1,2], *A. Sarnecka*[1,2], *Z. Staszczak*[1,3], *H. Galkowska*[1], *P. Andziak*[1,2], *W. Olszewski*[1,2], *M. Durlik*[1,2];
[1]*Mossakowski Medical Research Centre Polish Academy of Sciences, Warsaw, Poland,* [2]*Central Clinical Hospital, Ministry of Internal Affairs, Warsaw, Poland,* [3]*College of Inter-Faculty Individual Studies in Mathematics and Natural Sciences, Warsaw, Poland.*

Introduction: The wound healing process is important medical problem which still have gain no binding results. We choose two factors, strictly involved in inflammation, and connected in proper tissue healing.
Aim of study: The purpose of the study was to investigate SNP`s in TNFα (G-308A) and TGFβ (G-74C, T-29C) genes in patients and evaluate expression of mRNA levels in comparison with controls.
Material and methods: Group of 191 patients were divided into subgroups: A) chronic leg ulcers, B) chronic non-healing wounds, C) infected ischemic necrosis of foot, D) lymphatic ulcers symptoms of dermato-lymphangioadenitis (DLA). A control group comprised 129 blood donors. Detection of polymorphisms was performed using the PCR-RFLP method. The level of TNFα and TGFβ genes expression was performed by Real-Time PCR.
Results: Patients in subgroups showed higher frequency of genotypes TNFα-308GG and lower of GA than in controls. The homozygote TNFα-308AA was more frequent (subgroups B and C) than in controls (p<0,0001). TGFβ-74GG genotype was at highest values, in subgroup B. The GC genotype was at similar level in all subgroups being lower than in controls. TGFβ-29TT and TC genotypes was at similar level to controls. The presence of the polymorphic allele TNFα-308A correlated with an increased level of gene expression (subgroup A). In case of both TGFβ SNP`s the polymorphic allele C were correlated with increased gene expression.
Conclusions: The presence of polymorphic alleles could predispose to increased production of mentioned proteins. Protein overexpression may impair the proper conduct of wound healing contributing to formation of ulcers.

The study of the populations of the Volga-Ural region of Russia in the context of Eastern Eurasian mtDNA haplogroups

N. V. Trofimova[1], *S. S. Litvinov*[1], *K. Tambets*[2], *R. I. Khusainova*[1], *V. L. Akhmetova*[1], *I. M. Khidiyatova*[1], *R. Villems*[2], *E. K. Khusnutdinova*[1];
[1]*Institute of Biochemistry and Genetics, Ufa Scientific Center of the Russian Academy of Sciences, UFA, Russian Federation,* [2]*Estonian Biocentre, Tartu, Estonia.*

Volga-Ural region is a place of encounter of different peoples who vary in both linguistic and religious grounds. An emplacement in the crossroads of two continents, Europe and Asia, had a great influence on creation of this diversity.
The aim of our study was to analyze few lines that belong to the East Eurasian component of the genetic pool in the region. We focused on the lineages of haplogroup A namely A4b and A10.
Haplogroup A4b has previously been found in the study of Derenko et al., 2008 in the Evenk and Buryat populations from Siberia. In our research, we conducted a full genome sequencing of mtDNA samples with this haplogroup in Udmurt and Besermyan populations and found that mutations in the coding region do not correspond to those in the samples studied by Derenko et al., 2008. It is likely that these two lines are the two sub-branches of one subclade A4b. Although our populations showed similarity in difference with the Siberian A4b subclades on the other hand the presence of A4b in our populations itself shows some old connections with Siberian populations.
We also analyzed a full sequence of all known published examples of haplogroup A10 and compared with our results. We found that some new mutations that were not previously detected in Dolgan, Nganasan, Nogay and Tadjik populations. It is interesting that Tajik, Tatars from Kazan and Chuvash samples are likely belong to the one subgroup of this haplogroup, indicating the recent common ancestry of these populations.

Polymorphisms in the RIG-I-like receptors (RLRs) genes and susceptibility to multiple sclerosis in the German population

A. Varzari[1,2], *K. Bruch*[2], *A. D. Akkad*[2], *A. Chan*[3], *J. T. Epplen*[2], *S. Hoffjan*[2];
[1]*Laboratory of Human Genetics, Institute of Phthysiopneumology, Kishinev, Moldova, Republic of,* [2]*Department of Human Genetics, Ruhr-University, Bochum, Germany,* [3]*Department of Neurology, St. Josef-Hospital, Ruhr-University, Bochum, Germany.*

Multiple sclerosis (MS) is an autoimmune disease of the central nervous system potentially associated with viral infection. RIG-I-like receptors genes (*RIG-I*, *IFIH1* and *LGP2*) have been hypothesized as involved in the viral etiology of MS, since they are implicated in viral recognition. Previous studies have produced conflicting results regarding the association between *IFIH1* gene polymorphisms and MS. Here we examined the effects of 13 single nucleotide polymorphisms (SNPs) in the *RIG-I*, *IFIH1* and *LGP2* genes on MS in the German population. The study comprised 716 patients with MS and 706 healthy control individuals. Genotyping was performed using RFLP, TaqMan genotyping assays and high-resolution melting (HRM) analysis. There were no significant differences (p>0.05) between MS patients and healthy individuals for any of the investigated SNPs as well as haplotypes derived from these SNPs. Further, no differences were observed between healthy individuals and MS subgroups stratified according to disease characteristics. Our results suggest that variation in the *RIG-I*, *IFIH1* and *LGP2* genes does not exert a major influence on MS risk.

J17.38
Associations between MX2 polymorphism and the acquisition of HIV and co-infections in Caucasian intravenous drug users (IDUs)

E. Jõgeda[1], *K. Huik*[1], *R. Avi*[1], *M. Pauskar*[1], *E. Kallas*[1], *T. Karki*[1], *K. Marsh*[2], *D. Des Jarlais*[3], *A. Uusküla*[2], *I. Lutsar*[1];
[1]*Department of Microbiology, University of Tartu, Tartu, Estonia,* [2]*Department of Public Health, University of Tartu, Tartu, Estonia,* [3]*Beth Israel Medical Centre, New York, NY, United States.*

BACKGROUND: Until recently, myxovirus resistance protein 2 (MX2), a type I interferon-induced GTP-binding protein, was thought to be devoid of antiviral activity. Latest studies indicate MX2 to be involved in blocking of HIV-1 entry. We aimed to determine, whether C/T polymorphism of MX2 gene (rs45430) is associated with acquisition of HIV and co-infections (HCV, HBV, GBVC) in IDUs.
METHODS: Study included 345 IDUs and control group comprised of 301 blood donors (all HIV, HCV, and HBV negative). C/T polymorphism of MX2 gene was determined using TaqMan allelic discrimination assay.
RESULTS: Of IDUs, 50% were HIV+, 88% HCV+, 67% HBV+, and 33% GBVC+. In total 296 donors and 342 IDUs were successfully genotyped. C/T polymorphism was in Hardy-Weinberg equilibrium and allelic frequencies were similar in both groups (0.65 for T allele in IDUs, 0.6 for T allele in donors). No associations between C/T polymorphism and acquisition of HIV, HBV, and HCV were found. However, the prevalence of persons possessing at least one C allele was higher among GBVC- compared to GBVC+ (63% vs 51%, p=0.047). Persons with at least one C allele had decreased odds of being GBVC+ (OR=0.62, 95%CI=0.39-0.98), but after adjusting for co-variables associated with GBVC status (age, HIV positivity) it did not remain significant (OR=0.66, 95%CI=0.41-1.06), which might refer to underpowered groups.
CONCLUSIONS: This is the first study to investigate associations between MX2 (rs45430) polymorphism and acquisition of HIV and co-infections in high risk population. Whether this polymorphism plays a role in GBVC acquisition needs further evaluation.

Do polymorphisms affecting the ornithine transcarbamylase (OTC) gene affect myocardial infarction risk and blood pressure in the West Algerian population?

D. Meroufel[1,2], *S. Médiène-Benchekor*[3,2], *J. Dumont*[4], *S. Benhamamouch*[3], *P. Amouyel*[4], *T. Brousseau*[4];
[1]*Université des Sciences et de la Technologie d'Oran, Oran, Algeria,* [2]*Laboratoire de Génétique Moléculaire et Cellulaire, Université des Sciences et de la Technologie Mohamed Boudiaf, Oran, Algeria, Oran, Algeria,* [3]*Université d'Oran Es-sénia, Oran, Algeria,* [4]*U744 Inserm, Lille, France ; Institut Pasteur de Lille ; Université Lille 2, UMR-S744, Lille, France, Lille, France.*

Purpose: Recently, it has been shown that the rs5963409 polymorphism of the gene encoding ornithine transcarbamylase (OTC) is associated with hypertension and coronary vasomotor. On the basis of these results, we chose to study the association of two polymorphisms rs5963409, located at the 5' region of the promoter and rs1800321, located in exon 2 of the OTC gene with the risk of the occurrence of myocardial infarction (MI) and the values of systolic and diastolic blood pressures. Methods: Concerning MI, the polymorphisms were characterized in a case-control study (69 cases vs 67 age-matched controls) based on the male population originating from Oran, Algeria. The associations with blood pressure were assessed in an enlarged control group including 115 male subjects. Genetic characterization of two polymorphisms was performed by PCR (Polymerase Chain Reaction) followed by enzymatic digestion. Results: We neither showed associations of the rs5963409 and rs1800321 polymorphisms with variations in blood pressure values. However, we observed a significant interaction between the rs5963409 polymorphism and Body Mass Index (BMI) on the risk of the occurrence of MI. Conclusion: Our results indicate the two polymorphisms of the OTC are not associated with the MI in the West Algerian population.

J17.40

NLRP3 genotype CG increases the risk of HIV-1 in Caucasian intravenous drug users (IDUs)

E. Kallas[1], *K. Huik*[1], *R. Avi*[1], *M. Pauskar*[1], *E. Jõgeda*[1], *T. Karki*[1], *K. Marsh*[2], *D. Des Jarlais*[3], *A. Uusküla*[2], *I. Lutsar*[1];
[1]*Tartu University Department of Microbiology, Tartu, Estonia,* [2]*Tartu University Department of Public Health, Tartu, Estonia,* [3]*Beth Israel Medical Centre, New York, NY, United States.*

BACKGROUND: The increased stability of NLRP3 (Nod-like receptor family, pyrin domain containing 3) by rs10754558 G could lead to earlier immune response against viruses and it has been associated with decreased susceptibility to HIV in mother-to-child transmission. Whether and how the NLRP3 polymorphism is associated with susceptibility to HIV in IDUs is unknown.
METHODS: We studied 172 HIV+ IDUs and 20 highly exposed HIV- IDUs (HESNs). 301 blood donors negative for HIV, HCV and HBV were used as controls. The NLRP3 polymorphism rs10754558 (C/G) was determined using TaqMan allelic discrimination assay.
RESULTS: Altogether 191 IDUs were genotyped successfully. Of HIV+ 98.3% were HCV+ and 82.0% HBV+. Of HESNs 80.0% were HCV+ and 45.0% HBV+. NLRP3 C was the major allele in all groups and did not differ between groups (allelic frequencies 0.68 in HESNs, 0.63 in HIV+ and 0.60 in donors). The polymorphism was in Hardy-Weinberg equilibrium in all groups. The most common NLRP3 genotype was CG (52.9% in HESNs, 55% in HIV+ and 44.2% in donors). The distribution of NLRP3 polymorphisms did not differ between HESNs and HIV+ IDUs. However, HESNs possessed more NLRP3 CG genotype than donors (70.0% vs 44.2%; p=0.0373). No differences were found in CG heterozygotes in HIV+ (50.3%) compared to other groups.
CONCLUSIONS: Similar to mother-to-child transmission NLRP3 CG genotype might be associated with increased risk of HIV infection in Caucasian IDUs.

Molecular screening of PTPN11 hotspot exons in moroccan children with Noonan syndrome

I. Samri[1], **L. Bouguenouch**[1], *I. El Bouchikhi*[1], *M. Iraqui Houssaini*[2], *S. Trhanint*[1], *H. Sayel*[1], *S. Atmani*[3], *K. Ouldim*[1];
[1]*Department of Medical Genetics and Oncogenetics, Hassan II University Hospital, Fez, Morocco,* [2]*Laboratory of Microbial Biotechnology, Faculty of Sciences and Techniques, University of Sidi Mohammed Ben Abdellah, FEZ, Morocco,* [3]*Department of Pediatrics, HASSAN II University Hospital, Fez, Morocco.*

Noonan syndrome is an autosomal dominant disorder with an estimated incidence of 1 in 1 000–2 500 live births. It is characterized by short stature, typical facial dysmorphia and congenital heart defects. This disorder results in almost 50% of patients from protein-tyrosine phosphatase, non-receptor type 11 (*PTPN11*) mutations, that lead to gain of function in the non-receptor protein tyrosine phosphatase (SHP-2) into the signaling RAS- mitogen activated protein kinase (RAS–MAPK) pathway.
Till now, mutational screening of *PTPN11* has been carried out in different populations. Thus, the aim of this study was to screen the *PTPN11* mutations in series of Moroccan Noonan Syndrome patients.
Twenty-three patients were recruited in HASSAN II university hospital of Fez within the last five years. We have extracted genomic DNA from Blood samples. Then, we used PCR and bidirectional direct sequencing of the PTPN11 hotspot exons reached by mutations for 23 Moroccan children.
We detected 5 heterozygous missense mutations in 23 sporadic patients (21.7%). Those patients share the characteristic facial traits of Noonan syndrome. Most of them suffer from pulmonic stenosis.
The present study allowed identification of mutations clustered in hotspot exons of *PTPN11* gene in Moroccan Noonan syndrome cohort, and enabled us to give an appropriate genetic counseling to the mutation-positive patients.

J17.42

Role of the Neuregulin 1 gene(NRG1) in multiple sclerosis

R. Cittadella, *V. Andreoli, F. Trecroci, G. Di Palma, E. V. De Marco;*
Institute of Neurological Science, National Research Council, Mangone (CS), Italy.

Multiple sclerosis (MS) is a chronic autoimmune disease of the central nervous system, characterized by inflammation, demyelination and axonal injury, probably caused by environmental factors in genetically susceptible individuals.
Neuregulin 1 (NRG1) is involved in neuronal specification and migration, gliogenesis, neuron-glial signalling. Viehover et al. (2001) found that the expression of Neuregulin is dramatically reduced in MS lesions and hypothesized that the absence of this protein contribute to the paucity of remyelination in the disease. For these reasons, the NRG1 gene could represent a good candidate for a research on patients with immuno-related and demyelinating disordes. We focused our attention on it, aiming at evaluating its role in Southern Italy by means of a case control study.
We examined 226 patients with MS and 200 healthy controls. Genotyping was performed by amplification and subsequent digestion with the restriction enzyme CviQI.
We found significant differences of allele and genotype distributions (p=0.011 and p=0.05, respectively) between cases and controls. To our knowledge, this is the first study performed on NRG1 in patients with MS. On the basis of the preliminary data obtained in our population, we could hypothesize an involvement of the gene in the susceptibility to the disease. In particular, the presence of the T allele, under-represented in the patients, seems to be a protective factor against MS. However, due to the small number of participants, the confirmation of the role of NRG1 requires further studies extended to a larger sample of subjects and also to other populations.

J17.43

Variability of Genes Associated with Obesity in Populations of Russia and Neighboring Countries

I. Khitrinskaya, *V. Kharkov, V. Stepanov;*
Institute for Medical Genetics, Tomsk, Russian Federation.

The prevalence of obesity and related diseases reached a high level throughout the world. The role of genetic factors in the disease development has been proved by numerous studies on twins and adopted children by testing candidate genes predisposing to obesity. Genome-wide association studies (GWAS) is one of the advanced methods used to detect mutations associated with overweight. We selected 20 SNPs associated with obesity with high level of significance from GWAS-catalog. Allele frequencies for these SNPs, were analyzed in 14 populations of Russia (Yakuts, Buryats, Tuvans, Komi, Mordovians, Russians, Khanty, Kets, Chuvashes, Kabardinians, Karachai, Ossetians, Tatars, Udmurts and Karelians) and neighboring countries (Kazakhs, Uzbeks, Kyrgyz, Megrelians and Moldavans). Data on 7 native non-admixed populations from HapMap and "1000 Genomes" project were also included into analysis. Correlation analysis of allele frequencies and genetic diversity with geographic (latitude, longitude, elevation) and climatic (mean annual temperature, average temperature in January and in July, temperature range, maximum and minimum temperature and precipitations) parameters was performed. Allele frequency of 16 from 20 studied SNP correlated with climate and geography. 5 SNP showed correlation with latitude only (rs5762430, rs1805081, rs7138803, rs2531995 and rs11042023), 6 - with latitude and climate (rs1704198, rs9299, rs10182181, rs6110577, rs999943 and rs7603514) and 5 – with climate only (rs3101336, rs7784447, rs259067, rs2275848 and rs7474896). The revealed relationships between genetic and geo-climatic parameters may indicate the presence of positive selection on genes associated with obesity and adaptive changes in the gene structure in human populations during human dispersal out of Africa.

J17.44

The common polymorphism Val109Asp in the omentin gene is associated with daily energy intake in the Central-European population

Z. Splichal[1], *J. Novak*[1], *F. Zlamal*[1], *M. Forejt*[2], *A. Jackowska*[2], *J. Tomandl*[3], *M. Tomandlova*[3], *A. Vasku*[1], *J. Bienertova-Vasku*[4];
[1]*Department of Pathological Physiology, Masaryk University, Brno, Czech Republic,* [2]*Department of Preventive Medicine, Masaryk University, Brno, Czech Republic,* [3]*Department of Biochemistry, Masaryk University, Brno, Czech Republic,* [4]*Masaryk University, Brno, Czech Republic.*

Omentin was originally first described in 2003 and was reported to be expressed specifically in human omental adipose tissue. So far, very little is known about the relationship between the genetic variability of the omentin gene and pathophysiology of obesity. The aim of the study was to investigace two common polymorphisms in the omentin gene (rs2274908 and rs2274907) and dietary composition and anthropometric parameters of obesity in the Central European population.
Material and methods.The total of 495 subjects were included into the study that were further dividend into the non-obese, obese and morbidly obese cohorts. Dietary habits were established using the 7-d food records and selected anthropometric parameters were measured.
Results: There were significant differences in genotype distributions of rs2274907 between the obese and morbidly obese cohorts (Pg = 0.01). In the multivariate modelling, the rs2274907 polymorphism expressed independent prediction role for the daily energy intake, independently on the age and gender distribution (p = 0.03); the TT genotype being associated with the lowest average energy intake (7877± 2780 J/day) and the AA genotype with the highest daily intake of energy (8764 ± 2467 J/day). Significant association of the rs2274907 were also observed for the daily consumption of fat and proteins.
Conclusion: This is so far the first study to investigate the polymorphisms in the omentin gene in a large population cohort of obese and non-obese individuals. Based on our results, the rs2274907 polymorphism is associated

with the daily energy intake as well as daily intake of fat and protein.

J17.45
Associations between polymorphisms in PAX9 gene and congenital missing teeth

D. Belengeanu[1], *C. Bratu*[2], *C. Popescu*[3], *N. Meszaros*[3], *D. Marian*[4];
[1]*„Vasile Goldis" Western University of Arad, Discipline of Orthodonty-Pedodonty, Arad, Romania,* [2]*University of Medicine and Pharmacy "Victor Babes" of Timisoara, Discipline of Orthodonty-Pedodonty, Timisoara, Romania,* [3]*„Vasile Goldis" Western University of Arad, Discipline of Genetics, Arad, Romania,* [4]*„Vasile Goldis" Western University of Arad, Discipline of Pedodonty, Arad, Romania.*

The congenital missing of teeth is one of the most common developmental disorders in dental pathology with values between 4.4% and 8%. Autosomal dominant hypodontia is caused by abnormalities in genes MSX1 and PAX9. PAX9 gene plays a key role in ondontogenesis and gene polymorphisms were found in both familial forms but also in sporadic cases with dental agenesis. Recent studies show model PAX9 gene polymorphisms in patients with dental agenesis.
Our study group consisted of 180 adolescents aged 18-22 years and one hundred controls. In this group were found a total of 10 cases (5.5%) with specific agenesis, without signs of other disorder, and no other dental anomaly, of which 7 cases were sporadic and 3 cases with familial aggregation. In these families, besides the index, agenesis was also found in five individuals. In two families agenesis was present in grandmother, mother and daughter.
All patients were investigated clinically oral and extraoral and X-ray was performed. Selection of patients for the genetic analysis of gene PAX9 was based on the type of hypodontia clinically found, because families bearing PAX9 mutation had tooth agenesis as the only clinical sign. Heterozygous mutation C503G was detected in the female proband, in her mother and grandmother. One polymorphic A240P mutation site was found, in PAX9 gene, in two sporadic cases. This variant was found in subpopulations of African American and Europe, but had no relevance to the ethnic Chinese population.

J17.46
Association of the MMPs genes single nucleotide polymorphisms with gastric and duodenal ulcer in Volga-Ural region of Russia

E. Shaymardanova[1], *A. Nurgalieva*[1], *D. Prokofyeva*[1], *Y. Valova*[1], *A. Gizatullina*[1], *L. Gabbasova*[2], *O. Kuramshina*[2], *A. Krukova*[2], *E. Khusnutdinova*[3];
[1]*Bashkir State University, Ufa, Russian Federation,* [2]*Bashkir Medical State University, Ufa, Russian Federation,* [3]*Bashkir State University; Institute of Biochemistry and Genetics, Ufa Scientific Center, Russian Academy of Sciences, Russia, Ufa, Russian Federation.*

Peptic ulcer disease (PUD) is a chronic disease, which is based on recurrent gastric (GU) or duodenal ulcer (DU). Recent studies have indicated that gastric ulceration is associated with cleaving and remodeling of the extracellular matrix (ECM) by matrix metalloproteinases (MMP). DU and GU has a genetic background and the aim of this study was to investigate the allele and genotype distribution of SNPs in the MMP1 (rs49437), MMP2 (rs2285053), MMP3 (rs3025058), MMP9 (rs3918242, rs17576) and MMP12 (rs2276109) genes in patients with PUD and healthy donors from Volga-Ural region of Russia. The patient group consisted of 260 individuals with PUD, the control group included 272 unrelated non-ulcer individuals with different ethnic origins (Russians, Tatars, Bashkirs). Genomic DNA was extracted from peripheral blood leucocytes by standard phenol/chloroform method. Genotyping was performed by polymerase chain reaction - restriction fragment length polymorphism analysis. The analysis has revealed that Russians have significant higher frequency of rs494379*A/G and rs3025058*5A/5A genotypes in patients than in control group (P=0.02;OR=1.86 and P=0.0007;OR=5.31, respectively). We have also found the association of rs494379*A/G genotype with PUD in Tatars (P=0,001;OR=2,58). Genotype rs17576*A/G is a marker of the increased risk of PUD development in males (P=0,005;OR=1,79), whereas rs3918242*T/T and rs17576*A/A were protective (P=0.037;OR=0.10; P=0.01;OR=0.61, respectively). The association analysis of the rs228505 and rs2276109 with PUD has not revealed significant differences between patients and healthy donors (p>0,05). Thus, we have determined statistically significant association between MMPs genes polymorphisms and peptic ulcer in Volga-Ural region of Russia.

J17.47
Sequence analysis of *PMS2* exon 11 and homologous region in pseudogene *PMS2CL*

N. P. Babushkina, *M. V. Golubenko, N. Kucher;*
Institute of Medical Genetics, Tomsk, Russian Federation.

PMS2 gene product is involved in DNA mismatch repair process. Besides the gene, there are several pseudogenes in the human genome, showing high sequence homology. To describe and distinguish sequence polymorphism in highly homologous loci which could be co-amplified in PCR assays, we have sequenced "short" 243 bp fragment containing co-amplifying regions chr7:6026862-6027104 (part of *PMS2* exon 11) and chr7:6776854+6777096 (part of *PMS2CL* pseudogene) in 50 DNA samples. In 14 DNA samples, additional "long" fragment encompassing region chr7:6026862-6027488 (part of intron 10 and exon 11 *PMS2*) has been sequenced. The same heterozygous positions in both fragments, together with peak height differences in heterozygous positions within the short fragment allowed us to determine their location (gene/pseudogene) and to calculate MAF estimates. Altogether 6 variable positions were identified and most of them had been registered as SNPs in *PMS2* in public databases (NCBI). Among them were rs111255573 (C/T) in intron 10 (MAF=0,036) and rs15020462 (A/G, Gly460Asp) in exon 11 (MAF=0,080). High frequency was determined for rs1805321(C/T, Pro470Gly, allele T frequency 0.525) in additional 134 samples by restriction analysis. We have found that rs63750685 polymorphism (C/G, MAF=0.120) is actually located in the pseudogene (rs199736163), as well as novel SNP A/G in position chr7:6777067 (MAF=0.090). The previously known SNP rs1805320 (C/T) turned out to be a difference between the gene (C) and the pseudogene (T) sequences. Our results refine SNP list in the regions and emphasize careful probe design for SNP studies in the *PMS2* gene.

J17.48
The association of REN gene polymorphism with athlete status and muscle mass

L. J. Mustafina[1,2], *G. N. Khafizova*[1], *R. R. Almetova*[1], *R. R. Kasimova*[1], *E. S. Egorova*[2], *I. I. Ahmetov*[1,2];
[1]*Volga Region State Academy of Physical Culture, Sport and Tourism, Kazan, Russian Federation,* [2]*Kazan State Medical University, Kazan, Russian Federation.*

The renin-angiotensin system (RAS) is supposed to be one of the regulators of skeletal muscle growth and differentiation (Zhang et al. 2003; Johnston et al. 2011). Renin (encoded by *REN* gene), as a component of the RAS, activates the renin-angiotensin cascade by catalyzing the conversion of angiotensinogen to angiotensin I (Rupert, 2006). The aim of present study was to investigate the association between the intron 8 83A/G (rs2368564) polymorphism of the *REN* gene, athlete status and muscle mass in Russians. Two hundred and sixty eight Russian athletes (90 females and 178 males) from different sporting disciplines were involved in the study. *REN* genotype and allele frequencies were compared to 151 controls (74 females and 77 males). Genotyping for the *REN* polymorphism was performed by RT-PCR. Muscle mass parameters were assessed by bioelectrical impedance analyzer Tanita MC 980 (Japan) in 125 athletes (44 females and 81 males). We found that the frequency of the *REN* G allele was significantly higher in power-oriented athletes (78 vs 68%; P=0.021) compared to controls and this difference was even more pronounced in elite power-oriented athletes (89%; P=0.018). Furthermore, the *REN* G allele was positively correlated with fat-free mass, absolute muscle mass, muscle mass of trunk and left/right legs in elite athletes. In conclusion, we have shown that the 83A/G polymorphism of the *REN* gene is associated with power athlete status and skeletal muscle parameters in Russians.

J17.49
The association of *PPARD* and *PPARA* gene variants with physical performance in Lithuanian elite athletes

V. Ginevičienė[1], *G. Olšauskaitė*[1], *L. Tubelis*[2], *A. Utkus*[1];
[1]*Department of Human and Medical Genetics, Vilnius University, Vilnius, Lithuania,* [2]*Lithuanian University of Educational Sciences, Vilnius, Lithuania.*

Peroxisome proliferator-activated receptor (PPAR) delta and PPAR alpha (encoded by the *PPARD* and *PPARA* genes) play a role in energy homeostasis, vascular biology, mitochondrial function. Functional SNPs in the *PPARA (*rs4253778, intron7 G/C) *and PPARD* (rs2016520, 5'-UTR region of the exon4, +294T/C) have been associated with mRNA and/or protein activity. The aim of this study was to determine the allele/genotype frequency distributions among 130 Lithuanian elite athletes (endurance-oriented (n=40), power-oriented (n=52), mixed endurance/power athletes (n=38)) and 175 healthy non-athletes controls. Genotyping was performed by PCR-RFLP. Results showed the genotype distribution was in Hardy-Weinberg equilibrium within all groups (P>0.05). Genotype frequency differed significantly between the male athletes and the male controls (*PPARA* GG/GC/CC: 58.4/35.7/5.9% vs 76.2/22.9/0.9%; P=0.012; *PPARD* TT/TC/CC: 88.1/11.9/0% vs 75.2/21.9/2.9%; P=0.031). The *PPARA* GG genotype was more frequent among the athletes in endurance(67.5%) and mixed sports(71.1%) than the power (50%). In power-oriented events group significantly elevated frequencies of *PPARA* GC and CC genotypes were determined, compared to the endurance-orientated (P=0.039), mixed athletes (P=0.0005) and controls (P=0.008). These results support the positive as-

sociation of the *PPARA* C allele with power performance. *PPARD* genotype distribution in athletes with mixed endurance/power activity showed significant difference compared to controls (TT/TC/CC: 92.1/7.9/0% vs 53.1/40/6.9%; P=0.023). In conclusion, the *PPARA* C allele may help athletes to attain elite status in power-oriented sports, and the *PPARD* C allele is a factor unfavourable for athletics. This finding is relevant of physical performance; it may also be informative for the targeted prevention of diseases associated with low fitness.

J17.50
A polymorphism in a possible regulatory region of PGR associated with risk of spontaneous preterm labor with intact membranes (PTB-I)

L. G. Gimenez[1,2], *F. A. Poletta[1,2,3], A. M. Momany[4], J. A. Gili[1,2], M. Pawluk[1,2], B. Comas[1,2], V. Cosentino[1,2], C. Saleme[5], H. Krupitzki[1], E. Gadow[1], J. C. Murray[4], J. S. Lopez Camelo[1,2,3];*
[1]CEMIC, Buenos aires, Argentina, [2]ECLAMC (Estudio Colaborativo Latinoamericano de Malformaciones Congénitas), Buenos Aires, Argentina, [3]INAGEMP (Instituto Nacional de Genética Médica Populacional), Rio de Janeiro, Brazil, [4]Department of Pediatrics, University of Iowa, Iowa City, IA, United States, [5]Maternidad Nuestra Señora de la Merced, Tucuman, Argentina.

Background. Progesterone has been used to prevent recurrences of preterm labor suggesting that the progesterone receptor gene (*PGR*) may play a critical role in the maintenance of pregnancy. The aim of this work was to investigate the association between a single nucleotide polymorphism (SNP) located in a possible regulatory region of *PGR* (rs1942836) and two different clinical subtypes of preterm birth: spontaneous (PTB-I) and premature rupture of membrane (PTB-PROM). This SNP has been previously studied in a heterogeneous group of PTBs.
Methods. The sample included 412 triads (proband, mother, father) recruited at the Nuestra Señora de la Merced Maternity Hospital in Tucumán, Argentina. Of these triads, 200 had probands from PTB-I and 212 had probands from PTB-PROM. Genotyping was performed using Applied Biosystems Taqman probes and the Fluidigm genotyping platform. Both maternal and fetal genetic effects were analyzed using a log-linear method for analysis of case-parent–triad data (Weinberg et al. 1998).
Results. We found a significant association between rs1942836 (maternal effect) and PTB-I (OR: 2.01; IC 95%: 1.12-3.61; p= 0.01), but not between this SNP and PTB-PROM (OR: 1.05; IC 95%: 0.57-1.93; p= 0.85).
Conclusions. These results would suggest a specific association between the *PGR* gene (maternal effect) and PTB-I, but not with PTB-PROM. These findings may have implications in understanding the pathophysiology of clinical subtypes of preterm birth and the potential therapeutic role of progesterone in prevention of PTB-I.

J17.51
The diversity and prevalence rate of monogenic hereditary pathology among the children of Tatarstan Republic (Russia)

N. E. Petrina[1], *A. N. Petrin[2], R. A. Zinchenko[1];*
[1]Research Center for Medical Genetics, Russian Academy of Medical Sciences, Moscow, Russian Federation, [2]Scientific and Practical Center of medical care for children, Moscow, Russian Federation.

Results of prevalence rate and genetic diversity of monogenic hereditary disorders (MHDs) among the children's of eight investigated Districts of Tatarstan Republic (Russia) was submitted. The total size of investigated populations was made 268894 people, including 57648 (21.44%) children. The ethnic structure of considered sample on more that 80 % is presented by Tatar population. The study was conducted on the original protocol examined by standard protocol of medical genetic research elaborated in laboratory of genetic epidemiology, Research Centre for Medical Genetics. About 3500 MHD and syndromes of OMIM could be identified by this protocol. Clinical investigations were performed by pediatricians, clinical geneticists, neurologists, ophthalmologists, orthopedists, audiologist, and dermatologists, focused on diagnostic of MHD. The spectrum of MHP detected in the eight Districts comprises 158 nosologycal forms - 84- autosomal dominant (AD), 54- autosomal recessive (AR) and 20- X-linked. The total prevalence rate of children's population by all types MHD - AD, AR, and X-linked, separately for urban (1:187 children) and rural (1:89 children) populations was calculated. In rural populations, the prevalence is higher in 2 times higher than in urban. The total prevalence of MHD was 1:103 children. Given that this study can detect only half of hereditary diseases, the total prevalence of hereditary disorders in children more than 1,2%. In this study, we studied the prevalence of hereditary diseases among children Republics Bashkortotan, Udmurtia, Rostov Region and Chuvashia, in which the burden of hereditary diseases was 1.4%, 1.2%, 1.3% and 1.1%, respectively.

Birth defects in Chile: Implementing a National Registry and Surveillance System

C. Mellado[1,2], *A. Pardo[2,3], X. Carrasco[4], M. Hernandez[1];*
[1]Pontificia Universidad Catolica de Chile, Santiago, Chile, [2]Hospital Sotero del Rio, Santiago, Chile, [3]Universidad de Chile, Santiago, Chile, [4]Ministerio de Salud, Santiago, Chile.

Chile is an upper middle income country, has an infant mortality rate of 7.7 per 1000 births in 2011. Birth defects (BD) are an important public health problem, account for 35% of the infant mortality, being the second leading cause after prematurity. Aware of that Chilean Ministry of Health has designed a registry and surveillance system for BD (REVINACH) in stillbirths, newborns and infants less than a year in all public hospital in Chile. We report herein the characteristics of this national registry system.
The Department of Statistics at Ministry of Health will be in charge of clearing, encoding, statistical analyses and dissemination of data. Data collection will be in charge of any professional that detects a BD. This registry has 3 instruments for data collection (1) Online Birth Certificate with an open field named: „Congenital Malformations Anomaly" (2) Online database ex-post to collect information after birth named "REVINACH" (3) Online database to collect complex information named "Genetics Module" as a second step. All three systems are linked to a three partite system involving the Civilian Registry and the National Statistic Institute.
This system will be a source of information for surveillance of BD and will be essential to the planning, implementation, evaluation of public health practice and policies as well as prevention.

J17.53
Genetic predisposition to the development of restenosis in Kazakh population

E. V. Zholdybayeva[1], *P. V. Tarlykov[1], A. M. Aitkulova[1], O. A. Visternichan[2], D. Z. Taizhanova[2];*
[1]National center for biotechnology, Astana, Kazakhstan, [2]Karaganda State Medical Universit, Karaganda, Kazakhstan.

Restenosis is a renarrowing of the stented vessel that occurs after stent placement. At the moment, genetic factors of restenosis were studied mostly in Caucasian population. However, ethnical variability of genetic markers is well known. The purpose was to study association of genetic variation in candidate genes of patients diagnosed with restenosis in the Kazakh population.
This case-control study included patients with a diagnosis of coronary heart disease (CHD) who developed restenosis. The control group consisted of patients with CHD who have not developed restenosis within 6 months after stenting. Genomic DNA was extracted from peripheral whole blood samples. SNP genotyping was performed on QuantStudio 12K Flex. Allele frequencies in both case and control groups were in compliance with Hardy-Weinberg equilibrium. Odds ratios (OR) and p-values have been calculated for all studied SNPs. Confidence interval (CI) was set at 95% significance level.
Sampling data shows that men undergo stenting at an earlier age than women. In addition, an increased BMI was found in all patients. The results showed that known associations of polymorphisms with the risk of restenosis, shown by J.W. Verschuren in the European population, were not observed in Kazakh population. However, a statistically significant association with the risk of restenosis was found with fibrinogen beta-chain gene polymorphism rs1800790 (OR - 2.1, P-value - 0.009) and thrombomodulin (THBD) gene polymorphism rs1042579 (OR - 1.7, P-value - 0.01).
It can be inferred that both polymorphisms are likely to be predictors of restenosis, while THBD polymorphism is specific for Asian population.

J17.54
Dimorphism -23HphI of the INS gene (rs689): association with type 1 diabetes in several populations of the Russian Federation

O. N. Ivanova, *S. M. Stepanova, Y. S. Zvereva;*
Endocrinological Research Centre, Moscow, Russian Federation.

After HLA, the next-strongest genetic association with Type 1Diabetes (T1D) is seen for the *INS* gene. The aim of this study is cross-ethnic group comparisons of frequencies and analysis of associations with T1D -23*HphI INS* dimorphism (in promoter region of the gene, rs689) in Bashkir, Buryat, Udmurt, Yakut and Russian ethnic group of the Russian Federation. Case-control design was applied for assessment of 528 patients with T1D and 374 healthy sex and ethnos matched individuals. Allele identification was performed with RFLP or Real-Time PCR technique. Association of genetic markers with pathology was evaluated according to odds ratio index (*OR*), association was considered statistically significant when p-value<0,05). Allel A and genotype AA of rs689 are associated with T1D in Russian (*OR*=2,5 and 2,7 respectively), Bashkir (*OR*=5 and 6 respectively), Udmurt (*OR*=2,4

and 2,6 respectively) and Yakut (*OR*=3 and 4 respectively) populations. Allel T and genotype T+ of rs689 are protective markers in these populations (0,16<*OR* <0,4). Association of rs689 with T1D has not been identified in Buryat population (with low incidence of T1D). Cross-ethnic comparison of frequencies of alleles and genotypes showed statistically significant differences. Buryat population differs from all other examined populations by much higher frequency of allele A (87% vs. 69-75%, p<0,006) and of genotype AA (77% vs. 45–60%, p<0,01). It is concluded that in the Buryat ethnic group rs689 is not diabetogenic marker unlike all other examined groups.

J17.55

Spinocerebellar ataxias (SCAs) in Europe: updating current situation

M. A. Araujo[1,2], *M. Raposo*[1,2], *A. Ramos*[1,2], *N. Kazachkova*[1,2], *M. Lima*[1,2];
[1]*Centre of Research in Natural Resources (CIRN), Department of Biology, University of the Azores, Ponta Delgada, Portugal,* [2]*Institute for Molecular and Cellular Biology (IBMC), Porto, Portugal.*

Spinocerebellar ataxias (SCAs) represent a clinically, genetically and pathologically heterogeneous group of rare hereditary untreatable neurodegenerative disorders, which affect the cerebellum and its connections. As far as we known, there are more than 30 subtypes reported in literature. In Europe, it's estimated that one to three per 100 000 individuals suffer from a SCA subtype, but this number could vary among different ethnic and geographic groups. Epidemiological data on SCAs is considered scarce and fragmentised, with only their relative frequency within a population usually being better known. The goal of this study was to systematically compile and update the available information regarding prevalence of SCAs, as well as several indicators, namely number of published reports, expert centres, diagnostic tests, patient's organizations, available biobanks, as well as performed and ongoing clinical trials. Data were collected considering literature reports from 2000 until 2013, and using several databases, such as Orphanet and EuroGentest. Updating SCAs current data could be an important tool for needs assessment in specialized molecular diagnosis resources, planning future health and community services and better resources allocation, being helpful to evaluate if the available resources are in accordance with the real requirements in different European countries.

The SHBG gene polymorphism (rs12150660) is associated with elite power athlete status and muscle mass

E. S. Egorova[1], *L. J. Mustafina*[2], *I. I. Ahmetov*[2,1];
[1]*Kazan State Medical University, Kazan, Russian Federation,* [2]*Volga Region State Academy of Physical Culture, Sport and Tourism, Kazan, Russian Federation.*

Testosterone regulates muscle mass and strength, bone mass, fat distribution and the production of red blood cells. Sex hormone-binding globulin (SHBG) is the key protein responsible for binding and transporting of testosterone. SHBG regulates its bioavailability and therefore its effects in the body. Polymorphism at the SHBG gene locus (rs12150660 G/T) has been associated with testosterone concentrations. Since individuals with the TT genotype have higher serum testosterone concentrations in comparison with carriers of the G allele (data from GWAS), we hypothesized that the carriage of the T allele may give some advantage for strength and power performance. The aim of the study was to investigate the association between the SHBG G/T polymorphism, athlete status and muscle mass. A total of 363 Russian athletes and 130 controls were genotyped using RT-PCR. Muscle mass was measured by body composition analyzer Tanita MC-980. The frequencies of the T allele in power-oriented athletes (n=143, 20.3%; P=0.7462), endurance-oriented athletes (n=220, 15.0%; P=0.2054) and a whole cohort of athletes (17.1%; P=0.5078) were not significantly different from controls (18.8%). However, the frequency of the T allele in elite power-oriented athletes (n=65, 26.2 vs. 12%, P=0.0061) was significantly higher as compared with elite endurance-oriented athletes (n=58). Furthermore, correlation analysis showed positive association between the T allele and muscle mass among non-elite female athletes (n=8, P=0.0072, r= 0.8729). Although more evidence is needed, one might suggest that the SHBG gene G/T polymorphism is associated with power athlete status.

This study presents data on the carrier frequencies of the splice site mutation IVS1+1G>A in GJB2 gene, causing an autosomal recessive form of deafness among various ethno-geographical groups of Yakut population and in a random sample of Yakut individuals. 350 DNA samples of hearing individuals from various ethno-geographical groups of Yakut population: Central group (n=60), Vilyui group (n=60), Northern group (n=60), and random samples of Yakut individuals (n=170) were obtained from the DNA Bank of the Department of Molecular Genetics of Yakut Research Center of Complex Medical Problems of RAMS (Yakutsk, Russian Federation). The detected average carrier frequency of IVS1+1G>A mutation in Yakut population (n=350) was - 10.3%. Extremely high carrier frequency of the splice site mutation IVS1+1G>A in GJB2 gene in Yakut population is comparable to carrier frequency of the sickle-cell anemia in Africa, that may indicate a possible selective advantage of carriers of this IVS1+1G>A mutation in a subarctic climate.

Study was supported by RFBR (#12-04-00342_a, #12-04-98520_r_vostok_a, #12-04-97004_r_povolzhye_a, #14-04-01741_A), SB RAS Integration project #92 «Ethnogeny of indigenous peoples in Siberia and North Asia: comparative, historical, ethno-social and genomic analysis», the Sakha Republic President grant for Young Researchers for 2014 (RP#80), RAS Program «Fundamental Sciences for Medicine» (#30 for 2013-2015), and «Scientific and Educational Foundation for Young Scientists of Republic of Sakha».

Variations in nuclear genes are associated with elite sport performance in the Polish population

B. J. Peplonska[1], *K. Safranow*[2], *J. G. Adamczyk*[3], *M. Siewierski*[3], *H. Sozański*[3], *A. K. Gajewski*[3], *M. Berdynski*[1], *A. Maruszak*[1], *C. Zekanowski*[3];
[1]*Mossakowski Medical Research Centre Polish Academy of Sciences, Warszawa, Poland,* [2]*Department of Biochemistry and Medical Chemistry, Pomeranian Medical University, Szczecin, Poland,* [3]*Department of Sport's Theory, Institute of Sport, Jozef Pilsudski University oh Physical Education in Warsaw, Warszawa, Poland.*

Objectives: Single nucleotide polymorphisms are the most common type of human genetic variation. It is widely recognized that genetic factors located in mitochondrial and nuclear genomes influence sport performance. The aim of our study was to assess whether selected nuclear DNA variants are associated with athlete performance in the Polish population.
Methods: The study group comprised 413 unrelated elite athletes and the control group consisted of 451unrelated sedentary individuals. The athletes were stratified into two subgroups: the power athletes (n=188) and the endurance ones (n=225). The study group included 284 participants of Olympic and International Games and the remaining 129 athletes were national–level athletes. The DNA was isolated from peripheral blood lymphocytes using standard procedures. Genotyping of 10 nuclear DNA variants (*ACE*, rs4341; *ACTN3*, rs1815739; *GABPB1*, rs12594956; *CHRNB3*, rs4950; *AGT*, rs699; *FAAH*, rs324420; *PPARG*, rs1801282; *TFAM*, rs1937; *TFAM*, rs 2306604; *PGC1α*, rs 8192678) was conducted using TaqMan method. All statistical analyses were performed using Statistica ver. 10.
Results: We showed that six polymorphisms were associated with outstanding results in power (*TFAM*,rs 2306604, *FAAH*, *ACE*, *ACTN3*) or endurance sports (*CHRNB3*, *GABP1*). Gender and sport level of athletes were also significant
Conclusion: Our study indicates that in the Polish population genetic background could influence sport performance.

Gene pool of the Kazakhs according MTDNA and of ten X-chromosomal STR markers

G. M. Berezina[1], *G. S. Svyatova*[1], *D. N. Salimbayeva*[1], *V. Stepanov*[2], *K. Simonova*[2], *V. Kharkov*[2];
[1]*The Scientific Center of obstetrics, gynecology and perinatology, Almaty, Kazakhstan,* [2]*The Institute of Medical Genetics, Russian Academy of Medical Sciences, Tomsk, Russian Federation.*

The aim of the present research was: to study the polymorphism of mitochondrial DNA and 10 X-linked microsatellites (DXS8378, GATA172D05, DXS7132, DXS9898, DXS7423, DXS8377, DXS101, DXS6809, DXS6789, HPRTB) in population of Kazakh.
Genetic and geographic analysis of the genetic structure of Kazakh populati-

on using data of the frequencies of mtDNA haplogroups was conducted. The high degree of intensity of gene exchange between the Kazakh population and frontier populations of Russia was identified on the north-west, north, northeast and east of Kazakhstan. The phylogenetic tree was constructed for Kazakhs on female lineage and was detected position of the studied population between ethnic groups in Europe and Asia.
Ten STR loci demonstrate the high level of genetic diversity in Kazakhs. The average genetic diversity in a combined sample is quite high (mean diversity for 10 STRs, H=0.768). Rare alleles were detected for DXS8378 (7 repeats), DXS8377 (57, 59, 60), DXS101 (31), DXS6789 (12) loci. All rare alleles were confirmed by direct sequencing of PCR product. DXS8377 proved to be the most polymorphic locus (H=0.905). Three another STRs (DXS101, DXS6809 and DXS6789) also have genetic diversity index above 0.8 in a combined sample. The least polymorphic locus in Kazakhs is DXS7423 (H=0.662).
The area of Kazakhstan has been a place of interaction of many ethnic layers during a historically long period. Molecular-genetics methods give an objective criteria to study the origin, migration and ethno genesis of human populations.

Polymorphism of the lipoprotein lipase gene as genetic markers for stroke in Colombian population

L. C. Velasquez[1], *C. I. Vargas*[1], *F. A. Silva*[2];
[1]Universidad Industrial de Santander, Bucaramanga, Colombia, [2]Fundacion Cardiovascular, Bucaramanga, Colombia.

Recently, scientists are redirecting their researchers to find the genetic origin of diseases; stroke is part of them. Polymorphisms of the lipoprotein lipase gene have been extensively studied in different populations finding variations in results among societies. Showing that the HindIII and PvuII polymorphisms can act as risk markers for the development of cerebrovascular disease by increasing levels of tiacilgliceroles and decreasing HDL. However, Ser447X can be a protective marker causing an increase of HDL levels and reducing triglycerides levels. The aim of the study was to analyze if there is an association between the presence of polymorphisms in the LPL gene (HindIII , PvuII and Ser447X) with development of ischemic stroke in Colombian population. Sample size was 347 stroke patients (clinical diagnosis and x-ray CT) and 347 healthy subjects. PCR -RFLP technique was used to detect Ser447X , HindIII and PvuII polymorphisms in the LPL gene. Results were analyzed by Stata12 and Arlequin software. As results, allele and genotypic frequencies of the studied polymorphisms did not show a statistically significant difference between the cases and controls. In the present research was not found any association between any of the LPL gene polymorphism and stroke in the population sample used. These results suggest that in the Colombian sample used, LPL gene polymorphisms are not genetic markers for the development of stroke

J17.61
Recurrent spontaneous abortion - importance of testing the thrombophilic mutations. The experience of Genetic Center, Romania on 627 consecutive cases

M. S. Militaru[1,2], *A. Trifa*[1,2], *R. Popp*[1], *I. V. Pop*[1], *C. Andrei*[2], *C. Gug*[3], *M. Militaru*[4], *M. Stefanut*[2];
[1]University of Medicine and Pharmacie"Iuliu Hatieganu", Department of Medical Genetics,, Cluj-Napoca, Romania, [2]Genetic Center, Cluj-Napoca, Romania, [3]University of Medicine and Pharmacie"Victor Babes", Department of Medical Genetics,, Timisoara, Romania, [4]University of Medicine and Pharmacie"Iuliu Hatieganu", Department of Pediatrics 2, Cluj-Napoca, Romania.

Introduction: Recurrent spontaneous abortion represents a frequent and important medical problem. There are a lot of possible causes, but during last years a great proportion of the women with recurrent spontaneous abortion have been shown to harbor thrombophilic mutations.
Material and methods: Five thrombophilic mutations, namely Factor V Leiden, Prothrombin G20210A, PAI-1 4G/5G, MTHFR C677T and A1298C have been tested in 627 consecutive women with recurrent spontaneous abortion of unknown etiology (other causes, such as anatomical or endocrine factors, antiphospholipid syndrome, or chromosomial anomalies were excluded by specific investigations).The methods used were - PCR-based assays (PCR-RFLP, ARMS-PCR, tetra-primer PCR).
Results: Fifty-eight patients (9.2%) harboured the Factor V Leiden mutation, while the Prothrombin G20210A was seen in 37 patients (5.9%). Four patients (0.6%) harboured both mutations. At least one 4G allele of the PAI-1 mutation was seen in 482 patients (77%), of which 184 (29.3%) were 4G/4G homozygotes. At least a variant allele of the MTHFR mutations was seen in 546 patients (87%), of which 291 patients (46.4%) were either homozygotes for C677T or A1298C mutations, or compound heterozygotes. There were only 13 patients (2.1%) homozygous for the wild-type allele in case of all 5 mutations analyzed.
Conclusions: A great proportion of women with recurrent spontaneous abortion harbour thrombophilic mutations. It is important to test these mutations in these cases, since the results can guide towards appropriate therapeutic measures during next pregnancies - low-molecular-weight heparines, acetylsalicylic acid or folic acid, with favorable outcomes in most of the cases.

J17.62
Association between TLR8 and TLR9 gene polymorphisms and Pulmonary Tuberculosis

M. Taheri, *S. Hashemi-Shahri, G. Bahari, M. Hashemi;*
Zahedan University of Medical Sciences, Zahedan, Islamic Republic of Iran.

Background: Tuberculosis is steel a health problem through the world. Both genetic and environmental factors may contribute the susceptibility to tuberculosis. Toll-like receptors play a critical role in the recognition of Mycobacterium Tuberculosis (TB). The aim of this study was to evaluate the possible association between TLR8 rs3764880 and TLR9 rs148805533 polymorphisms and PTB in a sample of Iranian population.
Materials and methods: In this study, blood samples of 320 subjects including 160 PTB patients and 160 healthy subjects were collected. DNA was extracted and TLR8 rs3764880 polymorphism was analysed by Tetra Amplification Refractory Mutation System-Polymerase Chain Reaction (TARMS-PCR) and TLR9 rs148805533 polymorphisms was analysed by Allele specific PCR.
Results: The allelic and genotypic frequencies of the TLR8 rs3764880 not differ significantly between PTB and the controls. No significant difference was found between the groups regarding TLR9 rs148805533 polymorphism.
Conclusion: Our finding suggests that TLR8 rs3764880 and TLR9 rs148805533 polymorphism may not be a risk factor for susceptibility to tuberculosis in a sample of Iranian population.Larger studies are required to validate our findings.

J17.63
Admixture of Turks, Hungarians and Romas in the Carpathian Basin

Z. Bánfai[1,2], *A. Szabó*[1,2], *K. Sümegi*[1,2], *B. Duga*[1,2], *L. Magyari*[1,2], *E. Kövesdi*[1,2], *P. Mátyás*[1,2], *R. Szalai*[1,2], *B. Melegh*[1,2];
[1]University of Pécs, Department of Medical Genetics, Pécs, Hungary, [2]Szentágothai Research Centre, Pécs, Hungary.

Hungary was a part of the Ottoman Empire between the 16th and 17th centuries for about 150 years. It is also known that Roma, most significant ethnic group of Hungary, migrated through Turkey in the 12th century on their way to Europe. Genetic relationship of Turks with Hungarians and Roma living in the Carpathian Basin was investigated based on genome-wide autosomal single nucleotide polymorphism (SNP) data. Computational methods were carried out with pruned datasets containing 111,928 SNPs. In order to understand Turk, Hungarian and Roma relationship in context to other European and Middle East populations, principal component analysis was applied. Our collection of 27 Roma samples, 20 Turkish and 20 Hungarian samples were merged with 20 Stanford-HGDP populations and 13 populations from the Caucasus obtained from public domain. In order to infer population relationships in a model-based manner, clustering algorithm based on maximum likelihood estimation method was applied, also with 11 HapMap3 populations. The admixture events detected, based on these methods, were investigated with formal tests of admixture. The date of admixture event was inferred based on the exponential decay of admixture linkage disequilibrium. Our results show that extents of Hungarian genetic elements in Turks are significant, and admixture between Turks and Hungarians occurred during the 17th century. The proportion of Hungarian ancestry in Turks was 2 times higher than the share of ancestry from several groups of the Caucasus region, Balkars, Druze and Kurds. Interestingly, contribution of Roma genetic elements in Turks is difficult to detect.

Association of Polymorphism Gene for TGF-B1 with the Forming of Kidney Scars among the patients with vesicoureteral reflux (VUR) in children

D. Jugovic, *L. Brankovic, R. Milicevic, D. Radulovic, P. Miljkovic, T. Jevtovic - Stoimenov, M. Despotovic;*
Pediatric Clinic, Nis, Serbia.

Introduction: Transforming growth factor beta (TGF-B) family members are multi-functional cytokines that play a key role in differentiation, cellular growth, and proliferation. TGF- B1 stimulates the production of extracellular matrix protein and induces fibrosis in different tissue. Over expression of TGF-B1 is characteristic of all human and experimental models of kidney fibrosis.

Aim: To prove the role of polymorphism in the promoter region of TGF-B1 C-509-T gene as a possible risk factor in forming kidney scars within the patients with VUR.
Material and method: Samples of DNA were extracted by phenol-chloroform method from the peripheral blood of 50 children with VUR and 70 controls. The gene typing was performed by the PCR /RLFP method and detected after restriction enzyme digestion.
Results: Proportions of C homozygote, heterozygote, and T homozygote for TGF-B1 gene polymorphisms were 21.4/77.1/1.5% in the control and 14/64/22% in the patient group. Statistical analysis indicates that homozygote gene type T/T is obviously more frequent in the patients group ($\chi 2$ = 13,92, p = 0,0009), and that there is corelation of the genotype T/T with the kidney scars forming risk (TT vs.CT + CC: OR = 19.4615; CI 2.420-156.477; p = 0.0003).There wasn't statistical significance between genotypes with T alleles and the genotype C/C (T- vs. CC: OR = 1.675; CI 0.63-4.47; p>0,20).
Conclusion: The presence of the genotype T/T on the position -509 in the promoter region TGF-B1 gene is risk factor for the kidney scars development in patients with VUR in children.

Characteristics of Y-chromosome Polymorphisms in Kazakh Populations from the Perspective of Tribal-clan structure

M. Zhabagin[1,2], *Z. Sabitov*[3], *H. Dibirova*[4], *E. Balanovska*[4], *I. Zakharov*[2], *O. Balanovsky*[2];
[1]*Center for Life Sciences, Nazarbayev University, Astana, Kazakhstan,* [2]*Vavilov Institute of General Genetics RAS, Moscow, Russian Federation,* [3]*Gumilyov Eurasian National University, Astana, Kazakhstan,* [4]*Research Centre of Medical Genetics RAMS, Moscow, Russian Federation.*

The characteristic feature of the Kazakh nomadic society was the presence of a hierarchically organized and widely branched tribal-clan structure called "Shezhire", which reflected complex system of ethno-social organization. In the context of the Shezhire, Kazakh populations are divided into three ethno-territorial association of tribes called „Zhuz" (Great, Middle, and Small Zhuzes) and a group of aristocratic tribes (Tore, Kozha, Sunak).
This study aims to compare Y-chromosomal polymorphism of three Kazakh Zhuzs and group of aristocratic tribes (total sample size N= 1407). We analyzed 40 SNP and 17 STR Y-chromosomal markers. Summary statistics were calculated using Arlequin 3.5. Neighbor-joining tree was constructed by the program MEGA 5.0. Multidimensional scaling plot was drawn by the software package Statistica v.7.1.
Population pairwise FST values were calculated from the Y-chromosomal haplogroup frequencies to assess the genetic similarity among studied groups of Kazakh tribes. The most distant ones were the tribe of Sunak and the Small Zhuz (0.393), whereas the shortest distance was found between the tribe of Tore and the Great Zhuz (0,021). These genetic distances are associated with the geographic distances between studied populations. The distribution of Y-chromosomal haplogroups is strongly correlated with the tribal-clan structure of Kazakhs. Presence of certain haplogroups at high frequency at particular tribes is in favor to the hypothesis that many tribes go back to one biological founder, confirming the link between Kazakh family tree Shezhire with the genetic composition.

A mitogenomic phylogeny of haplogroups U2e and U3: revealing the phylogenetic signals for population expansions in the Slavs prehistory

B. Malyarchuk[1], *M. Derenko*[1], *T. Grzybowski*[2], *M. Perkova*[1], *G. Denisova*[1], *A. Litvinov*[1], *U. Rogalla*[2], *K. Skonieczna*[2];
[1]*Institute of Biological Problems of the North, Magadan, Russian Federation,* [2]*Institute of Forensic Medicine, Nicolaus Copernicus University, Bydgoszcz, Poland.*

To resolve the phylogeny of some uncommon and poorly studied West Eurasian mitochondrial DNA (mtDNA) haplogroups, we sequenced 32 U2e and 19 U3 complete mitogenomes of Central and Eastern Europeans (Czechs, Slovaks, Poles, Russians, Ukrainians and Belarusians) and re-analysed the available at the present time data on 74 U2e and 80 U3 complete mtDNAs. Molecular dating suggests that the coalescence time estimates are ~21 and ~35 thousand years (ky) for haplogroups U2e and U3, respectively. Detailed analysis of about 500 Slavic complete mitogenomes belonging to different haplogroups allowed us to identify a number of lineages that seem specific for Central and Eastern Europe (U3b1b, U4a2a1, U5a2a1c, U2e1b1a, U2e1b1, U3a1a, H5a1f, U5a1a1a1, U5a1c1, U2e2a1a, U4a2a, H5a2, U2e2a1d and U5a1b1b). These subhaplogroups consist of similar haplotypes revealed in different ethnic groups of modern Slavs, thereby proving the existence of ethnolinguistic community of Slavs through DNA testing. Evolutionary age of Slavic-specific subhaplogroups is calculated to approximately 3.9 ky (from 2.3 to 5.9 ky, according to the mutation rate proposed by Soares et al. (2009) for the entire mtDNA molecule). This indicates that the ancestors of modern Slavs inhabited areas of Central and Eastern Europe from the times of Bronze and Iron Ages, *i.e.* earlier than it was estimated on the basis of archaeological, historical and linguistic data. This study was supported by Russian Foundation for Basic Research (grant 14-04-00131) and the Program of Presidium of Russian Academy of Sciences (grant 12-I-P30-12).

Incidence of alpha globin gene defect in the Lebanese population: a pilot study

R. Badra[1], *K. Yunis*[2], *R. Daher*[1], *F. Fares*[2], **C. Farra**[1];
[1]*Department of Pathology and Laboratory Medicine, American University of Beirut Medical Center, Beirut, Lebanon,* [2]*Department of Pediatrics and Adolescent Medicine, American University of Beirut Medical Center, Beirut, Lebanon.*

Background*:* Inherited hemoglobin disorders are the most common monogenic defects described worldwide. It is well established that Mediterranean and Arab populations are at high risk for thalassemias in general, and for α-thalassemia in particular. Prenatal as well as premarital screening programs in countries with high prevalence have already been founded. In this study, we aim at assessing the incidence of alpha thalassemia deleterious alleles in the Lebanese population. **Methods:** DNA was extracted from 200 newborns dried blood cards remaining from routine neonatal screening at the American University of Beirut Medical Center. DNA samples were screened for the 21 most common α-globin deletions and point mutations reported worldwide, through multiplex Polymerase Chain Reaction (PCR) and Reverse-Hybridization technique. **Results:** The carrier rate of -thalassemia in our sample population was 8% which is higher than that reported from Jordan (2-4%). This finding is comparable to Mediterranean countries (Israel: 5-9%, Greece: 7%, Adana-Turkey: 7.5%) but lower than that reported in other Arab countries (UAE: 16.5%; Oman: 38.6%; Saudi Arabia: 50%). Two mutations were detected: the -3,7del single gene deletion (75%) and the non-gene deletion 2 IVS1 [-5nt] (25%). These mutations are common worldwide. Interestingly, the -α 4.2 and MED mutations, particularly common in Arab and Middle Eastern populations, were absent in our survey **Conclusion:** This study is the first dedicated to investigate α-thalassemia genotype incidence in Lebanon. Data obtained demonstrates a high carrier rate in a relatively, highly consanguineous population. These results may impact premarital and newborn screening policies in our country.

5-HTT genotype and sexual behavior traits in healthy female subjects

F. Cieri[1,2], *M. Sergi*[1], *M. Balsamo*[2], *M. Franzago*[1], *L. D'onofrio*[1], *A. Grilli*[2], *L. Picconi*[2], *M. Tommasi*[2], *A. Saggino*[2], *V. Gatta*[3], *L. Stuppia*[2,3];
[1]*Department of Neuroscience and Imaging, Chieti, Italy,* [2]*Department of Psychological Sciences, G. d'Annunzio University, Chieti, Italy,* [3]*Functional Genetics Unit, Center of Excellence on Aging (CeSI), Chieti, Italy.*

Serotonergic neurotransmission affects a large range of behaviors, from food intake to sensory processing and motor activity, cognition, emotion regulation, social behavior and most important to our proposal, reproductive activity. A key regulator for serotonergic neurotransmission is the serotonin transporter (5-HTT), which removes serotonin released into the synaptic cleft. The 5-HTT protein is encoded by a single gene, SLC6A4. Transcriptional activity of this gene is modulated by several variations, including a repetitive sequence, the SLC6A4 linked polymorphic region (5-HTTLPR). Specifically, the 5-HTTLPR short allele (s) has reduced transcriptional efficiency compared with the long allele (l), and individuals carrying the s allele tend to have, among other, an exaggerated amygdala response to threatening visual stimuli, biased processing of emotional information, likely resulting from altered functional connectivity within a corticolimbic circuit, impulsivity and increased anxiety related temperamental traits.
We used a new instrument for the measure of sexual behavior: "Sex-Promiscuity-Infidelity-Questionnaire" on a cohort of 154 female students recruited at the University of Chieti, in order to test the possible interactions between s carriers individuals and sexual behavior. Through an Explorative Factor Analysis (EFA) we explored the factor structure of the questionnaire, composed by three factors: "Demographic Informations", "Sexual Promiscuity" and "Sexual Instability". Furthermore the EFA showed significant s carriers' factor loadings on sexually instability behavior factor (-.35).
Our findings support the possible association between serotonergic neurotransmission, mediated by 5-HTTLPR affect, and the sexual behavior in female healthy subjects.

Screening for mutations in genes underlying familial atypical mycobacteriosis

A. Rudko[1], *A. Garaeva*[1], *E. Bragina*[1], *N. Babushkina*[1], *O. Kolokolova*[2], *O. Lipaenkova*[2], *M. Freidin*[1], *V. Puzyrev*[1,2];
[1]*Research Institute of Medical Genetics, Tomsk, Russian Federation,* [2]*Siberian State Medical University, Tomsk, Russian Federation.*

Several mutations in the IL12B, IL12RB1, IFNGR1, IFNGR2, STAT1, and IKBKG genes lead to the development of rare syndrome of atypical familial mycobacteriosis (OMIM # 209950). We set out to test whether rare variants and polymorphisms in these genes can predispose to tuberculosis. These genes were studied in two Siberian populations of Russians (304 patients, 265 controls) and Tuvinians (238 patients, 263 controls). First, we carried out the screening for most common mutation variants of the genes (IL12RB1 Gln32Ter, Gln376Ter, Arg213Trp; IFNGR1 Ile87Thr, 4-bp Del NT818, 1-bp Del NT818; IFNGR2 2-bp Del 278AG, Thr168Asn, 663Del27; STAT1 Leu706-Ser, Gln463His, Glu320Gln). All these variants appeared as "wild-type". Then we performed the search for rare variants of the studied genes by Sanger's sequencing in 10 individuals suffered from aggressive forms of TB. Direct sequencing did not reveal any mutations causing atypical familial mycobacteriosis; however, 15 previously established single nucleotide polymorphisms were identified (IL12RB1 rs11086087, rs11575934, rs17852635, rs401502, rs12461312, rs17882555, and rs3746190; IL12B rs919766; IFNGR1 rs2234711, rs17181457, rs7749390, rs11754268, and rs11914; IFNGR2 rs17883129; and STAT1 rs2066797). Using "case-control" design, we identified an association between the rs2066797 variant of the STAT1 gene and TB in Russians (p=0.02). Association of this polymorphism with TB was detected for the first time.
Our results suggest that rare mutations responsible for atypical familial mycobacteriosis are unlikely associated with TB.

J17.70
Pathway-VEGAS: A post-GWAS method in genetic epidemiology

A. Mishra, *D. R. Nyholt, J. N. Painter, G. W. Montgomery, S. Macgregor;*
QIMR Berghofer Medical Research Institute, Herston, Australia.

Genome wide association studies (GWAS) have revolutionised the field of gene mapping. As the GWAS field matures it is becoming clear that for many complex traits, a proportion of the missing heritability is attributable to common variants of individually small effect. Detecting these small effects individually can be difficult and statistical power would be increased if relevant variants could be grouped together for testing. We propose grouping markers together based on pre-specified biological pathways. We have implemented this pathway-based test in the program Pathway-VEGAS. The method is based on prior calculation of gene-based p-values using the existing Versatile Gene-based Association Study (VEGAS) software. Pathway-VEGAS uses the gene-based P-values to construct a pathway test based on a set of pre-specified pathways. The method appropriately takes into account situations where neighbouring genes are present in the same pathway - results for relevant regions are calculated by accounting for linkage disequilibrium between markers using simulations from the multivariate normal distribution. Pathway size is taken into account via a re-sampling approach. Importantly, since the approach only requires summary data, the method can be easily applied in all GWASs, including meta-analysis, singleton based, family based and DNA-pooling based designs. We found statistically significant findings using pathway-VEGAS on a number of traits including endometriosis, height and educational attainment. The approach identifies biologically relevant pathways, offering insights not possible with single marker approaches.

J17.71
Epidemiology of consanguineous families in Autism

K. Schmitz-Abe[1,2,3], *T. Yu*[2], *C. Walsh*[2], *K. Markianos*[2];
[1]*Harvard Medical School, Boston, MA, United States,* [2]*Division of Genetics and Genomics Boston Children's Hospital, Boston, MA, United States,* [3]*The Manton Center for Orphan Disease Research Boston Children's Hospital, Boston, MA, United States.*

Analyses of large autism datasets have provided statistical and functional evidence for the role of rare point mutations (O'Roak, 2012, Sanders, 2012; Yu, 2013) and transmitted and de novo copy number variants (CNVs) (Morrow, 2008; Pinto, 2010; Levy, 2011; Sanders, 2011), and offer crucial insights into the diverse genetic mechanisms that can lead to Autism Spectrum Disorders (ASDs). Here we present CNV analysis for a cohort of 183 consanguineous families with one or more children affected with ASD. We provide new insights into the genetic architecture of ASDs as our cohort is uniquely enriched for recessive loss of function variants. We follow up findings and draw comparisons with additional large ASD and control datasets: the Simons Simplex and the Autism Genetic Resource Exchange (AGRE) collections (2,670 affected individuals; 9681 total individuals). Comparing across these cohorts, we demonstrate that ascertainment can lead to selection of different underlying genetic mechanisms causing ASDs. These differences are reflected in metrics such as the affected male:female ratio and the relative contribution of de novo CNVs versus inherited homozygous deletions. Specifically, we find that de novo CNVs play a significant role in non-consanguineous families with a single affected child (p=0.04), but a lesser role in multiplex families, and they are no more common in ASD cases than controls in multiplex consanguineous families. In contrast, we present the strongest statistical evidence (p=0.013) to date that homozygous deletions, are a major contributor to ASD disease burden in consanguineous families, contributing to as much as 5-10% of cases.

Cost-effective designs for genotype imputation in sequencing based genome-wide association studies

S. Sanna[1], *G. Pistis*[1,2,3], *E. Porcu*[1,2,3], *C. Sidore*[1,2,3], *M. Steri*[1], *F. Danjou*[1], *F. Busonero*[1], *A. Mulas*[1,3], *M. Zoledwieska*[1], *A. Maschio*[1,2], *C. Brennan*[4], *S. Lai*[1], *M. Marcelli*[5], *M. F. Urru*[5], *M. Pitzalis*[1], *R. H. Lyons*[4], *H. M. Kang*[2], *C. Jones*[5], *A. Angius*[1,5], *G. R. Abecasis*[2], *F. Cucca*[1,3];
[1]*Istituto di Ricerca Genetica e Biomedica, Monserrato, Italy,* [2]*Department of Biostatistics, University of Michigan, Ann Arbor, MI, United States,* [3]*Dipartimento di Scienze Biomediche, Universita' di Sassari, Sassari, Italy,* [4]*Sequencing Core, University of Michigan Medical School, Ann Arbor, MI, United States,* [5]*CRS4, Pula, Italy.*

Genotype imputation is now an essential tool in genetic studies to systematically infer missing and untyped genotypes. Accordingly, progressively larger reference panels are being constructed based on whole-genome sequencing in various populations. Developing general guidelines for optimally cost-effective imputation designs, however, requires evaluation of performance issues that include the relative utility of population-specific compared to general/multi-population reference panels; genotyping with various array scaffolds; and effects of different ethnic backgrounds. Here we compared the effectiveness of a Sardinian specific (SardSeq) panel, derived from whole-genome sequencing of 2,120 Sardinians, to the 1000 Genomes Project (1000G) reference panels, using combinations of two genome-wide and three custom arrays as baseline genotype, in both Sardinians and other Europeans. In Sardinians, the SardSeq panel provided better coverage and genotype imputation accuracy than the 1000G panels, particularly for low frequency and rare variants (mean squared correlation with true genotypes 0.95 vs 0.68, respectively, at variants with MAF >1% and <5%). In particular, when imputing with the SardSeq panel, even gene-centered custom arrays interrogating a smaller number of variants (on the order of 200,000, as the Illumina CardioMetaboChip) provided highly informative content across the entire genome. Notably, in Sardinians a combined panel including both the SardSeq and the 1000G sequencing data did not provide substantial improvement. By contrast, we showed that a combined panel could be advantageous in other Europeans. We expect our results to be useful in planning future studies and in current sequencing efforts that are not part of the 1000 Genomes Project.

J17.73
Association of single nucleotide polymorphism in SLC30A8 gene with aging in Tehran lipid and glucose study

M. S. Daneshpour[1], **P. Eshraghi**[1,2], *M. S. Fallah*[1,3], *A. Ebrahimi*[1], *F. Azizi*[4];
[1]*Cellular and Molecular Endocrine Research Center, Obesity Research Center, Research Institute for endocrine sciences Shaheed Beheshti University of Me, Tehran, Islamic Republic of Iran,* [2]*Institute of Experimental Cancer Research, Comprehensive Cancer Center, Ulm, Germany,* [3]*Kawsar Human Genetics Research Center (KHGRC), Tehran, Islamic Republic of Iran,* [4]*4. Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.*

Background: Genome-wide association studies have identified thousands of variants that are associated with numerous phenotypes. One such variant, rs13266634, in Solute Carrier family 30 (zinc transporter), member 8, has been reported in several studies that has association with type-2 diabetes as such in European and Japanese population. Here we confirm association of rs13266634 with aging in Tehran lipid and glucose study (TLGS).
Method: 600 individuals in range of 20-35 years old as young group and 2347 individuals in range of 45-85 as old group were selected from participant of TLGS cohort and enrolled in the study and rs13266634 has been genotyped using the Centaurus (Nanogen) platform in DeCODE genetics. Association of G-allele with aging was tested using plink software.
Results: Apart from replicating previous findings, TLGS participants showed that T-allele of rs13266634 showed association with aging after comparison young and old groups ($p < 0.0025$).
Conclusion: Our findings showed the association between the presence of T allele in rs780094 and aging and related traits among Iranian population. However to address this issue, length of telomere as one of the aging factor in this cohort will of interest to investigate more in detail.

Catanzaro, Italy, [3]Regional Epilepsy Centre, Hospital of Reggio Calabria,, Reggio Calabria, Italy.

Gamma-aminobutyric acid (GABA) is the major inhibitory neurotransmitter in the brain, acting primarily via the GABA receptors. Multiple lines of evidence indicate that dysfunction of GABA B receptors may be involved in the pathogenesis of temporal lobe epilepsy (TLE). The aim of this study was to determine whether a single nucleotide polymorphisms (SNPs), +8A>G (rs2304391) at 3'UTR of subunit 2 of the GABA B receptor gene (GABBR2), contributes to TLE. We used a case-control approach comparing the frequency of the above-mentioned GABBR2 polymorphism between patients with TLE and controls. We enrolled 303 consecutive patients (167 women; mean SD age: 47.08 18.10), and 271 healthy controls (137 women; mean SD age: 64.20 ± 17.06), matched for age, sex and ethnicity. All patients had a diagnosis of non-lesional TLE, based on comprehensive clinical, neuropsychological, electroencephalographic, and brain MR evaluations. All patients and controls were Caucasian and were born in Italy. Patients and controls gave written informed consent prior to participation in the genetic studies. Patients and controls were genotyped for detection of the rs2304391 polymorphism using TaqMan Allelic Discrimination assays, on an Applied Biosystems PCR platform. The genotype distributions for both healthy subjects and epileptic patients were consistent with the Hardy-Weinberg equilibrium. Analysis of genotype or allelic frequencies between patients and controls showed no statistically significant difference, moreover the polymorphism did not influence severity and age at onset of epilepsy. Our data suggest that GABBR2 gene polymorphism does not act as a susceptibility factor for sporadic non-lesional TLE.

Gene-gene interaction analyses of variants in the GABA system and alcohol use

A. Ulgen[1], *W. Li*[2];
[1]*Eastern Mediterranean University. Mersin 10-Turkey, KKTC. Famagusta., Turkey,*
[2]*Robert S Boas Center of Genomics and Human Genetics, Manhasset, NY, United States.*

Epistatic or gene-gene interaction refers to the phenomenon that the joint effect of two genes is different from the sum of the individual effects of each gene. Recently, gene-gene interactions have been implied as a potential solution to the problem of missing heritability in the detection of genes for complex disorders. Furthermore, combinatorial approaches based on principal components analysis with the generalized multifactor dimensionality reduction method to study G x G and G x E interactions uniting nuclear families and unrelated individuals have been proposed. We apply methods of G x G interaction to a sample of 7224 individuals who have been phenotyped for their drinking and alcohol abuse and genotyped on 970 SNPs in 34 GABA system genes including 20 GABA receptor subunit genes. Results from applying both combinatorial approaches, PGMDR and Random Forest approaches based on classification trees, to the alcohol use data will be presented. We further discuss and compare the power to detect these interactions using these two methods and the resulting outcome. This should shed light into the functionality of these variants implied in the GABA receptor signaling pathway.

Unsupervised Clustering Analysis of Gene Expression in an extended pedigree from Norfolk Island Population

A. J. Rodriguez Acevedo[1], *M. Benton*[1], *R. Lea*[1], *A. Goldiner*[2], *L. Griffiths*[1];
[1]*Queensland University of Technology, Gold Coast, Australia,* [2]*University of Queensland, Gold Coast, Australia.*

Norfolk Island belongs to the Commonwealth of Australia and it comes from a settlement of 194 inhabitants resettled from the Pitcairn Islands in 1856. All of them were descendants of nine "Bounty" mutineers' men and twelve Tahitian women. The Island has been isolated and strict immigration and quarantine legislation restrict new founder from migration. In an attempt to understand and identify gene interactions in this unique population we performed a microarray analysis using an Illumina HumanHT-12 v4 array in venous blood samples from 335 related individuals. In order to compare the transcriptome structure from Norfolk Island population, we have taken previously published microarray data from the Atlanta CHDWB study. An unsupervised clustering analysis using k-means and principal component analysis (PCA) were performed using R. PCA showed that, in the Norfolk Island population, approximately 22% of the total variation is explained by its first principal component, against 14% of variation in the CHDWB population. On the other hand, the k-means analysis identified 24 clusters in the Norfolk Island population and 18 in the CHDWB population where approximately 31% of the transcripts could not be assigned to any of the clusters due to the lack of correlation. Enrichment analysis and Network visualization was performed. Our study supports a homogeneous structure of the Norfolk Island population and suggests a specific set of genes to explain different phenotypic traits. It also contributes to the identification of possible biomarkers in common diseases such as migraine and cardiovascular disease, common pathologies in the Norfolk Island population.

Chromosomal microarray analysis in paediatric patients with cognitive impairment/behavioural abnormalities/epilepsy and congenital anomalies: well-known syndromes, novel syndromes, parental contribution. A clinical perspective

R. Fischetto[1], *F. Papadia*[1], *F. Nicastro*[1,2], *F. Ortolani*[1,2], *M. Masciopinto*[1], *E. Piccinno*[1], *M. Vendemiale*[2], *O. Palumbo*[3], *P. Palumbo*[3], *L. Zelante*[3], *M. Carella*[3];
[1]*U.O.C. Malattie Metaboliche e Genetica Medica P.O. Giovanni XXIII, A.O.U. Policlinico Consorziale, Bari, Italy,* [2]*Servizio di Psicologia Clinica, Direzione Medica P.O. Giovanni XXIII, A.O.U. Policlincio Consorziale, Bari, Italy,* [3]*Laboratorio di Genetica Medica, Ospedale IRCCS Casa Sollievo Della Sofferenza, San Giovanni Rotondo, Italy.*

Chromosomal microarray analysis (CMA) has emerged as a powerful new tool to identify genomic abnormalities associated with a wide range of developmental disabilities and congenital anomalies.
The detection of submicroscopic copy number variants (CNVs), not visible by conventional karyotyping, helped the genetic diagnosis in our paediatric patients who had already received, with normal results, standard karyotype analysis, metabolic screening, single gene sequencing. Since 2008, 212 patients, aged 2 months-16 years, were analyzed using SNP-array technology and clinically significant submicroscopic imbalances were detected in 70 cases (33%). De novo imbalances were identified in 26 children (12 %), while inherited imbalances were recognized in 34 children (16 %). In 10 patients it was not possible to study both parents. In 59 patients (27,8%) a CNV was causative for the phenotype: in these cases, known microdeletion/microduplications syndromes and chromosomal region with a likely pathogenic correlation were identified. In 11 patients (5%) two or more CNVs were presents (2 CNV= 7 patients; 3 CNV= 4 patients): parents' analysys revealed that the rearrangements were inherited and contributed to child's clinical phenotype. Clinicians who evaluate children with developmental disabilities and congenital anomalies have the role to attempt to establish a genetic etiology. Furthermore, an analysis of parents or family members becomes a routine recommendation, given that incidental CNVs findings have a significant impact on risk counseling for future pregnancies and other family members at risk.

Bioethical, Humanistic And Technocratic Resources Of Enhancing Of Civilian Control Of Human Genetics

S. Sprincean[1], *M. Sprincean*[2,3];
[1]*Institute of Juridical and Political Researches of Academy of Sciences of Moldova, Chisinau, Moldova, Republic of,* [2]*Institute of Mother and Child, Chisinau, Moldova, Republic of,* [3]*State University of Medicine and Pharmacy "N. Testemitanu", Chisinau, Moldova, Republic of.*

Background: Civilian control on human genetics represents one of main practical leverages to increase benefits and reduce risks for society as well as for healthcare system at global, local and community levels, in context of scientific and technological progress in genetic research, for melioration of general-social acceptance rate of the most ambiguous biotechnological innovations. The approach of civilian control in decision-making for better exploitation of human genetics potential for sustainable and long-term improving of healthcare, individual and global security and innovation climate in society, represents a new mainstream in development of medicine, public healthcare, genetic research and human neuro- and bio- enchantment.
Materials and methods: The study used statistical data analysis and synthesis, observation, social survey, individual questioning.
Results: There are several categories of resources to increase importance of civilian control on human genetics: 1) stimulation of professionalism, deontological ethics and humanistic capacity of geneticists; 2) supremacy of bioethical committee expertise and normativity; 3) rising biotechnocratic social leadership class, involved into genetic decision-making.
Conclusion: A coordinated application of the full spectrum of available resources is required to streamline public monitoring on human genetics as a lever to ensure a high level of protection of society against abuses and distortions, based on a new concept of civilian control in decision-making in human genetics as a combination of bioethical and humanistic expertise and auditing, in the context of modernizing of society, where the protection of individuals and promotion of progressive innovations in human genetics are prerequisites for a global welfare.

Clinical outcome and genetic counselling in a rare complex small supernumerary marker chromosome with dup(9p21->pter) and

21(pter->21q21): case report

N. O. Teles[1], *C. Candeias*[1], *M. M. Freitas*[1], *C. R. Mota*[2], *M. F. Silva*[1];
[1]*Instituto de Genética Médica Jacinto Magalhães/CHP, Porto, Portugal,* [2]*Centro Hospitalar do Porto, Porto, Portugal.*

Abnormal unique complex small supernumerary marker chromosomes (sSMC) have been found in 0.9% of patients, making the correlation between the patient's phenotype and genotype particularly difficult. Some characteristic syndromes have been described; i.e., Pallister Killian [i(12p)], Cat-eye [i(22p~q)] and Emanuel [der(22)t(11;22)]. Genetic counselling for these new marker chromosomes may be challenging, both for the patients and the parents, particularly when the sSMC is a derivative of a maternally inherited translocation, resulting in partial trisomy of two chromosomes. The authors present the case of a 9 month female, referred for karyotyping with high resolution banding presenting with microcephaly, slow physical development and facial dysmorphisms. Classical cytogenetics revealed an abnormal sSMC. The father's karyotype was normal but the mother had a t(9;21) balanced translocation. Analysis of Fluorescence in situ hybridization (FISH - whole chromosome painting and centromeric probes, Cytocell) and Multiplex Ligation-dependent Probe Amplification (MLPA, MRC Holland) results in the proband allowed us to conclude that she has partial trisomy for chromosomes 9 (9p21->pter) and 21(pter->21q21). Final Karyotype: 47,XX,+mar.ish der(21)t(9;21)(p21;q21)(D13Z1/D21Z1+,wcp21+)mat. mlpa 9p,21psubtel(P036E1, P070E2)x3
As in the present case some publications have noted that sSMC resulting from apparently balanced translocations present in one of the progenitors will influence the phenotype by the presence of specific partial trisomies. As far as we know this is the first case found with an sSMC that originates in chromosomes 9 and 21. The authors emphasise the need for good characterization of these markers in order to define a reasonable/probable clinical outcome and allow appropriate counselling for the family.

Inconsistency between molecular and clinical data in subjects with a D4Z4 reduced allele should prompt to further investigations

J. Daolio[1], *G. Ricci*[1,2], *A. Nikolic*[1], *M. Govi*[1], *F. Mele*[1], *L. Vercelli*[3], *G. Antonini*[4], *A. Berardinelli*[5], *T. Mongini*[3], *L. Villa*[6], *L. Ruggiero*[7], *C. Angelini*[8], *M. Cao*[9], *A. Di Muzio*[10], *M. Moggio*[11], *L. Morandi*[12], *C. Rodolico*[13], *C. Rodolico*[13], *L. Santoro*[7], *G. Siciliano*[2], *M. Filosto*[14], *G. Tomelleri*[15], *R. Tupler*[1];
[1]*University of Modena and Reggio Emilia, Modena, Italy,* [2]*University of Pisa, Pisa, Italy,* [3]*University of Torino, Torino, Italy,* [4]*University of Rome Sapienza, Roma, Italy,* [5]*IRCCS 'C.Mondino' Foundation, Pavia, Italy,* [6]*University of Milan, Milan, Italy,* [7]*University Federico II of Naples, Naples, Italy,* [8]*University of Padua, Padua, Italy,* [9]*University of Pdua, Padua, Italy,* [10]*University 'G. d'Annunzio' of Chieti, Chieti, Italy,* [11]*University of Milano, Milano, Italy,* [12]*IRCCS Foundation, C. Besta Neurological Institute, Milano, Milano, Italy,* [13]*University of Messina, Messina, Italy,* [14]*University of Brescia, Brescia, Italy,* [15]*University of Verona, Verona, Italy.*

Out of 171 consecutive myopathic index cases recruited from the Italian National Registry for FSHD and carrying of a D4Z4 reduced allele (DRA) with 4-8 repeats, we identified 148 subjects completely fulfilled the clinical diagnostic criteria for FSHD and 23 subjects that presented myopathic features suggestive of an alternative diagnosis. In this group we observed a wide clinical heterogeneity, including 1) involvement of muscles that are not usually affected 2) sparing of muscles that are typically affected in FSHD, 3) non autosomal dominant inheritance, 4) additional clinical features. Molecular analysis of the 4q35 subtelomeric haplotype did not reveal any molecular element enabling us to differentiate these patients from classical FSHD cases. Further investigations in two patients with overlapping syndromes allowed us to identify additional mutations, respectively a heterozygous CAV-3 gene mutation and a heteroplasmic transition of mitochondrial tRNALeu. In an elderly woman the muscle biopsy resulted suggestive for the diagnosis of inflammatory myopathy with inclusion bodies. Three cases presented a bent spine syndrome: histological and immunohistochemical analysis of muscle biopsies failed to detect other pathological conditions and additional genetic testing are ongoing. Collectively, our analysis highlight the necessity to re-evaluate the significance and the predictive value of DRA, not only for research but also in clinical practice. Further clinical and genetic analysis of FSHD families will be extremely important for studies aiming at dissecting the complexity of FSHD. This approach will favor correct diagnosis and genetic counseling.

Constructing a family tree. Frequent mistakes and new needs

M. O. Mkheidze;
Academy for Postgraduate Teacher Education, St.Petersburg, Russian Federation.

Analyzing more than 1500 pedigrees some frequent mistakes were shown: a) the absence of a horizontal line for an offspring, b) symbol location between generation lines, c) displacement of children birth order, d) wrong numbering of generations, e) incorrect numbering of symbols in each generation. Human infertility is an important problem. 10 to 15 percent of couples all over the world are infertile. Assisted reproductive technology (ART) is modern effective therapy for overcoming infertility. To draw a pedigree with ART it is necessary to use adequate standard genetic symbols that are absent so far. The author offers to discuss the following symbols to construct a family tree with ART: 1) bold symbols of biological parents, 2) a broken line to image germinative cell donation, 3) a symbol of substitutive, ersatz-mother can be denoted by a circle that contains a pregnancy symbol inside. All particular facts of medical history and different kinds of medical treatment ought to be in legend. Some family trees that are drawn with different symbols are compared. Symbols suggested are founded by the author.

J18.06
Legislative and ethical peculiarities of human genetic data protection

D. Serapinas[1,2], **D. Lekarauskaite**[2];
[1]*Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania,* [2]*Mykolas Romeris university, Vilnius, Lithuania.*

Genetic science related to the individual as the main subject of the research is exposed to a wide range of ethical and legal issues. From the developments in genetic science other science have evolved, thanks to which the modern world is able to protect the genetic information of data, and to receive the sanction while ignoring the laws of such data. However, there are still many problems related to the protection of personal genetic information, such Regulatory standards, the inviolability of an individual, the assurance of freedom and privacy of information.
Genetic discrimination is strictly forbidden by international conventions and declarations (Convention on Human Rights and Biomedicine, Additional Protocol to the Convention on Human Rights and Biomedicine, concerning Biomedical Research, Directive 95/46/EC of the European Parliament), which means that discrimination on grounds of personal genetic information (diseases, abnormalities) is not available in all areas, including employment and insurance. However, individuals face some problems unable to get a job due to the publicity and information disclosure to their employers, or increasing the amount of insurance premiums. It is essential to protect genetic rights, because of that any form of discrimination against a person on grounds of his genetic heritage is prohibited and intervetion in the health field or disclosure of such information may only be carried out after the person concerned has given free and informed consent to it.

The impact of genetic counselling on prevention of mental retardation in south of Iran

P. Nikuie[1], *K. Malekzadeh*[1], *B. Mirzaei*[2], *H. Sajjadi*[1], *L. Shams*[1], *F. Hajizadeh*[3];
[1]*Molecular Medicine Research Center,Hormozgan University of Medical sciences, Babdar Abbas, Islamic Republic of Iran,* [2]*Department of Genetics,Science and Research Branch Islamic Azad University, Tehran, Islamic Republic of Iran,* [3]*Social Welfare Organization, Babdar Abbas, Islamic Republic of Iran.*

Introduction: Mental retardation has high prevalence in south of Iran because of consanguineous marriages. As uncurable nature,prevention is the best way.This study was designed to evaluate the impact of genetic counseling on prevention of mental retardation. Methods: This case control study was done between 2010-2013 and 120 women with mental retarded children were participated.All of them had another pregnancy after their mental retarded child.60 of them had pregnancy after genetic counseling (case group) and 60 women had pregnancy without doing genetic counseling (control group).The study data was analyzed using SPSS19. RESULTS: In case group mean maternal age was 33±4.9 and mean age of mental retarded children was 7.8±4.5 years.In control group it was 34±5.2 for mothers and 10±2.9 for mental retarded children.Genetic counseling before pregnancy was protective factor for having mental retarded child.(Odds Ratio 4.261, 95% confidence interval 1.312-13.834). 71.7% of parents in case group and 55% in control group had consanguineous marriages.Screening tests in pregnancy were done in 78.3% of mothers in case group and 21.7% in control group. Down syndrome was the most common cause of mental retardation in both groups. 3.3% of mothers in case group were referred for abortion because of abnormal amniocentesis. Conclusion: Genetic counseling is effective in prevention of mental retardation.

Hereditary Hyperferritinemia Cataract Syndrome in two Italian patients.

S. Bigoni[1], *G. Parmeggiani*[1], *E. Italyankina*[1], *C. Panteghini*[2], *B. M. Garavaglia*[2], *M. Neri*[1], *A. Ferlini*[1];
[1]*Department of Medical Genetics, Ferrara University, Ferrara, Italy,* [2]*Neurogenetics Unit, Neurological Institute "C. Besta", Milan, Italy.*

We describe two unrelated Italian patients with a combination of congeni-

tal nuclear cataract and hyperferritinemia without iron overload. Affected patients had normal serum iron, transferrin saturation, and transaminases, but high serum ferritin levels, 1819 and 823 ng/ml, respectively. The first patient was referred to us with the suspect of thalassemia trait. Only asking a detailed clinical story, a previous surgical intervention (at the age of 15) for cataract was referred. Pedigree analysis showed a brother with cataract. After this, in the brother hyperferritinemia levels were discovered too. The second one was referred, during pregnancy, because of the presence of cataract and hyperferritinemia. Pedigree analysis showed bilateral cataract and hyperferritinemia in several relatives. The association of hyperferritinemia in patients with congenital cataract and positive family history led us to consider a diagnosis of Hyperferritinaemia-Cataract Syndrome (HHCS). HHCS is an autosomal dominant syndrome characterized by cataract and high ferritin serum levels, not related to iron overload. The syndrome is caused by heterozygous mutations in the iron-responsive element (IRE) of the ferritin light chain gene (FTL). Direct sequencing of 5'UTR of FTL showed, in the first patient, an heterozygous deletion of 16 nucleotides (-178_-162 del 16 nt, NM_000146.3) and, in the second one, an heterozygous missense mutation (-163C>G), both causative of HHCS (Luscieti et al, 2013) We conclude that in patients with recurrent congenital cataract and hyperferritinemia without iron overload, HHCS should be explored in order to provide genetic counseling and targeted follow up.

Assessment of diagnostic criteria for HNPCC by comparative study of overall survival of CRC patients

Z. Daneberga, *I. Eglīte, M. Nakazawa-Miklasevica, E. Skuja, J. Gardovskis, E. Miklaševičs; Riga Stradins University, Institute of Oncology, Riga, Latvia.*

HNPCC is a clinical diagnosis, based on the Amsterdam criteria I (ACI) or revised Amsterdam criteria II (ACII). Due to cultural, socio-economical reasons and small size of families, in clinical practice often is hard to fulfil ACII and obtain an appropriate anamnesis for patients diagnosed with CRC. Therefore, based on different publications several modified criteria are in use. Studies also showed overall survival of CRC patients with HNPCC is better than sporadic CRC patients.
The aim of this study is to evaluate diagnostic criteria for HNPCC used in clinical practice by comparative study of overall survival of CRC patients.
The retrospective case-record data of 1423 patients were analysed. Patients were classified in eight groups by clinical diagnosis, family anamnesis, age of diagnosis, stages by TNM, criteria matching. HNPCC group was selected based on ACII. The mortality was analyzed using the Cox proportional hazards models. The diagnosed group, age, and stratified tumour stages were tested with multivariable linear regression models adjusted for covariates.
Patients group matching to ACII criteria (HNPCC) did show significantly better survival prognosis vs. any other patient group with cancer anamnesis in family and CRC patients without reported cancer anamnesis in family (sporadic CRC). All groups, except HNPCC, did not reach statistical significance for better overall survival compared to sporadic CRC group.
Our data suggest that despite small families and lack of appropriate family anamnesis, ACII criteria is still the most sensitive clinical diagnostic guideline for HNPCC if microsatellite instability testing is not available.

J18.10
Patient's use of the Internet for Medical Genetics Informations

V. Radoi[1,2], *L. Bohiltea*[2];
[1]*Life Memorial Hospital, Bucharest, Romania, Bucharest, Romania,* [2]*UMF Carol Davila, Bucharest, Romania.*

Clinical experience suggests that the Internet is increasingly becoming an important resource for patients seen in medical genetics. Patient-provider relationships will probably change and medical providers will face new challenges as patients obtain health informations from the Internet. Objectives To determine thene percentage of patients enrolled in a medical genetics practice who use the internet health information, to describe the types of information and to evaluate patient's perception of the quality of this information. Material and methods A prospective study was performed about patient use of the Internet before attending a medical genetics appointment . We analysed 61 questionnaires assessing : frequency of patient use of the internet for medical genetics informations, perceptions of the quality of this information, if patients discuss this with their doctors. Results Results show that 72,13 % (44/61) of patients have acces to the Internet , of which 63,6 % (28/44) report searching the Internet for genetic informations. 85,71% (24/28) of the patients found the information useful. Of those using the Internet for medical genetics informations 46,4% (13/28) did not discuss this informations with their doctor. Conclusions Medical genetics care providers should recognize that patients are using the Internet as a source of medical information and should be prepared to offer suggestions for Internet resources and to assist patients in evaluating the quality of medical information available on the web sites. The role of medical genetics professionals is changing as a result of the development of the Internet.

J18.11
Genetic counseling for a pregnant woman with Marfan syndrome

Y. Goto[1,2], *K. Mitsuzuka*[1], *O. Nishimura*[1], *K. Takahashi*[1,2], *Y. Ohnuki*[2], *A. Kondo*[1,2,3], *M. Mizoguchi*[2], *S. Izumi*[1,2];
[1]*Dept. of Obstetrics and Gynecology, Tokai University School of Medicine, Kanagawa, Japan,* [2]*Dept of Genetics, Tokai University Hospital, Kanagawa, Japan,* [3]*Dept of Obstetrics and Gynecology, National Health Organization, Shikoku Medical Center for Children and Adults, Kagawa, Japan.*

Marfan syndrome is well known autosomal dominant disorder of connective tissues and is caused by mutation of *FBN1*. Most cases are inherited from parents but 25% cases are caused by de novo mutation.
A pregnant lady aged 27 with Marfan syndrome was referred to genetic outpatient at 10 gestational weeks. She visited to us with her younger brother. Her main concern was the risk of Marfan syndrome for her baby, however she did not realized that neonatal presentation of severe and rapidly progressive disease in multiple organ systems. She knew she could take genetic test, but she was not into it and prenatal test, either.
She admitted maternal ward from 25 weeks because of her heart condition. She needed keeping rest and monitoring with cardiovascular team. At 27 weeks, Valsalva sinus expanded to 43mm and complained slight dyspnea gradually. At 31 weeks, we decided to perform Caesarean section because the circulating plasma volume usually increases at 30-32 weeks in pregnancy. She delivered a girl weighed 1532g with Apgar score
5/5. The girl is now 2 years old and does not show any symptoms.
Generally, pregnancy should only be considered after appropriate counseling from a medical geneticist or cardiologist familiar with this condition. However this lady did not have any counseling before pregnancy because the cardiologist asked her not to be pregnant. It is important to consider how we could share the genetic information with female patients who is not allowed to conceive, but might happen to be pregnant.

J18.12
The application of the Illumina NextSeq500 sequencing platform to whole human, exome and RNA sequencing

K. Hall[1], *V. Smith*[2], *M. Wang*[3], *C. Rogert*[4], *B. Crane*[4], *J. Moon*[4];
[1]*Illumina Ltd., Cambridge, United Kingdom,* [2]*Illumina, Cambridge, United Kingdom,* [3]*Illumina, San Diego, CA, United States,* [4]*Illumina Inc., San Diego, CA, United States.*

Here we will present data and analyses obtained on the Illumina NextSeq500 sequencing platform with whole human genome resequencing of clinically relevant samples, together with data from indexed exome and RNA samples.
Further developments by Illumina of their sequencing by synthesis chemistry together with advances in instrumentation design have enabled the production of the first desktop high throughput sequencing system.
The NextSeq500 is capable of producing up to 120G of high quality data with 400 million tags in <29 hours from paired 150 cycle runs. Shorter paired and single 75 cycle runs are also possible together with the availability of mid throughput configuration delivering 40G from 130 million tags with paired 150 cycle reads.
The system has a number of innovative features including the use of:
- Miniaturized optics
- Novel 2 channel chemistry
- Dry flowcells
- Simplified workflow with reagent cartridges

Connectivity to BaseSpace for cloud analysis or an onsite version enables simple secure storage and manipulation of data. Data can be analyzed using a variety of tools relevant to the sample such as BWA/GATK or the Illumina iSAAC pipeline for DNA samples. RNA data can be analyzed by the Tophat and Cufflinks applications.

J18.13
Silver-Russell syndrome - novel (epi)genotype-phenotype correlations

K. H. Chrzanowska[1], *A. Świąder-Leśniak*[1], *A. Marczak-Hałupka*[2], *H. Kołodziejczyk*[1], *M. Kalina*[3], *A. Tańska*[1], *D. Jurkiewicz*[1], *E. Ciara*[1], *M. Kugaudo*[1], *A. Cieślikowska*[1], *E. Arasimowicz*[1], *M. Krajewska-Walasek*[1];
[1]*The Children's Memorial Health Institute, Warsaw, Poland,* [2]*Pediatric Centre, Sosnowiec, Poland,* [3]*Medical University of Silesia, Katowice, Poland.*

Silver-Russell syndrome (SRS) is a congenital imprinting disorder with hypomethylation of ICR1 on chromosome 11p15.5 or maternal uniparental disomy of chromosome 7 (mUPD7), characterized mainly by severe pre- and postnatal growth retardation, relative macrocephaly and a small triangular face.
Retrospective and prospective assessment included 77 SRS patients (36 fema-

les and 41 males), at the mean age of 4.75 years (range 0.1-18.5 years), with the molecular confirmation of ICR1 hypomethylation in 63 (82%) and mUPD7 in 14 (18%) subjects.
Anthropometric measurements were performed using standard techniques and variables were expressed by number of standard deviations (SDS) in reference to the calendar age. Mean number of sessions per patient was 8 (range 1-35). Growth parameters, BMI, head characteristics and developmental anomalies were analyzed and scored.
Statistically significant differences were shown with regard to following parameters: mean SDS for weight, height, BMI and lower extremities length were lower in the mUPD7 group of patients but head circumference, length and breadth of head, forehead and bizygomatic breadth were larger compared to ICR1 hypomethylation group. Asymmetry (face/body/limbs) and major congenital anomalies were more frequent in patients with ICR1 hypomethylation. Interestingly, genital anomalies (underdevelopment of the uterus, gonadal dysgenesia/ambiguous genitalia, cryptorchidism, hypospadias) were scored only in patients with the loss of ICR1 methylation.
Systematic and long-term follow-up of both SRS groups enabled assessment novel correlations of the phenotype depending on epigenetic modulations.
The study was supported by National Science Centre, Poland (grant NN 407 285339).

J18.14
Floating Harbor syndrome - two additional cases, phenotype / genotype correlation

M. Havlovicová[1], *M. Simandlová*[1], *M. Malíková*[1], *E. Šilhánová*[2], *P. Hedvičáková*[1], *A. Křepelová*[1];
[1]Department of Biology and Medical Genetics, Charles University 2nd Faculty of Medicine and University Hospital Motol, Prague, Czech Republic, [2]Department of Medical Genetics, University Hospital Ostrava, Ostrava, Czech Republic.

Floating-Harbor syndrome (FHS; OMIM #136140) is a rare genetic condition characterized by short stature, delayed bone age and speech development, and typical facial dysmorphism. The face of FHS is the most distinctive aspect for making the right diagnosis; otherwise it can be difficult. The typical FHS phenotype consists of triangular facial shape, deep set eyes with long eyelashes and low set, large, often posteriorly rotated ears, nose narrow at the root broadening to the tip, low hanging columella, large nares, short philtrum and wide mouth with thin upper and everted lower lip.
Whole-exome sequencing revealed heterozygous truncating mutations (nonsense or frameshift) in the *SRCAP* gene in several affected persons (Hood at al., 2012). The mutations are *de novo*, some of them are recurrent and all are tightly clustered within the final exon, with the exception of a recently identified stop mutation in the penultimate exon 33 (Kehrer et al., 2013).
Here we present two patients with typical FHS facial features, although they slightly differ one from the other. In the first patient a nonsense mutation c.7330C>T (p.Arg2444*) was detected. This is a recurrent mutation described in several other patients. The parents of the patient did not harbour this mutation, thus supporting its *de novo* origin. A frame shift mutation c.7257_7258delAA (p.Gln2419*fs**23) was detected in the second case. To our knowledge this mutation has not been described yet. Phenotype / genotype correlation is further discussed.
Supported by 00064203 and CZ.2.16/3.1.00/24022.

J18.15
Two supernumerary marker-chromosomes in a healthy woman: a case report

P. Tesner, *R. Pourova, J. Drabova, E. Kocarek;*
Department of Biology and Medical Genetics, Charles University - 2nd Faculty of Medicine and University hospital Motol, Prague, Czech Republic.

Presence of supernumerary marker chromosome (SMC) is a rare chromosomal abnormality with broad-spectrum of possible clinical consequences. Most carriers are healthy people, but some SMCs could be associated with infertility, especially in males. They are also more frequent in intellectual disability and cases with various congenital defects. Genetic counselling in cases of prenatal detection of SMCs is rather challenging since prognosis differs widely depending on the SMC chromosomal origin and presence of specific segments. Thus, every new published case is valuable for decision-making.
Here, we report a case of the 33-year-old healthy woman referred to clinical geneticist as parent of the deaf child. She was cytogenetically examined due to chromosomal aberration in the pregnancy of her mother. In her peripheral blood lymphocytes two SMCs in a mosaic form were detected by various FISH methods. Our analysis revealed that the first SMC is derivative chromosome 7 containing Williams-Beuren region (7q11.23) which belongs to considered dosage-sensitive area of this chromosome but was clinically silent. Besides the larger SMC we also recognized a smaller SMC, where due to its low frequency and size it was impossible to determine its origin (likely from constitutive heterochromatin). Our observations are compared with similar case reports.
Supported by the GAUK-264811 and TACR-TA01010931.

J18.16
Mind as epigenetic modifier in mood disorders

D. Serapinas[1,2], **A. Serapiniene**[2];
[1]Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

Epigenetic modifications of DNA might be crucial for understanding the molecular basis of mood disorders. One reason for this is that epigenetic factors are sometimes plastic enough to react the external and internal environments. New scientific studies suggest, that these environmental factors can be not only food or chemicals, but also spiritual: positive emotional state, optimism, reaction to stress. The aim of this manuscript is to provide a conceptual background for studies by reviewing key findings from different forms of investigation. In order to provide an understanding the role of genetic and environmental (spiritual) factors in the causation of mental disorders here is a simplified account of some of the key features of how genes 'work'. Results of that review indicate that of particular interest, traumatic events or negative mind content may potentially alter our DNA methylation pattern and induce abnormal brain gene expression and ultimately depression, and other mood disorders. In summary, this review demonstrates that an epigenetic state of a genes responsible for mental health can be established through life experience and thinking manner and is potentially reversible.

J18.18
The analysis of reasons and expectations of women attending genetic counselling

D. Serapinas[1,2], **M. Šukys**[1];
[1]Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

Backround: Pregnant women are referred to genetic counselling when there are increased risk factors to a fetus. Often this is associated with increased stress or lack of information. The aim of the study was to identify the reasons why women attend genetic counselling, and their actions if a genetic disease would be found in their fetus.
Methods: A prospective analysis was based on original genetic questionnaire given to 277 pregnant women who were attending genetic counselling in LSMU central policlinic. The gathered data was analyzed using statistic program SPSS 17. The results' significance were assessed by Chi square test, with the level of confidence at 95%
Results and conclusions:
1. Most women attend genetic counselling due the older age, family history with hereditary disease.
2. Half of the patients would choose amniocentesis if there is found an increased risk for genetic disease. One third would choose amniocentesis because of the genetic decision.
3. Women, who do not agree with abortion, would like to get more information about keeping pregnancy before conception.
4. Most women (52%) would consult firstly with their husbands about the keeping the pregnancy. 16% would choose pregnancy termination, 10% would keep pregnancy.
5. More than half of women would choose termination of pregnancy when fetus is diagnosed with disease incompatible with life. Other would choose to give birth and leave everything to natural course.

J18.19
The meaning of informed consent in paternity testing

D. Serapinas[1,2], **D. Bekasėnė**[2];
[1]Department of Pulmonology and Imunology, Lithuanian university of Health sciences, Kaunas, Lithuania, [2]Mykolas Romeris university, Vilnius, Lithuania.

The following objectives have been set: to frame the concept and the requirements for informed consent, to analyse the legal acts of the Republic of Lithuania covering the issues regarding informed consent, to analyse types of and indications for paternity testing and to name legal and ethical problems arising from application of the informed consent.
The concept of informed consent is based on the principle of autonomy. The obligation of doctors to inform patients is inseparable from the requirement to receive informed consent. The two parts are mandatory for any medical procedures and interventions. The main requirements for the informed consent include rationality, sufficient and clear information, free will and the form of consent conforming to the legal acts. However, the informed consent is not an absolute requirement as the patient has a right to remain uninformed. Additionally, under certain circumstances it might be impossible to

inform patients or to receive consent from patients or their duly authorised representatives. The main problems of the informed consent in paternity testing, by outlining two stages of the process: conveyance before testing and interpretation of the results with it's effectivenes.

J18.20
Ethical aspects of medical genetic consulting and conducting of genetic research and testing

S. A. Todorova[1], *V. H. Petrova- Tacheva*[1], *B. Popov*[1], *K. Dimitrova*[2], *S. Georgieva*[3];
[1]medicine, Stara Zagora, Bulgaria, [2]ESTRE OOD, Sofia, Bulgaria, [3]Trakia University, Stara Zagora, Bulgaria.

Introduction: An important point of the genetic consulting is fixing a correct diagnosis, which most often requires the appointment and conduct of genetic research. Because of the hereditary nature of diseases and predispositions in our clinical practice when working with patients may result moral and ethical, psychological, social and legal cases and problems. **Goals:** The aim of our study is to investigate and analyze peoples personal position on the moral and ethical aspects of medical genetic consulting and conducting of genetic research. Materials and methods: In the study were included in general 140 people, aged from19 to 61 years, dominated by people aged between 20 and 22 years. The study was conducted on complete and voluntary and anonymous principles. **Discussion:** Significant contingent of respondents are positive about the conducting of genetic testing and genetic consultation. Most of them think that good, empathic attitude of the physician to the patient and the strict observance of medical confidentiality is very important. For 57% of respondents application of genetic test is a serious stressful situation, associated with a number of psycho-emotional and moral ethical factors. Therefore, consistent with the characteristics of the patient's presentation and interpretation of the results of the conducted genetic tests is crucial for the beneficial effect from the counseling itself. **Conclusion:** Genetic counseling requires abilities and approach to communicate, establishment of confidence and partnership between doctor and patient, correct presentation and interpretation of genetic information with respect for autonomy and the right of personal choice of the patient.

J18.20
Teaching workshops of Medical Genetics to students

R. Dragotoiu;
Medical and Pharmacy University „Carol Davila", Bucuresti, Romania.

Today the major guide for educators in establishing their teaching goals and objectives is Bloom's Taxonomy of the Cognitive Domain revised by Krathwohl. From only knowing the specific concepts, students should then develop more and new skills, so that they could analyze, synthesize and even critically evaluate their own work or their colleagues.
During each workshop that I taught from October 2013 to January 2014 students had to apply their knowledge to either create an original presentation (short story) or solve different problems. 100 first year students from the Medical and Pharmacy University 'Carol Davila' answered 20 questions at the beginning of their training and corrected these during the last workshop, to prove that they have learned fundamental genetics. The answers were then corrected by a peer and in the end by the teacher. Workshops were intended to strengthen students' knowledge by means of creative thinking and also a lot of comparative approaches. Because I replaced the frontal teaching with group or individual activity, during workshops students had to apply the concepts of the lectures to explain a certain practical situation, showing they were able to use under new circumstances what they had previously learned.
In the paper I discuss the comparative results and the degree to which students discovered and corrected their own mistakes, being thus aware of their personal improvement in knowledge besides connecting with peers and learning to work in groups.
The study demonstrates the achieved ability in understanding and interpreting genetic information of the medical students.

Predictive genetic testing in families with growth hormone deficiency: an Indian experience

A. Sharma, *S. Birla;*
All India Institute of Medical Sciences, New Delhi, India.

Growth is a multifactorial and complex process, yet its pattern is predictable in children. Deviations from normal pattern results in short stature which has serious psychological and social repercussions. Growth hormone (GH)/insulin like growth factor-I (IGF-1) axis has an established role in somatic growth regulation. Alterations impairing synthesis, secretion or biological action of GH results in a pathological phenotype called Growth Hormone Deficiency (GHD). GHD is eminently treatable, if supported by an early diagnosis and timely commencement of recombinant GH therapy which is highly expensive and prescribed over several years. In addition to the stigma of short stature, this exorbitant remedy is considered a burden by the patients in developing countries. High risk of inheritance in the next generation is also a matter of great concern. The present report on 100 families describes the impact of the disorder and socio-economic concerns which are a decisive factor in opting for treatment. Families with one child affected with GHD were ardent to discern the recurrence in subsequent pregnancies based on which were willing for termination. The solution to this problem in developing countries is predictive genetic testing enabling early detection for treatment and prenatal diagnosis for prevention. Timely genotyping can be provided if the genetic spectrum is known in the population as variations in mutation type and prevalence are documented worldwide. Equipped with this knowledge identification of common mutations will be easier and faster reducing anguish, improving risk perception, providing quality life and thereby eliminating the burden of morbidity.

Population genetic carrier screening for cystic fibrosis, fragile X syndrome and spinal muscular atrophy: Exploring experiences of carriers identified through the VCGS Reproductive Genetic Carrier Screening program

C. Beard[1,2], *L. Di Pietro*[3], *D. Amor*[2,4,5], *A. Archibald*[2,6,5];

With advancing genetic technologies, carrier screening for multiple inherited conditions can now be offered within the population. This research aimed to explore how women experience undergoing carrier screening for three common inherited conditions; cystic fibrosis (CF), spinal muscular atrophy (SMA) and fragile X syndrome (FXS), through the Victorian Clinical Genetics Services Reproductive Genetic Carrier Screening program. Adopting a qualitative approach using phenomenology as the theoretical framework, the study utilised in-depth semi-structured interviews, which were transcribed verbatim. The transcripts were coded using thematic analysis to identify emerging themes. Eight female participants took part: five received a carrier result for SMA and three for CF. The majority of participants were pregnant during screening and described the decision to have the test as straight forward. Participants experienced emotional responses such as anxiety and stress whilst waiting for their partner's test result and also completed online research to find out more about the relevant condition during this time. Participants were in favour of population carrier screening, preferably offered prior to conception. The findings of this study elucidated that genetic counsellors (GCs) play an essential role within this program to adequately support couples after they receive a carrier result given the varying consent processes undertaken prior to screening. The implementation of Internet resources and GC facilitated guidance to access reliable online information is crucial to help empower couples and assist the coping process. Improving awareness of the availability of population carrier screening within the community will also help improve knowledge levels and facilitate preconception screening.

The "utility" of incidental findings seen through the eyes of parents with children in genetic research

D. Esquivel Sada[1], *J. Hagan*[1], *K. Sénécal*[1], *B. M. Knoppers*[1], *D. Sinnett*[2,3];

The use of new generation sequencing technologies has added complexity to the issues surrounding the return of research results to participants. Guidelines are in flux in both the research and clinical settings. In ongoing scientific and bioethical discussions about a possible "duty" to return incidental findings (or not), the criteria of clinical utility plays a central role. Some authors have been arguing for a multi-dimensional concept of utility, including utility as perceived by patients as well (Foster et al., 2009, Grosse et al., 2010, Bollinger et al., 2012). But what does the concept of "utility of an incidental finding" actually entail from a research participant's standpoint?
Our presentation aims to shed light on this issue, drawing on semi-structured in-depth interviews conducted in Québec (Canada) with parents of children undergoing oncology treatment and participating in research. Following an overview of the concept of clinical utility under professional guidelines, we will analyse the multifold reasons as revealed behind the willingness of parents to know their child's incidental findings in four case-scenarios. Parents expressed very practical reasons, even though they do not necessarily rely on risk factors or on the "clinical" actionability of results. Finally, we propose some limits to the adoption of this broader concept of utility by parents in the hopes of informing bioethics guidelines on return of research incidental findings.
